As the result shown above, the XX *le*<sup>0</sup> construction occurs most frequently and perhaps also most prototypical among the [XX *postverbal element*] VRCs. As addressed earlier, in a usage-based account, the more frequent or productive word token or construction tends to be more entrenched or to be listed as a grammatical unit. The XX *le*<sup>0</sup> construction has a high type frequency which is listed in the mental lexicon. Therefore, it is predicted to be applied or inherited by the subtypes of VRCs or other newly [XX *postverbal element*] VRCs. As pointed out (Goldberg 1995), “in a type of link that recurs often throughout the grammar can be said to have a high type frequency and is therefore predicted to be productively applied to new cases which share the relevant factors associated with the existing cases” (ibid: 77).

## 5 Conclusion

The VRCs examined in this paper are found only in TSM, but not in Mandarin. In this paper we have uncovered their characteristics in phonology, syntax, semantics, and pragmatics. We propose to account for their usages and occurrences in the framework of construction grammar. Built on a usage-based account (Langacker 1987, 1988), we provide some evidence that the XX *le*<sup>0</sup> construction among the family of TSM VRC is the most frequent and productive, thus, the most entrenched. Other less frequent and productive subconstructions inherit from it in terms of the concept of “link” proposed by Goldberg (1995).

## Abstract

It is possible in Korean that a clause includes two nominative case-marked noun phrases, which I call *Double Nominative Construction* (DNC) in this paper. Not all DNCs show the same grammatical behavior. The focus of this study is to present an appropriate classification of DNC in Korean. In order to do this, I will investigate argument structures of predicates, with which each type of DNC is formulated. If an NP is not a selected argument, I will figure out how it is introduced to the structure. Based on the argumenthood of the NPs and the structural relation between them, I categorize Korean DNC into four major types.

**Keywords:** nominative, argumenthood, word order, focus.

## 1. Introduction

*Double Nominative Construction* (henceforth DNC), which is also called *Double Subject Construction*, is one of the most remarkable and widely studied phenomena in Korean. It indicates a construction which includes two nominative case-marked nominals in a single clause. Here are some examples.

- (1) *Mary-ka ttal-i yeyppu-ta*  
Mary-NOM daughter-NOM pretty-DECL  
'Mary's daughter is pretty'
- (2) *John-i Mary-ka coh-ta*  
John-NOM Mary-NOM fond-DECL  
'John likes Mary'

---

<sup>1</sup> The preliminary version of this paper was presented in the International Congress of Linguists (CIL) 18, held in July 2008 at Korea University, Seoul, ROK. I would like to thank the audience of my presentation for their interesting questions and valuable comments, which helped me to modify the analysis. The remaining errors are all mine.

- (3) *Haksayng-i yel-myeng-i hoyuy-ey chamsekhay-ss-ta*  
 Student-NOM ten-CL<sub>Person</sub>-NOM meeting-DAT attend-PAST-DECL  
 ‘Ten students attended the meeting’
- (4) *i siktang-i kalpi-ka masiss-ta*  
 This restaurant-NOM rib-NOM tasty-DECL  
 ‘At this restaurant, the rib is tasty’

The examples above apparently have the same format: N1-NOM N2-NOM V. For this reason, a lot of researches in the literature try to give them a unified analysis, which would account for all those cases. It would be fascinating that we could find a complete generalization about them, but it seems to be very hard to deal with that within formal grammar.

I argue that the constructions in (1-4) ought to be distinguished grammatically. There might be some common characteristics among them, as claimed by several researchers (Yoon 2007; and many others), but they hardly seem to have grammatical or logical implications.

## 2. Unified Approaches

In this section, I review some of the major lines of unified analyses on DNC, and figure out their shortcomings from a formal grammatical point of view.

### 2.1. Topic Analysis

Kuno (1973), dealing with DNC in Japanese, claims that *Aboutness* relation holds between the initial NP and the rest of the sentence in DNC. The definition of the notion is as follows.

- (5) *Aboutness* (Kuno 1973)  
 : The topic is the expression that denotes the thing that the sentence is about.

*Aboutness* appears to give a plausible generalization over all the cases in (1-4). However, regarding the general concept of *topic*, any sentence can be analyzed as ‘Topic-Comment’ structure. In other words, there is nothing special about DNC in the sense that the first phrase of the sentence is the topic. I don’t think that *Topic* provides a good ground for DNC analysis, since it is a pragmatic notion, rather than a grammatical

notion.

Alternatively, one might assume that Kuno's (1973) *Aboutness* is not correspondent to the general pragmatic/informational notion of topic, but restricted to Korean/Japanese-specific dislocated topic via *Topicalization*. In Korean and Japanese, the subject of the main clause is usually topicalized in the canonical word order and bears so-called topic marker: '(n)un' in Korean and 'wa' in Japanese. However, this pattern casts a little doubt on Kuno's analysis too. Although, for some speakers, the sentences in (1), (2) and (4) may sound a little less natural than the ones in (1'), (2') and (4') below, they are still grammatical<sup>2</sup>.

- (1') *Mary-nun ttal-i yeyppu-ta*  
 Mary-TOP daughter-NOM pretty-DECL  
 'Mary's daughter is pretty'
- (2') *John-un Mary-ka coh-ta*  
 John-TOP Mary-NOM fond-DECL  
 'John likes Mary'
- (4') *i siktang-un kalpi-ka masiss-ta*  
 This restaurant-TOP rib-NOM tasty-DECL  
 'At this restaurant, the rib is tasty'

We can confirm their grammaticality by putting DNC in an embedded clause. In the following examples, which are almost identical to (1), (2) and (4) except that the whole DNC is embedded in a relative clause, the slight oddity goes away.

- (1'') [*Mary-ka ttal-i yeyppu-ta*]-*nun sasil*  
 Mary-NOM daughter-NOM pretty-DECL-COMP fact  
 'The fact that Mary's daughter is pretty'
- (2'') [*John-i Mary-ka coh-ta*]-*nun sasil*  
 John-NOM Mary-NOM fond-DECL-COMP fact  
 'The fact that John likes Mary'
- (4'') [*i siktang-i kalpi-ka masiss-ta*]-*nun sasil*  
 This restaurant-NOM rib-NOM tasty-DECL-COMP fact  
 'The fact that the rib is tasty in this restaurant'

---

<sup>2</sup> I think that the slight degradation of (1-4) is due to the tendency such that the canonical subject usually bears topic marker in Korean and Japanese, unless it is focused.

The first NPs in (1''), (2'') and (4'') do not seem to be dislocated topics. Moreover, it's not clear why, especially in DNC, the topics are marked with nominative case marker, rather than topic marker as usual.

Another example potentially against topic analysis on DNC is given in (3'), which is identical to (3) except for the topic marker being attached to the first NP. Following topic analysis, there is no clear reason why the canonical topic marker makes the sentence even worse.

(3') \*?*Haksayng-un yel-myeng-i hoyuy-ey chamsekhay-ss-ta*  
 Student-TOP ten-CL<sub>Person</sub>-NOM meeting-DAT attend-PAST-DECL  
 'Ten students attended the meeting'

The ungrammaticality of (3'), comparing to (1'), (2') and (4'), also shows the example in (3) can be grammatically distinct from (1), (2) and (4), despite their apparent similarity. I will talk about this in detail in section 3.

## 2.2. Sentential Predicate Analysis

Yoon (2007) analyzes DNC based on the concepts of *Major Subject* (MS) and *Grammatical Subject* (GS). The former is the first occurrence of nominative case-marked nominal, which is not lexically selected by the predicate; and the latter is the second occurrence, which is actually in the predicate's argument structure. According to Yoon, the grammatical subject and the predicate form a new predicative unit, namely a *Sentential Predicate*, and the major subject is introduced to the construction as what is predicated of the sentential predicate.

One thing unclear in Yoon's analysis is how and by what the major subject is selected. It becomes more obscure, when there is one more NP<sup>3</sup>.

(6) *Mary-ka [x ttal-i [y nwun-i yeyppu-ta]]*  
 M-NOM daughter-NOM eye-NOM pretty-DECL  
 'Mary's daughter's eyes are pretty'

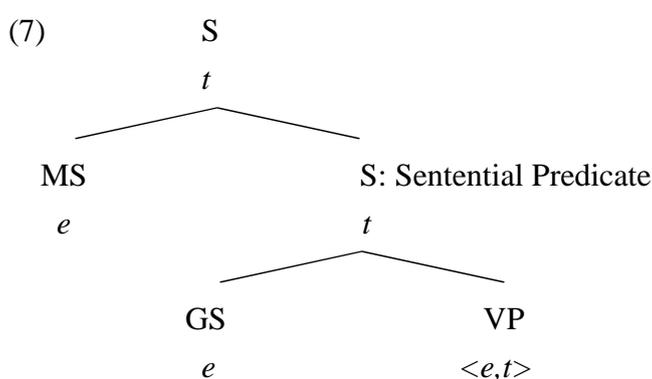

In the example in (6), 'daughter' can be either major subject or grammatical

<sup>3</sup> In Yoon's (2007) *Multiple Subject* analysis, this kind of predication relationship can be recursively created. In other words, the major subject and the newly created sentential predicate could form another bigger sentential predicate, when an extra NP is introduced.

i.e. NP1-NOM [<sub>SENTENTIAL PRED2</sub> NP2-NOM [<sub>SENTENTIAL PRED1</sub> NP3-NOM V]]  
 Major Subject Grammatical Subject

subject, depending on which of the two sentential predicates is considered (X or Y): As for Y, ‘daughter’ is the major subject which is predicated of it. However, at the same time it should be analyzed as the grammatical subject of the ‘predicate’ Y. Recall that he says the grammatical subject is in the argument structure of the predicate, which I interpret that ‘daughter’ is selected by Y in (6). Recursive introduction of new major subjects would create more of this kind of ambiguous identity. Although ambiguity itself is not a big problem, it still needs to be clarified what mechanism introduces extra arguments in the construction.

Another issue the sentential predicate analysis draws our attention to is the semantic interpretation of DNC. According to the usual definition in Type Theory, the sentential predicate is of type  $t$ , because its value will be truth or falsity. Following Yoon’s (2007) way of structuring DNC, the major subject is a separate argument by itself, which is of type  $e$ . As shown in the semantic structure of (7) below, there arises type mismatching between the major subject and the sentential predicate. There should be some fancy way of putting  $e$  and  $t$  together and producing another  $t$  or switching  $t$  to  $\langle e,t \rangle$ . However, there is no semantic motivation to do that.

Vermeulen (2005) tries to justify the type shifting in this case by assuming a free variable inside the grammatical subject: If there is a variable, Lambda Abstraction would give rise to the type shifting to find a way for the variable to be bound. But since Vermeulen, along with Yoon, doesn’t admit a syntactic movement, it is not clear how the presence of the variable is justified. Based on ‘no movement’, the only option left would be lexical selection. Since Yoon (2007) explicitly mentions that a major subject is not an argument of the main predicate, we should say it is selected by the sentential predicate. However, it is not clear how this obviously non-lexical but structurally composed chunk selects an argument.

Last of all, the claim itself fails to cover all the cases in (1-4) that the first

occurrence of nominative NP is not an argument of the predicate.

- (8) (*Mary-ka*)     *ttal-i*             *yeyppu-ta*             (=1)  
       Mary-NOM    daughter-NOM    pretty-DECL
- (9) \*(*John-i*)    *Mary-ka*     *coh-ta*             (=2)  
       John-NOM    Mary-NOM    fond-DECL
- (10) #(*Haksayng-i*)    *yel-myeng-i*     *hoyuy-ey*     *chamsekhay-ss-ta*    (=3)  
       Student-NOM    ten-CL<sub>Person</sub>-NOM    meeting-DAT    attend-PAST-DECL
- (11) (*i siktang-i*)             *kalpi-ka*    *masiss-ta*             (=4)  
       This restaurant-NOM    rib-NOM    tasty-DECL

In (9), deletion of the first NP makes the sentence ungrammatical<sup>4</sup>, whereas in (8) and (11) the deletion doesn't affect the grammaticality. In (10), the first NP can be deleted only when it is settled what category of people are specified by the quantifying expression marked as nominative. Even if the category is really general or random, we can still notice that the participant is at least a person, due to the presence of the classifier *-myeng* which is used only for a person. This contrast can also be a piece of evidence that the apparent DNCs above have different grammatical characteristics. In the following section, I will show some more grammatical differences among those types, and try to distinguish them.

### 3. Asymmetries

In this section, I am performing diagnostics, based on which the apparent DNCs in (1-4) are categorized into several types<sup>5</sup>.

#### 3.1. Argumenthood

We saw, in section 2.2, that the first NP is not selected by the predicate in (1) and (4), while it is in (2) and (3). In other words, the first NPs are arguments of the main predicate in (2) and (3), whereas they are not in (1) and (4). What about the second NPs

<sup>4</sup> Korean is arguably a *pro*-drop language. The example in (9) could be acceptable, when the deleted argument is contextually given. But it is still obvious that the first NP is an argument of the predicate.

<sup>5</sup> This paper focuses on the differences over their basic syntactic behavior. If some other semantic or pragmatic criteria are considered, each type could potentially be subcategorized further.

then? The following examples show if the second NP in each type is deletable or not.

- (12) *Mary-ka* (*ttal-i*) *yeyppu-ta* (=1)  
 Mary-NOM daughter-NOM pretty-DECL
- (13) *John-i* \*(*Mary-ka*) *coh-ta* (=2)  
 John-NOM Mary-NOM fond-DECL
- (14) *Haksayng-i* (*yel-myeng-i*) *hoyuy-ey* *chamsekhay-ss-ta* (=3)  
 Student-NOM ten-CL<sub>Person</sub>-NOM meeting-DAT attend-PAST-DECL
- (15) *i siktang-i* (*kalpi-ka*) *masiss-ta* (=4)  
 This restaurant-NOM rib-NOM tasty-DECL

Regarding the predicates in those examples intuitively, *yeyppu*- ‘pretty’ in (1) and *masiss*- ‘tasty’ in (4) need only one (obligatory) argument, but *coh*- ‘fond’ in (2) obviously requires two; a person who is fond of somebody, and other person who is being fond of. In (3), *chamsekha*- ‘attend’ only requires a person who attends some meeting, and a dative NP argument which indicates the meeting. The first NP in this case also seems more like an obligatory argument (*attender*) of the verb. However, comparing (10) to (14), deletion of the second NP makes more natural outcome than deletion of the first NP. This gives us a little piece of diagnostics. From now on, I will tentatively call DNCs such as (1) through (4) Types 1, 2, 3 and 4 respectively.

The question here is where the extra NPs which are apparently nominative case-marked. Only in Type 2, both nominative NPs are arguments of the predicate. For the other three types, we can expect either that the two apparent nominative NPs are a constituent at some point of the derivation, or that one of them is just an adjunct. The four types of DNC could vary in this respect too. I will talk about this issue in the following section.

### 3.2. Word Order

Korean is relatively free in word order, most likely due to explicit case markings on NPs. In order to check out how the two nominative NPs in DNC are related syntactically, we can get to switch their surface order. The following examples are made from the sentences in (1-4) by switching the orders of the first two NPs.

- (16) \**ttal-i* *Mary-ka* *yeyppu-ta*  
 daughter-NOM Mary-NOM pretty-DECL

- (17) %*Mary-ka John-i coh-ta*  
 Mary-NOM John-NOM fond-DECL  
 ‘Mary likes John’
- (18) \**yel-myeng-i haksayng-i hoyuy-ey chamsekhay-ss-ta*  
 ten-CL<sub>Person</sub>-NOM student-NOM meeting-DAT attend-PAST-DECL
- (19) *kalpi-ka i siktang-i masiss-ta*  
 rib-NOM this restaurant-NOM tasty-DECL  
 ‘At this restaurant, the rib is tasty’

In Type 1 and Type 3 (16 and 18), switching the NP order makes the sentence ungrammatical. From this, we can expect that in these two types the two nominative NPs are tied-up more tightly than ones in the other two types and in other usual cases. I hypothesize that in types 1 and 3 the two nominative NPs would form a constituent at some point of the derivation. I will get back to this in detail later. The order switching in (17) change its truth condition, which I indicate with %: the *liker-liked* relation is reversed here, but the sentence is still perfectly grammatical. This corresponds to the finding in section 3.1 on argumenthood. Since the two NPs are independent arguments in this type of DNC, word order would be basically free just as usual. In (19), the flipped order neither degrades the grammaticality of the sentence, nor creates any serious meaning difference. In this case too, the two NPs seem to be independent elements, although one of them is not a selected argument of the predicate.

Based on the judgments in (16-19), comparing to them with (1-4), we can roughly divide Korean DNC into two classes: Types 1 and 3 in one class, and types 2 and 4 in the other class. But this classification is obviously not enough. The examples in (8-11) show that types 1 and 4 in the same class and types 2 and 3 in the other class. I will perform some more diagnostics to get a refined classification.

### 3.3. Structure of Nominative NP

In this subsection, I will look more into the nominative NPs of each type, expecting that they have different internal structures. This expectation comes from the observations about the argument structures of the predicates from each type of DNC. Let us compare Type 1 and 2 first. As shown in (20-21) below, Type 1 DNC has corresponding possessive construction, Type 2 does not.

- (20) a. *Mary-ka ttal-i yeypu-ta* (=1)  
 Mary-NOM daughter-NOM pretty-DECL  
 b. *Mary-uy ttal-i yeypu-ta*  
 Mary-POSS daughter-NOM pretty-DECL
- (21) a. *John-i Mary-ka coh-ta* (=2)  
 John-NOM Mary-NOM fond-DECL  
 b. *\*John-uy Mary-ka coh-ta*  
 John-POSS Mary-NOM fond-DECL

There are two major lines of analyses on Type 1 DNC in the literature: (i) *Possessor Raising* analysis (Seo 1971), in which DNC as in (21a) is derived from possessive construction as in (21b), and (ii) *Non-derivational* analysis (Yoon 2007; Vermeulen), in which the possessor is independently merged by some kind of extra argument introducing mechanism. The contrast in (20-21) is often used as evidence against the possessor raising approach by the non-derivationalists. According to them, assuming that all DNCs are fundamentally one, some DNCs do not have possessive counterparts, as (21) shows. However, as shown in the previous sub-sections, the four tentative types of DNCs are different enough to be classified.

There is another remarkable difference among nominative NPs in Type 1 and Type 2 DNCs. The second NP in Type 1 DNC behaves differently from the others in *Wh*-question formation.

- (22) a. *Nwu-ka ttal-i yeypu-ni?*  
 Who-NOM daughter-NOM pretty-Q  
 ‘Whose daughter is pretty?’  
 b. *\*Mary-ka nwu-ka yeypu-ni?*<sup>6</sup>

<sup>6</sup> cf) *Mary-ka eti-ka yeypu-ni?*

M-NOM where-NOM pretty-Q

i. ‘Which part of Mary is pretty?’

ii. (lit.) The speaker thinks that Mary is not pretty.

Above question can either mean (i) or (ii), although the second reading is preferred by many speakers. I think there is some difference between *eti* ‘where’ and other *Wh*-words in Korean. The following example cannot have the interpretation (i).

e.g) *Mary-ka mwe-ka yeypu-ni?*

M-NOM what-NOM pretty-Q

i. ‘\*Mary’s what/which part is pretty?’

ii. (lit.) The speaker thinks that Mary is not pretty.

This patterns with the non-DNC cases. Even in the non-DNC questions, where the possessor

Mary-NOM who-NOM pretty-Q  
 ‘\*Mary’s who is pretty?’

- (23) a. *Nwu-ka Mary-ka coh-ni?*  
 Who-NOM Mary-NOM fond-Q  
 ‘Who likes Mary?’  
 b. *?John-i nwu-ka coh-ni?*  
 John-NOM who-NOM fond-Q  
 ‘Who does John like?’

I argue that (22b) is ruled out, because the second NP in this type of DNC is not a fully saturated NP on its own. The ungrammaticality of (22b) supports the possessor raising approach. According to this analysis, the possessor is moved from inside the host NP (the possessee). Then, we can say there is something missing in the second NP, which, I claim, is the raised possessor. Therefore, it cannot be *Wh*-ed all by itself. Compare (22b) with the following sentence. The argument of the predicate *yeyppu*-‘pretty’ can freely be *Wh*-ed, when there is no raised possessor out of it.

- (24) *Nwu-ka yeyppu-ni?*  
 Who-NOM pretty-Q  
 ‘Who is pretty?’

### 3.4. Syntactic Position

In this subsection, I will illustrate the differences between Types 1 and 3. Earlier in the paper, I hypothesized that in these two types the two nominative NPs are constituent at some point of the derivation. Strict word order restriction in Type 1,

---

and the possessee undoubtedly form a constituent.

- e.g) a. *\*Mary-ka nwu-ka yeyppu-ni?*  
 Mary-NOM who-NOM pretty-Q  
 b. *\*Mary-uy mwe-ka yeyppu-ni?*  
 M-POSS what-NOM pretty-Q  
 c. *Mary-uy eti-ka yeyppu-ni?*  
 M-POSS where-NOM pretty-Q

It is not clear what is the difference between *eti* ‘where’ and *mwue(s)* ‘what’/ *nwukwu* ‘who’. Maybe, *eti* ‘where’ has different syntactic status from other *Wh*-words. I don’t have a good answer for this question right now.

From this pattern, we can at least notice that N2 in DNC cannot be freely substituted by a *Wh*-word.

illustrated in section 3.2, supports this hypothesis. Some more pieces of supporting evidence are given below.

(25) Relativization

- a. [[  $t_i$  *ttal-i*]            *yeyppu-n*]    *Mary\_i*  
       daughter-NOM pretty-COMP Mary  
       ‘Mary whose daughter is pretty’
- b. \**[Mary\_i-ka t\_j yeyppu-n] [t\_i ttal]\_j*  
       Mary-NOM        pretty-COMP    daughter

(26) Subject-to-Object Raising

- a. *John-un Mary\_i-lul* [[  $t_i$  *ttal-i*]            *yeyppu-ta*]-*ko*        *sayngkakha-n-ta*  
       J-TOP    M-ACC        daughter-NOM pretty-DECL-COMP think-PRES-DECL  
       ‘John thinks that Mary’s daughter is pretty’
- b. \**John-un [t\_i ttal]\_j-ul [Mary\_i-ka t\_j yeyppu-ta]-ko sayngkakha-n-ta*  
       J-TOP    daughter-ACC    M-NOM        pretty-DECL-COMP think-PRES-DECL

I argue that the *b* sentences in (25-26) are ruled out, due to violating Proper Binding Condition (PBC).

(27) *Proper Binding Condition* (Fiengo 1977)

: A trace must be c-commanded by its antecedent.

In the *b* examples, the host NP, which is including the trace of the raised possessor, moves over the possessor (the antecedent). Then, the trace in the dislocated NP cannot be c-commanded by its antecedent, violating PBC. Interestingly, similar kind of word order restriction is observed in Type 3 too.

(28) Scrambling

- a. *Haksayng\_i-i [t\_i yel-myeng-i]            hoyuy-ey        chamsekhay-ss-ta* (=3)  
       Student-NOM        ten-CL<sub>Person</sub>-NOM    meeting-DAT    attend-PAST-DECL  
       ‘Ten students attended the meeting’
- b. \**[t\_i yel-myeng-i]\_j        haksayng\_i-t    t\_j hoyuy-ey        chamsekhay-ss-ta*  
       ten-CL<sub>Person</sub>-NOM    Student-NOM        meeting-DAT    attend-PAST-DECL

(29) Relativization

- a. [*Haksayng<sub>i</sub>-i* [*t<sub>i</sub> yel-myeng-i*] *chamsekha*]-*n hoyuy*  
 Student-NOM ten-CL<sub>Person</sub>-NOM attend-COMP meeting  
 ‘The meeting which ten students attended’
- b. \*[[*t<sub>i</sub> yel-myeng-i*]<sub>j</sub> *haksayng<sub>i</sub>-i* *t<sub>j</sub> chamsekha*]-*n hoyuy*  
 ten-CL<sub>Person</sub>-NOM student-NOM attend-COMP meeting
- (30) Subject-to-Object Raising
- a. ?*John-un haksayng<sub>i</sub>-ul* [*t<sub>i</sub> [t<sub>i</sub> yel-myeng-i] hoyuy-ey chamsekhay-ss-ta*]-*ko*  
 J-TOP student-ACC ten-CL<sub>Person</sub>-NOM meeting-DAT attend-PAST-DECL-COMP  
*sayngkakha-n-ta*  
 think-PRES-DECL  
 ‘John thinks that Mary’s daughter is pretty’
- b. \**John-un* [*t<sub>i</sub> yel-myeng-ul*] [*haksayng<sub>i</sub>-i t<sub>j</sub> hoyuy-ey chamsekhay-ss-ta*]-*ko*  
 J-TOP ten-CL<sub>Person</sub>-ACC student-NOM meeting-DAT attend-PAST-DECL-COMP  
*sayngkakha-n-ta*  
 think-PRES-DECL

So far, Types 1 and 3 show the same characteristics. However, there are also some asymmetries between them. First of all, the argument selected by the main predicate is the second NP in Type 1, whereas the first NP is the argument in Type 3. We can expect that the NPs in these types have different internal structure, in spite of their apparent similarities. Therefore, even in surface structure the NPs do not seem to take the same syntactic position.

- (31) a. *Tahayng<sub>hi</sub> Mary-ka ttal-i yeyp<sub>pu</sub>-ta*  
 Fortunately M-NOM daughter-NOM pretty-DECL  
 (i) It is fortunate that Mary’s daughter is pretty.  
 (ii) Fortunately, it is Mary whose daughter is pretty.
- b. *Mary-ka tahayng<sub>hi</sub> ttal-i yeyp<sub>pu</sub>-ta*  
 M-NOM fortunately daughter-NOM pretty-DECL  
 (i) It is fortunate that Mary’s daughter is pretty.  
 (ii) Fortunately, it’s her daughter who is the pretty one (among Mary’s kids).
- c. *Mary-ka ttal-i tahayng<sub>hi</sub> yeyp<sub>pu</sub>-ta*  
 M-NOM daughter-NOM fortunately pretty-DECL  
 (i) \*It is fortunate that Mary’s daughter is pretty.  
 (ii) It is fortunate that Mary’s daughter has at least the property of being pretty. (She doesn’t have any other positive property.)

- (32) a. *Tahayngghi haksayng-i yel-myeng-i hoyuy-ey chamsekhay-ss-ta*  
 Fortunately student-NOM ten-CL<sub>Person</sub>-NOM meeting-DAT attend-PAST-DECL  
 (i) It is fortunate that ten students attended the meeting.  
 (ii) Fortunately, it was students (not teachers) who attended the meeting.
- b. *Haksayng-i tahayngghi yel-myeng-i hoyuy-ey chamsekhay-ss-ta*  
 Student-NOM fortunately ten-CL<sub>Person</sub>-NOM meeting-DAT attend-PAST-DECL  
 (i) \*It is fortunate that ten students attended the meeting.  
 (ii) Fortunately, the number of students who attended the meeting was ten.
- c. *Haksayng-i yel-myeng-i tahayngghi hoyuy-ey chamsekhay-ss-ta*  
 Student-NOM ten-CL<sub>Person</sub>-NOM fortunately meeting-DAT attend-PAST-DECL  
 (i) \*It is fortunate that ten students attended the meeting.  
 (ii) Fortunately, it was the meeting which the ten students attended.

*Fortunately* is a sentential adverb, and adjoined to CP or TP, according to Alexiadou (2002). Here, I am targeting the readings in which *fortunately* scopes over the whole proposition, assuming that we would get the second reading (narrow scope reading), when a sentential adverb adjoined to an NP. Let's compare (31b) and (32b), in which *tahayngghi* 'fortunately' is placed between the first and the second NPs. (31b) has the wide-scope reading, while (32b) doesn't. This tells us that *ttal-i* 'daughter' in (31) takes higher position than *yel-myeng-i* 'ten (people)' does in (32).

### 3.5. Focus in DNC

Now, I turn to the last type. In section 3.2, we saw that in Type 4 the first occurrence of nominative NP is not a selected argument of the predicate. Then, we could expect that it is derived out of the other NP, but we also confirmed in 3.2 that there is no word order restriction between those two NPs. It doesn't directly exclude the possibility for derivation, but if we account for Type 4 derivationally, we would have to deal with the absence of word order restriction first. If it is not moved out of the argument NP, where does it come from? It seems to be quite appropriate to assume it is an adjunct. But then, how would an adjunct bear nominative case marking? I argue that this realization of nominative-looking particle is in fact a focus marker. In Korean, nominative and accusative case markers are sometimes used as focus markers<sup>7</sup>.

<sup>7</sup> Or we could say that case and focus markers happen to have the same morphological realization. It is not clear why there are two different forms of focus markers and how one of

- (33) a. yelum-i      Hawaii-ey kwankwangkayk-i ceyil manh-ta  
 summer-FOC Hawaii- in tourist-NOM      most many-DECL  
 ‘It is the summer when the largest number of tourists visit Hawaii’
- c. mwunmyengkukka-ka namca-ka phyengkyunswumyeng-i kil-ta  
 civilized.country-FOC male-NOM average.life.span-NOM long-DECL  
 ‘It is civilized countries where the average life span of man is long’
- (34) a. John-i      hakkyo-ey ka-ss-ta  
 John-NOM school-to go-PAST-DECL  
 ‘John went to school’
- a’. John-i      hakkyo-lul ka-ss-ta  
 John-NOM school-FOC go-PAST-DECL  
 ‘It is school where John went to’
- b. John-i      Mary-eykey chayk-ul cwu-ess-ta  
 John-NOM Mary-DAT book-ACC give-PAST-DECL  
 ‘John gave Mary a book’
- b’. John-i      Mary-lul chayk-ul cwu-ess-ta  
 John-NOM Mary-FOC book-ACC give-PAST-DECL  
 ‘It is Mary that John gave a book to’

The underlined NPs in (33-34) obviously don’t have the nominative or accusative property, and are (obligatorily) realized with high pitch accent. These examples at least show that *-i/ka* has a non-case-marking function. Now, the question is what supports the focus analysis on Type 4 DNC. Szabolcsi’s (1981) *exhaustivity* test gives a piece of evidence for that.

- (35) a. [*Burger King-kwa Wendy’s-ka*] hamburger-ka masiss-ta  
 BK-and Wendy’s-NOM hamburger-NOM tasty-DECL  
 ‘It is Burger King and Wendy’s where hamburger is tasty’
- b. [*Wendy’s-ka*] hamburger-ka masiss-ta  
 Wendy’s-NOM hamburger-NOM tasty-DECL  
 ‘It is Wendy’s where hamburger is tasty’
- : a ✗ b

---

them is selected in a sentence. I don’t have good answers for those questions now.

According to Szabolcsi (1981), the fact that (35a) which includes two conjuncts, Burger King and Wendy's, does not entail (35b) with only one of them shows the sentence is exhaustive, since (exhaustive) focus excludes other possibility than 'Wendy's' being the place where delicious hamburger is served.

#### 4. Concluding Remarks

In this paper, I classified Double Nominative Constructions into four types, and showed the asymmetries among them. Argument structure distinguishes Type 2 from the other three, since the two nominative case-marked NPs are both arguments of the main predicate in this type. Flipping the relative order between two nominative NPs changes the grammaticality in Types 1 and 3, but not in Types 2 and 4. I argue that it is because the two nominative NPs in Types 1 and 3 form a constituent underlyingly, and the second NP includes the trace of the first NP. Therefore, the inversed order of the nominative NPs violates Proper Binding Condition. Type 4 DNC also includes a non-argumental nominative NP, but there is no word order restriction. I argue that this non-argumental occurrence is, in fact, not a nominative NP, but a focus.

The current study is more like a preliminary work on Double Nominative Construction. There are lots of theoretical details, which are not included in this version. Each type of DNC needs further investigation, and it would be possible that each type is divided into several subtypes.

## Abstract

This paper aims to capture the correlation of the Case form of the stranded subject of a lower clause with the availability of remnant clause scrambling in three constructions in Korean, Raising-to-Object (RTO), Obligatory Control (OC) and Periphrastic Causative (PC) constructions. Adopting a *movement* approach to Case alternations, I suggest that the asymmetry between RTO and OC regarding the availability of remnant scrambling is due to the relative height of the landing site of a Case-alternating DP, which is a crucial factor for determining whether the edge of a Phase is extended on a par with Cyclic Spell-Out. I then show that the proposed analysis makes a correct prediction for the three-way Case alternations in PC.

**Keywords:** Case Alternations, Cyclic Spell-Out, Obligatory Control Construction, Periphrastic Causative Construction, Phase, Raising-to-Object Construction.

## 1. Introduction

Korean allows a DP subject in the lower clause to take different Case forms without changing the truth-conditional meaning of a sentence in bi-clausal contexts. Although Case alternations are prevalent in mono-clausal contexts as well, this paper focuses on those found in the bi-clausal contexts, such as Raising-to-Object (RTO) construction in (1), Obligatory Object Control (OC) construction in (2), and Periphrastic

Although the three constructions superficially look similar concerning Case alternations, however, they show different patterns when scrambling changes their original word orders. As shown in (4) through (6), scrambling applied to the complement clause brings about different results in the three constructions in question.

book-ACC read-COMP P.-NOM Y.-DAT do-PAST-DEC

The primary goal of this paper is to explain why the three constructions exhibit

different patterns regarding the derived word order in (4) through (6). For this purpose, I adopt a movement approach, which claims that Case alternations are made possible only when a Case-alternating DP moves to a position high enough to get a relevant Case form (e.g., Kim (1985) and Hong (2005) for RTO; Monahan (2003) and Kwon and Polinsky (2006) for OC). Under the movement approach, this paper proposes that the availability of remnant clause scrambling is correlated with differences in the landing sites of Case-alternating DPs in the  $\nu$ P/VP area, since the accessibility of a lower CP to a further syntactic operation is determined by whether or not the CP is spelled-out.

The paper is organized as follows. Section 2 offers an account for the word order patterns in (4a) and (4b) under the movement approach to RTO. Section 3 then explains (5a) under the movement analysis of the OC construction in terms of the standard condition on movement, and points out that the Proper Binding Condition (cf. Fiengo (1977)) incorrectly rules out (5b). Section 4 shows how a strict derivational approach that I proposed in Park (2007, to appear) building on Hiraiwa's (2003) Cyclic Spell-Out captures the grammaticality of (5b), as opposed to (4b), under the assumption that the landing sites of the accusative Case-marked DPs are different in RTO and OC. Section 5 shows how the proposed analysis can be extended to the word order patterns in the PC construction, and section 6 concludes the paper.

## 2. Case Alternations and Remnant Scrambling in RTO

### 2.1. Movement Analysis of Case Alternations in RTO

This paper adopts a movement approach to Case alternations in RTO, which basically claims that the change of a Case form of a lower subject is possible by its movement (e.g., Kim (1985) and Hong (2005), *inter alia*; cf. Kuno (1976) and Tanaka (2002) for Japanese), and this approach is different from a non-movement approach, which argues that the lower subject does not move out of the embedded CP regardless of its Case form (e.g., Lee (1992)). Taking (1) for example, according to the movement approach, the lower subject marked with nominative Case stays put inside the embedded clause, as in (7a), while the same subject marked with accusative Case ends up in a position in an upper clause, as in (7b).

- (7) a. Peter-ka [CP Mary-**ka** yeppu-ess-ta-ko] sayngkakhay-ss-ta.  
       P.-NOM       M.-NOM   be.pretty-PAST-DEC-COMP   think-PAST-DEC

“Peter thought that Mary was pretty”

b. Peter-ka Mary-**lul**<sub>i</sub> [<sub>CP</sub> *t*<sub>i</sub> yeppu-ess-ta-ko] sayngkakhay-ss-ta.  
P.-NOM M.-ACC be.pretty-PAST-DEC-COMP think-PAST-DEC

“Peter thought of Mary that she was pretty”

I assume that the lower subject in (7b) raises to an outer Spec-*v*P of a higher clause in order to check accusative Case against a light verb *v* (cf. Hong (2005)), and that Korean allows for multiple Case checking, which is widely attested in many languages (e.g., Massam (1985) and Fujii (2005), among many others).<sup>1</sup>

The movement approach makes a correct prediction for a number of data. Due to space reason, I will provide one of the arguments in favor of the movement approach, which has to do with the fact that the speaker-oriented adverb *papokachi* ‘stupidly’ can follow the accusative Case-marked subject, but not the nominative Case-marked one, as shown in the contrast between (8a) and (8b) (data adapted from Hong (2005: 81) and Tanaka (2002: 637)).

(8) a. Peter-ka (papokachi) [Mary-**ka** (\*papokachi) chencayta-ko]  
P.-NOM stupidly M.-NOM stupidly be.genius-PAST-DEC-COMP  
sayngkakha-n-ta.  
think-PAST-DEC

Intended reading: “Peter stupidly thinks that Mary is a genius”

b. Peter-ka Mary-**lul**<sub>i</sub> papokachi [<sub>i</sub> chencayta-ko]  
P.-NOM M.-ACC stupidly be.genius-PAST-DEC-COMP  
sayngkakha-n-ta.  
think-PAST-DEC

Intended reading: “Peter thinks of Mary stupidly as a genius”

On the movement approach, since the nominative Case-marked subject *Mary-ka* ‘Mary-NOM’ remains inside the embedded CP, it fails to precede the adverb modifying the matrix verb. The accusative Case-marked subject *Mary-lul* ‘Mary-ACC,’ on the other, has already moved to the outer Spec-*v*P, which can be higher than the adverb.

---

<sup>1</sup> There appear to be particular syntactic environments where Case alternations are possible in RTO. The most uncontroversial observation in the literature is that a DP may take different Case forms only when a selecting predicate is *stative*, which is dated back to Postal’s (1974) observation on the nature of ECM verbs in English.

Notice also that the movement approach can give us an account for (i) the syntactic distribution of an NPI relative to a lower subject; and (ii) the applicability of scrambling to the subject depending on its Case form RTO.<sup>2</sup>

## 2.2. Unavailability of the Derived Word Order in RTO

With the movement approach at hand, let us see how to explain the patterns of the derived word in RTO in (4a, b), repeated below.

- (4) a. \*yeppu-ess-ta-ko<sub>i</sub>                      Peter-ka    Mary-**ka**                      *t<sub>i</sub>*    sayngkakhay-ss-ta.  
           be.pretty-PAST-DEC-COMP    P.-NOM    M.-NOM                      think-PAST-DEC  
           Lit: “[was pretty]<sub>i</sub> Peter thought Mary *t<sub>i</sub>*”
- b. \*yeppu-ess-ta-ko<sub>i</sub>                      Peter-ka    Mary-**lul**                      *t<sub>i</sub>*    sayngkakhay-ss-ta.  
           be.pretty-PAST-DEC-COMP    P.-NOM    M.-ACC                      think-PAST-DEC

To begin with, if it is correct that the Case alternation in the RTO construction reflects the structural position of an embedded subject, the ungrammaticality of (4a) can be explained in terms of the standard condition on movement, which stipulates that only the constituent can be a target of movement (e.g., Radford (1988)). Notice that the fronted part in (4a) is neither a VP nor a TP, as a couple of verbal suffixes including the past morpheme *-ess*, the declarative ending *-ta*, and the complementizer *-ko* must be attached to the predicate before scrambling applies. Accordingly, if we pull out only part of the embedded CP, stranding the nominative Case-marked subject, the condition on movement will be violated, prohibiting the derived word order.

Turning to (4b), if we apply scrambling to the complement clause without pied-piping the accusative Case-marked subject, the sentence becomes ungrammatical as well. It seems that the traditional notion of the Proper Binding Condition (PBC) in (9) explains the unavailability of this pattern of the derived word order.

(9) *Proper Binding Condition*

Traces must be bound.

Fiengo (1977)

Given the claim that the accusative Case-marked subject is raised out of the complement clause, the trace of the displaced subject is supposed to be left behind

---

<sup>2</sup> See Hong (2005) and Park (2007, to appear) for more pieces of evidence.

inside the complement clause. Thus, fronting of the remnant clause by scrambling prevents the trace inside it from being bound, which renders the PBC violated.

### 3. Case Alternations and Remnant Scrambling in OC

#### 3.1. Movement Analysis of Case Alternations in OC

There are at least two possible approaches to Case alternations in OC in Korean. One is a PRO theory of Control (e.g., Chomsky and Lasnik (1993) and Martin (1996), *inter alia*), and another one is a movement approach to Control (e.g., Hornstein (2001), Monahan (2003), and Kwon and Polinsky (2006), *inter alia*). This paper adopts the movement approach arguing that an obligatory referential dependency between a matrix object and a lower subject in (2), repeated below, can be maintained not because a PRO is controlled by the matrix object, but because *Mary*, a persuadee argument, starts out in the lower clause and creates an A-chain as a result of A-movement into an object position in the matrix clause later. Crucially, it is assumed that theta-roles are features, and movement of a lower argument in OC is driven for theta-feature checking. On the movement approach, the OC sentence in (5), repeated below, can be analyzed as two different structures depending on the Case form of *Mary*, as shown in (10a) and (10b).

- (2) Peter-ka Mary-**ka/lul** ttena-tolok seltukhay-ss-ta.  
 P.-NOM M.-NOM/ACC leave-COMP persuade-PAST-DEC  
 “Peter persuaded Mary to leave”
- (10) a. Peter-ka  $t_i$  [Mary-**ka**<sub>i</sub> ttena-tolok] seltukhay-ss-ta.  
 P.-NOM M.-NOM leave-COMP persuade-PAST-DEC  
 b. Peter-ka Mary-**lul**<sub>i</sub> [ $t_i$  ttena-tolok] seltukhay-ss-ta.  
 P.-NOM M.-ACC leave-COMP persuade-PAST-DEC

The OC construction with the nominative Case-marked persuadee can be obtained by deleting a higher copy of the A-chain, as illustrated in (10a). The OC construction with the accusative Case-marked persuadee, on the other, can be derived by deleting a lower copy of the same chain, as represented in (10b).<sup>3</sup>

---

<sup>3</sup> I will not go into detail in this paper as to the way to determine which copy can be survived in which environment. See Hornstein (2001) for a relevant discussion.

Notice that it seems unclear how the PRO theory explains the OC construction with the nominative Case-marked persuadee in (10a). Given that the nominative Case in Korean is either assigned by the finite T, or realized as default Case, *Mary-ka* ‘Mary-NOM’ is supposed to remain inside the lower clause. Then, PRO that is referentially dependent on *Mary-ka* must be posited in the upper clause as a grammatical object of the matrix predicate, which leads to a fatal violation of the so-called PRO Theorem.<sup>4</sup>

In addition to this theoretical advantage, the movement approach makes a correct prediction for some empirical facts. Below in (11) and (12) are some of the data, which are naturally explained by the movement approach (data from Monahan (2003)).

- (11) Peter-ka    Mary-**\*ka/lul**    seltukhay-ess-ta.  
P.-NOM    M.-NOM/ACC    persuade-PAST-DEC  
“Peter persuaded Mary”
- (12) Peter-ka    Mary-**\*ka/lul**    kanghakey    kakey-ey    mayil    ka-tolok  
P.-NOM    M.-NOM/ACC    strongly    store-LOC    every.day    go-COMP  
seltukha-lke-ya.  
persuade-FUT-DEC  
“Peter will strongly persuade Mary to go to the store every day”

First, recall that the movement approach assumes that a DP may take more than one Case form only when it can appear in a canonical position for each type of Case: e.g., Spec of TP for nominative Case and outer Spec of vP for accusative Case. Therefore, it is predicted that if the predicate *seltukha-* ‘persuade’ takes only a DP argument, the Case form of the DP cannot alternate, and this prediction is borne out, as shown in (11). Secondly, the nominative Case-marked persuadee, as opposed to the accusative Case-marked one, cannot precede an adverb modifying the matrix verb, as in (12). Under the movement approach, the reason *Mary-ka* ‘Mary-NOM’ fails to be followed by the adverb is simply that it stays put inside the lower clause.

### 3.2. *Patterns of the Derived Word Order in OC*

In this section, let us see how the movement approach to the Case alternations in OC handles the patterns of the derived word order in OC. Consider first the word

---

<sup>4</sup> See Monahan (2003) for diagnostics showing that the verb *seltukha-* ‘persuade’ in OC is a three-place predicate, which takes two internal arguments, a DP and a proposition.

order in (5a), repeated below.

- |        |   |          |                  |                      |                   |
|--------|---|----------|------------------|----------------------|-------------------|
| (5) a. | *ttena-tolok <sub>i</sub>   | Peter-ka | Mary- <b>ka</b>  | <i>t<sub>i</sub></i> | seltukhay-ss-ta.  |
|        | leave-COMP  | P.-NOM   | M.-NOM           |                      | persuade-PAST-DEC |
|        | Lit: “[to leave] <sub>i</sub> Peter persuaded Mary <i>t<sub>i</sub></i> ” |          |                  |                      |                   |
| b.     | ttena-tolok <sub>i</sub>  | Peter-ka | Mary- <b>lul</b> | <i>t<sub>i</sub></i> | seltukhay-ss-ta.  |
|        | leave-COMP  | P.-NOM   | M.-ACC           |                      | persuade-PAST-DEC |

As shown in (5a), scrambling applied to the complement clause makes the sentence ungrammatical if we strand the nominative Case-marked controller. If it is correct that Korean allows a control sentence in which the nominative Case-marked controller resides in the embedded clause, the ungrammaticality of (5a) can be naturally explained. Simply put, the illegitimacy of (5a) is due to a violation of the ban on movement of a non-constituent, which is analogous to the illegitimacy of the RTO sentence in (4a).

Secondly, let us consider the second word order pattern in (5b) in which the complement clause is fronted with the accusative controller stranded. Notice that if the obligatory control relation is a residue of A-movement, a question arises as to why the application of local scrambling to the remnant complement clause in (5b) does not give rise to PBC effects, as opposed to the RTO sentence in (4b). That is, the trace of *Mary-lul* ‘Mary-ACC’ is embedded inside the complement CP, which is apparently in a higher position than the potential antecedent of the trace. Therefore, we would expect that the Proper Binding Condition rules out (5b), which is not the case. The grammaticality of (5b) looks puzzling if we compare it with the ungrammaticality of (4b), and section 4 will discuss how I resolved this puzzle in Park (2007, to appear).

## 4. Word Order Asymmetry between OC and RTO Revisited

### 4.1. Phase and Cyclic Spell-Out

In order to resolve the word order puzzle between (4b) and (5b), I highlighted the different property between the raising and control predicates with respect to the landing sites of accusative Case-marked DPs, and connected this difference to a derivational model of grammar, which builds on Chomsky’s Phase-based theory. Chomsky (2000, 2001a,b) claims that Phase (e.g., CP and *v*P) is a syntactic unit by which a derivation proceeds, and also suggests the Phase Impenetrability Condition (PIC) to capture

locality effects in agreement and movement, which is defined in (13).

(13) *Phase Impenetrability Condition* (Chomsky (2000: p.108))

In phase  $\alpha$  with head H, the domain of H is not accessible to operations outside  $\alpha$ , only H and its edge are accessible to such operations.

Given this condition, we can easily rule out the impermissible long-distance *wh*-movement in (14b). Notice that *what* in (14b) is forced to stay put in the *domain* of the lower  $C^0$  due to the existence of another *wh*-phrase *when* in the specifier position of the lower CP, an edge position to which the matrix  $v^0$  can have access. As a result, the matrix  $C^0$  cannot have a local syntactic relation with *what*, rendering (14b) unacceptable.

- (14) a. What<sub>i</sub> does John [<sub>vP</sub> t<sub>i</sub> [<sub>vP</sub> think [<sub>CP</sub> t<sub>i</sub> that Bill [<sub>vP</sub> t<sub>i</sub> [<sub>vP</sub> bought t<sub>i</sub>]]]]]]?  
b. \*What<sub>i</sub> does John [<sub>vP</sub> t<sub>i</sub> [<sub>vP</sub> think [<sub>CP</sub> when Bill [<sub>vP</sub> t<sub>i</sub> [<sub>vP</sub> bought t<sub>i</sub>]]]]]]?

As pointed out in Park (2007, to appear), however, there seems to be a small glitch in Chomsky's theory of locality in terms of PIC. That is, although Chomsky's notion of Phase and PIC are correct in preventing an operation from applying to any element inside the *domain*, nothing is directly said about whether the *domain* itself is accessible to an operation outside the Phase. In order to fix this problem, I assumed with Hiraiwa (2003) that the *domain* of a Phase should be spelled-out as soon as its *edge* (i.e., a Phase head or its specifier position) is extended. Following Hiraiwa (2003), I defined this type of Spell-Out, labeled 'Cyclic Spell-Out,' in the following way.

(15) *Cyclic Spell-Out*

If the *edge* of a Phase ( $=\alpha$ ) is extended by Re-Merge/Move of  $\beta$  from inside the domain, the domain ( $=YP$ ) should be spelled-out immediately.

It will be shown in section 4.2 how Cyclic Spell-Out in (15), a stronger version of PIC, explains the asymmetry between (4b) and (5b).

#### 4.2. Solving the Word Order Puzzle between RTO and OC

Let's begin with the illegitimate word order in (4b), repeated below again.

- (4) b. \*yeppu-ess-ta-ko<sub>i</sub>                  Peter-ka    Mary-**lul**        *t<sub>i</sub>*    sayngkakhay-ss-ta.  
           be.pretty-PAST-DEC-COMP P.-NOM    M.-ACC                  think-PAST-DEC  
 Lit: “[was pretty]<sub>i</sub> Peter thought Mary *t<sub>i</sub>*”

As discussed in 2.1, the lower subject undergoes movement out of the embedded CP, which targets the outer Spec-*v*P for checking accusative Case against *v*. In particular, this movement ends up extending the *edge* of a Phase (i.e., Spec of *v*<sup>0</sup>). Consequently, the movement of the embedded subject makes the remnant clause inaccessible to a further operation (i.e., scrambling), as the clause is already transferred on a par with the Cyclic Spell-Out in (15).

Secondly, let us now consider the legitimacy of the derived word order in (5b), repeated below, which the PBC fails to explain.

- (5) b. ttena-tolok<sub>i</sub>                  Peter-ka    Mary-**lul**        *t<sub>i</sub>*        seltukhay-ss-ta.  
           leave-COMP    P.-NOM        M.-ACC                  persuade-PAST-DEC  
 Lit: “[to leave]<sub>i</sub> Peter persuaded Mary *t<sub>i</sub>*”

Recall that the raising of the persuadee in the OC construction in (5b), i.e., *Mary-lul* ‘Mary-ACC,’ is motivated for theta-feature checking, which targets the specifier position of the matrix VP. Crucially, this movement does not extend the edge of the Phase, which is contrastive with the RTO construction in (4b). Therefore, even after the raising of the controller out of the embedded clause, the remnant clause remains accessible to local scrambling in (5b).

Now, we are left with a question of why scrambling of the remnant clause in the PC construction gives rise to diverging results depending on the Case form of the causee argument. In section 5, it will be shown that the proposed analysis based on Cyclic Spell-Out can successfully explain them.

## 5. Extending the Analysis: Patterns of the Derived Word Order in PC

### 5.1. A Dual Analysis of PC

It has been proposed that the PC construction in Korean can be subdivided into two depending on the form of a causee argument (e.g., Kang (1988), Kim (1990) and Park (1994)). To be more specific, when a causee argument is marked with

nominative or accusative Case, the PC construction can be structurally reanalyzed as RTO. When the same argument is marked with dative Case, on the other, the construction can be characterized as OC (although the analysis advanced by the three works above posits PRO in the lower clause). One of the arguments in favor of this dual analysis comes from NPI licensing. As in (16) below, the use of an NPI in the PC sentence with a nominative or accusative Case-marked causee is judged more acceptable than in the PC sentence with a dative Case-marked causee.<sup>5</sup>

- (16) a. John-un aitul-i/?ul amwu-to Mary-lul ttalici  
 J.-TOP children-NOM/ACC anybody-also M.-ACC hit  
 ani-ha-key hay-ess-ta.  
 not-do-COMP do-PAST-DEC  
 “John did not make any of the children hit Mary”
- b. ?\*John-un amwu-eykey-to Mary-lul ttalici ani-ha-key hay-ess-ta.  
 J.-TOP anybody-DAT-also M.-ACC hit not-do-COMP do-PAST-DEC  
 “John did not make anybody hit Mary” Park (1994: 204)

As Park (1994: 204) mentions, given the claim that an NPI must appear in the same clause as negation in order to be licensed in Korean, the contrast between (16a) and (16b) suggests that there are two different types of PC in Korean.

At this point, however, an acute reader might ask why the NPI connected to the accusative Case-marked causee in (16a) still makes the sentence better than the NPI as a dative Case-marked causee in (16b). Note that according to the movement approach, they should be equally bad, as both causee arguments end up being in the upper clause. Although a more careful investigation of the structures of the two types of PC is still necessary, the fact that only the pronominal causee marked with nominative can be bound by the causer seems to support the movement approach (cf. Yeo (2006)).

- (17) a. Peter-ka<sub>i</sub> ku<sub>i</sub>-ka totpoi-key hay-ss-ta.  
 P.-NOM he-NOM look.better-COMP do-PAST-DEC  
 Intended reading: “Peter made himself look better”
- b. \*Peter-ka<sub>i</sub> ku<sub>i</sub>-lul totpoi-key hay-ss-ta.  
 P.-NOM he-ACC look.better-COMP do-PAST-DEC

---

<sup>5</sup> Notice that Park’s (1994) original judgment on the sentence in (16a) is slightly modified, as the judgments made by my informants are different from his.

- b. \*Peter-ka<sub>i</sub> ku<sub>i</sub>-**eykey** totpoi-key hay-ss-ta.  
P.-NOM he-DAT look.better-COMP do-PAST-DEC

## 5.2. Explaining the Word Order Patterns of PC

If this dual analysis is correct, we could make an interesting prediction regarding the patterns of the derived word order in the PC construction. That is, in the PC construction with a nominative or accusative Case-marked causee, local scrambling of the remnant clause should be prohibited regardless of the Case form, and this prediction is borne out as in (6a) and (6b), repeated below.

- (6) a. \*chayk-ul ilk-key<sub>i</sub> Peter-ka Yenghi-**ka**  $t_i$  hay-ss-ta.  
book-ACC read-COMP P.-NOM Y.-NOM do-PAST-DEC  
Lit: “[read books]<sub>i</sub>’ Peter made Mary  $t_i$ ”
- b. \*chayk-ul ilk-key<sub>i</sub> Peter-ka Yenghi-**lul**  $t_i$  hay-ss-ta.  
book-ACC read-COMP P.-NOM Y.-ACC do-PAST-DEC
- c. ?chayk-ul ilk-key<sub>i</sub> Peter-ka Yenghi-**eykey**  $t_i$  hay-ss-ta.  
book-ACC read-COMP P.-NOM Y.-DAT do-PAST-DEC

First, since the PC construction with a nominative or accusative Case-marked causee falls under RTO, the fronting of the remnant clause stranding the nominative causee in (6a) would violate the ban on movement of a non-constituent. Second, the raising of the accusative causee in (6b) ends up extending the edge of a Phase (i.e., the higher  $vP$ ) because it targets the outer Spec- $vP$  for Case checking. As a result, the remnant CP, which is part of the complement *domain* of the Phase head  $v^0$ , becomes invisible to scrambling.

On the other hand, it is predicted that the PC construction with a dative causee allows for local scrambling of the remnant clause. Indeed, the sentence turns out to be acceptable, as in (6c) above, although the degree of acceptability seems to vary from speaker to speaker. According to the current analysis, the dative causee argument moves up to Spec-VP for theta-feature checking without extending the edge of a higher phase, keeping the remnant CP accessible to a further operation.

## 6. Conclusion

We have shown that the Case alternations in Korean RTO and OC constructions are reflections of the structural positions of Case-alternating DPs, which lends support for the movement approach. More importantly, the movement analysis of the RTO and OC constructions, coupled with a strict derivational model of grammar adopting Cyclic Spell-Out, enables us to explain the patterns of derived word order not only in RTO and OC. Taking one further step, we have also demonstrated that the proposed analysis can explain why the PC sentences are diverged into two with respect to the availability of remnant scrambling, under the assumption that they can be reanalyzed as RTO or OC depending on the Case form of a causee argument. Although we are left with many issues that still require careful examinations, the current work seems to open up the possibility that Case alternations in the RTO, OC and PC constructions that have been believed to have different syntactic structures can be explained in a uniform way.

# A Unified Approach to the Peculiarities of Comparative Inversion

Kwang-sup Kim

Hankuk University of Foreign Studies  
[kwangsup@hufs.ac.kr](mailto:kwangsup@hufs.ac.kr)

## Abstract

This article endeavors to show that the peculiarities of Comparative Inversion are not construction-specific but they follow from a general theory of ellipsis. There are two different approaches to the elided constructions: the deletion approach and the zero-form approach. I propose a unified approach by claiming that both deletion and zero forms are utilized in English. First of all, I propose that zero forms are divided into two types: the zero pronominal and the zero operator type, which amounts to saying that there are three sources for silence. The main claim of this article is that the three different sources for silence are regulated by a different licensing condition, which can be summarized as follows: (i) deletion is licensed when the target for deletion and its antecedent are structurally symmetric. (ii) zero pronominals are licensed when there is an anti-c-commanding antecedent. (iii) zero operators are licensed when there is a c-commanding antecedent. This article further argues that the three different types of silence display a different syntactic behavior: (i) deletion gives neither Inversion Effects, nor MaxElide Effects, (ii) zero pronominals show MaxElide Effects, but not Inversion Effects, and (iii) zero operators produce both MaxElide Effects and Inversion Effects. This article shows that this unified approach enables us to provide a principled account for various peculiarities of Comparative Inversion and many other elliptical constructions.

## 1. Introduction

VP ellipsis is usually optional, but there is a context in which VP must be missing. Merchant (2003) observes that VP must not be present in comparatives when the subject is preceded by an auxiliary V.

- (1) a. Tom knows more languages than does his father.  
b. Tom can play more instruments than can his father.
- (2) a. \*Tom knows more languages than does his father know.  
b. \*Tom can play more instruments than can his father play.

Besides the co-occurrence restriction on Subject-Aux Inversion, Comparative Inversion has many other peculiar properties. First, Subject-Aux Inversion is optional in the comparative constructions.

- (3) a. Tom knows more languages than his father does.  
b. Tom can play more instruments than his father can.

Chomsky (1977) proposes that there is a parallelism between the comparative constructions and the *wh*-interrogatives in that A'-movement takes place in both constructions. Let us assume that there is further parallelism between them: Comparative Inversion, just like Subject Aux Inversion of *wh*-interrogatives, results from T-to-C movement. If so, it is puzzling that Subject Aux Inversion is optional in the comparative constructions, since it is obligatory in the matrix *wh*-interrogatives. Second,

more than one auxiliary verb can precede the subject in the inverted comparative constructions. Just one auxiliary verb precedes the subject in case Subject-Aux Inversion is caused by T-to-C movement, for just one verb can undergo head-movement. But a cluster of auxiliary verbs can precede the subject in the construction, as Culicover and Winkler (2008) observe.

- (4) Anna ran much faster than could have MANNY. (Culicover & Winkler 2008:1)

Third, Subject-Aux Inversion is not permitted when there is an overt *wh*-operator. An overt *wh*-phrase, in stead of a null operator, can appear in some dialects of English. Interestingly, Subject-Aux Inversion is not allowed when the overt *wh*-phrase is present.

- (5) a. Tom knows more languages than what his father knows.  
b. Tom knows more languages than his father does.  
c. \*Tom can play more instruments than what does his father.

Fourth, the MaxElide Effects appear in the inverted comparative deletion, while they do not in the non-inverted comparative deletion. The maximal constituent that can be recoverable must be elided in the inverted comparative constructions, whereas either partial deletion or no deletion is permitted in the non-inverted constructions.

- (6) a. John has been awarded more accolades than has Tom {(\*been), (\*been awarded)}.  
b. \*John has been awarded more accolades than has been Tom  
(7) a. John has been awarded more accolades than Tom has.  
b. John has been awarded more accolades than Tom has been.  
c. John has been awarded more accolades than Tom has been awarded.

The main purpose of this article is to provide a principled account for the above-mentioned peculiarities of Comparative Inversion. There are two competing approaches to ellipsis: the deletion approach and the zero form approach. In this article I take the position that neither the deletion approach nor the zero form approach can be a complete theory of silence, and the two approaches must be complemented by each other. This article shows that deletion and zero forms are subject to a different licensing condition and display their own distinct syntactic behavior, and various puzzling phenomena revolving around ellipsis, including the above-mentioned peculiarities of the comparative constructions, follow if we correctly identify the source of silence.

## 2. A Repair-by-Ellipsis Approach to Comparative Inversion

Merchant (2003) makes the following two assumptions in his attempt to explain the requirement that Comparative Inversion co-occur with VP-ellipsis.

- (8) a. The null operator movement proceeds via adjunction to the VP sister of I.  
b. The ECP operates at PF.

He goes on to define the ECP as follows:

- (9) At PF, a trace of A'-movement must either be head-governed, or antecedent-governed.
- (10) a. Only the link at which lexical insertion occurs can be a head governor:  
the trace cannot be a head governor.
- b. The unpronounceable constituent cannot be an antecedent governor.

With the above assumptions in mind, let us examine why (10a) is ungrammatical. In accordance with (8a) the null operator drops by the edge of VP: that is, it creates a trace in the VP-adjoined position.

- (11) a. \*Susie can play more instruments than can her father play.
- b. ... than [<sub>CP</sub> Op<sub>1</sub> can [<sub>TP</sub> her father<sub>1</sub> t<sub>can</sub> [<sub>VP</sub> t<sub>1</sub>' [<sub>VP</sub> t<sub>2</sub> play t<sub>1</sub>]]]]

This VP-adjoined trace, that is,  $t_1'$  is an offending trace. It cannot be head-governed by the trace of *can*, since (10a) stipulates that the trace cannot be a head governor. Nor can it be antecedent-governed by the null operator in compliance with (10b). Therefore, (11a) is ill-formed. However, the ECP problem is repaired if VP is deleted, for VP deletion removes the offending trace.

- (12) Susie can play more instruments than can her father ~~play~~.

To sum up, T-to-C movement must be accompanied by VP-deletion, because T-to-C movement creates an ECP problem and it can be repaired by VP-deletion.

The-ECP-as-PF-constraint-account nicely captures the co-relation between Sub-Aux Inversion and VP-ellipsis. However, there are several empirical problems with this approach. First of all, it has the problem of undergeneration. As exemplified by (4), repeated here as (13), more than one auxiliary can precede the subject in Comparative Inversion.

- (13) Anna ran much faster than could have MANNY. (Culicover & Winkler 2008:1)

T-to-C movement preposes just one auxiliary verb. Accordingly, it is impossible to generate the string in (13) under the T-to-C movement approach. This lends support to the claim that T-to-C movement is not responsible for Comparative Inversion. Another problem with Merchant's analysis comes from the fact that the ECP-based approach is incongruous with Belfast English. In Belfast English Sub-Aux Inversion can take place in the embedded clause when long distance A'-movement takes place.

- (14) a. Who did John hope would he see t?
  - b. What did Mary claim [did they steal t]?
  - c. I wonder what did John think would he get t?
  - d. What did John say did Mary claim had John feared would Bill attack t?
- (Pesetsky & Torrego 2001: 365)

Sentence (14a) would be represented as (15) under the assumption that the *wh*-

movement proceeds via adjunction to VP.

(15) who did John t' hope t' would he t' see t'?

In (15) the VP-adjoined trace is neither antecedent-governed, nor head-governed; T-to-C movement destroys the configuration for head-movement, and the trace, which is not pronounceable, cannot be an antecedent governor. In short, the trace t' violates the ECP, but the representation in (15) is well-formed, which throws doubt on the possibility that the PF version of the ECP is correct.

### 3. A Zero-Operator-Approach to Comparative Inversion

This section explores the possibility of providing a zero-form-based account for the correlation between Comparative Inversion and VP-ellipsis without recourse to T-to-C movement and the ECP. In the course of explaining the non-inverted comparative constructions I argue that the zero-form approach must be complemented by the deletion approach.

#### 3.1 *So-anaphora and Twisted Structure*

It is well-known that there is a difference in interpretation between the second utterance of (16) and the second conjunct of (17): *so I was* and *so was I* are interpreted as (18a-b), respectively. It is self-evident that the semantic difference comes from the difference in word order, but it is unclear how they are related.

(16) A: You were excited yesterday. B: **So I was.**

(17) You were excited yesterday, and **so was I.**

(18) a. It is true that I was excited.

b. It is I too that was excited.

I propose that T-to-C movement does not trigger Subject-Aux Inversion in (17), and rather, raising of *so* triggers the inverted word order. In (16-17) *so* is a pro-form that takes the AP *excited* as its antecedent. The pronominalized predicate and the subject *I* can form a small clause, and furthermore, the pro-form can be a topic or a focus, even though it is a predicate, as (19a-b) below illustrate.

(19) a. [T<sub>[+EPP]</sub> [was [small clause (sc) I<sub>[+comment]</sub> SO<sub>[+topic]</sub> ]]]

b. [T<sub>[+EPP]</sub> [was [small clause (sc) I SO<sub>[+focus]</sub> ]]]

I propose that the topic as well as the subject can undergo A-movement to satisfy the EPP of T, and on the other hand, the focus cannot undergo A-movement.

(20) The topic, as well as the subject, can satisfy the EPP of T.

The idea is that the function of the EPP is to make sentences have either the subject-predicate structure or the topic-comment structure. Just as the subject co-occurs with a

predicate, the topic co-occurs with a comment. If the predicative topic occurs with a subject, the subject serves as a comment. If the subject *I* is a comment and *so* is a topic in (19a), topic raising, rather than subject raising, takes place. Under this analysis Subject-Aux Inversion takes place not because T moves to C but because the subject remains inside VP. As (21a-b) below illustrate, the inverted string *so was I* is generated when the topic *so* undergoes raising to the SPEC-T and then, the raised topic makes further A'-movement.

- (21) a. [SO<sub>[+topic]</sub> T<sub>[+EPP]</sub> [was [<sub>small clause (sc)</sub> I<sub>[+comment]</sub> so<sub>[+topic]</sub> ]]]: merger of the head  
Topic & Topicalization  
b. [SO<sub>[+topic]</sub> Topic [so<sub>[+topic]</sub> T<sub>[+EPP]</sub> [was [<sub>small clause (sc)</sub> I<sub>[+comment]</sub> so<sub>[+topic]</sub> ]]]

By contrast, let us suppose that *so* is not a topic but it is a focus, as in (19b). Since the focused item cannot undergo A-movement, the subject *I* raises to the SPEC-T, and then, if *so* undergoes focus movement, *so I was* is generated.

- (22) a. [T [was [<sub>sc</sub> I so<sub>[+focus]</sub> ]]]: raising of *I* to the SPEC of T  
b. [I [T was [<sub>sc</sub> I so<sub>[+focus]</sub> ]]]: focalization of *so*  
c. [so<sub>[+focus]</sub> Focus [I [T was [<sub>sc</sub> I so ]]]

In (22c) the predicative phrase is focused. When the predicative phrase is focused, the whole sentence can be focused, which is supported by the fact that focus spreads to the whole sentence when VP-preposing takes place.

- (23) Excited Mary was.  
(24) a. was [<sub>sc</sub> Mary excited]: raising of *Mary* to the SPEC of T  
b. Mary was [<sub>sc</sub> **Mary** excited]: focalization of *excited*  
c. Excited Mary was [<sub>sc</sub> **Mary** excited]

Now we can straightforwardly explain the contrast in interpretation between *so I was* and *so was I*. In the former string the predicative phrase is focused. Therefore, it is interpreted as 'it is true that I was excited'. On the other hand, in the latter, *so* is a topic and *I* is focused. Therefore, it is interpreted as 'It is I too who was excited'.

This line of approach can be extended to Locative Inversion. Either the locative phrase or the theme can occupy the sentence-initial position in the locative constructions.

- (25) a. In the plaza was a statue.  
b. A statue was in the plaza.

The locative and the theme form a small clause, and furthermore, the locative phrase can be a topic, since it is referential. If the locative *in the plaza* is a topic and the theme is a comment, then the locative undergoes raising to the SPEC-T.

- (26) a. [T<sub>[EPP]</sub> [was [a statue in the plaza<sub>[+topic]</sub> ]]]: raising of *in the plaza*  
b. [in the plaza<sub>[+topic]</sub> T<sub>[EPP]</sub> [was [a statue ~~in the plaza~~<sub>[+topic]</sub> ]]]: topicalization  
c. [in the plaza<sub>[+topic]</sub> Top [in ~~the plaza~~<sub>[+topic]</sub> T<sub>[EPP]</sub> [was [a statue ~~in the plaza~~<sub>[+topic]</sub> ]]]

If, on the other hand, the locative and the theme do not form a topic-comment relation but a subject-predicate relation, the subject *a statue* undergoes raising.

- (27) a. [T<sub>[EPP]</sub> [was [a statue in the plaza]]]: subject raising  
 b. [a statue T<sub>[EPP]</sub> [was [~~a statue~~ in the plaza]]]

In short, the inverted word order is generated if the locative phrase is a topic. The following pair of sentences can be treated in an analogous way. I propose that *stand*, just like the copula, is used as a raising predicate in the locative constructions.

- (28) a. In the plaza stood a statue.  
 b. A statue stood in the plaza.

Let us first consider (28a-b). If we assume that *in need of help* and *grandmother to the child* are not arguments of *stand* but predicates in (29-30), *stand* must be classified as a raising predicate that takes a state-denoting small clause as its complement.

- (29) a. They stand [~~they~~ in need of help]  
 b. They are [~~they~~ in need of help]  
 (30) a. Will you be [~~you~~ grandmother to the child]?  
 b. Will you stand [~~you~~ grandmother to the child]?

Likewise, (28a-b) can be analyzed as raising constructions, in which *stand* takes as its complement a small clause that denotes a state.

- (31) T stand [a statue in the plaza]

The locative expression *in the plaza* can be a topic. If it is a topic, it undergoes raising, and if not, *a statue* moves to the SPEC-T.<sup>1</sup>

Let us recapitulate the claim made above. The small clause usually consists of a subject and a predicate and the subject undergoes raising. In some marked cases, however, the small clause is made up of a predicative topic and a nominative comment, which is usually focused. In that case, not the nominative comment but the predicative topic undergoes raising, which results in Subject-Aux Inversion.

- (32) a. [TP T [Subject Predicate]]: Subject Raising  
 b. [TP Subject T [~~Subject~~ Predicate]]  
 (33) a. [TP T [Subject<sub>[+comment]</sub> Predicate<sub>[+topic]</sub>]]: Topic Raising  
 b. [TP Predicate<sub>[+topic]</sub> T [Subject<sub>[+comment]</sub> ~~Predicate<sub>[+topic]</sub>]]: Topicalization  
 c. [TopP [Predicate<sub>[+topic]</sub> Top [TP [~~Predicate<sub>[+topic]</sub>~~ T [Subject<sub>[+comment]</sub> ~~Predicate<sub>[+topic]</sub>]]]]~~~~

In what follows I am going to argue that this perspective sheds light on Comparative Inversion.

---

<sup>1</sup> The head of a small clause may be a predicative expression, as Stowell (1981) argues: that is, the grammatical category of the constituent [*a statue in the plaza*] may be a PP.

### 3.2 A Zero-Operator-Approach to Comparative Inversion

Under the approach advocated above, there are two sources for Subject-Aux Inversion: T-to-C movement and predicative topic raising. Subject-Aux Inversion is obligatory when it results from T-to-C movement. For instance, T-to-C movement in the matrix interrogative clauses is obligatory. By contrast, Subject-Aux Inversion is optional when it is generated via raising of the non-Subject, as we have seen from the *so*-constructions and the Locative Inversion. Comparative Inversion is not obligatory, which hints at the possibility that it is triggered not by T-to-C movement but by predicative topic raising.

- (34) a. John can speak more languages than his father can.  
b. John can speak more languages than can his father.

I assume that there is a zero form for DP, VP, or TP. This zero form is usually used as a zero pronoun, which behaves like an overt pronoun, but the zero form can be a zero operator, which, just like an overt *wh*-operator, undergoes movement. In short, there are two types of zero forms: the zero-pronominal type and the zero operator type. They have a different licensing condition. The zero pronominal is available when there is a non-c-commanding antecedent. In (35) the antecedent vP does not c-command the zero pronominal vP.

- (35) John [<sub>vP</sub> loves Mary], and Tom does  $\emptyset_{vP}$  too.

On the other hand, the zero operator is available in a context that it has a c-commanding antecedent. For instance, the zero operator in the relative clause has a c-commanding antecedent.

- (36) the girl [ $\emptyset_i$  [John loves  $\emptyset_i$ ]]

Briefly speaking, what the zero pronominal and the zero operator have in common is that they must have an antecedent, and their difference lies in whether or not there is a c-commanding antecedent.

- (37) a. The zero pronominal is licensed if there is a non-c-commanding antecedent for it.  
b. The zero operator is licensed if there is a c-commanding antecedent for it.

In comparative constructions, as in relative clauses, the c-commanding antecedent is available, so that the zero operator can be licensed. It is well-known that there is a zero operator movement in comparative constructions. The typical category for the zero operator is DP. I claim that the zero operator can be vP/VP or AP, just as a relative pronoun can take vP/VP or AP as its antecedent. If we assume that *than*-phrase is adjoined to vP/VP, the zero vP is c-commanded by its antecedent vP.

- (38) a. Tom can play more instruments than can his father.

- b. [ Tom can [<sub>VP</sub> [<sub>VP</sub> play more instruments ] [than  $\emptyset_{VP}$  can his father  $\emptyset_{VP}$ ... ]]

If the zero form is DP, it cannot find its c-commanding antecedent at the surface structure. However, I propose that *more*-phrase undergoes QR, taking scope over the whole sentence, as (39-40) illustrate.

- (39) Tom can play more instruments than his father can play.  
 (40) a. [<sub>TP</sub> Tom can [<sub>VP</sub> [<sub>VP</sub> play [<sub>DP</sub> more instruments]] [ than  $\emptyset_{DP}$  his father can play  $\emptyset_{DP}$ ... ]]: QRing of *more*-phrase to the edge of vP and then to the edge of TP  
 b. [<sub>TP</sub> [<sub>DP</sub> more instruments] [<sub>TP</sub> Tom can [~~[<sub>DP</sub> more instruments]~~ [<sub>VP</sub> [<sub>VP</sub> play [<sub>DP</sub> more instruments]] [ than  $\emptyset_{DP}$  his father can play  $\emptyset_{DP}$ ... ]]]]]]

In (40b) the zero DP is c-commanded by its antecedent.

We are now in a position to explain the puzzle raised at the outset of the article: why does Comparative Inversion require VP to be absent? In (41a) the zero VP-operator merges with the subject *his father*. The zero VP-operator, just like *so*, can be a topic. If so, the zero VP-operator, not Subject, moves to the SPEC of T, and as a consequence, the subject is preceded by an auxiliary verb.

- (41) a. [<sub>TP</sub> T [<sub>sc</sub> his father<sub>[+focus]</sub>  $\emptyset_{VP[+topic]}$ ]]: raising of the zero VP-operator  
 b. [<sub>TP</sub>  $\emptyset_{VP[+topic]}$  T [<sub>sc</sub> his father<sub>[+focus]</sub>  $\emptyset_{VP[+topic]}$ ]]: topicalization  
 c. [<sub>TopicP</sub>  $\emptyset_{VP[+topic]}$  Top [<sub>TP</sub>  $\emptyset_{VP[+topic]}$  T [<sub>sc</sub> his father<sub>[+focus]</sub>  $\emptyset_{VP[+topic]}$ ]]]]]

Under this analysis the zero vP/VP-operator is responsible not only for the silence of vP/VP but also for Subject-Aux Inversion, requiring the co-presence of the elided vP/VP and Subject-Aux Inversion. Hence, (42a-b) are ungrammatical.

- (42) a. \*John knows more languages than does his father know.  
 b. \*John can play more instruments than can his father play.

Subject-Aux Inversion cannot take place in the embedded clause without merger of a zero predicative topic. In (42a-b), however, there is an overt predicative phrase. Therefore, those sentences are not grammatical.

Thus far, I have availed myself of a zero vP/VP-operator. It does not mean that deletion is not available in English. Both merger of a zero form and deletion are permitted.<sup>2</sup> In fact, deletion is the only way of generating (43a). Comparative Deletion cannot be generated via merger of a zero vP-pronominal. The zero pronominal must have a non-c-commanding antecedent, but it is c-commanded by the antecedent vP in the comparative constructions. Therefore, the zero vP-pronominal cannot be licensed in the comparative constructions.

- (43) a. John knows more languages than his father thinks he does.  
 b. \*John [<sub>VP</sub> [<sub>VP</sub> knows more languages] [than his father thinks he does  $\emptyset_{VP}$ -pronominal]]

<sup>2</sup> Deletion is subject to the Symmetry Condition, which will be discussed in Section 4.

The zero vP-operator cannot be licensed either. Let us attempt to generate (44) while assuming that the zero vP-operator is available.

(44) \*John knows more languages than his father thinks does he.

Suppose that the zero vP-operator merges with *his father* and it undergoes raising. Raising to the SPEC-T and further A'-movement to the SPEC-C are permitted. However, the vP-operator cannot move out of the matrix vP.

(45) his father [<sub>vP</sub> thinks [<sub>CP</sub>  $\emptyset_{vP[+topic]}$  [<sub>TP</sub>  $\emptyset_{vP[+topic]}$  T [<sub>sc</sub> he<sub>[+focus]</sub>  $\emptyset_{vP[+topic]}$ ]]]]

\_\_\_\_\_||\_\_\_\_\_||\_\_\_\_\_||

\*

The matrix vP contains the vP-operator, so that it is a violation of A-over-A Condition to move the vP-operator out of the matrix vP. Therefore, (44) is not grammatical. Generally speaking, the zero vP-operator is bound to violate a locality condition if it is deeply embedded, and the zero vP pronominal cannot be licensed in every comparative construction. This consideration leads us to a conclusion that the only way of generating (44a) is to make use of vP-deletion. (43a) can be generated via deletion as follows:

(46) a. than  $\emptyset_{DP}$  his father  $\emptyset_{DP}$  thinks  $\emptyset_{DP}$  he T [ $\emptyset_{DP}$  [know  $\emptyset_{DP}$ ]]: vP-deletion  
 b. than  $\emptyset_{DP}$  his father  $\emptyset_{DP}$  thinks  $\emptyset_{DP}$  he T [ $\emptyset_{DP}$  [~~know  $\emptyset_{DP}$~~ ]]: *do*-insertion  
 c. than his father thinks he does

First of all, the zero DP-operator merges with *know* and it undergoes A'-movement after the whole clause is generated, as illustrated by (46a). If the optional operation vP-deletion is applied to the string in (46a), (43a) is generated, and if not, the full sentence is generated.

The zero-vP-based account can be carried over to the non-restrictive relative clause. The *as*-constructions display the same pattern as comparative constructions: inversion is permitted under the condition that vP/VP must not be pronounced.

(47) a. Dulles suspected Philby, as did Angelton.  
 b. Dulles suspected Philby, as Angelton did.  
 c. Dulles suspected Philby, as Angelton suspected.  
 d. \*Dulles suspected Philby, as did Angelton suspect.

If the zero vP topic operator merges with the subject *Angelson*, it must undergo raising, which gives rise to Subject-Aux Inversion.

(48) a. [<sub>TP</sub> T [<sub>sc</sub> Angelton  $\emptyset_{vP}$ ]]: raising of  $\emptyset_{vP}$  to the SPEC of T  
 b. [<sub>TP</sub>  $\emptyset_{vP}$  T [Angelson  $\emptyset_{vP}$ ]]: topicalization  
 c. [<sub>TopicP</sub>  $\emptyset_{vP[+topic]}$  Top [<sub>TP</sub>  $\emptyset_{vP[+topic]}$  T [Angelson  $\emptyset_{vP}$ ]]]: merge of *as*  
 d. [than [<sub>TopicP</sub>  $\emptyset_{vP[+topic]}$  Top [<sub>TP</sub>  $\emptyset_{vP[+topic]}$  T [Angelson  $\emptyset_{vP}$ ]]]]

On the other hand, (47b) is generated via deletion of vP. First of all, the string in (49a) is generated after a series of merger and null DP-operator movement. Deletion is optional.

If it takes place, (47b) is generated, and if not, (47c) is generated.

- (49) a. as  $\emptyset_{DP}$  Angelton T [ $\emptyset_{DP}$  [suspect  $\emptyset_{DP}$ ]]: VP-deletion  
 b. as  $\emptyset_{DP}$  Angelton T [ $\emptyset_{DP}$  [suspect  $\emptyset_{DP}$ ]]: *do*-insertion  
 c. as Angelton did

(47d) is not grammatical for the same reason that (42a-b) are not. T-to-C movement does not take place in the embedded clause and so predicative topic raising is the only source for Subject-Aux Inversion in *as*-constructions, but the predicate is not a topic in (47d). Therefore, it is not grammatical.

As mentioned above, some dialects of English make use of an overt *wh*-operator in the course of generating comparatives and Comparative Inversion is not permitted in those constructions.

- (50) a. John speaks more foreign languages than what Mary does.  
 b. \*John speaks more foreign languages than what does Mary

This does not come as a surprise. Subject-Aux Inversion takes place when the zero vP/VP-operator undergoes movement. When vP/VP-operator movement takes place, DP-operator movement cannot take place, and vice versa. (50b) can be generated if both overt DP-operator movement and covert vP/VP-operator take place, but the two movements are not compatible. Therefore, the sentence is not grammatical.<sup>3</sup>

Let us recall the peculiarities of Comparative Inversion mentioned in section 1. First, Comparative Inversion requires VP ellipsis, second, it is optional, third, more than one auxiliary verb can precede the subject, fourth, it is not allowed when there is an overt *wh*-operator, and finally, Comparative Inversion displays the MaxElide Effects, while the non-inverted VP-elided comparatives do not. This section has shown that the first four characteristics straightforwardly follow from the claim that the zero vP topic operator triggers Subject Aux Inversion. Let us reiterate the gist of the claim. If the zero vP operator is a topic, it can undergo raising, which bleeds raising of *his father*. Since merger of the zero vP topic results in Subject-Aux Inversion, Comparative Inversion must be co-present with the elided vP/VP.

- (51) than [<sub>TopicP</sub>  $\emptyset_{vP[+topic]}$  Top [<sub>TP</sub>  $\emptyset_{vP[+topic]}$  T [<sub>sc</sub> his father<sub>[+focus]</sub>  $\emptyset_{vP[+topic]}$ ]]]

The zero vP operator, like the pro-form *so*, is optionally given the topic feature. It may or may not undergo raising, depending on whether it has the topic feature. Therefore, Comparative Inversion is optional.

- (52) than [<sub>CP</sub>  $\emptyset_{vP}$  [<sub>TP</sub> his father T [<sub>sc</sub> ~~his father~~  $\emptyset_{vP}$ ]]]

In this analysis it is quite natural that the subject can be preceded by a cluster of verbs. In (4), rewritten as (53), the maximally recoverable constituent is *run t*. If the zero operator, which takes *run t* as its antecedent, undergoes raising, the subject *Manny*

---

<sup>3</sup> The word *what* is a DP and its antecedent must be a DP. Even if it can take vP as its antecedent, it cannot undergo topicalization, since the *wh*-word cannot be a topic.

comes to be preceded by two auxiliary verbs.

(53) Anna ran much faster than could have MANNY.

(54) than [<sub>TopP</sub>  $\emptyset_{vP[+topic]}$  [<sub>TP</sub>  $\emptyset_{vP[+topic]}$  could have [<sub>sc</sub> Manny  $\emptyset_{vP[+topic]}$ ]]]

Now the remaining issue is the (anti)-MaxElide Effects. In (55a) the VP *been awarded* is the largest constituent that can be deleted and if the smaller constituent is deleted, an ungrammatical sentence is generated. By contrast, this MaxElide Effects do not appear in the non-inverted comparative constructions.

(55) a. John has been awarded more accolades than has his brother ({\*been, \*been awarded}).

b. John has been awarded more accolades than his brother has ({been, been awarded}).

I have claimed that Comparative Inversion results from raising of the zero vP/VP-operator and the non-inverted vP/VP-elided comparative constructions is generated via vP/VP-deletion. The next section shows that this claim provides a clue to the puzzle posed by the contrast in (55a-b).

#### 4. (Anti)-MaxElide Effects

We have seen that the inverted comparative constructions display the MaxElide Effects. The inverted comparatives are not alone with regard to the MaxElide Effects (Sag 1976, Williams 1977, Fox and Lasnik 2003, Merchant 2008, among many others). In (56) it is possible to delete TP in the second conjunct, since it is recoverable from the first conjunct. In this context the smaller constituent VP cannot be deleted.

(56) I believed the claim that he hit someone, but they don't know who (\*I did).

Fox and Lasnik (2003), Lasnik (2007), Merchant (2003), and Merchant (2008) present the MaxElide Effects as major empirical evidence in support of the repair-by-ellipsis. This section argues that the MaxElide Effects cannot be properly handled by the repair-by-ellipsis approach, and rather, they turn out to be supporting evidence for the claim that both merger of a zero form and deletion are possible. I am going to claim that the MaxElide Effects follow from the Principle of Economy, according to which the largest possible constituent must be pronominalized. This claim makes a prediction that if the unpronounced part is generated via merger of a zero form, then the MaxElide Effects show up, and if it is generated via deletion, there are no MaxElide Effects. This section shows that this prediction is borne out.

##### 4.1 Repair-by-Ellipsis and MaxElide Effects

This sub-section introduces two representative island-repair-by-ellipsis approaches to MaxElide Effects: Fox and Lasnik's (2003) approach and Merchant's (2008) approach. Let us first examine Fox and Lasnik's approach. According to the

repair-by-ellipsis approach, a well-formed sentence is generated if all the offending traces are deleted. In many cases, however, it is not enough to delete all the offending traces. For illustration, let us consider (56). Fox and Lasnik (2003) and Lasnik (2007) assume that A'-movement proceeds via adjunction to the TP-adjoined position. If so, the second conjunct of (56) would be represented as (57).

(57) they don't know who [<sub>TP</sub> t'''' [<sub>TP</sub> I [<sub>vP</sub> t'''' believed the claim that t'' he t' hit t]]

In (57) the offending trace is *t''*; there are two bounding nodes between *t''* and *t''''*. If we simply delete the vP that contains the offending trace, however, a grammatical sentence cannot be generated. In an attempt to resolve this problem, Fox and Lasnik (2003) and Lasnik (2007) claim that all the traces in the second conjunct, whether or not they are offending traces, must be deleted unless there is a corresponding trace in the first conjunct. In the first conjunct of (56) there is no trace that corresponds to *t''''*. Therefore, TP, not vP, must be deleted. What is crucial in this approach is that *wh*-movement drops by the TP-adjoined position; without this assumption, there would be no reason that TP must be deleted. However, this assumption leads us to a wrong prediction about the grammaticality of (58a). In the second conjunct of (58a) there is a trace in the TP-adjoined position. By contrast, there is no corresponding trace in the first conjunct of the sentence; even though the focused phrase undergoes a covert movement, it does not move to the SPEC of C but to the TP-adjoined position, which is supported by the fact that focalization can take place inside *that*-clauses. If so, it is incorrectly predicted that (58a) is ill-formed.

(58) a. ABBY took GREEK, but I don't know what language BEN did.  
 b. [<sub>TP</sub> GREEK [<sub>TP</sub> ABBY took ~~GREEK~~]], but I don't know [<sub>CP</sub> what language [<sub>TP</sub> t'' [<sub>TP</sub> Ben t' took t]]]

In short, Fox and Lasnik (2003) and Lasnik (2007) make use a TP-adjoined trace with a view to explaining the MaxElide Effects in (56), but the TP-adjoined trace causes a problem in (58a).

Merchant (2008) takes a little different approach to the MaxElide Effects. He proposes a condition called the MaxElide Condition, which requires that the largest possible constituent must be deleted. The MaxElide Condition correctly predicts that in (56) TP must be deleted, since it is the largest deletable constituent, and that *been awarded t* must be deleted in (55a), since it is the largest recoverable constituents. However, this approach runs into immediate counterexamples. Sentences (59a-b) do not conform to the MaxElide Condition.

(59) a. Ben knows that she invited Klaus, but her father doesn't.  
 b. Ben knows that she invited Klaus, but her father doesn't know that she did.  
 (Merchant 2008: 142)

Merchant resolves this problem by stipulating that the MaxElide Condition applies only to XPs that contain a *wh*-trace. He argues that there is no MaxElide Effect in (59a-b), since there is no *wh*-movement in the second conjunct. However, comparative constructions run counter to Merchant's stipulation. In (60) partial deletion is possible

even if A'-movement takes place.

- (60) a. Abby has been awarded more accolades than what her father has been.  
 b. Abby has been awarded more accolades than what her father has.

These examples pose a serious problem to the MaxElide Condition approach.

Merchant (2008) proposes one more condition, which is also problematic: once an offending trace is made, all the traces generated via further movement are offending traces. Let us first consider the examples that motivate this proposal. In (61) the possible largest target for deletion is the elided VP, so that the MaxElide Condition is satisfied. Furthermore, the offending trace is removed if vP is deleted. However, the sentence is ungrammatical.

- (61) \*Abby DOES want to hire someone who speaks GREEK/a certain Balkan language,  
 but I don't remember what kind of language  $t''''$  she DOESN'T [~~vP  $t''''$  want to  $t''$  hire someone who  $t''$  speaks  $t$~~ ]. (Merchant 2008: 148)

In (61) the offending trace is  $t''$ . As mentioned above, however, Merchant assumes that once an offending trace is generated, all the traces that are generated via further movements are offending traces: that is,  $t''''$ ,  $t''''$  and  $t''$  as well as  $t''$  are offending traces. He argues that (61) is ill-formed, since the offending trace  $t''''$  still remains even after vP-deletion. This account manages to explain why (61) is unacceptable. However, it conflicts with his analysis of the comparative constructions. Let us recall that according to Merchant (2003), in (62)  $t'$  is an offending trace that violates the ECP; it cannot be antecedent-governed, nor can it be head-governed. Merchant (2008) assumes with Fox and Lasnik (2003) that *wh*-movement proceeds by adjunction to intervening maximal projections, including TP: the trace  $t''$  is created via the null operator movement. Since  $t'$  is an offending trace,  $t''$  is also an offending trace. The string in (62) contains an offending trace, but it is well-formed.

- (62) Mary has been awarded more accolades than has [<sub>TP</sub>  $t'$  Tom [<sub>VP</sub>  $t'$  [<sub>VP</sub> been awarded  $t$ ]]]

To recapitulate, the MaxElide Effects appear to be supporting evidence for the repair-by-ellipsis account, but we have seen that neither Fox and Lasnik's (2003) approach nor Merchant's (2008) approach is descriptively adequate.

#### 4.2 Pronominalization Economy

Thus far, we have seen that it is almost impossible to make a generalization about when the MaxElide Effects appear, to say nothing of providing a principled account for it. In what follows I am going to argue that if the unpronounced constituent is generated via merger of a zero form, the MaxElide Effects show up, and otherwise, they do not. There is a striking similarity between the comparative construction in (55a) and the *so*-constructions in (63) in that the repeated part must be minimal.

- (63) John has been awarded many accolades.  
a. So have I.  
b. \*So have I been.  
c. ??So have been I.

So can pronominalize VP or AP, so that it can pronominalize either *been awarded many accolades* or *awarded many accolades*. However, sentence (63) shows that the maximal constituent must be pronominalized. I propose that pronominalization is subject to the Principle of Economy, according to which it is more economical to pronominalize the bigger constituent.

(64) Pronominalization Economy

If there is a choice between pronominalizing a bigger constituent and a smaller one, the bigger one is pronominalized on account of the Principle of Economy.

It is possible to pronominalize either *awarded* or *been awarded* in (63), but the Pronominalization Economy in (64) requires that the bigger constituent be pronominalized. Therefore, (63b-c) are ill-formed.

In this article I have assumed that there are three sources for silence: deletion, zero pronominals, and zero operators. The Pronominalization Economy applies only to the zero forms: a zero pronominal or a zero operator, for the zero pronominal is an unbound pronominal, while the zero operator is a bound pronominal, and they are subject to the Pronominalization Economy. Therefore, it is predicted that the MaxElide Effects appear only when the source of the silence is merger of a zero pronominal or a zero operator. Before examining whether this prediction is correct, let us consider the licensing condition on deletion.<sup>4</sup> I propose that deletion is subject to the Symmetry Condition outlined below.

(65) Symmetry Condition

The target for deletion and its antecedent are symmetric with regard to A'-movement.<sup>5</sup>

Deletion takes place on the basis of structural identity as well as semantic identity. Accordingly, it is not unexpected that it is subject to the Symmetry Condition. On the other hand, pronominalization does not comply with the Condition, since it does not care about the internal structure of the antecedent, as long as a well-formed LF is generated. There are three cases with regard to the movement of the elided constituent and its antecedent if we exclude the case in which there is movement in the antecedent

---

<sup>4</sup> The licensing condition for zero-forms is specified in (37).

<sup>5</sup> This is reminiscent of Fox and Lasnik's (2003) Principle of Parallelism, but there are important differences between them. First, the Symmetry Condition requires the elided constituent and its antecedent to be symmetric, while the Principle of Parallelism requires the first conjunct and the second conjunct to be in parallel: it cares about the whole structure, not just the elided constituent and its antecedent. Second, violation of the Symmetry Condition, unlike that of the Principle of Parallelism, cannot be repaired under ellipsis.

but there is no movement in the target for deletion.

(66)

	Antecedent	Target for Deletion
Asymmetric 1. No deletion 2. MaxElide Effect	There is no A <sup>2</sup> -trace	There is A <sup>2</sup> -trace
Symmetric 1. Deletion 2. No MaxElide Effect	There is no A <sup>2</sup> -trace	There is no A <sup>2</sup> -trace
	There are A <sup>2</sup> -traces.	There are corresponding A <sup>2</sup> -traces.

If the target for deletion and its antecedent are asymmetric, deletion cannot take place. In this case, the elided constituent in the second conjunct is generated via merger of a zero form, which conforms to the Pronominalization Economy. If they are symmetric, deletion is permitted, and it is not governed by the Principle of Economy; at PF it is possible not to delete at all, and it is even possible to insert some constituent in order to satisfy a PF constraint. Under this analysis the MaxElide Effects show up only when the elided constituent and its antecedent are asymmetric. Sentence (56), repeated here as (67), belongs to the asymmetric case; the second conjunct contains A<sup>2</sup>-movement, but the first conjunct does not.

(67) I believed the claim that he hit someone, but they don't know who (\*I did).

This means that the sentence is generated only via merger of a pronominalized zero form, which obeys the Pronominalization Economy in (64). Therefore, (67) is ungrammatical if the elided constituent is vP. Sentence (55a), rewritten as (68), is also subject to the Pronominalization Economy, since Subject-Aux Inversion is triggered by a predicative zero topic.

(68) John has been awarded more accolades than has his brother ({\*been, \*been awarded}).

Comparative Inversion results from raising of a zero VP topic, and the zero form conforms to the Pronominalization Economy. Therefore, the MaxElide Effects appear in the inverted comparative constructions.

Let us now turn to the symmetric case. In the non-inverted comparative constructions the MaxElide Effects disappear, as we have seen from (55b)—(69).

(69) John has been awarded more accolades than his brother has ({been, been awarded}).

As mentioned in the preceding section, *more* has a sentential scope when the whole clause is compared and so, the *more*-phrase undergoes a covert movement to the TP-adjoined position. On the other hand, the null operator undergoes A<sup>2</sup>-movement in *than*-clauses. This means that the antecedent vP and the target for deletion are symmetric.

(70) [more accolades Abby has [t' [been awarded t]]] than [∅ her father has t' been awarded t]

The representation (70) shows that the first conjunct and the second conjunct are symmetric with regard to the bigger vP *t''been awarded t* and the smaller vP *awared t*. Therefore, both vPs can be deleted and both (69a-b) are grammatical. Let us now consider another symmetric case—(59a-b), repeated here as (71a-b). These sentences are symmetric in that there is no A'-movement in both conjuncts.

- (71) a. Ben knows that she invited Klaus, but her father doesn't.  
 b. Ben knows that she invited Klaus, but her father doesn't know that she did.  
 (Merchant 2008: 147)

So it is possible to apply the operation 'deletion', which does not require the maximal constituent to be deleted. Therefore, both (71a) and (71b) are grammatical.<sup>6</sup>

If the embedded clause of the second conjunct is a *wh*-interrogative, the correlate of the *wh*-operator is usually an indefinite. But other kinds of correlates are possible (see Chung *et al.* 1995 for relevant discussion). For instance, names can be associates if they are focused. The constructions with a name as a correlate do not display MaxElide effects.

- (72) a. Abby speaks GREEK, but I don't remember what OTHER languages.  
 b. ABBY took GREEK, but I don't know what language BEN did. (Merchant 2008: 147)

This can be explained if we assume that the focused phrase undergoes movement.

- (73) a. [GREEK [Abby speaks t]], but I don't remember what OTHER languages  
~~{Abby speaks t}~~  
 b. [GREEK [ABBY [took t]]] but I don't know what language BEN ~~{took t}~~

In the first conjunct *GREEK* undergoes A'-movement and in the second conjunct *what language* undergoes A'-movement. As a consequence, (73a) is symmetric with regard to TP, and (73b) is symmetric with regard to vP-symmetric. Therefore, both (72a) and (72b) are grammatical.<sup>7,8</sup>

---

<sup>6</sup> Merchant (2008) observes that both (ia) and (ib) are grammatical.

- (i) Some student solved the problem, but I'm not sure  
 a. who  
 b. who did (Merchant 2008: 143)

It is not surprising that (ia) is grammatical, since the zero pronominal can be licensed in (ia). Sentence (ib) is an interesting case. In the sentence the antecedent vP and the elided vP are symmetric in that there is no A'-movement inside vP.

- (ii) [TP some student T [vP t solve the problem]], but I am not sure [TP who [TP t T [vP t solve the problem]]]

Therefore, vP-deletion is permitted.

<sup>7</sup> In (72a-b) the variable in the first conjunct and the one in the second conjunct denote a different referent. The pro-form is not available if (i) the two variables do not share the same referent and (ii) the antecedent variable is presupposed. (72a-b) satisfy these two conditions, since the variable introduced by a focused phrase is presupposed. Therefore, the pro-form cannot be used in these constructions. With this

Besides indefinites and focused names, the correlate can be a quantified phrase.

(74) Abby met most applicants, but I can't remember exactly which ones.<sup>9</sup>

Merchant (2008) makes an interesting observation about the interaction between quantifiers and focus. If the subject is focused, partial deletion is permitted, and if not, it is not permitted.

(75) a. ABBY interviewed exactly two thirds of the applicants, but I don't remember how many of them BEN did.  
b. ??Abby met most applicants, but I can't remember exactly which ones she did.

(Merchant 2008: 152)

I propose that this contrast follows from the asymmetry in QR between the two sentences. Fox proposes that QR takes place only if it affects a scope relation. Names are not scope-bearing constituents. If they are focused, however, they turn into scope-bearing ones: that is, there is a scope interaction between a focused phrase and a quantified phrase.<sup>10</sup>

(76) a. ABBY interviewed exactly two thirds of the applicants.

---

in mind, let us reconsider sentence (61), repeated here as (i), where the variable in the two conjuncts have a different referent and the antecedent variable is presupposed. First of all, the zero pro-form is not available here. Furthermore, the sentence cannot be generated via deletion either, for an island condition is violated in course of deriving the second conjunct and the island violation cannot be repaired by ellipsis.

(i) \*Abby DOES want to hire someone who speaks GREEK/a certain Balkan language, but I don't remember what kind of language t<sup>1</sup> she DOESN'T [<sub>vP</sub> t<sup>2</sup> want to t<sup>2</sup> hire someone who t<sup>2</sup> t<sup>2</sup> speaks t].

Therefore, there is no way to generate sentence (i).

<sup>8</sup> Another possibility is that (72b) is an instance of pseudo-gapping, as (i) illustrates.

(i) ABBY took GREEK, but I don't know what language BEN did ~~take~~ t

<sup>9</sup> In (74) sluicing is possible since the quantifier *most* is vague. The following sentence is anomalous, since *every* is not vague.

(i) #Abby met every applicant, but I can't remember exactly which ones.

<sup>10</sup> In (i) type-shifting QR can take place: that is, raising to the SPEC of vP is possible, but in compliance with the scope economy *most applicants* cannot undergo raising to the TP-adjoined position.

(i) Abby met most applicants.  
(ii) a. [Abby [most applicants [met t]]]  
b. \*[most applicants [Abby [meet t]]]

However, (iia) may be interpreted as (iiib) if *Abby* undergoes  $\lambda$ -operation.

(iii) a. Abby  $\lambda y$  [most x [applicants(x)] [y met x]]  
b. Most x [applicants(x)] Abby met x

b. Abby met most applicants.

If *Abby* is focused, the pair-list reading is available. According to the reading, there is a name list, and *Abby* pairs with *two thirds of the applicants* and implies that someone else pairs with another proportion. The pair-list reading is available when a presupposed set of QPs takes scope over the variable introduced by the focused subject. Put differently, if QR takes place, the pair-list reading is available, and otherwise, it is not. In accordance with the scope economy QR can take place in this context.

- (77) a. [exactly two thirds of the applicants [ABBY T [interview t]]  
b. \*[most applicants [Abby met t]]

On the other hand, QR cannot be applied in (76b), since it does not give rise to semantic effects. In short, in (75a) the two conjuncts are symmetric with respect to vP, but in (75b) they are not.

- (78) a. [exactly two thirds of the applicants [ABBY T [t' [interview t]]] but I don't remember how many of them BEN did [t' [interview t]]  
b. [Abby [most applicants [met t]]] but I don't remember how many of them BEN did [t [interview t]]

Therefore, vP-deletion is possible in (75a), but not in (75b), and there is a contrast in acceptability between them.<sup>11</sup>

We started this section with the following puzzle: why the inverted comparatives display the MaxElide Effects, while the non-inverted comparatives do not. This section has shown that their difference follows from a general theory of ellipsis: merger of zero forms, not deletion, conforms to the Pronominalization Economy, which gives rise to the MaxElide Effects, and deletion is subject to the Symmetry Condition, which requires the target for deletion and its antecedent to be structurally identical.

## 5. Summary and Conclusion

This article has endeavored to show that the peculiarities of Comparative

---

<sup>11</sup> In (ia-b) *wh*-movement takes place in both conjuncts: they are symmetric, and as expected, partial deletion is permitted.

- (i) a. I know which book John said that Mary read, but **you** don't know which one.  
b. ?I know which book John said that Mary read, but **you** don't know which one he did.  
(Lasnik 2007: 151)

It is worthwhile to note that the embedded subject must be focused when partial deletion is applied. If the subject is focused, the *wh*-expression can have scope associated with the focused subject. In this context, partial deletion is possible. Which constituent is to be deleted is dependent on which constituent is to be contrasted. If the pair {<I, which book>, <you, which one>} is to be contrasted, then partial deletion takes place, and if what is contrasted is the truth of the first and the second conjuncts, the maximal vP is deleted.

- (ii) I know which book John said that Mary read, but you don't.

Inversion are not construction-specific but they follow from a general theory of ellipsis. There are two different approaches to the elided constructions: the deletion approach and the zero-form approach. I have proposed a unified approach by claiming that both deletion and zero forms are utilized in English.<sup>12</sup> The major claim made in this article is that zero forms are divided into two types: the zero pronominal and the zero operator type, and the three sources for silence are regulated by a different licensing condition, which can be summarized as follows:

- (79) a. Deletion is licensed when the target for deletion and its antecedent are structurally symmetric.  
 b. Zero pronominals are licensed when there is an anti-c-commanding antecedent.  
 c. Zero operators are licensed when there is a c-commanding antecedent.

Deletion, zero pronominals, zero operators display a different syntactic behavior: (i) deletion gives neither Inversion Effects, nor MaxElide Effects, (ii) zero pronominals show MaxElide Effects, but not Inversion Effects, and (iii) zero operators produce both MaxElide Effects and Inversion Effects.

(80)

	Inversion Effects	MaxElide Effects
Deletion	X	X
Zero Pronominals	X	O
Zero Operators	O	O

This article has shown that the unified approach outlined in (79-80) enables us to provide a principled account for various peculiarities of Comparative Inversion and many other elliptical constructions.

## Abstract

This study adopts on-line self-paced reading tasks in order to investigate how untrained language users process resumptives in Chinese relative clauses and to shed light on the debate as to whether resumptives exist to facilitate processing. The on-line reading times show that optional resumptives were dispreferred because of a garden-path effect. However, optional resumptives were preferred when the gap relative clauses led to a garden path, thus increasing the difficulty of reconstruction. There was no preference one way or the other when the relative clauses involved complex structures or complicated processing domains. These results suggest that the use of resumptives in Chinese is not only constrained by grammaticality requirements but also conditioned by a processability effect (i.e., the garden-path effect).

**Keywords:** resumption, processability, garden-path effect

## 1. Introduction

A number of studies have demonstrated that resumptives may be regarded as a last resort rescuing the violations such as island constraints or ECP (Alexopoulou & Keller, 2007; Aoun, 2000; Chao & Sells, 1983; Chomsky, 1982; Meral, 2004; Sells, 1984; Shlonsky, 1992). Some researches (Alexopoulou & Keller, 2007; McCloskey, 2006) further point out that generally there are three kinds of resumption:

- (i) **Movement resumptives** behave like a syntactic variable that is A'-bound by an Operator. They, as *wh*-traces, are subject to islands and crossover effects. In addition, movement resumptives should allow reconstruction and be able to license parasitic gaps, which are the properties of *wh*-traces as well.
- (ii) **Base-generated resumptives**, on the contrary, lack the properties that the movement resumptives possess.
- (iii) **Intrusive/processing resumptives** appear to remove the parsing load caused by the longer distance between the filler and the gap.

In Ning, Her, & Lin (2008), it is asserted that Chinese resumptives are base-generated elements since they do not possess the properties of movement resumptives. Chinese resumptives are further divided into two categories, obligatory and optional. In order to support this claim, three grammaticality judgments on a 7-point scale were conducted. The results of the rating suggest that Chinese employs resumptives as a grammatical device to save ungrammaticality (that is, resumptives are obligatory when the gaps result in ungrammaticality). On the other hand, the acceptability of the optional resumptives may be affected by processability. In other words, resumptives could be optional but dispreferred due to the fact that they induce a main-clause illusion, which makes relative clauses less processable. The goal of this paper is thus to investigate what kind of factors would contribute to processability by making use of on-line self-paced reading comprehension tasks.

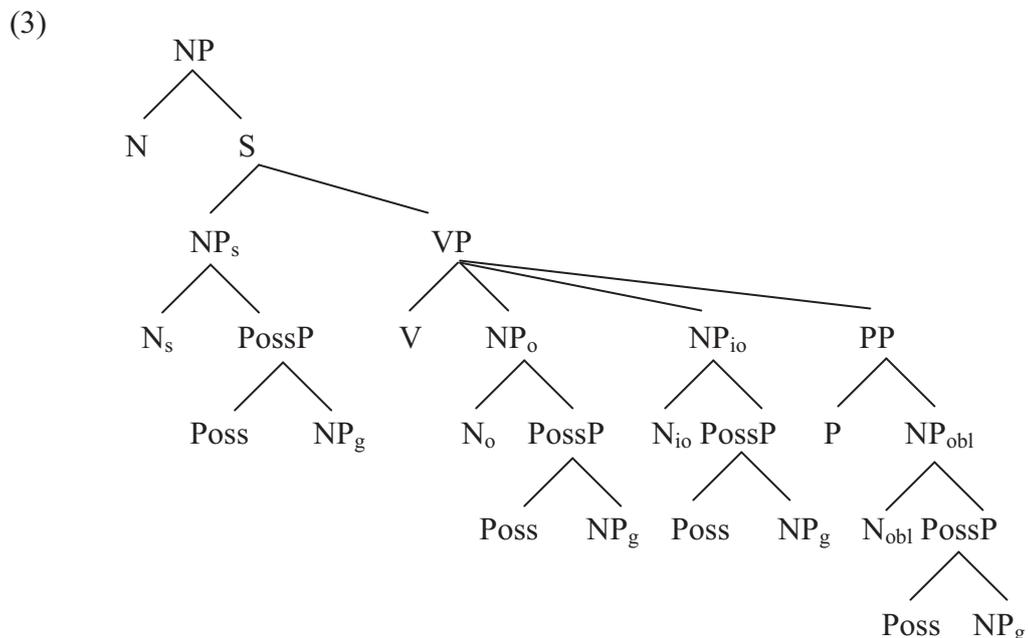

In processing studies, resumptives in head-initial relative clauses are claimed to facilitate processing when the distance between a filler and a gap is quite far (distance

effect) or when the filler is extracted from a hierarchically lower position (embedding effect) (Alexopoulou & Keller, 2007; McKee & McDaniel, 2001). The use of resumptives is advantageous in these conditions because they specify the extraction sites so as to make the association with the fillers easier. This lightens the memory load as well (Dickey, 1996).

To predict under what conditions resumptives turn out to be advantageous, Hawkins (1999) proposes a Filler-Gap Domain [FGD] and the principle of Minimize FGDs to define the minimal domain for long-distance dependency.

- (1) a. Filler-Gap Domain [FGD]: An FGD consists of the smallest set of terminal and nonterminal nodes dominated by the mother of a filler and on a connected path that must be accessed for gap identification and processing.
- b. Minimize FGDs: The human processor prefers FGDs to be as small as possible.
- (2) Noun Phrase Accessibility Hierarchy (AH)  
 SUBJ > OBJ > INDIRECT OBJ > OBL > GEN > OBJECT OF COMPARISON  
 (Keenan & Comrie, 1977)

To illustrate this, let us calculate the minimal FGD sizes for relativizations on each of the AH positions. Assume that there is an SVO language whose relative clauses are head-initial such as (3). As counted in (4), the number of nodes increases down the AH. When nodes increase, morphosyntactic or semantic computations also multiply. This has been corroborated by a number of studies showing that object relative clauses are more difficult to process than subject relative clauses (Keenan & Hawkins, 1987; King & Just, 1991).<sup>1</sup>

<sup>1</sup> There is still a controversy over the issue of whether subject relative clauses or object relative clauses are easier to process in head-final relativization. For discussion, see Hsiao & Gibson (2003) and Lin & Bever (2006) for Chinese, Kwon (2004) for Korean, Miyamoto & Nakamura (2003) for Japanese.

(4) Minimal FGDs for relativization on (Hawkins, 1999: 255):

- SU = 5 [N, NP, V, VP, S]
- DO = 7 [N, NP, N<sub>s</sub>, NP<sub>s</sub>, S, V, VP]
- IO = 9 [N, NP, N<sub>s</sub>, NP<sub>s</sub>, S, V, VP, N<sub>o</sub>, NP<sub>o</sub>]
- OBL = 9 [N, NP, N<sub>s</sub>, NP<sub>s</sub>, S, V, VP, P, PP]
- GEN-SU = 9 [N, NP, N<sub>s</sub>, NP<sub>s</sub>, S, Poss, PossP, V, VP]
- GEN-DO = 11 [N, NP, N<sub>s</sub>, NP<sub>s</sub>, S, V, VP, N<sub>o</sub>, NP<sub>o</sub>, Poss, PossP]
- GEN-IO = 13 [N, NP, N<sub>s</sub>, NP<sub>s</sub>, S, V, VP, N<sub>o</sub>, NP<sub>o</sub>, N<sub>io</sub>, NP<sub>io</sub>, Poss, PossP]
- GEN-OBL = 13 [N, NP, N<sub>s</sub>, NP<sub>s</sub>, S, V, VP, P, PP, N<sub>obl</sub>, NP<sub>obl</sub>, Poss, PossP]

Based on this observation, Hawkins (1999) suggests a Gap Avoidance Hypothesis: gaps are avoided when processing becomes complicated and difficult.

(5) Gap Avoidance Hypothesis: If a (potential) FGD of complexity  $n$  on a hierarchy  $H$  is avoided by employing a semantically equivalent alternative structure, then gaps in all more complex environments on  $H$  ( $n+1$ ) will be avoided as well.

As indicated in (4), processing genitive gaps involves a larger processing domain which in turn places a greater burden on a parser's load. Resumptives, on the other hand, can illuminate the extracted environment and improve the recognition of the role of the head in relative clauses. Thus, when a filler-gap dependency exists in a complex environment, resumptives surface as a method of rescue to remove the difficulty of associating the filler with a gap in large FGD domains. It seems that, in the higher positions of AH where the processing complexity is relatively low, resumptives never win over gaps. This could be explained by the advantage of economy (Haiman, 1983; Hawkins, 1999). Gaps under most conditions entail fewer computations than lexical arguments (resumptives) but can also create well-constructed interpretation. After the competition, gaps win over resumptives when the extracted positions are recoverable and accessible.

Another line of research on the processing of relative clauses is concerned with structural differences (that is, head-initial versus head-final relative clauses). Unlike head-initial relative clauses, head-final relative clauses such as those in Chinese manifest a garden-path effect. The parser does not notice a gap initially and has to trace back to search for an appropriate position when the filler is encountered. That is to say, the parser has to reanalyze the syntactic structure of the parsed words (Lin, 2008a, 2008b; Lin & Bever, 2007).

Take a subject relative clause (6) and an object relative clause (7) for example.

(6) <u>trace</u>	<u>Verb</u>	<u>Object</u>	<u>de</u>	<u>Head</u>	<u>Noun</u>
<i>(pro)/t<sub>i</sub></i>	<i>kan-dao</i>	<i>wo</i>	<i>de</i>	<i>na-ge</i>	<i>ren<sub>i</sub></i>
	see-PERF	me	REL	that-CL	man <sub>i</sub>

----->

(Main-clause illusion with *pro*-drop)

----->

(Recognize the relative clause  
and reanalyze the initial analysis)

'the man who saw me'

(7)	<u>Subject</u>	<u>Verb</u>	<u>trace</u>	<u>de</u>	<u>Head Noun</u>	
	<i>wo</i>	<i>kan-dao</i>	<i>t<sub>i</sub></i>	<i>de</i>	<i>na-ge</i>	<i>ren<sub>i</sub></i>
	I	see-PERF	<i>t<sub>i</sub></i>	REL	that-CL	man <sub>i</sub>
	----->					
	(Main-clause illusion)					
	----->					
	(Recognize the relative clause and reanalyze the initial analysis)					
	'the man whom I saw'					

Prior to the relativizer *de*, the initial parse of (6) could be a main clause with a *pro*-drop. *Pro*-drop is available in Chinese (C. N. Li & Thompson, 1981). Thus, when the parser reads the relativizer *de* and head noun, it has to revise the main-clause analysis and regress to search for an appropriate position for the filler (head noun).

Consider relative clauses with resumptive pronouns in Chinese (8–9). The main-clause illusion still remains when resumptives occupy the extracted positions, because they create a complete NVN pattern.

(8)	<u>RP</u>	<u>Verb</u>	<u>Object</u>	<u>de</u>	<u>Head Noun</u>	
	<i>ta<sub>i</sub></i>	<i>kan-dao</i>	<i>wo</i>	<i>de</i>	<i>na-ge</i>	<i>ren<sub>i</sub></i>
	he	see-PERF	me	REL	that-CL	man <sub>i</sub>
	----->					
	(Main-clause illusion)					
	'the man who (*he) saw me'					
(9)	<u>Subject</u>	<u>Verb</u>	<u>RP</u>	<u>de</u>	<u>Head Noun</u>	
	<i>wo</i>	<i>kan-dao</i>	<i>ta<sub>i</sub></i>	<i>de</i>	<i>na-ge</i>	<i>ren<sub>i</sub></i>
	I	see-PERF	him <sub>i</sub>	REL	that-CL	man <sub>i</sub>
	----->					
	(Main-clause illusion)					
	'the man whom I saw (*him)'					

Under this circumstance, processing does not seem to be filling a gap any more. It is clearly indicated that, in Chinese grammar, reconstruction fails (no empty positions can be filled) when resumptives occur (Aoun & Li, 2003; Y.-H. A. Li, 2007). This failure may affect the way that processing is performed. Thus, in addition to the garden-path effect which arises due to the main-clause illusion, resumptives suffer from a higher degree of difficulty in processing than gaps because fillers under this condition (resumptive relative clauses) fail to find an empty position for themselves. The interpretation of resumptives, instead, needs to depend on a referential coindexation. This low processability resulting from the garden-path effect and the failure of reconstruction may influence the preference for resumptives in relative clauses.

In this paper, two on-line self-paced reading experiments were conducted to examine whether the dispreference for optional resumptives in Chinese would result from the garden-path effect. The materials involved the same conditions investigated in Ning, Her, & Lin (2008) but excluded oblique object relative clauses and control object relative clauses whose resumptives are obligatory. Experiment 1 involved subject relative clauses, long-distance subject relative clauses, object relative clauses, and genitive relative clauses while in Experiment 2, they involved indirect object

relative clauses with the ‘Give’ verbs, indirect object relative clauses with the ‘Take’ verbs, embedded subject relative clauses, and object relative clauses with adverbials. Throughout these experiments, it is assumed that the parser was likely to briefly adopt a main-clause analysis, prior to being garden-pathed by the relative clause analysis. Also, it is predicted that the garden-path effect would be much more severe in the case of resumptive relative clauses than in the case of gap relative clauses due to the failure in reconstruction.

## 2. Experiment 1

The critical conditions in Experiment 1 involved subject relative clauses, long-distance subject relative clauses, object relative clauses, and genitive relative clauses. Example sentences are presented in (10).

(10) a. Subject relative clauses

*(ta)souji yuliao de na-wei xuezhe fabiao-guo*  
 he collect corpus DE that-CL scholar publish-PERF  
*ji-pian wenzhang.*  
 several-CL article

‘That scholar who collected a corpus published several articles.’

b. Long-distance subject relative clauses

*(ta)xinkudi zai yanjiushi zuanyan jibing*  
 he hardily at research.office delve.intodisease  
*wenti de na-wei yisheng chenzui zai yanjiu lequ*  
 problem DE that-CL doctor indulge in research pleasure  
*zhong.*  
 in

‘That doctor who delved into the problem of disease threw himself deeply into the pleasure of doing research.’

c. Object relative clauses

*xuexiao yaoqing (ta) de na-wei zuojia ceng huode*  
 school invite him DE that-CL author ever obtain  
*yiwendajiang.*  
 literary.award

‘The author whom the school invited has obtained a literary award.’

d. Genitive relative clauses

*(ta)nuer fabiao xinshu de na-wei fuqin*  
 his daughter publish new.book DE that-CL father  
*zao chengwei zhongshi de duzhe.*  
 already become faithful DE reader

‘That father whose daughter published a new book has already become a faithful reader.’

The question that this experiment was meant to address was whether the main-clause illusion in processing is related to the fact that resumptives are not as favorable as gaps in the judgment tasks (Ning, Her, & Lin, 2008). To answer the question, Experiment 1 compared the reading times of the resumptive relative clauses and of the gap relative clauses, and compared these results with the grammaticality judgments in Ning, Her, & Lin (2008).

## **2.1 Methods**

### **2.1.1 Participants**

Sixteen native speakers of Chinese studying at National Taiwan Normal University were paid NT 100 dollars each to participate in the experiment. All were naïve as to the purpose of the experiment. No participants who participated in this experiment took part in the questionnaire tasks of Ning, Her, & Lin (2008).

### **2.1.2 Materials**

In order to investigate where the garden-path effect takes place, each sentence was divided into several regions based on the phrasal boundaries. Verbs and objects were separated in this experiment. The divisions are shown with a slash between regions in Appendix A.

Two lists were created from the total of 64 (8 sentences x 2 strategies x 4 conditions) sets of experimental sentences, so that each list contained eight sentences of each type of relativization type, and one version of each set. The experimental sentences were mixed with 68 fillers, resulting in a total of 100 items. The sentences were presented in an individually randomized order created by Linger.

### **2.1.3 Procedure**

Participants were tested individually. The program used was Linger written by Doug Rohde. Participants were required to press the spacebar to reveal each block of words in a moving-window self-paced reading task. Hidden words were masked by dashes and there were small gaps between characters. The parsed words became dashes again when participants moved on to the next region. After the participants had read the whole sentence, one comprehension question appeared. Comprehension was checked in all trials by presenting a yes-no question. Feedback was given only when the response was not correct; a pop-up screen would show *dacuo-le o* 'It's wrong'. Participants were encouraged to achieve high accuracy and to respond as quickly as possible if they knew the answer.

Before the formal experiment, there were 12 practice items. In the experimental phase, the 100 items were randomly distributed into four blocks by Linger. After every 25 items, there was a short break. Participants could press any key to continue. Reaction time was calculated for each block of words and also for the response to the comprehension questions. The entire experiment lasted approximately 20 minutes.

## **2.2 Results**

In this experiment, the average accuracy for the comprehension questions was 91%, with no participant scoring below 78%. The reading times of head nouns and the following verb phrases were analyzed for each condition. These regions were chosen because they are referred to as disambiguating regions. A longer reading time (i.e., a garden-path effect) was expected for such disambiguating regions. Comparisons of interest involved relative clauses with gaps which enable the head nouns to reconstruct to the extracted empty positions, and the relative clauses with resumptives that require the head nouns to anaphorically link with pronouns.

Reading time values beyond 2 SDs away from the condition mean for the head noun regions were replaced by the mean since the mean is the most unbiased estimated value. This excluded 5% of the data in by-participant analysis and 4% of the data in by-item analysis.

For the reading times on the head nouns and the following verb phrases, two repeated measures ANOVAs were performed, treating participants ( $F_1$ ) and items ( $F_2$ ) as random effect variables. The use of a strategy (a gap or a resumptive pronoun) was treated as within-participants or within-items factors. The results of the disambiguating regions for each condition are reported in Table 1. Participant means are presented in tables along with standard errors. The results of  $F$  tests are presented beneath the means. Results are reported as significant if the participant and item analyses rejected the null hypothesis at the .05 level.

Table 1. Participant mean reading times in milliseconds and  $F$  tests in Experiment 1

	Head Noun	Main Verb	Object
<b>Subject relative clauses</b>			
Gap	692 (39.19)	649 (50.17)	865 (65.50)

Note: Standard error of the mean is in the parentheses.

### 2.2.1 Subject relative clauses

In the case of the subject relative clauses with resumptives, it took longer to read the head noun (692 vs. 910ms;  $F_1(1, 15) = 3.815, p = .07$ ;  $F_2(1, 7) = 2.322, p = .171$ ) and the following verb phrase positions (verb: 649 vs. 744ms;  $F_1(1, 15) = 2.154, p = .163$ ;  $F_2(1, 7) = .561, p = .478$ ; object: 865 vs. 905ms;  $F_1(1, 15) = .094, p = .763$ ;  $F_2(1, 7) = .150, p = .710$ ) than those positions in the case of the subject gap relative clauses. The readers may have suffered from a greater garden-path effect when subject resumptives appeared in the relative clauses. However, this effect was only near significant by participants in the head noun regions. No other regions reached significance.

### 2.2.2 Long-distance subject relative clauses

In the case of the resumptives, it significantly took longer to read the

long-distance subject relative clauses after the head nouns were parsed. This garden-path effect was significant, both by participants and by items, for the main verb (538 vs. 689 ms;  $F_1(1, 15) = 5.289, p < .05$ ;  $F_2(1, 7) = 6.571, p < .05$ ) and the following objects (703 vs. 901 ms;  $F_1(1, 15) = 8.427, p < .05$ ;  $F_2(1, 7) = 11.535, p < .05$ ). On the head nouns, the effect was only significant by items (674 vs. 813 ms;  $F_1(1, 15) = 2.330, p = .148$ ;  $F_2(1, 7) = 6.118, p < .05$ ).

### 2.2.3 Object relative clauses

In the case of the object relative clauses, it took the parser significantly longer to read the resumptive relative clauses in the head noun positions (741 vs. 1021 ms;  $F_1(1, 15) = 6.560, p < .05$ ;  $F_2(1, 7) = 10.386, p < .05$ ). The effect of this long reading time exercised an influence in the main verb and the object regions, but it did not approach significance (main verb: 699 vs. 805 ms;  $F_1(1, 15) = 1.629, p = .221$ ;  $F_2(1, 7) = 1.198, p = .31$ ; object: 896 vs. 1071 ms;  $F_1(1, 15) = 2.536, p = .132$ ;  $F_2(1, 7) = 1.840, p = .217$ ).

### 2.2.4 Genitive relative clauses

In the case of the genitive relative clauses, the reading times for the resumptive sentences were quite similar to those of the gap relative clauses. No significant effect was found for the head noun (900 vs. 867 ms;  $F_1(1, 15) = .154, p = .700$ ;  $F_2(1, 7) = 2.122, p = .189$ ), the main verb (853 vs. 832 ms;  $F_1(1, 15) = .060, p = .809$ ;  $F_2(1, 7) = .078, p = .788$ ) or the object regions (967 vs. 972 ms;  $F_1(1, 15) = .001, p = .978$ ;  $F_2(1, 7) = .004, p = .950$ ). An inspection of the mean reading times in relation to the genitive gap relative clauses and the subject/object gap relative clauses reveals that there could be a relative difficulty in processing the genitive gaps. As a result, no significant difference between the genitive gaps and the genitive resumptives was found. A plausible account for this result is offered in the discussion below.

## 2.3 Discussion

Overall, due to the main-clause illusion prior to the head nouns, the relative clauses which appeared with resumptives suffered from the garden-path effect. The effect was revealed by the longer reading times in the head noun positions or the following regions. In addition, the structural complexity predicted whether the gaps would suffer from the garden-path effect as the resumptives and whether the gaps would be significantly preferred over the resumptives. For the sake of comparison, the grammaticality judgment results in Ning, Her, & Lin (2008) are presented in Table 2.

In the subject relative clauses, the garden-path effect was only nearly significant in the resumptive versions ( $p = .07$ ). However, when the distance between the subject resumptives and the head nouns was lengthened by two adjuncts, the parser was garden-pathed. The garden-path effect was salient in the long-distance subject conditions. Comparison of the results of the on-line reading task and of the grammaticality judgments revealed that the resumptives in the subject or long-distance subject relative clauses were not preferred in the judgments because they involved processing difficulty resulting from the reanalyses of the initial main clause readings.

In the object relative clauses, as is predicted, a significant garden-path effect appeared in the head noun positions where the possessive readings crashed. It seems that this processing difficulty would make the resumptives dispreferred in the grammaticality judgments.

Finally, in the genitive relative clauses, it appears that the possessors (the head nouns) were not easy to be placed back to the extracted positions since they involve a larger filler-gap dependency domain as Hawkins (1999) suggests. The reading times of the head nouns in the genitive gap versions were longer than those in the subject or object gap relative clauses. It is plausible that this processing difficulty (resulting from the structural complexity) removed the preference for the gap strategy of the genitive relative clauses in the grammaticality judgments.

To summarize, the fact that the resumptives were dispreferred may be due to the garden-path effect aroused by the main-clause illusion. This validates our results and assumption in the grammaticality judgments of Ning, Her, & Lin (2008) that the resumptives in the subject relative clauses, the long-distance subject relative clauses, the object relative clauses and the genitive relative clauses were ‘less processable’. It becomes clear that processability is related to the garden-path effect. The ‘less processable’ is defined as ‘garden-pathed’ presented in Table 2. On the other hand, when the structural complexity increased, the gaps might have garden path and fail to show an advantage in the relativization. In this experiment, it is corroborated in the genitive relative clauses.

Table 2. Predictions and results of gap/resumptive occurrences in Experiment 1

RC Types/ Strategy		Grammaticality	Processability	Predictions	Judgment results	Reading time results
		Grammatical: + Ungrammatical: -	Processable: + Garden-pathed: -			
SRC	Gap	+	+	Preferred	Better* (6.34)	quicker* (Head:692)
	RP	+	-	Dispreferred	Worse (4.3)	slower (Head:910)
Long- distance SRC	Gap	+	+	Preferred	Better* (5.68)	quicker* (Head:674)
	RP	+	-	Dispreferred	Worse (3.52)	slower (Head:813)
ORC	Gap	+	+	Preferred	Better* (6.1)	quicker* (Head:741)
	RP	+	-	Dispreferred	Worse (4.34)	slower (Head:1021)
Genitive RC	Gap	+	-	No preference	No difference (4.32)	slow (Head:900)
	RP	+	-	Dispreferred	No difference (4.08)	slow (Head:867)

*Note.* The judgment results are adopted from the experiments conducted in Ning, Her, & Lin (2008). A single asterisk (\*) denotes that the effect reaches significance. Means are presented in the parentheses.

### 3. Experiment 2

In Experiment 2, a self-paced reading comprehension task was conducted. The critical conditions involved the indirect object relative clauses with the ‘Give’ verbs, the indirect object relative clauses with the ‘Take’ verbs, the embedded subject relative clauses, and the object relative clauses with adverbials. Exemplary sentences

are repeated in (11).

(11) a. Indirect object relative clauses with the ‘Give’ verbs

*nanyou song-le (ta) shengriliwu de na-wei nuhai*  
boy.friend give.PERF her birthday.gift DE that-CL girl  
*louchu-le xiyue de xiaorong.*  
show-PERF happy DE smile  
‘That girl whom her boy friend gave a birthday gift showed a happy smile.’

b. Indirect object relative clauses with the ‘Take’ verbs

*qiezei tou-le (ta) yi-lian jiche de na-wei*  
thief steal-PERF her one-CL motorcycle DE that-CL  
*xiaojie xiang qingqiu jingcha de xiezhu.*  
lady want ask police DE help  
‘That lady whom the thief stole a motorcycle from wanted to ask the police for help.’

c. Embedded subject relative clauses

*mishu lianluo-shang huizhang xiwang (ta) chuxi*  
secretary contact-PERF president hope he attend  
*shenghui de na-wei huiyuan.*  
grand.meeting DE that-CL associator  
‘The secretary contacted the associator whom the president hoped that he can attend the grand meeting.’

d. Object relative clauses with adverbials

*zongtong jiejian (ta) liang-ci de na-wei xuezhe*  
President receive him two-times DE that-CL scholar  
*jiang jingxing yi-zhou de fangcha.*  
will begin one-week DE inspection  
‘That scholar whom the President received twice is going to inspect for one week.’

As Experiment 1 suggests, the main-clause illusion affected the processing of the resumptive relative clauses, and the ease of reconstruction determines the preference of the gap relative clauses. It is assumed in this experiment that the main-clause illusion in the resumptive versions of each condition takes place as well. Hence, the longer reading times in the positions posterior to the relativizer are predicted.

As for the gap versions, let us first consider the indirect object relative clauses. As is mentioned in Ning, Her, & Lin (2008), the base argument structure of the ‘Give’ verbs is different from that of the ‘Take’ verbs.<sup>2</sup>

- (12) a. Base argument structure of the ‘Give’ verbs: <x, y, z>, where x is an Agent, y is an Experiencer, and z is a Theme. Derived forms can be <x, z, y>, <x, y> or <x, z>.  
b. Base argument structure of the ‘Take’ verbs: <x, z>, where x is an Agent

<sup>2</sup> This assumption is made based on the data from Sinica Corpus Version 4.0. It is revealed that within the declarative and non-idiomatic sentences, the ‘Take’ verbs such as *tou* ‘steal’ are surfaced as <Agent, Theme> (100%) while the ‘Give’ verbs such as *song* ‘send’ can be realized as <Agent, Experiencer, Theme> (38%), <Agent, Theme, Experiencer> (12%), <Agent, Theme> (44%) or <Agent, Experiencer> (16%).

and z is a Theme. Derived forms can be <x, y, z> or <x, y>, where y is an Affectee.

If this is on the right track, the indirect object gaps (i.e. Affectee—y) of the ‘Take’ verbs should be processed without ease since the reconstruction becomes more difficult. It is not easy for the parser to predict an Affectee in the ‘Take’ verbs whose base structure is <x, z>. However, the reconstruction might be easier for the indirect object gaps of the ‘Give’ verbs since the parser might assume an indirect object (Experiencer) in the processing even though the role does not always appear.

Second, in the embedded subject relative clauses,<sup>3</sup> consider the example in (13) and the illustration of processing steps in Table 3.

- (13) *mishu* *lianluo-shang* [<sub>NP/RC</sub> *huizhang* *xiwang* [<sub>CP</sub> *t/ta* ***chuxi***  
 secretary contact-PERF president hope t/he attend  
*shenghui*] *de* *na-wei* *huiyuan*].  
 grand.meeting DE that-CL associator  
 ‘The secretary contacted the associator whom the president hoped that he  
 can attend the grand meeting.’

Table 3. Processing steps in the embedded subject relative clauses

Regions	0:S	1: V of main clause	2:S of RC	3: complement V of RC	4: gap/RP

<b>How to process</b>					
<b>Step 4</b>	Complement clause continues. ....				
<b>Step 5</b>				Reanalyze the complement clause (from region 4 to	

<sup>3</sup> The embedded subject relative clauses were all placed in the objects of the matrix sentences rather than in the sentential subject positions. This manipulation was to ensure that only the embedded subject relativization reading is appropriate.

The embedded subject gaps may become less processable in comparison with other gap relative clause conditions since the parser assumes that a subject of the complement clause, instead of a verb *chuxi* ‘attend’, would appear after the verb *xiwang* ‘hope’. Therefore, the resumptive pronoun which is masked as the beginning a complement clause could be easier to process than the gap.

Finally, notice the object relative clauses with adverbials.<sup>4</sup> The gaps in this condition should be processable since the structures they involve are not as complex as those in the indirect object relative clauses or the genitive relative clauses. Therefore, the gaps in the object relative clauses with adverbials should still be preferred.

### **3.1 Methods**

#### *3.1.1 Participants*

Sixteen native speakers of Chinese in National Taiwan Normal University were paid NT 100 dollars to participate in the experiment. All were naïve to the purpose of the experiment. No participants who participated in this experiment took part in the Experiment 1 and the questionnaire tasks of Ning, Her, & Lin (2008).

#### *3.1.2 Materials*

In order to investigate where the garden path takes place, each sentence was divided into several regions based on the phrasal boundaries. Verbs and objects were separated in this experiment. The divisions are shown with a slash between regions in Appendix B.

Two lists were created from the total 64 (8 sentences x 2 strategies x 4 conditions) sets of experimental sentences, so that each list contained eight sentences of each relativization type, and one version of each set. The experimental sentences were mixed with 68 fillers, resulting in a total of 100 items. The sentences were presented in an individually randomized order created by Linger.

#### *3.1.3 Procedure*

The procedure was identical to Experiment 1. As in Experiment 1, the entire experiment lasted about 20 minutes.

### **3.2 Results**

In this experiment, average accuracy for the comprehension questions was 92%, with no participant scoring below 84%. The same statistical analyses of reading times on the head noun and the verb phrase regions were carried out as in Experiment 1. Reading time values beyond 2 SDs away from the condition mean for the head noun regions were replaced by the mean. This excluded 6% of the data in by-subject analysis and 4% of the data in by-item analysis. The results of the disambiguating

---

<sup>4</sup> Some researchers (Houng, 1986; Huang, Li, & Li, 2006) point out that object resumptives turn out to be acceptable when adverbials appear following the relativized object positions. However, no significance was found within the resumptive strategies of the two conditions in the grammaticality judgments of Ning, Her, & Lin (2008).

regions for each condition are reported in Table 4.

Table 4. Participant mean reading times in milliseconds and *F* tests in Experiment 2

	Head Noun	Main Verb	Object
<b><i>Indirect object relative clauses of the ‘Give’ verbs</i></b>			
Gap	1031 (100.06)	686 (58.16)	997 (94.16)

	$F_1 = 4.319, p = .055$ $F_2 = 1.129, p = .323$	$F_1 = .406, p = .534$ $F_2 = .270, p = .619$	$F_1 = 1.848, p = .194$ $F_2 = 3.461, p = .105$
<b><i>Indirect object relative clauses of the ‘Take’ verbs</i></b>			
Gap	1234 (104.54)	836 (94.50)	1000 (98.19)
RP	1319 (113.04)	644 (44.28)	855 (62.54)
	$F_1 = .617, p = .444$ $F_2 = .271, p = .655$	$F_1 = 4.629, p < .05$ $F_2 = 5.081, p = .059$	$F_1 = 4.741, p < .05$ $F_2 = 2.335, p = .170$
<b><i>Embedded subject relative clauses</i></b>			
Gap	1331 (113.27)	NA	NA
RP	1392 (132.97)	NA	NA
	$F_1 = .142, p = .712$ $F_2 = .196, p = .671$		
<b><i>Object relative clauses with adverbials</i></b>			
Gap	909 (116.11)	533 (43.86)	1006 (111.80)
RP	1207 (145.36)	619 (47.76)	806 (59.49)
	$F_1 = 5.892, p < .05$ $F_2 = 22.870, p < .01$	$F_1 = 2.619, p = .126$ $F_2 = 1.273, p = .296$	$F_1 = 2.044, p = .173$ $F_2 = 2.443, p = .126$

Note: Standard error of the mean is in the parentheses.

### 3.2.1 Indirect object relative clauses of the ‘Give’ verbs

The indirect object relative clauses with resumptives were read slightly longer than those with gaps in the head noun positions (1031 vs. 1231 ms;  $F_1(1, 15) = 4.319, p = .055$ ;  $F_2(1, 7) = 1.129, p = .323$ ). This effect only reached near significance. The head nouns of these gap relative clauses (1031 ms) were also read remarkably longer than those of the subject (692 ms) or object (741 ms) gap relative clauses in Experiment 1. It is possible that processing difficulty increased in the indirect object gap relative clauses of the ‘Give’ verbs.

### 3.2.2 Indirect object relative clauses of the ‘Take’ verbs

In the head noun positions, the resumptive relative clauses exhibited the similar reading times to the gap relative clauses (1234 vs. 1319 ms;  $F_1(1, 15) = .617, p = .444$ ;  $F_2(1, 7) = .271, p = .655$ ). However, the resumptive relative clauses were read slower than the gap relative clauses in the main verbs, which was significant in the participants analysis and approximately significant in the items analysis (836 vs. 644 ms;  $F_1(1, 15) = 4.629, p < .05$ ;  $F_2(1, 7) = 5.081, p = .059$ ). In the final object region, the resumptive relative clauses were still parsed slower than the gap relative clauses, but this effect was only significant by participants (1000 vs. 855 ms;  $F_1(1, 15) = 4.741, p < .05$ ;  $F_2(1, 7) = 2.335, p = .170$ ). This significant difference in the verb phrase positions (main verb plus object) was not discovered in the previous indirect object

relative clauses of the ‘Give’ verbs.

### 3.2.3 Embedded subject relative clauses

Consider Figure 1. The reading times of the resumptive relative clauses were similar to those of the gap relative clauses. There was an increase in the reading times in the final head noun regions of both strategies. No significant difference was found in any regions.

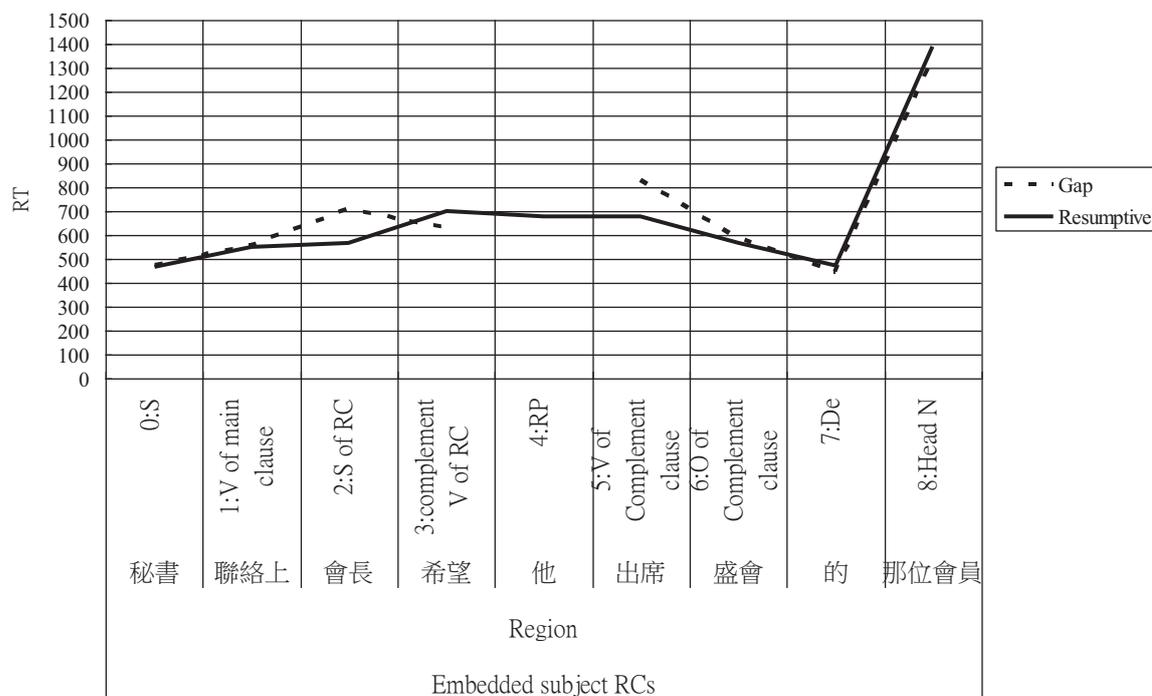

Figure 1. Participant mean reading times for regions in the embedded subject relative clauses

### 3.2.4 Object relative clauses with adverbials

In the object relative clauses with adverbials, significant difference was only found in the head noun positions both by participants and by items analyses (909 vs. 1207 ms;  $F_1(1, 15) = 5.892, p < .05$ ;  $F_2(1, 7) = 22.870, p < .01$ ). This effect was also presented in the object relative clauses in Experiment 1.

## 3.3 Discussion

As mentioned in the Experiment 1, both resumptives and gaps could suffer from the garden-path effect. While resumptives may trigger a main-clause reading initially, gaps could turn out to be difficult to process when the structural complexity interferes with the processing. The pattern of results from this experiment is remarkably similar to the pattern from Experiment 1. Results of the two experiments are presented in

Table 5.

Table 5. Summary of the predictions and results of gap/resumptive occurrences in Experiment 1 and 2

RC Types/ Strategy		Grammaticality	Processability	Predictions	Judgment results	Reading time results
		Grammatical: + Ungrammatical: -	Processable: + Garden-pathed: -			
SRC	Gap	+	+	Preferred	Better* (6.34)	quicker* (Head:692)
	RP	+	-	Dispreferred	Worse (4.3)	Slower (Head:910)
Long- distance SRC	Gap	+	+	Preferred	Better* (5.68)	quicker* (Head:674)
	RP	+	-	Dispreferred	Worse (3.52)	Slower (Head:813)
Embedded SRC	Gap	+	-	No preference	No difference (4.06)	Slow (Head:1331)
	RP	+	-	Dispreferred	No difference (3.76)	Slow (Head:1064)
ORC	Gap	+	+	Preferred	Better* (6.1)	quicker* (Head:741)
	RP	+	-	Dispreferred	Worse (4.34)	Slower (Head:1021)
ORC with adverbials	Gap	+	+	Preferred	Better* (4.70)	quicker* (Head:909)
	RP	+	-	Dispreferred	Worse (3.91)	Slower (Head:1207)
IORC of the 'Give' verbs	Gap	+	-	No preference	No difference (4.00)	Slow (Head:1031)
	RP	+	-	Dispreferred	No difference (3.94)	Slower (Head:1012)
IORC of the 'Take' verbs	Gap	+	-	Dispreferred	Worse (3.56)	slow in Head:1234; slower in V: 836
	RP	+	+	Preferred	Better* (3.93)	quicker in V:644*
Genitive RC	Gap	+	-	No preference	No difference (4.32)	Slow (Head:900)
	RP	+	-	Dispreferred	No difference (4.08)	Slow (Head:867)

*Note.* The judgment results are adopted from the experiments conducted in Ning, Her, & Lin (2008). Shaded tables refer to the conditions in Experiment 2. A single asterisk (\*) denotes that the effect reaches significance. Means are presented in the parentheses.

In the 'Give' verb conditions, there was a small garden-path effect in the resumptive relative clauses. More importantly, the reading times of the gaps in the 'Give' verbs also increased, compared to the gaps in the subject or the object relative clauses. This longer reading time suggests that the indirect object gaps of the 'Give' verbs became less processable, which was consistent to the predictions and the results of the judgments. The structural complexity of the indirect object relative clauses made the reconstruction comparatively complicated. It became relatively hard to quickly identify a position for the head noun to fill in, though this reconstruction process could be done finally. Therefore, the preference for gaps was eliminated in the grammaticality judgments of the indirect object relative clauses of the 'Give' verbs because the gaps were less processable, to be specific, were garden-pathed with the intricate reconstruction. This kind of effect, structural complexity, is also revealed in the genitive gap relative clauses in Experiment 1.

As can be seen from the reading times, the resumptives in the indirect object relative clauses of the ‘Take’ verbs were easier to process than the gaps. This advantage was found in the grammaticality judgments as well (Ning, Her, & Lin 2008). As is mentioned above (see (14) repeated from (12)), it is claimed that the basic argument structure of the ‘Take’ verbs involves <Agent, Affectee>, which is quite distinct from that of the ‘Give’ verbs, <Agent, Experiencer, Theme>.

- (14) a. Base argument structure of the ‘Give’ verbs: <x, y, z>, where x is an Agent, y is an Experiencer, and z is a Theme. Derived forms can be <x, z, y>, <x, y> or <x, z>.  
 b. Base argument structure of the ‘Take’ verbs: <x, z>, where x is an Agent and z is a Theme. Derived forms can be <x, y, z> or <x, y>, where y is an Affectee.

Therefore, one plausible account for the preference for the resumptives would be that the indirect object gaps (i.e. Affectee—y) of the ‘Take’ verbs were processed without ease when they are relativized since the parser had a difficulty in creating a position for the Affectee (difficult reconstruction) within the <x,z> sequence (see (15)). The <x,z> sequence prior to the relativizer *de* would be masked as an argument-complete clause. Hence, the reconstruction of the head noun y would become difficult.

- (15) Relativization of the indirect objects (y) of the ‘Take’ verbs  
 $x\ y\ z \rightarrow x\ z\ DE\ y$

As for the embedded subject relative clauses, the gaps had long reading times as the resumptives since the parser was garden-pathed in both conditions. In the gap relative clauses, the traces in the embedded subjects violated the parser’s expectation for CP argument structure. In the resumptive relative clauses, again, the main-clause illusion misled the parser. Due to these processing difficulties, there was no preference in the strategy, as is shown in the results of the grammaticality judgments. In the object relative clauses with adverbials, the resumptives had the garden-path effect of the main-clause illusion so that the gaps which were more processable were preferred.

#### 4. Conclusion

Overall, it could be concluded with some confidence that although the grammar provides two options to form a relative clause (Ning, Her, & Lin 2008), the garden-path effect plays an important role in determining which strategy will be chosen in the end. In addition to the obligatory resumptives in the oblique object resumptives and the control object relative clauses constrained by Chinese grammar, optional gaps and resumptives concern about three kinds of results with regard to the garden path—gaps preferred, resumptives preferred, and no preference. It is the processability as well as the grammaticality that dominates the productivity of the resumptives. They appear obligatorily only when the gap sentences are ungrammatical. Otherwise, they are optional in the construction of the relative clauses. Resumptives are optional or not so common due to the fact that they suffer from the garden-path effect. However, optional resumptives could demonstrate a processing advantage over gaps when the gaps suffer from the difficulty of reconstruction in

processing.

## Appendix

### A. Experimental items and comprehension questions in Experiment 1

Conditions	No	Items	Yes-no questions
Subject RC	1a	參訪醫院的那位官員 感受到 健保的重要。	官員認為健保不重要。 N
	1b	他 參訪醫院的 那位官員 感受到 健保的重要。	
	2a	成立協會的那位女士 很關懷 弱勢族群。	關懷弱勢族群的人是協會創始人。 Y
	2b	她 成立協會的 那位女士 很關懷 弱勢族群。	
	3a	蒐集語料的那位學者 發表過 幾篇文章。	學者有蒐集語料。 Y
	3b	他 蒐集語料的 那位學者 發表過 幾篇文章。	
	4a	研究經濟的那位院士 提出了 改革宣言。	院士認為經濟不需要改革。 N
	4b	她 研究經濟的 那位院士 提出了 改革宣言。	
	5a	尋求幫忙的那位母親 收到了 一筆善款。	母親沒有拿到善

	5b	她尋求幫忙的那位母親收到了 一筆善款。	款。 N
	6a	調查真相的那位警探找到了蛛絲馬跡。	警探找到了有關真相的線索。 Y
	6b	他調查真相的那位警探找到了蛛絲馬跡。	
	7a	榮獲大獎的那位經理分享了成功的秘訣。	經理有獲得大獎。 Y
	7b	他榮獲大獎的那位經理分享了成功的秘訣。	
	8a	堅持理想的那位考生得到了家人的肯定。	考生得不到肯定。 N
	8b	他堅持理想的那位考生得到了家人的肯定。	
Long-distance subject RC	1a	辛苦地在研究室鑽研疾病問題的那位醫生沈醉在研究樂趣中。	醫生常因為不能休息而感到痛苦。 N
	1b	他辛苦地在研究室鑽研疾病問題的那位醫生沈醉在研究樂趣中。	
	2a	不停地 在各鄉鎮 推展 資源回收 的那位婦女 參與了 環保的 宣導。	婦女在推廣資源回收。 Y
	2b	她不停地 在各鄉鎮 推展 資源回收 的那位婦女 參與了 環保的 宣導。	
	3a	大聲地在會議上 追問 經費流向 的那位監委 表達了 強烈的 不滿。	監委不滿經費的使用。 Y
	3b	她大聲地在會議上 追問 經費流向 的那位監委 表達了 強烈的 不滿。	
	4a	特意地在選舉間 推動 反貪污案 的那位部長 卻傳出 受賄的 醜聞。	部長沒有收受賄賂。 N
	4b	他特意地在選舉間 推動 反貪污案 的那位部長 卻傳出 受賄的 醜聞。	
	5a	近日來 在台各地 拜會 地方首長 的那位立委 想角逐 主席的 寶座。	立委拜會了主席。 N
	5b	他近日來 在台各地 拜會 地方首長 的那位立委 想角逐 主席的 寶座。	
	6a	默默地 在屋簷下 承受 異樣眼光 的那位傭人 意識到 自己的 權利。	傭人受到異樣的眼光。 Y
	6b	她默默地 在屋簷下 承受 異樣眼光 的那位傭人 意識到 自己的 權利。	
	7a	偷偷地 在校園裡 販賣 走私毒品 的那位學長 坦承了 自己的 錯誤。	學長坦承自己販賣毒品。 Y
	7b	他偷偷地 在校園裡 販賣 走私毒品 的那位學長 坦承了 自己的 錯誤。	
	8a	近年來 在街頭旁 仰賴 社會救助 的那位老翁 習慣了 落魄的 生活。	老翁自己賺錢過活。 N
	8b	他近年來 在街頭旁 仰賴 社會救助 的那位老翁 習慣了 落魄的 生活。	
Object RC	1a	學校邀請的那位作家曾獲得藝文大獎。	學校榮獲大獎。 N
	1b	學校邀請他的那位作家曾獲得藝文大獎。	
	2a	公司續聘的那位廠長將拓展貿易版圖。	廠長打算拓展版圖。 Y
	2b	公司續聘他的那位廠長決定拓展貿易版圖。	
	3a	菲傭照顧的那位畫家進行過多次化療。	畫家已經接受過好幾次的治療。 Y
	3b	菲傭照顧他的那位畫家進行過多次化療。	
	4a	秘書聯絡的那位新人正進行密集的訓練。	秘書正接受密集的訓練。 N
	4b	秘書聯絡他的那位新人正進行密集的訓練。	
	5a	歹徒恐嚇的那位藝人雇用了強悍的保鏢。	歹徒雇用了保鏢。 N
	5b	歹徒恐嚇他的那位藝人雇用了強悍的保鏢。	
	6a	流氓毆打的那位男子正接受警方的偵訊。	接受偵訊的是中年男子。 Y
	6b	流氓毆打他的那位男子正接受警方的偵訊。	
	7a	會長稱讚的那位學生得到了比賽冠軍。	會長稱讚了學生。 Y
	7b	會長稱讚他的那位學生得到了比賽冠軍。	
	8a	神父告發的那位歹徒遭到了法院的起訴。	神父遭到了起訴。 N
	8b	神父告發他的那位歹徒遭到了法院的起訴。	
Genitive RC	1a	女兒發表新書的那位父親早成為忠實的讀者。	父親發表了新書。 N
	1b	他女兒發表新書的那位父親早成為忠實的讀者。	
	2a	兒子偷藏刀槍的那位母親不瞭解孩子的情況。	那位母親的兒子偷藏刀槍。 Y
	2b	她兒子偷藏刀槍的那位母親不瞭解孩子的情況。	
	3a	外甥盜用公款的那位董事將辭去管理職位。	董事的外甥盜用公款。 Y
	3b	他外甥盜用公款的那位董事將辭去管理職位。	
	4a	妻子喜歡美食的那位律師常光顧新的餐廳。	律師常常到一樣的地方用餐。 N
	4b	他妻子喜歡美食的那位律師常光顧新的餐廳。	
	5a	弟弟洩漏秘密的那位學生否認了翹課的行為。	學生洩漏了秘密。 N
	5b	他弟弟洩漏秘密的那位學生否認了翹課的行為。	
	6a	孩子受到表揚的那位家長流下了歡喜的淚水。	那位家長的孩子受到了表揚。 Y
	6b	她孩子受到表揚的那位家長流下了歡喜的淚水。	
	7a	孫女就讀小學的那位奶奶準備了豐盛的早餐。	奶奶為她的孫女準備早餐。 Y
	7b	她孫女就讀小學的那位奶奶準備了豐盛的早餐。	
	8a	婆婆罹患癌症的那位婦人辭掉了工廠的工作。	婦人罹患了癌症。 N
	8b	她婆婆罹患癌症的那位婦人辭掉了工廠的工作。	

## B. Experimental items and comprehension questions in Experiment 2

Conditions	No	Items	Yes-no questions
Indirect object relative clauses of the 'Give' verbs	1a	男友送了生日禮物的那位女孩露出了喜悅的笑容。	男友露出了笑容。 N
	1b	男友送了她生日禮物的那位女孩露出了喜悅的笑容。	
	2a	市長賞了一塊匾額的那位局長炫耀著自己的功勞。	局長炫耀自己的功勞。 Y
	2b	市長賞了他一塊匾額的那位局長炫耀著自己的功勞。	
	3a	師傅教了一個秘訣的那位學徒做出了法式蛋糕。	

	3b	師傅教了他一個秘訣的 那位學徒 做出了 法式蛋糕。	
	4a	廠長 加了 一成紅利的 那位技師 正計畫 出國的行程。	廠長計畫出國。 N
	4b	廠長 加了 他 一成紅利的 那位技師 正計畫 出國的行程。	
	5a	對方 輸了 三十幾分的 那位隊長 心想著 穩定勝出。	贏了三十幾分的那位隊長覺得自己得到了勝利。 Y
	5b	對方 輸了 他 三十幾分的 那位隊長 心想著 穩定勝出。	
	6a	騎士 賠了 上千萬元的 那位老人 難平復 喪子之痛。	老人賠了上千萬。 N
	6b	騎士 賠了 他 上千萬元的 那位老人 難平復 喪子之痛。	
	7a	學校 付了 兩倍費用的 那位舞者 將會有 盛大的演出。	舞者拿到兩倍的演出費用。 Y
	7b	學校 付了 他 兩倍費用的 那位舞者 將會有 盛大的演出。	
	8a	鄰居 還了 國文課本的 那位同學 瞥見了 塗鴉的痕跡。	那位同學的課本被亂畫了。 Y
	8b	鄰居 還了 他 國文課本的 那位同學 瞥見了 塗鴉的痕跡。	
Indirect object relative clauses of the 'Take' verbs	1a	竊賊 偷了 一輛機車的 那位小姐 想請求 警察的協助。	小姐偷了機車。 N
	1b	竊賊 偷了 他 一輛機車的 那位小姐 想請求 警察的協助。	
	2a	男子 搶了 手提背包的 那位太太 發出了 求救的聲音。	男子搶了那位太太。 Y
	2b	男子 搶了 他 手提背包的 那位太太 發出了 求救的聲音。	
	3a	對手 贏了 將近十分的 那位選手 讚美著 對方的技巧。	對手贏了那位選手將近十分。 Y
	3b	對手 贏了 他 將近十分的 那位選手 讚美著 對方的技巧。	
	4a	朋友 騙了 一大筆錢的 那位女子 不接受 和解的訴求。	那位女子去騙錢。 N
	4b	朋友 騙了 她 一大筆錢的 那位女子 不接受 和解的訴求。	
	5a	老闆 欠了 多次薪水的 那位員工 放棄了 這項職務。	老闆離開了公司。 N
	5b	老闆 欠了 他 多次薪水的 那位員工 放棄了 這項職務。	
	6a	銀行 賺了 百萬利息的 那位卡奴 將號召 聲援的活動。	卡奴號召聲援活動。 Y
	6b	銀行 賺了 他 百萬利息的 那位卡奴 將號召 聲援的活動。	
	7a	顧客 吃了 一頓大餐的 那位台商 成交了 這筆生意。	台商請顧客吃飯。 Y
	7b	顧客 吃了 他 一頓大餐的 那位台商 成交了 這筆生意。	
8a	情人 花了 好幾百萬的 那位商人 隱瞞著 這件事情。	情人瞞著花大錢的事情。 N	
8b	情人 花了 他 好幾百萬的 那位商人 隱瞞著 這件事情。		
Embedded subject relative clauses	1a	里長 碰見了 大家 以為 遇到 山難的 那位耆老。	里長碰見了大家。 N
	1b	里長 碰見了 他 以為 他 遇到 山難的 那位耆老。	
	2a	秘書 聯絡上 會長 希望 出席 盛宴的 那位會員。	秘書聯絡上那位會員。 Y
	2b	秘書 聯絡上 他 希望 他 出席 盛宴的 那位會員。	
	3a	縣長 獎勵了 家屬 覺得 幫了 大忙的 那位隊員。	縣長獎勵了那位隊員。 Y
	3b	縣長 獎勵了 他 覺得 他 幫了 大忙的 那位隊員。	
	4a	讀者 很鄙棄 報社 懷疑 抄襲 文章的 那位作家。	讀者鄙棄報社。 N
	4b	讀者 很鄙棄 他 報社 懷疑 他 抄襲 文章的 那位作家。	
	5a	主播 正介紹 球迷 期待 現身 球場的 那位主將。	主播正在介紹現場的球迷。 N
	5b	主播 正介紹 他 期待 他 現身 球場的 那位主將。	
	6a	校長 鼓勵著 導師 擔心 放棄 升學的 那個孩子。	校長鼓勵那個孩子。 Y
	6b	校長 鼓勵著 他 導師 擔心 他 放棄 升學的 那個孩子。	
	7a	媒體 想採訪 檢方 認為 涉嫌 貪污的 那位總理。	媒體想採訪的是那位總理。 Y
	7b	媒體 想採訪 他 檢方 認為 他 涉嫌 貪污的 那位總理。	
8a	影迷 很看好 導演 期望 拿下 寶座的 那位主角。	影迷看好導演會得獎。 N	
8b	影迷 很看好 他 導演 期望 他 拿下 寶座的 那位主角。		
Object relative clauses with adverbials	1a	總統 接見 兩次 的 那位學者 將進行 一週的 訪察。	總統將進行訪察。 N
	1b	總統 接見 他 兩次 的 那位學者 將進行 一週的 訪察。	
	2a	專家 晤談 三次 的 那位家屬 放不下 心中的 陰霾。	專家跟家屬晤談了三次。 Y
	2b	專家 晤談 他 三次 的 那位家屬 放不下 心中的 陰霾。	
	3a	議員 質問 三遍 的 那位局長 作出了 敷衍的 回應。	局長隨便地回應問題。 Y
	3b	議員 質問 他 三遍 的 那位局長 作出了 敷衍的 回應。	
	4a	主任 痛罵 多次 的 那位員工 改不掉 遲到的 習慣。	主任改不掉遲到的習慣。 N
	4b	主任 痛罵 他 多次 的 那位員工 改不掉 遲到的 習慣。	
	5a	老師 教訓 一頓 的 那位學生 修改了 提交的 論文。	老師修改了提交的論文。 N
	5b	老師 教訓 他 一頓 的 那位學生 修改了 提交的 論文。	
	6a	警衛 痛打 一頓 的 那位囚犯 爬回去 自己的 房間。	警衛打到囚犯用爬的回去。 Y
	6b	警衛 痛打 他 一頓 的 那位囚犯 爬回去 自己的 房間。	
	7a	男孩 刺了 一下 的 那個嬰兒 沒發出 任何的 聲音。	嬰兒被刺了也沒哭。 Y
	7b	男孩 刺了 他 一下 的 那個嬰兒 沒發出 任何的 聲音。	
8a	老人 踩了 一下 的 那位少年 大罵了 好幾句 髒話。	罵髒話的是老人。 N	
8b	老人 踩了 他 一下 的 那位少年 大罵了 好幾句 髒話。		

# A Uniform Hypothesis of Count/Mass Expressions New Syntactic Evidence

Mario Saltarelli

University of Southern California

Los Angeles California

[saltarel@usc.edu](mailto:saltarel@usc.edu)

## Abstract

The grammar of Count/Mass nouns is reassessed as interface derivations of syntactic expressions. The analysis is in light of new typological evidence from languages, like Marsican, which do not exhibit complementarity (Chierchia 1998, Borer 2005). It is argued that a uniform syntactic DP(NP) hypothesis optimally meets interface conditions under a derivational mechanism operating on a Count/Non-Count category of grammar.

**Keywords:** Marsican, Determiner, count, mass, derivations, interface.

## 1. The Problem

The essential issue this paper addresses is the unacceptability of nominal expressions like (1b)ii) in the paradigm (1), where (1b)ii) is ungrammatical on two apparently separate accounts (2).

- (1) (a)(i) The latest poem was read by every poet
- (ii) The latest poetry was read by every poet
- (b)(i) The latest two poems were read by every poet
- (ii) The latest two \*poetry/( \*poetries) were read by every poet

- (2) (a) Mass expressions don't take quantifiers
- (b) Mass nouns don't take plural inflection

### 1.1 Previous Work

There are at least two conflicting semantic assessments in linguistics and philosophy of the extensional properties of mass nouns: (a) they denote singular terms (Quine 1960) vs. they denote pluralities (Chierchia 1996).

“Grammatically they [mass nouns] are like singular terms in resisting pluralization and articles. Semantically they are like singular terms in not dividing their reference.” Quine 1960:91

“...mass nouns come out of the lexicon with plurality already built in and that is the (only) way that they differ from count nouns. [The Inherent Plurality Hypothesis]”(Chierchia 1998:53) ...“The reason why mass nouns cannot take plural morphology is obvious: they are already plurals.” (Chierchia 1998:70)

“The fundamental assumption which standardly underlies the supposed dichotomy CN and MN is that there is a specific and more or less determinate category of concrete nouns which answers to the no-RD [reference division] criterion—the putative category of MNs, to be precise. The reality however is that insofar as the use of ‘MN’ rests on this criterion, no such category exists”. (Laycock 2004:4)

Other recent proposals doubt the necessity of the mass/count lexical distinction all together on cross-linguistic considerations.

“...nouns are not classified into rigid categories, but rather that they be allowed to appear as either mass or count, depending on the syntactic structure that accompanies them.” (Castillo 2001: 102)

“Not only is the case that classifier languages do not (appear to) have plural inflection, but languages which mark plural do not appear to have classifier inflection. In other words it would appear that classifier inflection and plural inflection are in complementary distribution, as already observed by T’sou [(1976)].” (Borer 2005: 92)...”all nouns in all languages are mass and are in need of being portioned out...in Chinese-like languages through the projection of classifiers...in languages like English by the plural inflection. (Borer 2005: 93)

*Outline of the paper:*

- 1.2 Claims and Proposal
2. The Marsican Data: Beyond Classifiers and Plurals
3. The Syntactic Account
- 3.1 Hypothesis and Derivations
4. Implications beyond Marsican: Extended Typology
5. Conclusions: Count or Mass?

*1.2 Claims and Proposal*

It’s my assessment from the debate (1.1) that the opposition Count/Non-Count is a more precise category regarding the grammar of (1) at the lexical-conceptual interface. Accordingly it’s proposed that Count expression are Determiner Phrases (DP) and Non-Count (including Mass) are Nominal Phrases (NP).

- (3) (a) Count expressions are syntactic DPs,
- (b) Non-Count (née Mass) expressions are syntactic NPs.

## 2. The Marsican Data

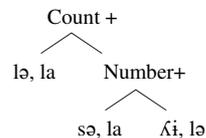

Comparative data was elicited in 30 Marsican communities (Cianciusi, 1998). The examples I will be discussing are strictly from the vernacular of Pescasseroli (L'Aquila, Abruzzo), an endangered Italo-Romance language.

### 2.1 The Determiner system

(4) DETERMINER (DEF.)	Singular	Plural
a. Masculine (i) Count	[sə]/[a]*	[ʎi]
(ii) nonC	[lə]	-----
b. Feminine (i) Count	[la]	[lə]
(ii) nonC	[la]	-----

- (4) (a)(i) [sə-<sup>1</sup>kanə]/ [ʎi-<sup>1</sup>kanə] 'the dog/dogs'  
theM-dog theMPl dog  
(ii) [lə-<sup>1</sup>vinə]/ \*Plur. 'wine/\*plur.'  
theM-wine  
(b)(i) [la-<sup>1</sup>kasa]/ [lə-<sup>1</sup>kasə] 'the house/houses'  
theF-houseF/theFPl-house  
(ii) [la<sup>1</sup>ssɔŋa]/ \*Plur. 'pork fat/\*plur.'  
theF-fatF

(4') Count < Number

Marsican languages distinguish Count/Non-Count Nouns (N) by selecting etymologically distinct forms of the Determiner (D): (4ai/ii).

The distribution of the D (4) is exhaustively described in (4'). Number (Sing and Plur) implies Count+ (A coerced reading is possible). Non-Count Nouns are inert as to Number (Laycock 2004). From the implicational hierarchy Count<Number (4'), the property (2b) follows descriptively. (See 3. for its derivational consequences). It is important to observe that unlike English, Marsican does not allow bare nouns as arguments. Moreover, unlike Italian and English, a generic reading is not available for singular expression (4ai) [sə<sup>1</sup>kanə]. All other forms allow both generic and existential readings. (Note, incidentally, that women/men select distinct morphs [sə] / [a] for D.)

### 2.2 Demonstratives (Dem) and (deictic) question words: Proximate (Prox), Distal (Dist), Remote (Rem)

The D-driven system (4) is robustly confirmed with Demonstratives with both Count (5ai) and Non-Count Nouns (5aii), as well as with Question words (5b).

(5)(a)(i) Demonstrative+Count noun :

*Qui-ste cane ecche* "this dog here"

Dem-Prox dog hereProx

[<sup>1</sup>kwistə]

*Qui-sse cane esse* "that dog there"

Dem-Dist dog thereDist

[<sup>1</sup>kwissə]

*Qui-se/a cane loche* "that dog over there"

Dem-Det dog thereRem

[<sup>1</sup>kwɪsə/<sup>1</sup>kwɪa]

(ii) Demonstrative+ non-Count noun: *que*-Deictic

*Que-ste pane ecche* "this bread here (near me)"

Dem-Prox bread here-Prox

[<sup>1</sup>kwestə]

*Que-sse pane esse* "that bread there (near you)"

Dem-Dist bread there-Dist

[<sup>1</sup>kwessə]

*Que-le pane loche* "that bread over there"

Dem-Det(-C) bread there-Rem

[<sup>1</sup>kwelə]

(5)(b) Question-(deictic) word + Count/non-Count noun: *qua*-Det

Q: *qua-se cane?* "which dog?"

wh-Det(+C) dog

*qua-le pane?* "which bread?"

wh-Det(-C) bread

A: *qui-se!* "that one!"

Dem-Det(+C)

*que-le!* "that one!"

Dem-Det(-C)

Demonstratives (Dem) morphologically incorporate the D in its contrastive Count/Non-Count forms. Semantically, Demonstratives override the functional property of the D: [<sub>Dem</sub> Dem<D...]. Hence, Demonstrative expressions do not admit generic readings. Observe the extension to question words (5b).

### 2.3 Presentational deixis *ecche* 'here', *esse* 'there', *elle* 'yonder'

Marsican uses the same form for Determiners and unstressed pro/en-clitic pronouns.

(5)(c)(i) Pronominal presentatives with Count nouns (ex. 'dog')

(The same form is used for Determiners and unstressed Pronouns)

*ecche-se/ecchi-a vi* "here-it (is), see" *se* = Count

hereProx-Pro(+C)  
 ['ɛkkəsə/'ɛkkia]  
*esse-se/essi-a vi* “there (it is), see”  
 thereDist-Pro(+C)  
 ['ɛssəsə/'ɛssia]  
*elle-se/elli-a vi* “over there (it is), see”  
 thereRem-Pro(+C)  
 ['ɛlləsə/'ɛllia]

- (ii) Pronominal presentatives with non-Count nouns (ex. ‘bread’)  
*ecche-le vi* “same English glosses as above (i)” *le* = Non-Count  
 thereProx-Pro(-C)  
 ['ɛkkələ]  
*esse-le vi*  
 thereDist-Pro(-C)  
 ['ɛssələ]  
 ?*elle-le vi*  
 thereRem-Pro(-C)  
 ['ɛllələ]

Presentatives are like Demonstratives in their deictic specification. Presentatives clitically annex the same Count morphs: [sə]/[a], [lə]. In presentative expressions Count morphs are referential and case marked object pronominals. Hence, presentative expressions do not admit generic interpretation.

#### 2.4. Unstressed object pronouns and the definite article

Recall that D is realized with the same morph as Pronouns in Marsican.

- (6)(a)(i) hai visto **il** fratello di Francesco (It.) ‘Did you see Francesco’s brother?’  
 Have2ps seen **theMs(+C)** brother of ...  
 (i') *si viste se frate Frangisc* (Mars.) (*se* with +C nouns in Pescasseroli)  
 Be2ps seen **theMs(+C)** brother of ...  
 [si 'vvistə sə 'fratə fran'gisk]
- (ii) *sì, l'ho visto* (It.) “Yes, I saw him”  
 Yes, **him**-have1ps seen-Ms
- (ii') *scine, se so viste* (Mars.) (*se* as pro- and –enclitic)  
 Yes, **him(+C)** Be1ps seen  
 [ 'ʃinə sə sso 'vvistə ]
- (iii) ora che l'-hai visto, chiama-**lo!** (It.) “Now that you saw him call him!”  
 now that **him(+C)**-Have2ps, call-**him(+C)**
- (iii') *mo che se si viste, chiama-se!* (Mars.)  
 now that **him(+C)** Be2ps,call-**him(+C)**

[mo kkə ssə si 'vvistə 'kjaməsə]

- (b)(i) hai visto **il** pane di Francesco? (It.) “Did you see Francesco’s bread?”  
 Have-2ps seen **the(-C)** bread of Frank
- (i') *si viste **le** pane de Frangisc* (Mars.) (*le* with mass nouns)  
 Be2ps seen **the(-C)** bread of F.  
 [si 'vvistə lə 'panə fran'gisk]
- (ii) *sì l'ho visto* (It.) ‘Yes, I saw it’  
 yes, **it(-C)**-have1ps seenMs
- (ii') *scine, **le** so viste* (Mars.)  
 yes, **it(-C)**-Be1ps seen  
 [ʃinə lə so 'vvistə ]
- (iii) ora che l'hai visto, prepara-**lo** (It.) “Now that you saw it, prepare it”  
 now that **it(-C)**-Have2ps seen, fix-**it(-C)**
- (iii') *mo che **le** si viste, accongiale* (Mars.) (*le* with pro- and -enclitics)  
 now that **it(-C)** Be2ps seen, fix-**it(-C)**  
 [mo klə llə si 'vvistə ak'k:ondzələ]

We have observed that the Count contrast is morphologically encoded via the same morphs ([sə]/[lə]) across the categories of Determiners (articles) in (4), Demonstratives (5a), Question words (5b), Presentatives (5c) and now the object clitic system (6).

Moreover, the cross-category encoding of the morphemic system presented in (4) reclaims the functional prominence of the category Count and its derivational mapping across the morphological, syntactic and semantic interface in the grammar of this language type. Incidentally, the cross-category realization of Count/Non-Count may also suggest transparent learnability implications.

Finally, the descriptive statement (4) also invites the question as to the role of the lexicon and the derivational architecture of the syntax.

## 2.5 De-adjectival (headless) nominals: determiner+ adjective

### *The semantic role of the D morpheme*

Like Italian (but unlike English), Marsican allows headless adjectival phrases with referential readings (7a). Unlike Italian, however, the singular reading is unambiguously Count or non-Count depending on the choice of Determiners. This description of Marsican suggests that the Count/non-Count semantic reading is morphologically derived, since there is no obvious lexical source.

- (7)(a) [ DP se [D' e [ NP [ N' e [ AP nire ] ] ] ] ]  
 (a') *se nire* ‘the black (one (suit, car, etc.))’  
**theMs(+C)** black  
 [sə 'nɪrə]
- (b) [ NP le [ N' e [ AP ] ] ]  
 (b') *le nire* ‘the black (one: color)’

**theMs(-C) black**

[lə 'nɪrə]

- (c)(i) *sse presutte m'è custate care* “that(Dist) ham cost me dearly”  
**thatMsDist(+C)** ham meBe3ps cost dear  
[<sub>DP</sub> sse [<sub>D'</sub> presutte [<sub>NP</sub> [<sub>N'</sub> presutte ]]]] ....
- (ii) *le presutte nen ge piace* “s/he doesn't like ham”  
**theMs(-C)** ham ...  
[<sub>NP</sub> le [<sub>N</sub> presutte ]] ...

Crucially, the semantic reading alternation of Count/non-Count expressions in (7c) needs not be lexically defined, since it is in strict correlation with the contrastive and obligatory determiner system.

Provisionally, the data suggests that Marsican instantiates a language type where the Count value of the semantic reading is morphologically encoded through a D morpheme opposition.

## 2.6 De-verbal (headless) nominalization: determiner+infinitive = non-count

With de-verbal expressions (8) only the non-Count realization (*le*) of the D is found, as expected.

- (8)(a) (\*il) mangiare troppo tardi fa male (It) “eating too late is bad for you”  
the eatINF ...
- (b) \*(il) mangiare non è buono qui (It.) “food in not good here”  
the eatINF
- (c) *le/\*se magnà n'è bune ecche* (Mars.) (generic reading only)  
**theMs(-C)** eatINF  
[lə ma'ɲɲa nɛ 'bbunə 'ɛkkə]
- (c') [<sub>NP</sub> [<sub>N'</sub> e [<sub>VP</sub> *magnà* ]]] ...

As in the case of de-adjectival headless nominals (7), de-verbal NPs project a phonetically empty head, with the exception that an existential reading of the expression seems is precluded. It seem reasonable to assume, along with de-adjectivals, that the unrealized head of de-verbal nominal is also a variable, akin to arbitrary PRO. It's suspected that the restriction to non-count morphology and parallel interpretation may be attributed to the non-argument status of the VP.

## 3. The Syntactic Analysis

The typologically new evidence from Marsican reclaims the following syntactic hypothesis (9a-c) as a uniform characterization of Count/Non-Count expressions.

### 3.1 Hypothesis

- (9) (a) DP (count), NP  
 (b) D(count) selects NP: if D(count), then DP(NP)  
 (c) Number selects DP: if Num, then NumP (DP(NP)).

As assumed in 1.2, the hypothesis (9a) rests on a Count/(non-Count) reassessment of the Count/Mass category (Laycock 2004). Accordingly, (9b,c) syntactically articulate the descriptive hierarchy (4'): Count<Number.

### 3.2 Derivations

The derivational syntax of the grammar (9) is illustrated in (10)

- (10) Derivations:  
 i. [<sub>NumP</sub>  $\lambda$ i [<sub>Num</sub> kanə [<sub>DP</sub> [<sub>D</sub> ~~kanə~~ [<sub>NP</sub> [<sub>N</sub> ~~kanə~~]]]]]]] *gli cane* 'the dogs' Count,Pl  
 ii. [<sub>DP</sub> sə [<sub>D</sub> kanə [<sub>NP</sub> [<sub>N</sub> ~~kanə~~]]]]] *se cane* 'the dog' Count, Sg  
 iii. [<sub>NP</sub> lə] [<sub>N'</sub> panə]]] *le pane* 'bread' Non-C,Sg  
 (iv. -----\*Non-Count(Mass)Pl

In (10ii), in accordance with (9b) D (the count [sə] morpheme) is functional (a probe) selecting NP. Computationally N (the goal) merges in D, the expression derived as DP with appropriate denotation. Num selects DP (9c) deriving (10i) a NumP expression, with appropriate interface denotation. In (10iii) D (non-count [lə]) is functionally inert, hence, as a goal it merges in N the expression derived as NP, as Non-Count. Note that (10iv) is un-derived by the grammar (9), hence accounting for the paradigmatic ungrammaticality of (10ii) and the observation (2b)

## 4. Beyond the Marsican Determiner

Rohlf's (1968:108) reports the use of the dual determiner system north of La Marsica to areas of Umbria and Le Marche, west to Lazio and south to Campania, Lucania and Apulia. A remarkable variant encodes the contrast in the duality of the Determiner prosodically (11).

- (11)(i) o kafè 'coffee ground' (non-count)  
 Det(-C) coffee  
 [o.kə.'fe]  
 (ii) o kafè '(a cup of) coffee' (count)  
 Det(+C) coffee  
 [ok.kə.'fe] (prosodic contrast)

### 4.1 Asturian: Phonemic contrast (F1) in the inflectional affix

- |          |   |  |
|----------|---|--|
| (12)     | Ye fierr-o machaca-o<br>is iron-m.s. hammered-m.s.<br>“It’s hammered iron”                          | iron (metal)   |
| (13)     | Isti fierr-u ta machaca-u<br>This iron is hammared<br>“This (piece of) iron is hammered”            | a piece (of iron)<br><br>(Castillo 2001:82; Neira 1978:262)      |
| (14) (a) | el camín ta enllenu fueya seco<br>the road is full leaf-f dry-*f<br>“the road is full of dry leaf “ | ‘leaf’ (mass)<br>‘dry’ does not agree in gender                  |
| (b)      | cuelle una fueya seca<br>picks up a dry-f leaf-f<br>“she picks up a dry leaf”                       | ‘leaf’ (count)<br>‘dry’ agrees in gender<br>(Cano González 1992) |

The Count value of the category opposition has been described as metaphony of the citation form, namely the phonetic raising of the inflectional vowel [o] to [u]. Note, moreover, that an effect the effect gender agreement is suspended (14a).

#### 4.3 Typology of count realization (so far)

- (16)(a)(i) Determiner: Morpheme *se/le* contrast: Marsican-like languages
- (ii) Determiner: Morpheme *the/0* (bare N) contrast: English-like languages
- (iii) Determiner: prosodic duration *o#C/o#CC* contrast: Neapolitan-like languages
- (b) Inflection: -affix phonological (F1) contrast: Asturian-like languages
- (c) Classifiers: Classifier contrast: Chinese-like languages

### 5. Summary and Conclusions

The Count/Mass dichotomy reassessment as Count/Non-Count (Laycock 2004) is supported as a satisfactory account for the grammatical issue raised in the paradigm (1). The analysis of the Marsican D-driven system (4) is uniformly described by the Count<Number hierarchy (4’). Accordingly the hypothesis is proposed that DP denotes Count, NP Non-count (9a). In formalizing the descriptive hierarchy (4’), the syntax (9b,c) derives DPs (10ii) and NPs (10iii).

In general the analysis offers a principled reason for the incompatibility of (1bii) and the related statement (2b). Typologically, the analysis of Marsican (9), instantiates a additional system in the realization of the category Count/Non-Count (née Mass) based on the contrastive morphological determiner system (4’). The results, if substantiated, invite a reconsideration of the Inherent Plurality Hypothesis (IPH) (pace Chierchia 1998) as well as a re-elaboration of the complementary hypothesis limited to Classifiers and Inflection (Borer 2005).

# **Clause patterns and the semantics-syntax interface.**

## **Towards a sender's grammar of Estonian**

**Peep Nemvalts**

Tallinn University

Narva mnt 25, 10120 Tallinn, Estonia

Peep.Nemvalts@tlu.ee

### **Abstract**

This paper discusses some crucial issues of a communicative grammar of Estonian. The approach is based on the conviction that a human language should be considered both as a process and as a system, where different layers and levels are partly conflated. The rich morphology of Estonian as a Finnic language makes the semantics-syntax interface even more multidimensional compared with Indo-European ones. The paper presents some examples of how sender's grammar processes the perceived situations into Estonian clauses through the different levels of semantic, syntactic and morphological layers. The most active actant (participant) of the situation, e.g. AGENT etc., is not always marked as a subject of the clause, but may become an indirect subject – like a targetted actant of the situation, e.g. EXPERIENCER, may be formed as an indirect object. The sender's grammar, some fragments of which are discussed here, aims to describe the functioning of the Estonian language system as it is used for communication from the sender's viewpoint.

**Keywords:** semantics-syntax interface, morphosyntax, Estonian clause patterns, phrase order

## **1. Introduction**

The structure of the language system contains three layers: semantic, syntactic and morphological. Within every layer, different levels can be distinguished. In the semantic layer, lexeme, notional and situational levels can be distinguished; the syntactic layer comprises word level, phrase level, clause/sentence level and text level; the morphological layer covers morpheme level and word form level, partly also phoneme level. All these different layers and levels of the system are partly conflated and simultaneous

y processed by the sender in order to communicate the message.

The communicative functions of language are essential to the analysis of its structure (cf. Van Valin & Lapolla 1997). As communication is bidirectional, the system of a language seems to some extent different when seen through the eyes of the sender or the receiver. Both of them have the pragmatic knowledge and cognition as a support and underlying setting (cf. Larjavaara 2007). When describing the structure of the language, it is possible to choose between a semantic-centred (the sender's) or a (morpho)syntactic-centred (the receiver's) point of view. Here the first-mentioned is chosen. The sender of the message (the speaker) departs from the extralinguistic situation (often termed *state of affairs*) he is about to describe with a sentence, i.e. moves in language processing from the semantic layer to the syntactic layer. The interplay of the layers and levels in the structure of Estonian has been described in Nemvalts 2005. I do share many convictions of functional grammar:

Dik concentrates on speakers' competence, seeing his grammar as (1980, p. 47) 'a theory of the grammatical component of communicative competence'. The notion of communicative competence derives from Hymes (1971a). It consists of grammatical competence, the speaker's ability to form and interpret sentences, and pragmatic competence, the ability to use expressions to achieve a desired communicative effect. Dik shares, in some measure, Chomsky's view of grammar as a part of cognitive psychology. Halliday makes no separation of grammatical and pragmatic competence; he sees grammar as a meaning potential shared by a language and its speakers. (Malmkjær 1996: 142)

## **2. The main pragmasemantic types of situations and clause patterns**

One and the same message can be conveyed in many ways, with the help of diverse types of sentences /clauses (and other syntactic constructions). The interaction of semantics and syntax takes various shapes, and can result in a number of morphological forms in sentence processing. One of the central questions has been, how many and what kind of sentence types and/or clause patterns there are in a particular language. Or, to p

ut it more specifically: what kind of clauses/sentences should be distinguished in a communicative sender's grammar?

Erelt (2003: 93) argues for the “two basic syntactic patterns of clauses in Estonian: normal (or non-inverted) and inverted types of clauses”. The “normal sentences” are subdivided into 4 sub-patterns of intransitive clauses and 4 sub-patterns of transitive clauses, while the “inverted clauses” are subdivided into 6 sub-patterns. Morphosyntactically, and considering some semantic information, Rätsep (1978) has accounted for 380 elementary sentences (clause/sentence patterns) in Estonian. So, are there 2, 14 or 380 clause patterns? How basic or elementary are these?

As I have shown earlier (Nemvalts 2001), three general types of clauses/sentences can be postulated, according to the main pragmasemantic types of situations. In the sender's grammar, the clause is defined as a linguistic sign for a situation, used for conveying information in the communication process. These situations are determined by the ontology of situation nuclei. The most essential kinds of situation nuclei can be distinguished at the notional level with the help of two main semantic features: dynamic vs. static and agentive vs. non-agentive. (Nemvalts 2001, 2005: 251-254)

Primarily, a situation with dynamic nucleus will be denoted by an operative clause which has the underlying structure [ACT] + [OP] (+ [ACT2]), like in (1)-(3).

If the nucleus has semantic features [+dynamic, +agentive], it is notionally *an action*. Which sort of action it is, will be determined by the situation as perceived by the sender, but primarily it results in an operative clause with minimum one actant [ACT] (also termed *participant*) denoted by NP (SbP). If there are two actants, it may be a transitive situation like in (2). Observe that transitivity is primarily, from the sender's viewpoint, a feature of just situation, not of verb (cf. Nemvalts 1996). Verb can be understood as a transitive one only from the viewpoint of receiver.

If the nucleus has semantic features [+dynamic, -agentive], it is notionally *a process*, yielding mostly to another kind of operative situation, as in (3).

- (1) *Poiss mängib*  
boy[NOM.SG] play:PRS.3SG  
[ACT] [OP]  
“The boy plays ~ is playing”

- (2) *Poiss mängib korvpalli*  
 boy[NOM.SG] play:PRS.3SG basketball[PART.SG]  
 [ACT] [OP] [ACT2]  
 “The boy plays ~ is playing basketball”

- (3) *Pall veereb*  
 ball[NOM.SG] roll:PRS.3SG  
 [ACT] [OP]  
 “The ball rolls ~ is rolling”

If the nucleus has semantic features [-dynamic, -agentive], it is notionally *a state* and the situation may be described by the sender with a stative clause which has the underlying structure [ACT] + [ST], like (4). Syntactically, the [ST] nucleus is often marked with a predicative VP, which includes a copula plus an adjective or an “adverb of state”.

A situation with semantically [-dynamic, -agentive] nucleus can be perceived pragmatically as existential, with the underlying structure ([CIRC] +) [EX] + [ACT], where a locative circumstance [CIRC] usually plays an essential role, as in (5). The neutral phrase order (Nemvalts 1996: 121-125, 142-143; 2003: 184-185) of Estonian existential sentences is (X)PS, i.e. Adverbial–Predicate–Subject, where subject-NP is coded morphologically as nominative or partitive, like in (5). The most basic characteristics of some central levels are summarised in Table 1.

- (4) *Poisid olid pikad*  
 boy:NOM.PL be:IMPF;3PL long:NOM.PL  
 [ACT] [ST]  
 “The boys were long”

- (5) a. *Väljakul lebasid pallid*  
 court:ADE;SG lie:IMPF;3PL ball:NOM.PL  
 b. *Väljakul lebas palle*

court:ADE;SG lie:IMPF;3SG ball:PART.PL

[CIRC] [EX] [ACT]

“There were balls lying on the court”

layer	level			
morpho- nological	morpheme	stems, derivational affixes, inflectional morphemes		
syntactic	clause	operative	stative	existential
semantic	situational	[ACT] + [OP] + ([ACT2])		[ACT] + [ST]
		notional	nucleus	[OP]
	action [+dyn, +ag]			process [+dyn, -ag]
				state [-dyn, -ag]

Table 1. Essentials of some central levels in the layered structure of language.

### 3. Coding actants in interaction of the different layers and levels

Here follow some examples of how sender’s grammar processes actants of the perceived situations into Estonian clauses all the way through the different levels of semantic, syntactic and morphonological layers.

I fully agree with Hudson (2007: 182) in that “language structure is very similar to the structure found in the other parts of our cognitive network. But of course syntax has a particular subject-matter – how words combine in sentences in such a way as to express complex meanings – so it does use some entities and relations which are not found elsewhere; but the list is very short.”

*Sentence/clause level* syntactic functions relate particular constituent phrases to the sentence nucleus, i.e. VP. In the framework of communicative sender’s grammar I would emphasize, that a syntactic function of an immediate constituent phrase combines the semantic information of the actant [ACT] or circumstantial [CIRC] entity denoted by this phrase with morphological coding, making it possible to understand the sentence as a whole – as a sign of a situation.

In operative sentences the subject-NP (SbP) is coded as nominative, cf. (*pikk poiss* in (1)-(2), (6). The object-NP (SbP) is case-marked primarily as partitive, like (*nauditavat korvpalli* in (2), but depending on the art of the situation and semantic features both of the verb and object noun (substantive), the partitive is replaced by genitive or nominative, as in (6) and (7), cf. Table 2.

layer	level		
morpho- nological	morpheme	<b>nominative,</b> partitive	<b>partitive,</b> genitive, nominative
syntactic	clause	SUBJECT SbP (NP)	OBJECT SbP (NP)
semantic	notional	The active actant of the situation: AGENT, (LAUNCHER, ACTUATOR etc.) or PATIENT	The (directly) targetted actant of the situation: EXPERIENCER (PATIENT, UNDERGOER etc.)

Table 2. Subject and object phrases within interacting levels in the layered structure of Estonian.

- (2) b. [*Poiss*]<sub>SUBJ</sub>                      [*mängib*]<sub>PRED</sub> [*korvpalli*]<sub>OBJ</sub>  
 c. [*Väga pikk poiss*]<sub>SUBJ</sub>    [*mängib*]<sub>PRED</sub> [*nauditavat korvpalli*]<sub>OBJ</sub>  
 very tall boy[NOM.SG]    play:PRS.3SG    enjoyable basketball[PART.SG]  
 [ACT]                                      [OP]                      [ACT2]  
 “The very tall boy plays ~ is playing enjoyable basketball”

The indirect object-NP (SbP) is an item, which has caused many disputes among Estonian linguists. Most of them had taken the axiomatic viewpoint that there is no such function in Estonian, preferring to see phrases like *sõbrale* in (6) as adverbials. In the Estonian translation of the textbook of general linguistics by Fred Karlsson, the translators/editors have added examples from Estonian and made several comments. One of these is:

*Eesti keeles ei ole kaudobjekti. Vastavat tähendust väljendatakse allatiivi (-le) kasutades. Allatiivis olev saajat tähendav NP ei erine morfosüntaktiliselt millegi*

*poolest adverbiaalidest, milles esineb sageli samuti kohakääne.* (Karlsson 2002:179)

‘Estonian has no indirect object. Respective meaning is indicated by using allative (-le). The allative NP denoting recipient does not differ in any way from adverbials, which are likewise often represented by some locative.’

The problem is that adverbial as a syntactic category has become so diffuse, that the lack of explanatory power in using this is obvious. There are too many sorts and sub-sorts of adverbials, and a lot of exceptions in definitions of those. Some of colleagues have confessed that adverbial as a category is defined negatively:

*Määrust ehk adverbiaali määratletakse negatiivselt: see on verbi laiend, mis pole sihitis ega öeldistäide, samuti igasugune omadus- ja määrsõna laiend. [---] Määrusel ... puudub selgepiiriline süntaktiline funktsioon lauses, jääkliikmena saab teda pidada üheks lauseliikmeks vaid tinglikult.* (EKG II 1993:60)

‘The adverbial is defined negatively: it is a verb modifier, which is not object nor predicative, likewise every modifier of adjectives and adverbs. [---] Adverbial has no clearcut syntactic function in a sentence, as a waste part [of a sentence] it can only conditionally be considered as one constituent category of a sentence’

What does this mean? Purely that it is a waste category – and a large one, including some 25 +/-3 types of adverbials. But, if we take the consequent viewpoint of the sender, we can greatly diminish the volume and diffuseness of this trash. Acknowledging that actants and circumstances are two principally different kinds of participants of a situation signified by the sentence, also principally different syntactic functions are needed to codify these. Thus, adverbials are needed for explaining how circumstances of the situation are signified. Phrases like *sõbrale* in (6), however, are clearly used for actants, and differ only slightly from those functioning as object phrases. Semantically, indirectly targeted actants are signified with SbP (NP) marked as allative or relative, or with some substitutional AdpP and are naturally sinking in the system of

sender's grammar, when described as indirect objects by their syntactic function (cf. Kure 1963, Klaas 1988, Nemvalts 1980, 2001). The place of indirect object phrases in the language system is exemplified in the Table 3.

(6) [Poiss]<sub>SUBJ</sub> [annab]<sub>PRED</sub> [raamatu(d)]<sub>OBJ</sub> [sõbrale]<sub>I-OBJ</sub>  
 boy[NOM.SG] give:PRS.3SG book[GEN.SG](NOM.PL) friend:ALL.SG  
 [ACT] [OP] [ACT2] [ACT3]  
 “The boy gives the book (books) to a friend”

layer	level	
morpho- nological	morpheme	allative (-le), substitutional AdpP elative (-st)
syntactic	clause	INDIRECT OBJECT SbP (NP), AdpP
semantic	notional	The indirectly targetted actant of the situation: INTENT, EXPERIENCER (BENEFICIENT, etc.)

Table 3. Indirect object phrases within interacting levels in the layered structure of Estonian.

Recently, also some linguists who earlier denied the usefulness of the indirect object concept in describing Estonian, have started to move in the same direction:

In POSSESSIVE CLAUSES the oblique object expresses the possessor and is in the adessive case. The possessor is typically animate, as *Jaani* [Ade] *on* [is] *vend* [N] ‘Jaan has a brother’, but sometimes it may be inanimate as well, as in *Autol* [Ade] *on neli ratast* ‘The car has four wheels’. (Erelt 2003: 94)

Still, this “oblique object” is not defined properly. Moreover, what we find here, is another diffuse category often referred to as simply “oblique”:

The modal verbs *tulema* ‘have to’, *tarvitsema* ‘need’, *maksma* ‘be worth (doing)’, *pruukima* ‘use’, *tasuma* ‘be worth (doing)’, *vaja olema/minema* ‘be needed’, *tarvis*

*olema/minema* ‘be needed’ are less grammaticalized because they require a pattern with the adessive **oblique**, cf. *Ta võtab rohtu* ‘He takes medicine’ - *Tal* [Ade] *tuleb/tasub rohtu võtta* ‘He has to take medicine / he will benefit from taking medicine’. (Erelt 2003:106)

Such instances are clearly related to the subject phrases like those in (2) or (6). There is no difference at semantic layer, only adding of certain modal verbs to the clause nucleus causes change at morphological layer: the sender is led to use adessive marking of the NP (SbP). Therefore, I have earlier (Nemvalts 2001) proposed *indirect subject* as the syntactic function of such phrases, like *poisil* in (7). The position of indirect subject phrases in the language system is exemplified in the Table 4.

- (7) [*Poisil*]<sub>I-SUBJ</sub> [*tuleb anda*]<sub>PRED</sub> [*raamat*]<sub>OBJ</sub> [*sõbrale*]<sub>I-OBJ</sub>  
 boy:ADE;SG have-to give:INF book[NOM.SG] friend:ALL.SG  
 “The boy must ~ has to give the book to a friend”

layer	level	
morpho- nological	morpheme	adessive (-/), allative (-le),
syntactic	clause	INDIRECT SUBJECT SbP (NP)
semantic	notional	The active actant of the situation: AGENT, (LAUNCHER, ACTUATOR etc.) PATIENT, EXPERIENCER (in a state sentence)

Table 4. Indirect subject phrases within interacting levels in the layered structure of Estonian.

However, one cannot say that modality *per se* triggers the adessive marking of the SbP referring to the most active actant. If the sender chooses modal verb *pidama* for conveying exactly the same message of necessive modality as in (8a), it results in (8b) with nominative subject phrase.

- (8) a. [*Meil*]<sub>I-SUBJ</sub> [*on vaja mõelda*]<sub>PRED</sub>

we:ADE be-need think:INF

“We need ~ have to think”

b. [*Meie*]<sub>SUBJ</sub> [*peame mōtlema*]<sub>PRED</sub>

we:NOM must:PRS.1PL think:SUP

“We must think”

Rather, the adessive-marked phrase in (7) and (8a) indicates closeness to possessive constructions (*Meil on pall* “We have a ball”), which is also true about (9a). But sentences like (9a) can not be possessive sentences. They are (existential) state sentences with adessive indirect subject. The same stative situation can be expressed also by (9b), and even by (9c), though the latter has different connotation: somebody else, e.g. mother felt the boy was cold. The indirect subject can be also marked morphologically with allative, depending on which predicate verb is chosen by the sender, as in (10).

(9) a. [*Lumise l poisil*]<sub>I-SUBJ</sub> [*oli külm*]<sub>PRED</sub>  
snowy:ADE;SG boy:ADE;SG be:IMPF.3SG cold[NOM.SG]  
“The snowy boy felt cold”

b. [*Lumine poiss*]<sub>SUBJ</sub> [*külmetas*]<sub>PRED</sub>.  
snowy[NOM.SG] boy[NOM.SG] freeze:IMPF.3SG  
“The snowy boy froze”

c. [*Lumine poiss*]<sub>SUBJ</sub> [*oli külm*]<sub>PRED</sub>  
snowy[NOM.SG] boy[NOM.SG] be:IMPF.3SG cold[NOM.SG]  
“The snowy boy was frozen/cold”

(10) [*Pikale poisile*]<sub>I-SUBJ</sub> [*meeldib*]<sub>PRED</sub> [*korvpall*]<sub>SUBJ</sub>  
long:ALL.SG boy:ALL.SG like:PRS.3SG basketball:NOM.SG  
“The long boy likes basketball”

Accordingly to Erelt (2003) clauses like (5), (9a) and (10) are not normal clauses,

but inverted ones. Among Erelt's 14 sub-patterns there is none which corresponds to clauses like (7), (8a). However, all the clauses (1)-(10) are completely normal, neutral structures in Estonian. Invertedness is meaningful only when used for description of information structure, where shift in the phrase order of a neutral syntactic structure is contextually/pragmatically caused. All six Erelt's sub-patterns of what he calls "inverted clauses" are, in fact, syntactically normal neutral clauses, and reducible to one and the same basic phrase order pattern (X)PS. Existential sentences can certainly also be inverted, if it is needed because of contextual conditions in communication.

#### **4. Conclusion**

The sender has freedom to choose, how he wants to put forward a message about the situation he has perceived. It can be done in many ways, with the help of diverse types of clauses/sentences. In the sender's grammar, the clause is defined as a complex linguistic sign for a situation. It seems most appropriate to distinct three general patterns of clauses, according to the main pragmasemantic types of situations: operative, stative and existential. In describing operative clauses, indirect object is a useful syntactic function, in addition to the subject and object. In sender's grammar, also indirect subject is needed, when accounting for, first of all, some state clauses, but also operative clauses with certain modal verbs.

The interaction of semantics and syntax takes various shapes, and can result in a number of morphological forms in sentence processing even within the same basic sentence pattern. All three general patterns, inclusive existential sentences, are inevitably used by sender for constructing normal clauses and all of them may be used with inverted phrase order, if context imposes.

## Abstract

This paper provides a morphosyntactic account of three spatial postpositional phrases in Japanese: the *-ni*, *-e* and *-eto* phrases. It shows that the incompatibility between the *-ni* phrase and a manner-of-motion verb, which appears to follow Talmy's descriptive generalizations for verb-framed languages (VFLs) such as Japanese, is rooted in failing to satisfy a locality condition for secondary predication, and that it is the degraded grammaticality of the *-e* phrase with a manner-of-motion verb that follows the generalizations at issue. It further shows that the *-eto* phrase is compatible with a manner-of-motion verb because *-eto* consists of the directional postposition *-e* and the indeterminate aspectual head *-to* that rescues an aspectual mismatch between the *e*-phrase and a co-occurring manner-of-motion verb.

**Keywords:** Talmy's typology, morphosyntactic properties of spatial PPs, aspect, Japanese

## 1. Introduction

Talmy (1985, 1991) has shown that languages differ with respect to how semantic features such as Manner, Motion and Direction (Path in Talmy's terminology) are mapped onto Vs and PPs, and that differences in lexicalization patterns can surface in various ways. In Romance languages and Japanese, which are classified as verb-framed languages (VFLs), unergative verbs of manner-of-motion cannot appear with a directional PP because Direction is expressed in a verb not in a satellite. On the other hand, in Germanic languages such as Dutch and English, which are called satellite-framed languages (SFLs), the same type of verbs can appear with a directional PP because Direction is expressed in a satellite. Consider the contrast between VFLs and SFLs, as shown in (1)-(5):

**Verb-framed languages (VFLs):** Japanese French and Spanish

- (1) \**Taroo-ga kooen-ni arui-ta.* [Japanese]  
Taroo-Nom park-NI walk-Past  
"Taroo walked to the park."
- (2) \**J'ai marché au parc.* [French]  
I have walked to.the park  
"I walked to the park."
- (3) ??*Juan caminó a la puerta.* [Spanish]  
Juan walked to the door  
"Juan walked to the door."

**Satellite-framed languages (SFLs): Dutch and English**

(4) *Hij is naar huis gelopen.* [Dutch]

He is to house run  
“He ran home.”

(5) I walked **to** the park. [English]

However, there seem to be counterexamples to the typological descriptions. Consider (6):

- (6) a. *??Taroo-ga kooen-e arui-ta.*  
Taroo-Nom park-E walk-Past  
“Taroo walked to the park.”  
b. *Taroo-ga kooen-eto arui-ta.*  
Taroo-Nom park-ETO walk-Past  
“Taroo walked to the park.”

(6a) shows that when *-ni* in (1) is replaced by *-e*, the improved grammaticality results. Further, with *-eto* as in (6b), the sentence becomes perfectly grammatical.

(7), (8) and (9) summarize the observations so far. The *-ni* phrase cannot appear with unergative verbs of manner of motion, while the *-e* phrase can with degraded grammaticality. Further, the *-eto* phrase is perfectly compatible with unergative verbs of manner of motion.

- (7) \* $V_{\text{MOTION\&MANNER}} + -ni$  phrase [ungrammatical]  
(8)  $??V_{\text{MOTION\&MANNER}} + -e$  phrase [degraded but not ungrammatical]  
(9)  $V_{\text{MOTION\&MANNER}} + -eto$  phrase [grammatical]

This paper is organized as follows. Section 2 will observe how the three types of PPs behave morphosyntactically. In Section 3, I will present my proposals for the morphosyntactic properties of the *-ni*, *-e* and *-eto* phrases. Section 4 will show that the proposals can receive empirical support. Section 5 will present implications of my proposed analysis of the *-ni* phrase. Finally, Section 6 will conclude this paper.

## 2. Morphosyntactic behavior of *-ni*, *-e* and *-eto*

It should be noted first that the three types of PPs are all compatible with unaccusative verbs of directed motion. The facts in (10) and (11) illustrate that.

- (10) *Taroo-ga Pari-ni/-e/-eto it-ta.*  
Taroo-Nom Paris-NI/-E/-ETO go-Past  
“Taroo went to Paris.”  
(11) *Taroo-ga Pari-ni/-e/-eto tui-ta.*  
Taroo-Nom Paris-NI/-E/-ETO arrive-Past  
“Taroo arrived at Paris.”

However, there is a crucial difference with respect to whether they are permitted

in existential sentences. As shown in (12) and (13), only the *-ni* phrase can appear in the existential sentences and express Location, not the *-e* and *-eto* phrases.

- (12) *Kooen-ni/\*-e/\*-eto hunsui-ga ar-u*  
 park-NI/-E/-ETO fountain be-Pres  
 “There is a fountain in the park.”
- (13) *Uraniwa-ni/\*-e/\*-eto risu-ga ir-u*  
 backyard-NI/-E/-ETO squirrels be-Pres  
 “There are squirrels in the backyard.”

Third, *-eto* can be decomposed into the postposition *-e* and the suffix *-to*. This decomposition analysis receives support from the fact that a gap can intervene between *-e* and *-to*, as in (14) and (15):

- (14) *Taroo-ga kooen-e, -to arui-ta.*  
 Taroo-Nom park-E, -TO walk-Past  
 “Taroo walked to the park.”
- (15) *John-ga mukoo-gisi-e, -to oyo-da.*  
 John-Nom other-shore-E, -TO swim-Past  
 “John swam to the other side (e.g., the other side of the lake).”

Of the three phrases, the *-ni* phrase exhibits behavior that the other two do not. Takezawa (1993, 2000) shows that *-ni* can be used as a suffix for secondary predicates. Consider the facts in (16), (17) and (18).

- (16) *Aisukuriimu-ga katikati-ni koot-ta.*  
 ice cream-NOM solid-NI freeze-PAST  
 “The ice cream froze solid.”
- (17) *\*Aisukuriimu-ga katikati-e koot-ta.*  
 ice cream-NOM solid-E freeze-PAST  
 “The ice cream froze solid.”
- (18) *\*Aisukuriimu-ga katikati-e-to koot-ta.*  
 ice cream-NOM solid-E-TO freeze-PAST  
 “The ice cream froze solid.”

The *-ni* resultative secondary predicate can only be predicated of the unaccusative Subj and the direct Obj. (19) and (20) show that the Subj of the unaccusative sentence and the direct Obj of the transitive sentence can be the antecedents of the respective resultative secondary predicates, while (21) and (22) show that the subject of the transitive sentence and that of the unergative sentence cannot.

- (19) *Aisukuriimu-ga katikati-ni koot-ta.*  
 ice cream-Nom solid-NI freeze-Past  
 “The ice cream froze solid.”
- (20) *John-ga aisukuriimu-o katikati-ni koorase-ta.*  
 John-Nom ice cream-Acc solid-NI freeze-Past  
 “John froze the ice cream solid.”

- (21) \**John-ga kuruma-o hetoheto-ni migai-ta.*  
 John-Nom car-Acc tired-NI polish-Past  
 “John polished the car tired.”
- (22) \**John-ga kutakuta-ni odot-ta.*  
 John-Nom exhausted-DE/-NI dance-Past  
 “John danced (when he was) exhausted.”

In this section, I have provided an overview of the morphosyntactic behavior of the three types of spatial PPs in Japanese. The summary of their behavior is given in table (23). All of the three PPs are compatible with unaccusative verbs, but only the *-ni* phrase can co-occur with stative verbs and can be used as a secondary predicate. Finally, the *-ni* phrase is incompatible with unergative verbs of manner of motion, but replacing it with the *-e* phrase and *-e-to* phrases results in improved and perfect grammaticality, respectively.

(23) Summary of the behavior of the *-ni*, *-e* and *-e-to* phrases:

	unaccusative	stative	secondary predicate	unergative
<i>-ni</i>	OK	OK	OK	*
<i>-e</i>	OK	*	*	?/??
<i>-e-to</i>	OK	*	*	OK

### 3. Proposed analysis for the three types of spatial PPs in Japanese

On the basis of the observations provided in Section 2, I will propose the following. First, the spatial PPs in (1) and (6) can involve up to three heads: locational P, directional *p* and an aspectual head (van Riemsdijk 1990, Hasegawa 1998, Koopman 2000, Ramchand & Svenonius 2002, Svenonius 2004, Asbury, Gehrke & Hegedus 2006, among others).

(24)  $[_{AspP} [_{pP} DP_{Figure} [_{p'} [_{PP} DP_{Ground} [_{locationalP} -ni]]] [_{directionalP} -e]]] [_{Asp} -to]]$

Note that in (24), *-ni* and *-e* do not morphologically co-occur due to a ban on postposition stacking in Japanese.

Second, the postposition *-ni* is a locational P, not a directional *p* as its compatibility with stative predicates indicates. The *-ni* locational phrase constitutes a single layered structure, with the Ground argument in the complement position of locational P.

(25)  $[_{PP} DP_{Ground} [_{locationalP} -ni]]$

Third, the *-e* directional phrase has a double layered structure, containing a null locational P, directional *p*, Ground DP and Figure DP.

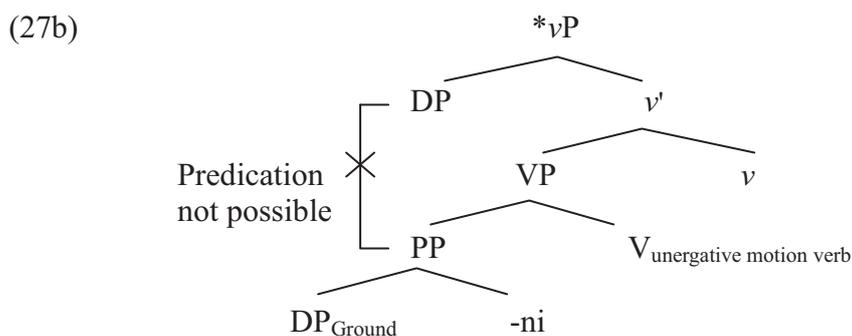

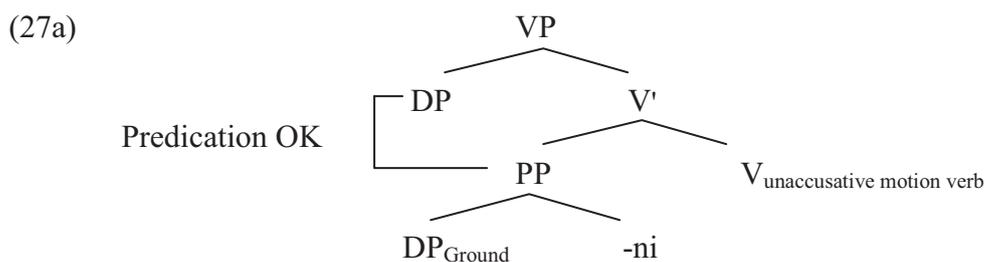

(26)  $[_{pP} DP_{Figure} [_{p'} [_{PP} DP_{Ground} [_{locationalP} \emptyset]]] [_{directionalP} -e]]]$

In what follows, I will provide a more detailed analysis of the three types of

spatial PPs at issue. First, the relevant facts concerning the *-ni* phrase are given in (1) and (10) repeated below:

- (1) \**Taroo-ga kooen-ni arui-ta.*  
 Taroo-Nom park-NI walk-PAST  
 “Taroo walked to the park.”  
 (10) *Taroo-ga Pari-ni it-ta.*  
 Taroo-Nom Paris-NI go-Past  
 “Taroo went to Paris.”

Following Takezawa (1993, 2000), the *-ni* locational phrase, which exhibits parallel behavior to resultative secondary predicates, is base-generated under VP as well as its antecedent. This configuration satisfies the locality requirement imposed on resultative secondary predication, as in (27a).<sup>1,2</sup> On the other hand, in unergative sentences, the antecedent (i.e., Subj in unergative sentences) is base-generated in [Spec, v], while the *-ni* phrase is under VP, which violates the locality condition as shown in (27b), hence the incompatibility of the *-ni* phrase with unergative verbs of manner of motion. Note that directional (Goal) meaning in (10) is derived from the secondary predication relationship between the *-ni* phrase and its antecedent.<sup>3</sup>

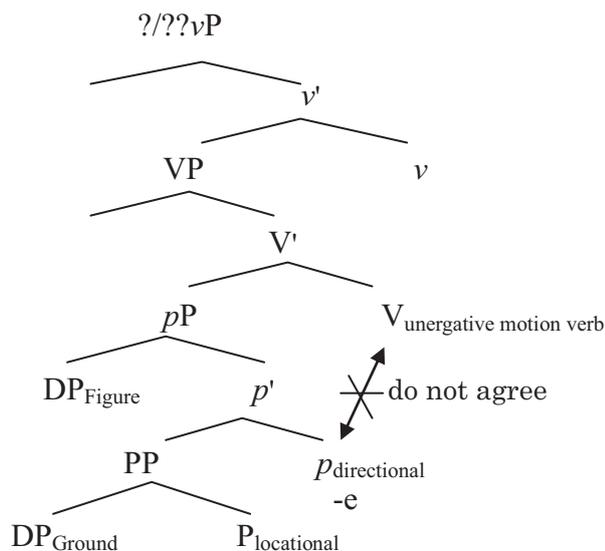

Second, turning to the *-e* phrase, the relevant facts are repeated below:

- (6a) *???Taroo-ga kooen-e arui-ta.*  
 Taroo-Nom park-E walk-Past  
 “Taroo walked to the park.”  
 (10) *Taroo-ga Pari-e it-ta.*  
 Taroo-Nom Paris-E go-Past  
 “Taroo went to Paris.”

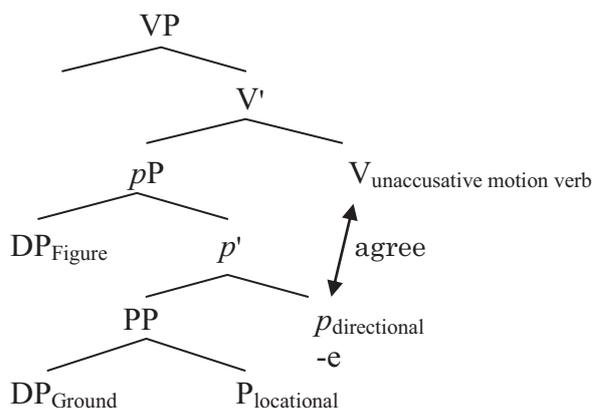

The degraded grammaticality of (6a) follows from Talmy's typological generalization: verb framed languages do not allow unergative verbs of manner of motion to co-occur with a directional (Goal) phrase. I claim that this typological description can be recaptured as an aspectual mismatch between the unergative verb (atelic) and the directional (Goal) PP (telic), as illustrated in (28a). This analysis is based on the assumption that the morphosyntactic properties of a P and those of a co-occurring V are fixed when they are selected from the lexicon.

(28a)

In contrast to (6a), (10) shows a match between the unaccusative verb (telic) and the directional PP (telic), as in (28b).

(28b)

Note that the mismatch as in (6a) is absent, for example, in Dutch since manner-of-motion verbs can alternate between unergative verbs of manner of motion and unaccusative verbs of directed motion. This alternation allows the aspect of verbs such as *walk* to match with the aspect of a directional PP. The following Dutch examples illustrate the alternation at issue. With the prepositional phrase expressing Location, the auxiliary verb selected is *hebben* 'have,' but with the directional postposition, the auxiliary verb is *zijn* 'be.' Consider (29):

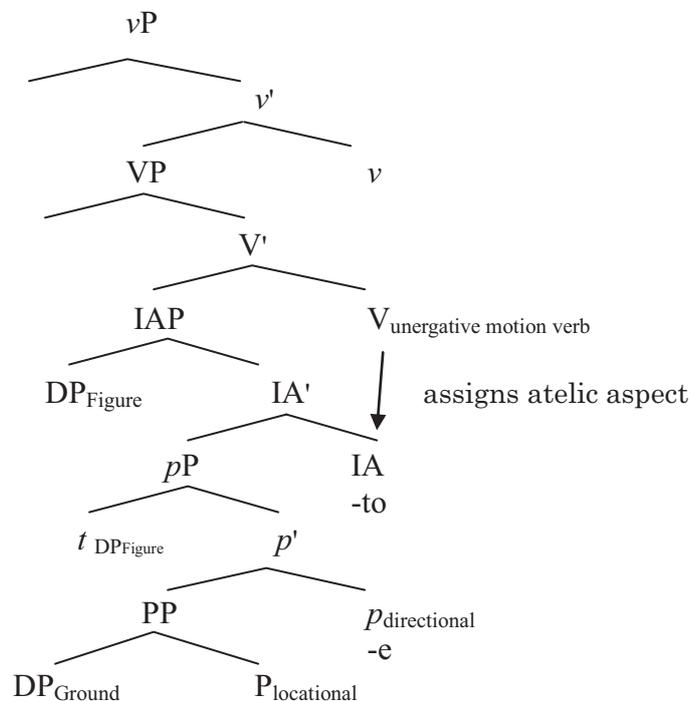

- (29) a. *dat Jan [op de berg] heeft gereden* [locational]  
 that Jan on the mountain has driven  
 “that Jan drove on the mountain top”  
 b. *dat Jan [de berg op] is gereden* [directional]  
 that Jan the mountain up is driven  
 “that Jan drove up the mountain”

Turning to the *-e-to* phrase, recall that it is compatible with unaccusative verbs of directed motion and unergative verbs of manner of motion. The relevant facts are in (6) and (10) repeated below:

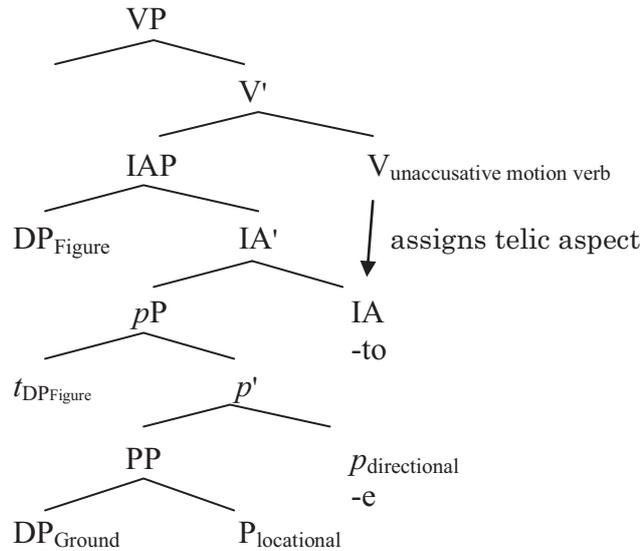

- (6b) *Taroo-ga kooen-e-to arui-ta.*  
 Taroo-Nom park-E-TO walk-Past  
 “Taroo walked to the park.”  
 (10) *Taroo-ga Pari-e-to it-ta.*  
 Taroo-Nom Paris-E-TO go-Past  
 “Taroo went to Paris.”

The proposed structure of the *-e-to* phrase is as follows. It consists of three heads: the morphologically covert locational P, the directional *-e*, and the indeterminate aspectual head (IA) *-to*.<sup>4</sup> This three-layered structure contains both Figure and Ground DPs. The value of this indeterminate head is assigned by the verb that selects the IA phrase, as illustrated in (30a) and (30b):

(30a)

(30b)

The kind of mismatch observed between the *-e* phrase and unergative manner of motion verbs does not occur in (30b) since the IA mediates between the directional head and the unergative verb as shown in (30a).

#### 4. Empirical support for the proposed analysis

The above proposals receive empirical support. In what follows, I will first show that the *-ni*, *-e* and *-e-to* phrases are base-generated under VP and have argument properties. As I have already mentioned, the *-ni* locational phrase exhibits behavior parallel to the resultative secondary predicate, and thus is considered a complement under VP. Further, both *-e* and *-e-to* phrases should be arguments under VP, for the Figure DP to raise out of *pP*. Second, I will provide evidence for the indeterminate nature of *-to* with respect to its aspectual properties and show that its aspect is assigned by the verbs that select the *-e-to* phrase. Finally, I will show evidence that the *-e* postposition is inherently directional as opposed to *-ni* and *-to* whose aspectual properties are externally determined.

##### 4.1. VP constituency for *-ni*, *-e* and *-e-to* phrases: Pseudo-clefting and VP-fronting

It can be empirically supported that the *-ni*, *-e* and *-e-to* phrases have argument properties and are base-generated under VP.

First of all, two VP-constituency diagnostics, namely, pseudo-clefting and VP-fronting, show that another spatial phrase, the *-de* locational phrase, is not under VP.<sup>5,6</sup> Consider (31):

- (31) a. *Gakusee-ga kooen-de si-ta-no-wa aruku-koto da-ta.*  
student-Nom park-DE do-Past-Nml-Top walk-Nml Cop-Past  
“What the students did in the park was to walk.”

- b. *Aruki-sae gakusee-ga kooen-de si-ta.*  
 walk-even student-Nom park-DE do-Past  
 “Even walked, the student did in the park.”

In contrast to the *-de* phrase, the same VP-constituency diagnostics show that *-ni*, *-e* and *-e-to* phrases are under VP, as in (32):

- (32) a. \**Gakusee-ga kooen-ni/-e/-e-to si-ta-no-wa iku-koto*  
 student-Nom park-NI/-E/-E-TO do-Past-Nml-Top go-Nml  
*da-ta.*  
 Cop-Past  
 “What the students did to the park was to go.”  
 b. \**iki-sae gakusee-ga kooen-ni/-e/-e-to si-ta.*  
 go-even student-Nom park-NI/-E/-E-TO do-Past  
 “Even went, the student did to the park.”

Second, the *soo-suru* diagnostic confirms that the *-de* locational phrase is outside the domain of *soo-suru* “do so,” hence the grammaticality of the examples in (33):

- (33) a. *Hanako-ga kyoositu-de ohirugohan-o tabe-ta.*  
 Hanako-Nom classroom-DE lunch-Acc eat-Past  
*Taroo-mo gakusyoku-de soo-s-ita.*  
 Taroo-also cafeteria-DE so-do-Past  
 “Hanako ate lunch in the classroom. Taroo did so in the classroom.”  
 b. *Taroo-ga eki-de kippu-o kat-ta.*  
 Taroo-Nom station-DE ticket-Acc buy-Past  
*Hanako-mo intaanetto-de soo-s-ita.*  
 Hanako-also internet-DE so-do-Past  
 “Taroo bought a ticket at the station. Hanako did so on the internet.”

On the other hand, the *-ni*, *-e* and *-e-to* phrases are inside the domain of *soo-suru* “do so,” hence the ungrammaticality of the examples in (34):

- (34) a. *Hanako-ga Tokyo-eki-ni/-e/-e-to tui-ta.*  
 Hanako-Nom Tokyo-station-NI/-E/-E-TO arrive-Past  
 (*Onazi-koro*) \**Taroo-mo Osaka-eki-ni/-e/-e-to*  
 same-time Taroo-also Osaka-station-NI/-E/-E-TO  
*soo-s-ita.*  
 so-do-Past  
 “Hanako arrived at Tokyo Station. (At about the same time) Taroo did so at Osaka Station.”

- b. *Taroo-ga Tokyo-ni/-e/-eto syuttyoo-s-ita.*  
 Taroo-Nom Tokyo-NI/-E/-E-TO business.trip-do-Past  
 \**Hanako-mo Kyoto-ni/-e/- e-to soo-s-ita.*  
 Hanako-also Kyoto-NI/-E/-E-TO so-do-Past  
 “Taroo went to Tokyo on business. Hanako did so to Kyoto.”

#### 4.2. Evidence for *-to* as an indeterminate aspectual head

Turning to the proposed analysis of *-to* in *-e-to*, indeterminate aspectual properties of the affix in question receives support from *-teiru* facts. As illustrated in (35), when suffixed by *-teiru*, Japanese verbs express either progressive or perfective, depending on the types of verbs.

(35) The *teiru* diagnostic in Japanese (Kindaichi 1950):

- |  |               |                      |
|--|---------------|----------------------|
| $V_{\text{transitive/unergative}} + teiru$ | $\Rightarrow$ | atelic (progressive) |
| $V_{\text{unaccusative}} + teiru$          | $\Rightarrow$ | telic (perfective)   |

The sentences with the *-e-to* phrases in (36) and (37) show that they can co-occur with the unergative verbs of manner of motion and the unaccusative verbs of directed motion, respectively, which does not affect the aspect of the entire VPs. The facts in (36) and (37) can be taken to show that *-to* is indeterminate with respect to aspect.

(36) Atelic (progressive):

- a. *Taroo-wa eki-e-to arui-teiru.*  
 Taroo-Nom station-E-TO walk-teiru  
 “Taro is walking to the station.”
- b. *Hanako-wa mukoo-gisi-e-to oyoideiru.*  
 Hanako-Nom opposite-shore-E-TO swim-teiru  
 “Hanako is swimming to the opposite side (e.g, the opposite side of a lake).”

(37) Telic (perfective):

- a. *Honsya-wa koogai-e-to itens-iteiru.*  
 main.office-Top suburb-E-TO move-teiru  
 “The main office has now moved to the suburb.”
- b. *Hanako-wa humoto-e-to ori-teiru.*  
 Hanako-Top mountain.foot-E-TO descend-teiru  
 “Hanako has descended to the foot of a mountain.”

It should be pointed out again here that as far as unergative sentences are concerned, without *-to*, the sentences in (36) become degraded for the reason I have already discussed.

- (38) a. *??Taroo-ga eki-e arui-teiru.*  
 Taroo-Nom station-E walk-teiru  
 “Taro is walking to the station.”
- b. *??Hanako-ga mukoo-gisi-e oyoideiru.*  
 Hanako-Nom opposite-shore-E swim-teiru

“Hanako is swimming to the opposite side (e.g., the opposite side of a lake).”

Interestingly, *-to* can be used in non-spatial contexts as well, expressing either resultative or depictive (Kageyama 1996). Again, the choice between the two depends on the aspectual properties of selecting verbs.

(39) Resultative:

- a. *Tempura-ga karat-to agat-ta.*  
tempura-Nom crisp-TO fry-Past  
“Tempura fried crisp.”
- b. *Gohan-ga hukkura-to take-ta.*  
rice-Nom soft-TO boil-PAST  
“Rice cooked soft.”

(40) Depictive:

- a. *Kawa-ga yuttari-to nagare-teiru.*  
river-Nom slow-TO flow-teiru  
“The river is flowing slow.”
- b. *Taroo-ga kyuuuka-o nonbiri-to sugosi-ta.*  
Taroo-Nom holiday-Acc leisure-TO pass-Past  
“Taroo spent his holiday leisurely.”

From a crosslinguistic perspective, the IA head *-to* is equivalent to the result head R proposed in Ramchand and Svenonius (2002), which occupies an intermediate position between PP and VP. For example, in English, this position can be occupied by particles such as *out* in (41b):

- (41) a. Throw the dead rat out.  
b. Throw out the dead rat.

According to Ramchand and Svenonius (2002), (41) has the structure that contains four different heads, *v*, V, a result head R and a particle head PRT: [<sub>VP</sub> *v* [<sub>VP</sub> V [<sub>RP</sub> R [<sub>PRT</sub> PRT]]]]. In (41b), the object DP occupies the Spec of the particle head PRT and the particle *out* moves up to adjoin to the R head (Ramchand and Svenonius 2002). In contrast to the particles in (41), which undergo telic interpretation, (42) shows that particles can be atelic (Ramchand and Svenonius 2002), which gives support to our proposed analysis that *-to* in Japanese can be either telic or atelic. Note that in (42b), the particle *around* can also move to adjoin to a depictive head D (Irimia 2005).

- (42) a. John moved the rat poison around (for hours).  
b. John moved around the rat poison (for hours).

Having provided empirical support for *-to* as an IA head, let us now turn to the *-e* postposition.

#### 4.3. The postposition *-e* as an inherent directional p

The contrast in (43) between the *-e* phrase on the one hand, and the *-ni* and *-e-to* phrases on the other provides support for my proposal.

- (43) *Tokyoo-e-no/\*-ni-no/\*-e-to-no*      *kippu*  
Tokyo-E-Gen/\*-NI-Gen/\*-E-TO-Gen ticket  
“a ticket to Tokyo”

The *-e* phrase can express Direction even in the NP-internal position, without the presence of unaccusative verbs of directed motion. On the other hand, the *-ni* and *-e-to* phrases are not allowed in the NP-internal position since their values are externally determined by co-occurring verbs. Given the absence of such verbs in (43), *-ni* and *-e-to* cannot undergo interpretation, hence the ungrammaticality.

Note that the unaccusative verbal noun (VN) in Japanese cannot license *-ni* nor *-e-to* in the NP-internal domain.

- (44) *Taroo-no Tokyo-e-no/\*-ni-no/\*-e-to-no*      *tootyaku-ga*  
Taroo-Gen Tokyo-TO-Gen/-NI-Gen/-TO-IA-Gen arrival-Nom  
*okure-ta.*  
be.delayed-Past  
“Taroo’s arrival at Tokyo was delayed.”

It is interesting to notice, however, that with aspectual suffixes such as *-go* ‘after’ and *-tyuu* ‘during,’ which allow VNs to behave just like verbs, the *-ni* and *-e-to* phrases can be licensed as well as the *-e* phrase.

- (45) *Taroo-ga Tokyo-e/-ni/-e-to tootyaku-go, ....*  
Taroo-Nom Tokyo-E/-NI/-E-TO arrival-after  
“After Taroo’s arrival at Tokyo, ....”

Given that the VN in (45) behaves like an unaccusative verb, the facts in (45) can be considered parallel to the facts in (10) and (11).

## 5. Implications of the present study: A note on resultative secondary predication in Japanese

In this section, I will show that the proposed analysis of the spatial *-ni* phrase has implications for Japanese resultative secondary predication. Following Takezawa (1993, 2000), I have proposed (i) that a result head is involved neither in the *-ni* locational phrase nor in the *-ni* secondary predicate and (ii) that given a certain configuration between the predicate and the antecedent, a resultative or a directional reading is derived. Provided that the proposed analysis is on the right track, it can be predicted that there should be a difference between languages that have recourse to a result head and those do not.

It has been pointed out in the literature that there is a contrast between English on the one hand and Japanese on the other with respect to the types of resultative secondary predication permitted in the respective languages (Kageyama 1996, Washio 1997,

Hasegawa 1998).

First, Japanese resultative secondary predication patterns with that of English, as in (46) and (47).

- (46) a. John polished the glasses shiny.  
b. Mary wiped the table clean.
- (47) a. *John-ga megane-o pikapika-ni migai-ta.*  
John-Nom glasses-Acc shiny-NI polish-Past  
“John polished the glasses shiny.”  
b. *Mary-ga teeburu-o kiree-ni hui-ta.*  
Mary-Nom table-Acc clean-NI wipe-Past  
“Mary wiped the table clean.”

However, there are cases where English secondary predication and that of Japanese exhibit different behavior.

- (48) a. John pounded the metal flat.  
b. Mary raced the horse sweaty.
- (49) a. \**John-ga kinzoku-o taira-ni tatai-ta.*  
John-Nom metal-Acc flat-NI pounded  
“John pounded the metal flat.”  
b. \**Mary-ga uma-o asedaku-ni hasirase-ta.*  
Mary-Nom horse-Acc sweaty race-Past  
“Mary raced the horse sweaty.”

The contrast between the examples in (46) and (47) and those of (48) and (49) has been analyzed as a difference between weak resultatives and strong resultatives, respectively (Washio 1997). That is, Japanese does not allow strong resultatives, in which the meaning of a verb and that of a secondary predicate are independent of each other. On the basis of the proposed analysis of the *-ni* secondary predicate, the unavailability of strong resultatives in Japanese seems to suggest that it is rooted in the absence of an independent head such as a result head R (Hasegawa 1998, Takamine 2007) that licenses secondary resultative predication (see Neelman & Van de Koot (2002) for a different approach to the phenomenon at issue here). In contrast, English makes use of such head in order to license strong resultatives. Although it is an interesting topic to pursue, I will leave an in-depth analysis for future research.

## 6. Conclusions

I have shown in this paper that a contrast observed between the *-ni* phrase and the *-e* phrase with respect to their compatibility with unergative verbs of manner of motion can be accounted for as the violation of a locality condition for secondary predication for the former and an aspectual mismatch for the latter. Further, the *-e-to* phrase is compatible with unergative verbs of manner of motion because the suffix *-to* is an indeterminate aspectual head, which serves to rescue the aspectual mismatch between the directional postposition *-e* and an unergative verb of manner of motion. I have

provided the empirical support for my proposal analysis for the three types of spatial PPs. Furthermore, I have suggested that the proposed analysis for the *-ni* phrase has implications for the contrast between secondary predication in Japanese and that in English.

### Notes

\* This paper is based on my earlier work presented at the 31st Berkeley Linguistics Society meeting, which dealt with the *-made* “until/as far as” phrase that contradicts Talmy’s typological descriptions and concluded that the *-made* phrase is an adjunct rather than an argument. However, that paper left unanswered the question as to what exactly the *-e-to* phrase was, which is yet another counterexample to the typology. I would like to thank Yuuka Tsuji for having challenged me in one of my class lectures on this topic. Also, my BLS paper overlooked the contrast in grammaticality between the *-ni* and *-e* phrases with respect to the compatibility with unergative verbs of manner of motion. The research for this paper is supported in part by a Grant-in-Aid for Scientific Research (B) from the Japan Society for the Promotion of Science (#20320058).

<sup>1</sup> Secondary predication is subject to a locality condition (Rothstein 1983, among others). Consider the contrast between (i) and (ii):

- (i) a. John loaded *the wagon full* with hay.
- b. John loaded *the hay* into the wagon *green*.
- (ii) a. \*John loaded the wagon [<sub>PP</sub> with *hay*] *green*.
- b. \*John loaded the hay [<sub>PP</sub> into *the wagon*] *full*.

<sup>2</sup> Takezawa (2000) argues that the *-ni* locational phrase is base-generated in a higher position within VP in comparison with the *-ni* secondary predicate, based on floating numeral quantifier diagnostics. Since the alleged difference is irrelevant to the present study, I simply assume that both of them are in the complement position of V.

<sup>3</sup> As Takezawa (2000) suggests, it may be that the postposition *-ni* is indeterminate concerning its spatial meaning (namely, between Location and Direction (Goal)), which is determined by the aspectual property of the verb that selects it. One possibility is that the directional interpretation of the *-ni* phrase is licensed by the presence of an morphologically covert directional *p*, but I leave this question open for further research. In this paper, I assume that *-ni* is inherently locational and that directional (Goal) interpretation is derived from the secondary predicative relationship established between the *-ni* phrase and the subject of an unaccusative sentence.

<sup>4</sup> A question naturally arises as to why *-to* does not co-occur with other directional (Path and Source) phrases in Japanese. Path (i.e., “through” in English) is covert and obligatorily incorporated into Vs, hence its incompatibility with *-to*. As to the Source P *-kara* “from,” it is not clear why it cannot appear with *-to*, but it may have something to do with its incorporability into V (Takezawa 2000, Ayano 2002).

<sup>5</sup> The *-made* phrase exhibits behavior that contradicts Talmy’s typological description, in that the *-made* phrase, which appears to express Direction (Goal), can co-occur with unergative verbs of manner of motion. I have shown in my earlier work (Ayano 2007) that it behaves like an adjunct.

<sup>6</sup> Secondary depictive predicates are suffixed by *-de*. In contrast to secondary resultative predicates, they can be predicated of transitive (including unergative)

subjects (subject oriented) as well as of transitive objects and unaccusative subjects (object oriented). Koizumi (1994) has shown that the object-oriented secondary depictive predicates are base-generated in the complement position of a verb whereas the subject-oriented ones are base-generated outside VP by using numeral-quantifier, VP-preposing, pseudo-clefting, *soo-suru* 'do so' and bound variable diagnostics. That is to say, the *-de* spatial phrase behaves like subject-oriented secondary depictive predicates, and object-oriented secondary depictive predicates are base-generated in the same position as secondary resultative predicates.

## Abstract

One of the defining properties of the Japanese middles and *tough* constructions is that the internal argument must be marked as nominative or topicalized, and the external argument remains non-overt. Given this property, it appears plausible that the internal argument is the subject of the sentence. In this paper, however, we discuss what the nature of the subject in these constructions is, and claim that the syntactic subject is the non-overt external argument, which bears an inherent dative Case, and that the internal argument remains as an object throughout the derivation. We demonstrate that our claim is supported by the data showing that the non-overt external argument passes three subjecthood tests and that the internal argument passes an objecthood test.

**Keywords:** middle constructions, *tough* constructions, internal/external argument, subjecthood/objecthood tests

## 1. Introduction

One of the defining properties of middles and *tough* constructions is that the internal argument must be marked as nominative, and the external argument remains non-overt, as shown in (1)a and (1)b:

---

\* We thank Farrell Ackerman, Jonathan Bobaljik, Željko Bošković, Jean Crawford, Hideki Maki, Marijana Marelj, Sean Mehmet, Jong Un Park, Mamoru Saito, Tsuyoshi Sawada, Keun-Won Sohn, Susi Wurmbrand, and the audience at CIL 18 for comments, discussion, and/or judgments.

- (1) a. This floor washes nicely.  
 b. This floor is nice to wash.

In Japanese middles and *tough* constructions, on the other hand, the internal argument must be either marked as nominative or topicalized, and the external argument remains non-overt as shown in (2)a and (2)b, respectively (cf. Nakau 1991):

- (2) a. *Kono hon-ga/wa kantanni yom-e-ru.*  
 this book-nom/top easily read-MS-pres  
 ‘This book can be read easily.’  
 b. *Kono hon-ga/wa yomi-yasu-i.*  
 this book-nom/top read-easy.to-pres  
 ‘This book is easy to read.’

Given this property, it appears plausible that the internal argument is the subject of the sentence, as in the English middle and *tough* constructions (1). In this paper, however, we discuss what the nature of the subject in (2) is, and put forth two proposals. One is that the syntactic subject is the non-overt external argument, which bears an inherent dative Case, and the other is that the internal argument remains as an object throughout the derivation. We demonstrate that our claim is supported by the data showing that the non-overt external argument passes three subjecthood tests and that the internal argument passes an objecthood test.

## 2. Preliminaries: Syntactic vs. Lexical Middle Languages

To begin with, let us assume that languages are classified into syntactic and lexical middle languages, following Marelj (2004). In particular, we show that Japanese is a syntactic middle language, and propose a syntactic analysis of Japanese middles, which has rarely been attempted so far.

Marelj points out differences between syntactic and lexical middle languages. We are concerned here with only two of them. Specifically, Marelj argues that English is a lexical middle language on the grounds that the English middle formation does not involve morphological marking on verbs and imposes selectional restrictions on verbs. This observation is exemplified by (3) and (4). (3) shows that English middles are not marked by a construction-specific morpheme, and (4) shows that perception and psych

verbs cannot participate in the English middle formation:

(3) These books read poorly.

(4) a. Perception Verbs

\*The mountains see best after rain.

b. Psych Verbs

\*Anniversaries forget easily.

Turning to Japanese middles such as (5) and (6), however, we find that they involve construction-specific morphological marking on verbs.<sup>1</sup> Also, it should be noted that the selectional restrictions on verbs such as those observed in English middles are absent in Japanese middles.

(5) *Korerano kinoko-ga/wa taber-are-ru.*

these mushroom-nom/top eat-MS-pres

‘This mushroom can be eaten (by anyone).’

(6) a. Perception Verbs

*Yugamine-ga/wa santyoo-kara yoku mi-e-ru.*

Mt. Yugamine-nom/top top.of.mountain-from well see-MS-pres

‘Mt. Yugamine can be seen from the top of the mountain.’

b. Psych Verbs

*Iyana koto-ga/wa kantanni wasurer-are-ru.*

bad thing-nom/top easily forget-MS-pres

‘Bad things can be forgotten easily.’

Assuming that Marelj’s diagnostic tests are reliable for classifying languages into lexical or syntactic middle languages, we conclude that Japanese is a syntactic middle language (cf. Taguchi to appear).

### 3. Proposal

---

<sup>1</sup> The middle suffix (*are*), glossed as MS in the examples, is homophonous with the potential suffix (and the passive suffix in some cases), which is glossed as PS in the examples below.

In this section, we put forward two proposals regarding the syntactic properties of Japanese middles and *tough* constructions. One is that the syntactic subject of these constructions is the external argument which is not realized overtly, reinforced by the claim that the nominative or topicalized argument stays as the object throughout the derivation (cf. Taguchi to appear), and the other is that the non-overt external argument bears an inherent dative Case.

Before elaborating upon this proposal, we claim that analyzing *tough* constructions in parallel with middles is well motivated. In fact, the analyses along the same line have been proposed for the English data like (1) (e.g. Oosten 1977, Fellbaum 1986, Massam 1988, and Hoekstra and Roberts 1993), based on the observation that both are generic sentences describing the facility of the action denoted by the verb. We would like to claim that the Japanese middle and *tough* constructions like (2) should be analyzed in parallel as well, in the sense that they are also generic sentences describing facility. Although the semantic properties of middles mentioned above are intriguing issues to pursue further, we do not discuss them any further in this paper and leave them to further research.

Given the parallelism between middles and *tough* constructions in Japanese, we propose that the subject in these constructions is an external argument syntactically realized as a non-overt pronominal *pro*. In order to show that our proposal is on the right track, let us consider three diagnostic tests for subjecthood that have been proposed in the previous literature on Japanese syntax. First, as is widely discussed (e.g. Kuno 1973, Katada 1991, etc.), a reflexive anaphor *zibun* ‘self’ in Japanese must be licensed by a [+human] subject antecedent. The grammaticality of (7), where *zibun* is properly licensed, shows that middles and *tough* constructions have such a subject, even though it is not overtly realized:<sup>2</sup>

- (7) a. *Zibun-no hon-ga/wa kantanni yom-e-ru.*  
 self-gen book-nom/top easily read-MS-pres  
 (lit.) ‘Self’s book can be read easily.’
- b. *Zibun-no hon-ga/wa yomi-yasu-i.*  
 self-gen book-nom/top read-easy.to-pres  
 (lit.) ‘Self’s book is easy to read.’

Second, Ura (1999, 2000) claims that the missing subject of an adjunct clause headed by

---

<sup>2</sup> See, however, Ackema and Schoonermer (1995) and Marelj (2004) for the claim that the syntactic presence of a subject (more precisely, an agent) in middles cannot be evidenced by anaphor binding, if Reinhart and Reuland’s (1993) approach to the Binding Condition A is adopted (cf. Zribi-Hertz 1993).

*nagara* ‘while’ must be controlled by the matrix subject. The grammaticality of (8), where the missing subject of the adjunct clause is properly licensed, shows that middles and *tough* constructions have a subject that controls the missing subject.

- (8) a. [ *tanosimi-nagara (demo)* ], *kono hon-ga/wa kantanni yom-e-ru.*  
 enjoying-while (even) this book-nom/top easily read-MS-pres  
 (lit.) ‘(Even) while enjoying, this book can be read easily.’
- b. [ *tanosimi-nagara (demo)* ], *kono hon-ga/wa yomi-yasu-i.*  
 enjoying-while (even) this book-nom/top read-easy.to-pres  
 (lit.) ‘(Even) while enjoying, this book is easy to read.’

Third, subject honorification (SH) requires a syntactic subject, which is an SSS, as defined by Harada (1976) as (9) (see also Shibatani 1977, 1978, and others). The grammaticality of (10), where readers in general are taken to be honorified, shows that middles and *tough* constructions have a subject that triggers SH.

(9) Subject Honorific Marking:

Mark the predicate as [Subject Honorific] if its subject is an SSS (a person who is socially superior to the speaker).

- (10) a. *Kono hon-ga/wa kantanni o-yomi-ninar-e-ru.*  
 this book-nom/top easily SH-read-SH-MS-pres  
 ‘This book can be read easily.’
- b. *Kono hon-ga/wa o-yomi-ninari-yasu-i.*  
 this book-nom/top SH-read-SH-easy.to-pres  
 ‘This book is easy to read.’

We thus conclude that middles and *tough* constructions in Japanese involve a syntactic subject that is not overtly realized.

Now, let us turn to our second claim that the non-overt subject of the Japanese middle and *tough* constructions bears an inherent dative Case. We would like to consider two pieces of evidence for this claim. For one thing, Ura (1999, 2000) shows that the above diagnostic tests for subjecthood apply not only to nominative subjects, but also to dative subjects. In this respect, we are arguing that Japanese middles and *tough* constructions are variations of the dative subject construction, as will be discussed below. For another, let us consider the unacceptability of (11) under the middle reading. (11) is

acceptable only under the interpretation that the non-overt subject is recovered from the context (i.e., the subject does not have the arbitrary interpretation, but is interpreted as the non-overt counterpart of a nominative pronoun like *he*, *she*, and *they*).

- (11) #*Kono hon-o kantanni yom-e-ru.*  
this book-acc easily read-MS-pres  
'This book can be read easily.'

We account for the unacceptability of (11) as a middle sentence, with recourse to Shibatani's (1977: 802) filter, which is defined as (12).

- (12) A non-embedded clause of Japanese may have more than one nominative NP, but it requires at least one such NP.

Specifically, if the non-overt subject is indeed marked as nominative in (11), it is predicted that the sentence should be acceptable as a middle sentence, because (12) is satisfied by that subject. However, the prediction is incorrect. On the basis of the unacceptability of (11) under the middle interpretation, we conclude that the non-overt subject in Japanese middles is unable to satisfy Shibatani's filter (12), because it is assigned a Case other than nominative. We thus claim that the subject receives an inherent dative Case. It therefore follows that (2)a, repeated here as (13), is fully acceptable as a middle sentence because (12) is satisfied by the internal argument marked as nominative.

- (13) *Kono hon-ga/wa kantanni yom-e-ru.*  
this book-nom/top easily read-MS-pres  
'This book can be read easily.'

So far, we have been mainly concerned with subjecthood of the non-overt external argument. Now, we would like to turn to the question of what the nature of the internal argument is. Given a well-known fact that Japanese is a multiple subject language, one may wonder if the Japanese middle and *tough* constructions are also instances of multiple subject constructions. However, we follow Taguchi (to appear) in assuming that the internal argument in these constructions does not become the subject, but stays as the object throughout the derivation; for, it does not pass the three diagnostic tests for subjecthood. First, let us compare (14) and (15). Notice that *kono hito-ga/wa* 'this

person-nom/top’ in these examples has the [+human] feature, but it cannot be interpreted to be coreferential with the reflexive pronoun *zibun* in (15). This shows that *kono hito-ga/wa* cannot be taken as the antecedent of *zibun*, because it is not a subject but an object.

(14) a. *Kono hito<sub>i</sub>-ga/wa kantanni damas-e-ru.*  
 this person-nom/top easily deceive-MS-pres  
 ‘This person can be deceived easily.’

b. *Kono hito<sub>i</sub>-ga/wa damasi-yasu-i.*  
 this person-nom/top deceive-easy.to-pres  
 ‘This person is easy to deceive.’

(15) a. \**Kono hito<sub>i</sub>-ga/wa zibun<sub>i</sub>-nitotte kantanni damas-e-ru.*  
 this person-nom/top self-for easily deceive-MS-pres  
 (lit.) ‘This person can be deceived easily for self.’

b. \**Kono hito<sub>i</sub>-ga/wa zibun<sub>i</sub>-nitotte damasi-yasu-i.*  
 this person-nom/top self-for deceive-easy.to-pres  
 (lit.) ‘This person is easy to deceive for self.’

Next, the examples in (16) show that they do not allow the interpretation that *kono hito-ga/wa* controls the missing subject in the embedded *nagara*-clause. These examples are fine if the non-overt external argument in the matrix clause is interpreted as the controller. This means that the non-overt external argument is, but *kono hito-ga/wa* is not a subject.

(16) a. #[ *Warai-nagara (demo)* ], *kono hito-ga/wa kantanni damas-e-ru.*  
 smile-while (even) this person-nom/top easily deceive-MS-pres  
 (lit.) ‘(Even) while smiling, this person can be deceived easily.’

b. #[ *Warai-nagara (demo)* ], *kono hito-ga/wa damasi-yasu-i.*  
 smile-while (even) this person-nom/top use-easy.to-pres  
 (lit.) ‘(Even) while smiling, this person is easy to deceive.’

Finally, let us consider (17), in which *kono hito-ga/wa* triggers SH. Again, these sentences are unacceptable as such, and become fully acceptable middle and *tough* sentences only if the non-overt external argument is interpreted as the trigger of SH. This should be taken as another piece of evidence that the non-overt external argument is, but

*kono hito-ga/wa* is not a subject.

- (17) a. #*Kono hito-ga/wa kantanni o-damasi-ninar-e-ru.*  
this person-nom/top easily SH-deceive-SH-MS-pres  
'This person can be deceived easily.'
- b. #*Kono hito-ga/wa o-damasi-ninari-yasu-i.*  
this person-nom/top SH-deceive-SH-easy.to-pres  
'This person is easy to deceive.'

Before concluding this section, let us have a look at some important data showing that the nominative or topicalized argument in the Japanese middle and *tough* constructions is an object rather than a subject, and that these constructions should be treated on a par with the dative subject construction, as discussed above. First, the examples in (18) show that the nominative or topicalized argument *kono ryoori-ga/wa* in the dative subject construction cannot trigger SH, but it is capable of triggering object honorification (OH), which requires that an SSS must be included in the object, as defined by Harada (1976) as (19):

- (18) a. *Taroo-ni-wa kono ryoori-ga/wa oisiku taber-are-ru.*  
Taroo-dat-top this cuisine-nom/top deliciously eat-can-present  
'This cuisine can be eaten deliciously for Taro.'
- b. #*Taroo-ni-wa sensee-no ryoori-ga/wa oisiku mesia-g-are-ru.*  
Taroo-dat-top teacher-gen cuisine-nom deliciously eat.SH-PS-present  
'The teacher's cuisine can be eaten deliciously for Taro.' (SH)
- c. *Taroo-ni-wa sensee-no ryoori-ga oisiku itadak-e-ru.*  
Taroo-dat-top teacher's cuisine-nom deliciously eat.OH-PS-present  
'The teacher's cuisine can be eaten deliciously for Taro.' (OH)

(19) Object Honorific Marking:

Mark the predicate as [Object Honorification] when an SSS is included in

- (a) the indirect object, if the predicate is ditransitive, or  
(b) the direct object, if the predicate is transitive.

The examples in (20) and (21) show the same pattern; namely, *kono ryoori-ga/wa* in these middle and *tough* sentences cannot trigger SH, but it can trigger OH:

- (20) a. *Kono ryoori-ga/wa oisiku taber-are-ru.*  
 this cuisine-nom/top deliciously eat-middle-present  
 ‘This cuisine can be eaten deliciously.’
- b. #*Sensee-no ryoori-ga/wa oisiku mesiag-are-ru.*  
 teacher-gen cuisine-nom/top deliciously eat.SH-middle-present  
 ‘The teacher’s cuisine can be eaten deliciously.’ (SH)
- c. *Sensee-no ryoori-ga/wa oisiku itadak-e-ru.*  
 teacher-gen cuisine-nom/top deliciously eat.OH-middle-present  
 ‘The teacher’s cuisine can be eaten deliciously.’ (OH)

In this section, we claimed that the syntactic subject of the Japanese middle and *tough* constructions is the external argument which is not realized overtly and bears an inherent dative Case. The nominative or topicalized argument of these constructions, on the other hand, stays as the object throughout the derivation.

#### 4. Conclusion, Consequences, and Further Discussion

In this paper, we have argued that in the Japanese middle and *tough* constructions, the non-overt external argument is the subject realized as a dative *pro*, whereas the internal argument is the object. This argument is evidenced by the observation that the non-overt external argument has the ability of triggering SH, and that OH can, but SH cannot be triggered by the internal argument. In addition, we have shown that the Japanese middle and *tough* constructions pattern with the dative subject construction in these respects.

One of the consequences of our proposal is that Marelj’s account of syntactic

middle languages needs to be reconsidered (cf. Taguchi to appear). Her claim on the [+human] feature is summarized in (22):

(22) In syntactic middle languages, the [+human] feature that is responsible for agentivity of middles, is introduced only in LF.

However, there are two observations that argue against Marelj's claim. First, given Belletti and Rizzi's (1988) observation that Condition A of the Binding Theory may apply in overt syntax, it is hard to account for the successful binding relation in (7), repeated as (23). More specifically, given the claim by Kuno (1973), Katada (1991), and others that a reflexive anaphor *zibun* in Japanese must be licensed by a [+human] subject antecedent, it should follow that the [+human] feature must have been introduced in overt syntax.

- (23) a. *Zibun-no hon-ga/wa kantanni yom-e-ru.*  
 self-gen book-nom/top easily read-MS-pres  
 (lit.) 'Self's book can be read easily.'
- b. *Zibun-no hon-ga/wa yomi-yasu-i.*  
 self-gen book-nom/top read-easy.to-pres  
 (lit.) 'Self's book is easy to read.'

Second, let us turn to another consequence by taking seriously Niinuma's (2003) claim that honorification is a syntactic Agree operation with respect to the [+human] feature. Crucially, Boeckx and Niinuma (2004) and Boeckx (2006) explicitly claim that honorification must apply prior to short scrambling of the object that triggers object honorification. This is shown by the examples in (24), where the Defective Intervention Condition on Agree is still at work after short scrambling of the object:

- (24) a. *#Taroo-ga Mary-ni Tanaka sensee-o go-syookai-si-ta.*  
 Taroo-nom Mary-dat Tanaka teacher-acc OH-introduce-OH-past
- b. *#Taroo-ga Tanaka sensee-o Mary-ni go-syookai-si-ta.*  
 Taroo-nom Tanaka teacher-acc Mary-dat OH-introduce-OH-past  
 'Taro introduced Prof. Tanaka to Mary.'

If honorification must take place prior to purely syntactic operations such as scrambling, the [+human] feature must be introduced in overt syntax, rather than in LF.

Finally, we would like to touch slightly on the difference between English and Japanese regarding the licensing of the internal argument in middles and *tough* constructions. We suspect that the difference may be due to either of the following two reasons. One is that in Japanese, the internal argument can have its nominative Case checked off by AgrO/v (cf. Saito and Hoshi 1999, Tada 1992, 1993, Yatsuhiko 1999, Wurmbbrand 2001, etc.). In English, on the other hand, the internal argument must move to SpecTP. The other is that in Japanese, *pro* moves to SpecTP and thus the internal argument remains as the object (contra Takahashi 2001). In English, on the other hand, *pro* is unavailable and thus the internal argument moves to SpecTP.

## Another Middle Construction in Taiwanese Southern Min: *buebai+V*\*

Shih-Yin Chiang

National Tsing Hua University

g944712@oz.nthu.edu.tw

### Abstract

This paper introduces a Middle Construction in Taiwanese Southern Min<sup>1</sup>: *buebai+V*, e.g., *Tsit khuan tsinn buebai than* ‘This kind of money is quite easy to earn.’ It is argued that *buebai+V* is categorized as Middles because it fits the following general properties of Middles: (i) the logical object is expressed as the grammatical subject, (ii) no syntactically-expressed logical subject allowed, (iii) no intentional adverbs/ purposive clauses allowed, (iv) no imperative mood and progressive aspect allowed, and (v) no long-distance binding allowed.

A new perspective on the controversial Agent expression *tui gua lai kong* ‘for me/ as far as I am concerned’ is solved in this paper, and it also claims that *buebai* is a prefix rather than a free morpheme by (i) independence test and (ii) constituent insertion between *buebai* and its following V. Besides, it is noticed that in TSM Middles, there are no adverbials. It’s not an adverbial but a prefix that triggers dethematicization in TSM Middles.

---

\* I am sincerely grateful to my university classmates Kun-Hui Lin, Cheng-Nan Kao, Chih-Kang Chou for their creative insight to provide me this topic.

<sup>1</sup> Taiwanese Southern Min= TSM

Different from what had been claimed by Fagan (1992) “Adverbials in Middles are used to convey certain properties of their subjects...”, this paper then argues that those Middle prefixes in TSM, such as *ho* ‘good’, *bai* ‘bad’, *u* ‘have’, *bo* ‘have no’ (Lien, 2005), and *buebai* ‘not bad’, and Middle adverbs in English/German, such as *easily* and *well*, all modify the repeatability, easiness or difficulty of the action itself, rather than the properties of the grammatical subject. For example, in *Tsit khuan tsinn buebai than* ‘This kind of money is quite easy to earn,’ the prefix *buebai* ‘not bad’ modifies the verb *than* ‘earn’ rather than the subject *tsit khuan tsinn* ‘this kind of money’ because the easiness/difficulty of earning money has nothing to do with the goodness or badness of the money.

At last, I observed a contact-induced Middle occurring between TSM and Mandarin used by youngsters in Taiwan: *bucuo* + V. *Bucuo* + V becomes rather productive after it is borrowed from TSM into Mandarin in recent years and becomes part of Mandarin. However, it is not as productive as *buebai*+V in TSM, and there are still certain differences in its c-selection.

## **1. Introduction**

Middle Construction is a heterogeneous construction, which lies between active voice and passive voice. Toughs and Middles in Chinese are usually mentioned together because their similar semantic and syntax representation. However, there are still some crucial

characteristics for us to tell between them: Toughs allow overt presentation of Agent and non-local subject which is embedded, while Middles can only bear implicit Agent and no non-local subject.

In this paper, I discuss the syntactic structure of ‘*buebai* + V’ in TSM, by first arguing that the syntactic behaviors of ‘*buebai* + V’ is Middles in that it bears implicit Agent and no non-local subject, which are the main differences between Toughs and Middles. Then I tried to argue Agent in Middles is syntactic covert but semantically overt. Besides, that the adverbials in Middles are to present the properties of the subject is proved incorrect, but I claim that it presents actually the difficulty or easiness of the action itself.

In Section 2, I review those earlier analyses about Middles in English, German, and French to conclude that Middles are heterogeneous. Section 3 encloses the behavior of *buebai* + V construction, and Section 4 claims that *buebai* + V is Middles but it also behaves “untypically” in certain aspects. Section 5 is the structure of *buebai*+V, and finally, in Section 6 is the conclusion.

## **2. Previous Analysis on Middle Construction**

A two-place predicate is a predicate that features internal argument and external argument in terms of argument structure. Middle construction is a voice system between agentive voice and passive voice. The typical properties of Middles are as follows: (i)

Middles are generic statements that do not describe particular events; (ii) intentional adverbs, purposive phrases, and small clauses are not allowed in Middles; (iii) Middles are also not allowed in imperative or progressive constructions; (iv) Agent in Middles is syntactic implicit; (v) the grammatical subject of the Middles is its notional or logical object; (vi) Middles do not allow non-local subject.

## 2.1 Generic/ Non-eventive Reading

Middles convey generic /non-eventive reading (Keyser and Roeper, 1984) and not to refer to actual events, which refers to single or repeated actual performances of the action expressed. Meanwhile, generic reading is the crucial difference between English ergatives and Middles, as in (1). Ergatives describe particular events in time while Middles don't.

- (1) a. \*The truck handled smoothly *yesterday*. (Middles)  
b. The ice melted *yesterday*. (Ergatives)

Although Middles sometimes occur in progressive construction, as in (2), they are not considered as eventive in that this progressive focuses on the change over time; that is, this middle progressive actually focuses on the differences in degree between *sets of related states/a succession of states* rather than change of a single event (Bland, 1988).

- (2) a. The truck *is handling* smoothly.

What is “generic/non-eventive” about Middles is not always the action itself but the

expression that any potential Agent can perform, or could have performed, the action with the result, or in the manner, indicated. Thus, it is not the action but Agent that is nonspecific or generic.

## 2.2 Forbiddance of Intentional Adverbs, Purposive Phrases, and Small Clauses

Intentional adverbs, purposive phrases, and small clauses are not allowed in Middles, as shown in (3).

- (3) a. \*Bureaucrats bribe easily *intentionally*. (Intentional adv)  
b. \*The book sells *to secure government contracts* easily. (Purposive Clause)  
c. \*The floor waxes more easily *naked*. (Small clause)

Middles are said to posit a generic reading and describes the qualities of the Patient-subject (Fellbaum, 1986). Therefore, that *intentionally* posits an eventive reading and a subject-oriented agentivity leads the ungrammaticality of (3). The ungrammaticality of (3) is in that Patient controls a subsequent purposive clause, while Agent implicit in Middles (PRO) can never exercise control, shown as in (4). The small clause *naked* in (3) posits an eventive reading, but Middles can only have a generic reading, which triggers the ungrammaticality.

- (4) \*The book<sub>i</sub> sells [to [PRO secure government contracts t<sub>i</sub>] easily]

## 2.3 Forbiddance of Imperative or Progressive Forms

Middles don't form in an imperative mood. The "addressee" of an imperative mood based on the active form of a verb is always the Agent of the action referred to, and progressive aspect describes an ongoing event. However, Middles tend to make certain properties of the Patient/Instrument/Location outstand and suppress the role of Agent. It is generic and descriptive, but does not "command" someone to have certain properties in certain time, as in (5).

- (5) a. \*Bribe easily, bureaucrats!
- b. \*Bureaucrats are bribing easily.

Vendler (1967) distinguishes four classes of verbs: activities, accomplishments, achievements, and states. Among them, only activities and accomplishments are valid in Middles.

- (6) a. *Activity*: This ball plays easily.
- b. *Accomplishment*: This book reads easily.
- c. *Achievement*: \*The blackbird recognizes easily.
- d. *State*: \*The fact knows easily.

In addition, corresponding to Middles, progressives treat activities and accomplishments valid to but achievements and states invalid.

- (7) a. *Activity*: This boy is playing the ball.

- b. *Accomplishment*: This boy is reading the book.
- c. *Achievement*: \*I am recognizing the blackbird.
- d. *State*: \*He is knowing the fact.

Note that the progressive test does not always functions well in that it can't account for the contrast between *buy* and *sell* (Fagan, 1992) as in (8), cf. (9). It looks that aside from aspectual characteristics and thematic characteristics of the verbs, we need a more accurate standard--*Agentivity*.

- (8) a. \*This book buys well.
- b. This book sells well.
- (9) a. John is buying the book.
- b. John is selling the book.

## 2.4 Agentivity

In Ackema and Schoorlemmer (1995), Condoravdi (1989), Fagan (1992), Fellbaum (1986), Stroik (1992), Hoekstra and Roberts (1993), the Agent of Middles has been argued either to be present at certain semantic level or to be syntactically realized. They assume the presentation of Agent as the main characteristic of Middles.

The present of the Agent in Middles is a controversial issue. Many linguists claim that the Agent in Middles can be overtly present as a *for*-phrase, shown as in (10).

- (10) a. No Latin text translates easily *for Bill*.
- b. French books read easily *for educated people*.

But this assumption is too weak because identical *for*-phrases can also occur in the non-middle sentences without any implicit argument, as in (11). It is just a semantic requirement of Middles to identify the one who expresses his/her opinion with the Agent of the Middles. Therefore, A&S (1995) argue that *for*-phrases don't present the Agent but the experiencer of Middles. There is no evidence showing that Agent phrases in Middles are syntactically present. In (11), *Mary* or *Bill* is just the experiencer but the Agent. Fagan (1992) and H&R (1993) adopt "Affectedness Constraint" to limit the Agent range in Middles. But this claim is much weaker in that there are so many Middle verbs triggering no effect on their Patient, as in (12).

- (11) a. That book is too thick **for Mary**.
- b. As far as translation is concerned, no Latin text poses a problem **for Bill**.

- (12) This book reads easily.

Fellbaum (1986) claims the subject of Middles has some syntactic features of both Agent and Patient; both roles seem to merge in one NP tolerated by this construction. French, German, and Russian do not have syntactically distinct Middles, in order to express the equivalent meaning, they employ constructions where Agent and Patient have the same

referent.

On the other hand, Stroik (1992) used anaphor binding to argue that Agent in Middles can actually license an anaphor in DS. Nevertheless, no matter which side we take, either that the Agent is base-generated as *pro*, as in (13), or that there is a PRO in DS as the antecedent of the anaphor, shown as in (13) and Binding Principle A is applied everywhere, the claim that no NP-movement takes place in Middle will crash. Thus, I tend to say that Agent in Middles is syntactically suppressed, and that the reflexive pronoun in (13) is in fact a logophoric expression, SELF, which do not need a syntactic antecedent, rather than an anaphor.

(13) a. [IP[Books [about oneself]]<sub>i</sub> [I' I [VP *pro* [V' write t<sub>i</sub> poorly.]]]]

b. [IP[Letters [to oneself]]<sub>i</sub> [I' I [VP [VP [V' compose t<sub>i</sub> quickly.]]PRO]]]

Given that Agent in Middles can never be present overtly, Middles are syntactically agentless constructions. However, they do not exclude Agent semantically, and it is clearly implied as volitional instigators of the action referred to (Fellbaum, 1986).

Roberts (1987) takes intentional adverbs (*deliberately/intentionally*) and purposive phrases (*in order to*) as tests for agentivity to support his claim that only activities and accomplishments semantically have external Agents, as in (14).

(14) a. *Activity*: John deliberate ran to keep fit. (Fagan, 1992)

- b. *Accomplishment*: John intentionally built the house to show off his expertise.
- c. *Achievement*: ?John voluntarily noticed Mary in order to incriminate her.
- d. *State*: ?John deliberately believed Mary in order to annoy other people.

There're still other tests for agentivity in Fagan's (1992) work yielding similar results. For example, (i) a sentence contains Agent if it can occur as the complement of a control verb (*persuade, force, command, ask...*), (ii) a verb exhibits Agent argument if it can form imperative sentences. However, in order to account for the *buy/sell* puzzle, she takes *Responsibility*<sup>2</sup> and *an aspectual approach* as the standard constraints on English Middles in the end.

It looks that crucial restrictions in Middles are language-specific. In English/German Middles, they are *Responsibility* and *an aspectual approach*; in French, it's *transitivity*. Besides, different from English/German Middles, French Middles can be used to describe events, and aspectual properties in French Middles play no important role.

## 2.5 No non-local subject in Middles

Middles do not allow non-local subject, as shown in (15). *The bureaucrats* is no longer the legitimate object of *bribe* and turns into the matrix subject of *tries*, which causes a semantic change that violates the expression that the one who is bribed is the bureaucrat. The

---

<sup>2</sup> The concept "responsibility" proposed by Van Oosten (1977,1986) means that the object of a verb can be used as the subject of a middle if it is understood to be responsible for the action of the verb.

ungrammaticality of (15) is the same as the reason why Middles do not allow purposive clause: the Patient controls a subsequent purpose clause, while Agent can never exercise control.

(15) \*The bureaucrats<sub>i</sub> try [<sub>CP</sub> to [<sub>IP</sub> PRO [bribe t<sub>i</sub> easily]].

There are many papers talking about the NP-movement of the grammatical subject (the logical object) and arguing that the middle verb's logical object moves from the complement of the verb to [Spec, IP]. The verb's subject theta-role is assigned to pro in VP-internal subject position (H&M, 1990), as in (16), or to PRO adjoined to VP (Stroik, 1992), as in (16).

(16) a. [<sub>IP</sub> The walls<sub>i</sub> [<sub>I'</sub> I [<sub>VP</sub> pro [<sub>V'</sub> paint t<sub>i</sub> easily]]]]

b. [<sub>IP</sub> The walls<sub>i</sub> [<sub>VP</sub> [<sub>VP</sub> [<sub>V'</sub> paint t<sub>i</sub> easily]]PRO]]]

However, A&S (1995) and K&R (1984) claim that the grammatical subject in Middles undergoes no movement. If Middles are derived from NP-movement, just like passive construction, it should have allowed preposition stranding as in (17).

(17) a. John<sub>i</sub> was laughed at t<sub>i</sub>.

b. \*John<sub>i</sub> laughs at t<sub>i</sub> easily.

Here, the subject of Middles is argued to be base-generated in [Spec, IP]. The dethematization of the verb in Middles are triggered by an operator moving from the complement of the verb to [Spec, VP], and the subject coindexes with the operator, illustrated

in (18).

(18) [IP The walls<sub>i</sub> [VP OP<sub>i</sub> [VP PRO [v' paint t<sub>i</sub> easily]]]]

## 2.6 Adverbs in Middles

The adverbs in English Middles convey the most important information in the sentences. Middles can only make oblique reference to Agent through the adverb (Fellbaum, 1986). It has a part of the meaning implicating that it is the subject's property that causes Agent to perform the action with ease. The adverb rescues the construction by licensing the generic in habitual reading, a reading in which the speaker is not talking about a specific set of metal, but a specific set of events of the same type metal (Hale & Keyser, 1993, 2002). The meaning is that every time an event of this type is performed, the event is performed easily, as in (19).

(19) a. The book sells easily

b. \*The book sells.

While passives allow adverbs of all kinds, Middles admit only a limited group of adverb, one of which is called "facility adverb" (Vendler, 1984), such as *fast*, *quickly*, *in a jiffy*, *beautiful*, which refer to the degree of facility and speed with which any Agent can perform the action expressed in the sentences. It is the Patient that governs the choice of the adverb, and it's also the reason why Agent is suppressed rather than Patient. Those adverbs allowed in Middles refer not to qualities of individual Agents, but to Agent-Patient features pertaining to

the performability of the action (Fellbaum, 1986). As we can see that the following three sentences in (20) refer the same.

- (20) a. This flashlight plugs in easily.
- b. *Anybody* can easily plug in this flashlight.
- c. This flashlight can be plugged in easily *by anybody*.

That the implicit Agent of Middles can be translated into *anybody* is due to Middles conveying generic reading and it does not refer to specific Agent. The action in Middles is performable by any Agent but only the Patient's properties are reflected in the adverbs.

## 2.7 Verbs in Middles

Verbs in English Middles change the argument structure, making the Patient as the subject and dethematizing Agent, shown as (21). It is *the bureaucrat* that is bribed; *the bureaucrat* is the notional object of *bribe*.

- (21) The bureaucrat bribes easily.

Fagan (1992) demonstrate that Middle verbs must (i) not be achievements or states, (ii) must be agentive, and (iii) must not be ditransitive. Besides, Fellbaum (1986) also claims that verbs in English Middles must contain a transitive form of a transitive/intransitive pair as (22). If Middles were intransitive, it ought to be able to form verbal compounds the way like (23), c.f. (24). If Middles were ditransitive, the dethematization would cause a conflict in focus.

K&R (1984) agree with that a very large number of verbs which requires volitional cooperation or involvement of Patient cannot appear in Middles, like verbs of perception, doubting, understanding, emotion, etc, as in (25). These verbs seem to require Agent with specific mental properties/states of mind; such properties cannot be attributed to the nonspecific Agent implied in Middles.

(22) a. The engine lifts/ \*rises out easily.

b. The mosquitoes kill/\*die only with a special spray.

(23) a. The river *runs* slowly. (intransitive)

b. This is a slow-running river.

(24) a. She *makes* peace easily. (transitive)

b. \*She is an easy-making person.

(25) a. \*The employee doubts easily.

b. \*This kind of storybooks understands easily.

Another evidence for that the verbs in Middles are transitive is that, only intransitive, but not transitive verbs, can form gerundive adjectives, as in (26) and (27). And we found that Middle verbs cannot, either, as illustrated in (28). The unacceptability of (28) is actually due to that the gerundive adjectives do not refer to permanent properties of the modifée. Gerundive adjectives are eventive (Fagan, 1988), and thus convey no generic reading, which

is one of the characteristic of Middles.

- (26) a. The rapidly revolving gears  
b. The endlessly babbling senators

- (27) a. \*The reading book  
b. \*The hitting balls

- (28) a. \*The bribing officer  
b. \*The selling book

### 3. Syntax of *buebai*+V

The first obvious characteristic of *buebai*+V is that *buebai*+V has the logical object realized as the grammatical subject, and when *buebai* is added in this construction, Agent is suppressed. In (30), the *gua* 'I' in the PP *dui gua lai kong* 'as far as I am concerned' appears to be Agent of Middles. But from the above discussions, we know that it is just an Experiencer but Agent. We may take certain tests to see if there's also Agent in TSM Middles, shown as in (31).

- (29) a. *gua khuann tsit pun tshe*  
I read this CL book  
'I read this book.'

b. tsit pun tshe buebai khuann

this CL book not bad read

‘This book reads easily.’

c. \*gua buebai khuann tsit pun tshe

I not bad read this CL book

(30) **dui gua lai kong** tsit pun tshe buebai khuann

as far as I am concerned this CL book not bad read

‘As far as I am concerned, this book reads easily.’

(31) a. *Intentional Adv Test*

\*tsit pun tshe **tiaokang** buebai khuann

this CL book intentionally not bad read

‘\*This book intentionally reads easily.’

b. *Purposive Phrases Test*

\*tsit pun tshe **uitio** **be be** **tshutkhi** buebai khuann

this CL book in order to want sell out not bad read

‘\*In order to be sold, this book reads easily.’

c. *Long-distance Binding Test*

\*tsit pun tshe **iaokiu** buebai khuann

this CL book command not bad read

‘\*This book commands to read easily.’

d. *Imperative Sentence Test*

\*tshe, buebai khuann!

book not bad read

‘\*Book! Read easily!’

Since passive form *hoo paklang* (‘by others’), unaccusative, locative-existential predicates, transitive sentient verbs, and unergative sentient verbs are all agentivity-oriented (Tsai, 2008). When taking them as tests of agentivity, it’s obvious that Agent is syntactically suppressed.

(32) a. \*tsit pun tshe buebai **hoo paklang** khuann (Passive)

this CL book not bad by others read

‘\*This book reads easily by others.’

b. \*tsit tiunn pisai buebai su (Unaccusative)

this CL contest not bad lose

‘This contest loses easily.’

c. \*intao buebai lai tsit e shiochia (Locative-existential)

their house not bad come one CL lady

‘\*A lady comes easily.’

d. \*tsit chiong hue buebai kayi (Transitive sentient verbs)

this CL flower not bad like

‘\*This kind of flowers like easily.’

e. \*ato buebai hao (Unergative sentient verbs)

Ato not bad cry

‘Ato cries easily.’

The second characteristic of *buebai*+V is that it denotes a generic reading, as in (33).

The generic reading is said to come from the properties of the subject. However, along with other TSM Middles in (34), we can see that the properties of the subject have nothing to do with the degree of easiness or difficulty of the action. For example, in (34), the goodness/badness has nothing to do with the easiness of buying. Furthermore, (34) also shows us that not only adjectives but also verbs would affix onto Middle verbs. When using *u* ‘have’ or *bo* ‘have no’ as the Middle prefix, it is much harder to say they are the properties of the subject. Therefore, I may say that at least in TSM, the generic reading in Middles does not come from the Patient<sup>3</sup>.

(33) a. tsit ki pit buebai sia

---

<sup>3</sup> This characteristic is semantically similar to that of the adjective in Tough Construction, and this might be why Middles and Toughs in Chinese usually look similar.

this CL pen not bad write

‘This pen writes well.’

b. \*tsit ki pit tsang buebai sia

this CL pen yesterday not bad write

‘\*This pen wrote well yesterday.’

c. \*tsit ki pit tsimma buebai sia

this CL pen PROGRESSIVE not bad write

‘\*This pen is writing well now.’

(34) a. tsit ki pit **ho** be

this CL pen good buy

‘This pen buys easily.’

b. tsit ki pit chin **bo** sia

this CL pen very have no write

‘This pen is not durable.’

c. tsit ki pit chin **u** sia

this CL pen very have write

‘This pen is durable.’

Third, it seems that grammatical objects are all possible in Middles, but Middles reveal a

(39) \***tsit tsia tsiaoa** buebai pue  
 this CL bird not bad fly  
 ‘This bird flies easily.’ <Agent>

(40) \***tsit tiao kua** buebai thianntio  
 this CL song not bad hear  
 ‘\*This song hears easily.’ <Experiencer, Patient >

What’s worth noticing is that when *buebai* takes transitive V with locative arguments (as (36)), it is Location rather than Patient that goes to be the subject. When *buebai* takes verb with instrumental arguments as (37), Instrument rather than Patient would be the subject. However, not all three-place predicates result in the same construction; that is, to leave Patient aside and take the rest argument as its subject. When *buebai* takes verb with Goal, it is Patient but not Goal that comes out to be the subject.

(41) There seems to have a ranking:  
 Location, Instrument > Patient > Goal

Fifth, *buebai+V* construction doesn’t go with progressive sentences, shown as in (31), repeated here as (43).

(42) \***tsit ki pit tsimma** buebai sia  
 this CL pen PROGRESSIVE not bad write

‘\*This pen is writing well now.’

Finally, the subject of *buebai*+V is base-generated rather than moved. If Middles are derived from NP-movement, just like passive construction, it should have allowed reconstruction (43)<sup>5</sup>.

(43) a. **tsit ki pit** buebai sia  
this CL pen not bad write  
‘This pen writes easily.’

b. \*gua buebai sia **tsit ki pit**  
I not bad write this CL pen

#### 4. *Buebai*+V Construction as Middles

From the above syntactic behaviors, we may clearly define *buebai*+V construction as Middles because it fits the following general properties of Middles: (i) the logical object is expressed as the grammatical subject, (ii) no syntactically-expressed logical subject allowed, (iii) no intentional adverbs/ purposive clauses allowed, (iv) no imperative mood and progressive aspect allowed, and (v) no long-distance binding allowed.

However, in addition to the above properties, *buebai*+V construction contains some other special behaviors which are a little different from ‘typical’ Middles.

---

<sup>5</sup> Since prepositions in Chinese (including TSM) is hard to define, I would not take preposition stranding as a test.

First of all, typical Middles seem to be infelicitous without an adverb of manner, like *easily, well...* etc, but TSM Middles are observed to contain only prefixes and no manner adverbials. Moreover, making Middle sentences with postverbal adverbials is only possible when we use a Middle aspect morpheme *qilai*<sup>6</sup> (in Mandarin Chinese) or *khitlai* (in TSM); otherwise, it results in ungrammaticality, as in (44). Notice when we use *khitlai*, various adverbials are valid; when we use Middle prefix *buebai* 'not bad', *ho* 'good', *bai* 'bad' or 'have' or *bo* 'have no', no postverbal adverbials are allowed, as in (45). (Due to that there's no adverbial forms for *buebai*, we take another Middle prefix *ho* 'good' as an example.)

(44) a. tsit ki pit sia-khitlai chin **sun**  
 this CL pen write-KHITLAI very smoothly  
 'This pen writes quite smoothly.'

 this CL pen good write  
 'This pen writes smoothly.'

b. \*tsit ki pit sia **ho**

---

<sup>6</sup> Please refer to Wang Yu-yun (2004) for further information.

this CL pen write well

This may raise two questions: Why are manner adverbials necessary in English Middles but not in TSM Middles? Without Middle morphemes like *khitlai*, how do *ho/bai/u/bo/buebai*+V form a Middle voice? After getting to know Middles in other languages, we know that Middles without adverbials are also natural. In Fagan's (1992) work, although French Middles often occur with an adverbial expression, an adverbial is by no means obligatory, as in (46). Besides, although German and English Middles "typically" require the presence of adverbials; with pragmatic consideration, not all Middles involve overt adverbials, as in (47).

(46) *French Middles without Adverbials*

a. Ce papier se lave.

'This paper is washable.'

b. Cette racine se mange.

'This root is eadible.'

(47) *German Middles without Adverbials*

dieses Kleid knopft sich zu

this dress botton be to

'This dress buttons.'

Then, how Middles without adverbials are triggered? As to TSM, it seems reasonable to say that *buebai* plays the role. The same as modifiers like adverbials, *buebai* morphologically (but not syntactically) modifies the difficulty or easiness of the action. In this sense, sentence (46) logically means “in general, events in which someone x write words with this pen are not bad for x.” It may be written as:

(48)  $G^7[\text{write}(x, \text{words}, e)](\text{not bad}(e, \text{for } x))$

On the other hand, that *buebai* is a prefix rather than a free morpheme is attested through (i) independence test, (ii) constituent insertion between *buebai* and its following V, and (iii) attachment of phase markers.

If what we called as prefixes in Middles (*buebai* ‘not bad’, *ho* ‘good’, *bai* ‘bad’ *u* ‘have’ and *bo* ‘have no’) are all free morphemes in Middles, showing up independently should be possible. However, in (49), although it is possible, the semantic entailment of its free form is different from that of its prefix form. Besides, when in free forms, they act quite differently. Among them, *buebai* ‘not bad’, *ho* ‘good’, and *bai* ‘bad’ represent the properties of the subject, but *u* ‘have’ and *bo* ‘have no’ are not possible for this construction. The most plausible explanation would be that *buebai* ‘not bad’, *ho* ‘good’, and *bai* ‘bad’ are originally adjectives (or adjective verbs in some people’s sense), which are used to modify objectives,

---

<sup>7</sup> G is a generic operator.

while *u* ‘have’ and *bo* ‘have no’ are possessive verbs, which cannot present pluraction/duration in their free forms<sup>8</sup>. Therefore, since the semantic entailment of the free forms of *buebai* ‘not bad’, *ho* ‘good’, and *bai* ‘bad’ differs from that in Middles, I believe in Middles they are prefixes rather than free morphemes.

(49) *Independence Test*

a. tsit ki pit **buebai/ho/bai**  
 this CL pen not bad/good/bad  
 ‘This pen is quite good.’

b. \*tsit ki pit **u/bo**  
 this CL pen have/have no

Similarly, if what we called as prefixes in Middles are actually free morphemes, inserting a constituent between it and the verb would also be possible. In (50), we see that it’s not possible for *buebai*+V to be inserted by an adjunct *ti-toa-ting* ‘on the table.’ From the above discussion, *buebai* is concluded as a prefix and *buebai*+V is a complex predicate.

(50) *Constituent Insertion*

tsit ki pit buebai (**\*ti toa ting**) sia  
 this CL pen not bad be table upon write

---

<sup>8</sup> Obviously, *u* ‘have’ and *bo* ‘have no’ underwent grammaticalization to be the prefix of Middle verbs.

‘\*This pen writes smoothly on the table.’

## 5. Location of Middle Verbs

As to the placement of Middle verbs, I adopted A&S (1995), K&R (1984) and Tsai’s (2007) analysis on two types of light verbs in Mandarin Chinese and correspondent examples in TSM to locate Middle verbs in the “inner” light verb. In (51), *tsit ki pit* ‘this pen’ base-generates in [Spec, vP] as a causer, and the verb *sia* ‘write’ moves from V to v [CAUSE]. Therefore, I may analogize to say that in (51), *tsit ki pit* ‘this pen’ also base-generates in [Spec, vP], and the verb *sia* ‘write’ moves from V to v [BE]. (That I assume the entailment of this light verb as BE is because semantically, the subject has the property of being used smoothly. Note that the whole predicate represents the properties of the subject, but the adverbial itself represent only the difficulty/easiness of the action.)

(51) a. *tsit ki pit [sia-ka]<sub>k</sub>+CAUSE Abingt<sub>k</sub> jiošhiungkhi*

this CL pen write-Res Abing furious

‘This pen made Abing write such that he became furious.’

b. *tsit ki pit [buebai-sia]<sub>k</sub>+BE t<sub>k</sub>*

this CL pen not bad-write

‘This pen writes smoothly.’

c.  $[_{IP} \text{tsit-ki-pit}_i [_{VP} [_{v'} \text{buebai-sia}_k [_{VP} \text{OP}_i [_{VP} \text{PRO} [_{V'} t_k t_i]]]]]]]$

At last, I observed a contact-induced Middle occurring between TSM and Mandarin used in Taiwan: *bucuo* + V in Mandarin. *bucuo* + V becomes rather productive after it is borrowed from Taiwanese into Mandarin in recent years and becomes part of Mandarin. However, it is not so productive as *buebai*+V in Taiwanese Southern Min, and there are certain differences in their c-selection.

## 6. Conclusion

In this study, we have argued that the *buebai* + V in Mandarin is Middle because of the following properties of *buebai* + V: (i) the Patient in *buebai*+V construction is realized as the matrix subject, (ii) verbs in *buebai*+V construction suppress the appearance of its Agent, (iii) *buebai*+V construction doesn't allow intentional adverb, and it would not be in purposive clauses or small clauses, (iv) *buebai*+V denotes a generic property of the subject, (v) *buebai*+V does not have imperative or progressive constructions, and (vi) *buebai*+V does not allow non-local subject. Among those characteristics, that the implicit Agent in *buebai*+V construction and the required local subject are the crucial points for us to categorize *buebai*+V construction as Middle.

The controversial Agent expression *tui gua lai kong* 對我來說 'for me/ as far as I am concerned' in Mandarin and TSM is proved not to be an agentive expression. Besides, it is noticed that in TSM Middle, there are no adverbials. It's not adverbials but prefixes that

trigger dethematicization in TSM Middles. I also proved that *buebai* in Middles is a prefix rather than a free morpheme because it doesn't fit (i) independence test, (ii) constituent insertion between *buebai* and its following V and (iii) attachment of phase markers.

Different from what had been claimed by Fagan (1992), this paper argues that those Middle prefixes in TSM, and Middle adverbs in English/German, all modify the repeatability, easiness or difficulties of the action itself, rather than the properties of the grammatical subject.

At last, a contact-induced Middle occurring between TSM and Mandarin used by youngsters in Taiwan is introduced for further study: *bucuo* + V. *Bucuo* + V becomes rather productive after it is borrowed from Taiwanese into Mandarin in recent years and becomes part of Mandarin. However, it is not as productive as *buebai*+V in TSM, and there are still certain differences in their c-selection.

# A Lexical Analysis of Korean Relative and Topic Constructions: Gaps, Island Constraints, and Resumptive Pronouns

Sun-Hee Lee

Wellesley College  
Department of East Asian Languages and Literatures  
106 Central Street  
Wellesley MA 02481, USA  
Slee6@wellesley.edu

## Abstract

In Korean, relativization and topicalization license similar unbounded dependencies between a filler and a gap. Relative clauses (RCs) and topic constructions (TCs) also each divide into two subcategories: gapped constructions vs. gapless constructions, depending on the presence or absence of a gap. In addition, gapped relative clauses and gapped topic constructions show similar behaviors in terms of island constraint violations and strong crossover phenomena, as well as in terms of semantic and pragmatic constraints. The current analysis focuses on gapped constructions and investigates various semantic and syntactic constraints on these constructions. It provides a lexical analysis for representing filler-gap dependencies in gapped RCs and TCs, while accounting for similarities in their grammatical behaviors with respect to islands and resumptive pronouns.

**Keywords:** relative clauses, topic constructions, long-distance dependency, trace, island constraints, strong crossover

## 1. Introduction

Korean Relative Clause Constructions (hereafter RCs) differ from English counterparts in two ways. There are no overt relative pronouns, and the presence of an RC is marked by verbal suffixes such as *-nun*, *-ul*, *-un*, and *-ten*, as in example (1).

- (1) Mira-ka             $e_i$             mek-nun/un/ten            sakwa  
Mira-Nom                            eat-REL                            apple  
'the apple that Mira eats/ate/had eaten'

Whereas a relativized head noun appears in the rightmost position of a clause a topicalized element appears in the leftmost sentence-initial position, as in (2).

- (2) sakwa-nun            Mira-ka             $e_i$             mek-nun/-essta  
 Apple-Top            Mira-Nom                            eat-REL  
 ‘As for the apples, Mira eats/ate/had eaten them.’

In both constructions, an extracted element has an interpretation of semantic uniqueness or exclusiveness. In an RC, the relative clause adds a restriction to the set (or individual) specified by the head noun. Topicalization provides a restriction that the comment that follows is attributed to the topic element but not to others.

Gapped RCs and Topic Constructions (hereafter TCs) are different in that only TCs hold a strong dependency between a gapped element and its filler by maintaining syntactic connectivity; the topicalized element can be accompanied by the morphosyntactic case marker that originated from the gapped position. Korean RCs do not show strong dependency because they lack overt relative pronouns. However, RCs do show semantic connectivity between a gap and the following head noun.

Previous research on both constructions has focused on how to account for syntactic structure licensing an unbounded dependency between a gap and its filler. This approach seems logical given that gapped Korean RCs and TCs have very similar patterns with respect to island constraints of the complex noun phrase constraint (CNPC), the sentential subject constraint, and the adjunct constraint. The current analysis includes a new structural mechanism that licenses unbounded dependencies of both gapped RCs and TCs in Korean within the framework of Head-Driven Phrase Structure Grammar. In contrast to previous work, this paper also provides data demonstrating that island constraints are not dependent on syntactic structure, but on semantic, pragmatic, and processing factors. The analysis supports the argument that gapped RCs and TCs show similar long-distance relationships based upon similar semantic predication between the head noun and its modifying relative clause and between the topic and the comment.

## 2. Gapless Constructions

Both Korean RCs and TCs can be divided into gapless constructions and gapped constructions. However, the subclassification will be different. This section examines

gapless RC and TC constructions before turning to gapped constructions with unbounded dependencies.

### 2.1. Gapless Relative Constructions

There are three kinds of gapless RCs: pseudo RCs, noun complement RCs, and bound noun complement RCs. These three types of RCs are considered to be non-canonical due to low frequency. These RCs lack a gap and thus lack binding between a gap and its head noun. This is shown in the following examples.

#### (3) [Pseudo RCs]

- a. [RC sayngsen-i tha-nun] naymsay  
 fish-Nom burn-Rel smell  
 ‘the smell of fish burning’
- b. [RC mwul-i hulu-nun] soli  
 water-Nom flow-Rel sound  
 ‘the sound of water flowing’

#### (4) [Noun Complement RCs]

- a. [RC John-i Mary-lul manna-n] sasil  
 John-Nom Mary-Acc meet-Rel fact  
 ‘the fact that John met Mary’
- b. [RC Mira-ka aphuta-nun] somwun  
 Mira-Nom sick-Rel rumor  
 ‘the rumor that Mira is sick’

#### (5) [Bound Noun RCs]

- a. Min-i [[RC totwuk-i tomangka-nun] kes]-ul capassta.  
 Min-Nom thief-Nom run away-Rel thing-Acc caught  
 ‘Min saw -a thief running away.’
- b. Jiyong-i [[RC Min-i norayha-nun] kes]-ul sihehanta.  
 Jiyong-Nom Min-Nom sing-Rel thing-Acc dislike  
 ‘Jiyong dislikes Min’s singing.’

The semantic and pragmatic properties of head nouns in these RCs are different from those in canonical RCs. As mentioned in Nam (1996) and Kim (1998b), the head nouns of pseudo RCs belong to a certain semantic class of perception nouns, which are related to vision, hearing, or taste, or to nouns such as feeling, scene, etc. The words in the

following list can appear as head nouns of pseudo RCs.

(6) *naymsay* ‘smell’, *solli* ‘sound’, *mas* ‘taste’, *mosup* ‘figure’, *casay* ‘posture’, *nukkim* ‘feeling’, *huncek* ‘trace’, *kwangkyeng* ‘scene/sight’, *phwungkyeng* ‘scenery’, etc.

A similar kind of restriction exists in noun complement RCs. Head nouns are restricted to a certain type of noun, exemplified in (7), which includes events, thought, ideas, rumors, facts, etc.

(7) *sasil* ‘fact’, *somwun* ‘rumor’, *cwucang* ‘claim’, *cwungke* ‘evidence’, *kiek* ‘memory’, *il* ‘happening’, *kyenghem* ‘experience’, etc.

Head nouns of non-canonical RCs do not appear alone in out of the blue contexts unless the previous context provides enough information related to the head noun. As pointed out by Kim (1998), non-canonical RCs have different morpho-syntactic properties than canonical RCs. First, relativizers in non-canonical RCs are more restricted. Whereas canonical RCs take various relativizers representing different tense and aspect information, relativizers in non-canonical RCs depend on properties of the following head noun. For example, the head noun *solli* and *naymsay* follow a verb ending with the present tense relativizer *-nun*, but not with the past tense relativizer *-un* or future tense relativizer *-ul*. In parallel, head nouns of noun complement RCs combine with predicates containing certain relativizers. For instance, *kiek* ‘memory’ only combines with predicates ending with the past tense relativizer *un*, but not with present *-nun* and future *-ul*.

Second, coordination and stacking facts support the idea that non-canonical RCs are distinct from canonical RCs. Canonical RCs cannot be coordinated together with non-canonical RCs, as shown in (9), whereas canonical RCs and non-canonical RCs can combine with the same types of RCs as in (8)

- (8) a. [RC 존-이  $e_i$  읽-은] 그리고 [RC 메리-가 기억하-는] 책<sub>i</sub>  
 [RC John-i  $e_i$  ilk-un] kuliko [RC Mary-ka kiekha-nun] chayk<sub>i</sub>  
 John-Nom read-Rel and Mary-Nom remember-Rel book  
 ‘the book that John read and Mary remembers’
- b. [RC 생선-이 타-는 ] 그리고 [고기-가 썩-는] 냄새  
 [RC sayngsen-i tha-nun ] kuliko [koki-ka ssek-nun] naymsay  
 fish-Nom burn-Rel and meat-Nom rot-Rel smell

- ‘the smell of the fish burning and the meat rotting’
- (9) a. \*<sub>RC</sub> 존-이 <sub>e<sub>i</sub></sub> 좋아하-는] 그리고 [생선-이 타-는] 냄새  
 \*<sub>RC</sub> John-i <sub>e<sub>i</sub></sub> cohaha-nun] kuliko [syangsen-i tha-nun] naymsay  
 John-Nom like-Rel and fish-Nom burn-Rel smell  
 ‘the smell that John likes and the fish burning’
- b. \*<sub>RC</sub> 존-이 <sub>e<sub>i</sub></sub> 알고 있-는] 그리고 [<sub>RC</sub> 메리-가 결혼하-는] 사실  
 \*<sub>RC</sub> John-i <sub>e<sub>i</sub></sub> alko iss-nun] kuliko [<sub>RC</sub> Mary-ka kyelhonha-nun] sasil  
 John-Nom know being-Rel and Mary-Nom marry-Rel fact  
 ‘the fact that John knows and Mary marries’

## 2.2. Gapless Topic Constructions

Like RCs, TCs also have gapless constructions as in (10), where there is no gap in the comment phrase.

- (10) a. kkoch-un cangmi-ka yepputa  
 flower-Top roses-Nom beautiful  
 ‘Speaking of flowers, roses are beautiful.’
- b. sayngsen-un kwange-ka masissta.  
 fish-Top catfish tasty  
 ‘Speaking of fish, catfish is tasty.’

In (10), the NPs marked with the marker *-un* do not have corresponding gaps elsewhere in the sentences. This gapless topicalization is only licensed when a semantic taxonomic relation holds between the topic NP and the subject NP of the comment phrase. The topic-comment interpretation is allowed through the semantic predication based upon the taxonomic hierarchy between the topic and the NP in the comment phrase. Similar to taxonomic relations in gapless TCs, pseudo RCs are based upon semantic and pragmatic dependencies between the subject in a relative clause and the head noun. For example, in (3) the head noun and the subject have close morphosemantic combinations by forming a composite NP such as 생선 냄새 *sayngsen-namsay* ‘fish smell’, 물소리 *mwul-soli* ‘water sound’. In addition, the relative clause specifies the meaning of the head noun by narrowing down its reference in pseudo RCs, while predication of the topic element is narrowed down through the taxonomic relation between the topic and the following subject noun.

In addition to the semantic restriction based upon taxonomic hierarchy, gapped

and gapless topicalization show different grammatical properties. First, they are different with respect to relativization. Whereas the topics of a gapped topic construction can be the head noun of a relative clause as in (11), the topic in a gapless construction cannot as in (12).

- (11) a. 선생님<sub>i</sub>-은 [지우-가  $e_i$  선물-을 드렸다].  
sensayngnim<sub>i</sub>-un [Jiwoo-ka  $e_i$  senmwul-ul tulyessta].  
 teacher-Top Jiwoo-Nom present-Acc gave  
 ‘As for the teacher, Jiwoo gave (her/him) a present.’
- b. [지우-가  $e_i$  선물-을 드리-ㄴ ] 선생님  
 [ Jiwoo-ka  $e_i$  senmwul-ul tuli-n ] sensayngnim  
 Jiwoo-Nom present-Acc give-Rel teacher  
 ‘the teacher whom Jiwoo gave a present’
- (12) a. \*[장미-가 예쁘-ㄴ ] 꽃  
 \*[cangmi-ka yeppu-un ] kkoch  
 Roses-Nom pretty-Rel flower
- b. \*[광어-가 맛있-는] 생선  
 \*[kwange-ka masiss-nun] sayngsen  
 Catfish-Nom tasty fish

Second, topics of gapless TCs can be realized as parts of adverbial phrases as in (13). This is not allowed in the canonical gapped TC in (14b).

- (13) 꽃-으로 말하자면, [장미-가 예쁘다].  
 kkoch-ulo malhacamyeon, [cangmi-ka yepputa].  
 flower-as talk about roses-Nom pretty  
 ‘If we speak about flowers, roses are pretty.’
- (14) a. 장미-는 [미라-가  $e_i$  좋아한다].  
 cangmi-nun [Mira-ka  $e_i$  chohahanta].  
 Flower-Top Mira-Nom like  
 ‘Speaking of roses, Mira likes them.’
- b. \*장미로 말하자면 [미라가  $e_i$  좋아한다].  
 \*cangmi-lo malhacamyeon [Mira-ka  $e_i$  cohahanta].

Third, coordination and stacking facts support the idea that non-canonical TCs are distinct from canonical TCs, just as in RCs. In the following examples, a gapped TC can

be coordinated with another gapped TC as in (15), whereas a gapped TC cannot be coordinated with a gapless TC as in (16).

- (15) 연극-은      존-이       $e_i$       좋아하-고      메리-도       $e_i$       좋아한다.  
 yenkuk-un    John-i     $e_i$     chohaha-ko    Mary-to     $e_i$     cohahanta<sub>i</sub>  
 play-Top      J-Nom            like-and            Mary-also            likes  
 ‘the play that John likes and Mary likes’
- (16) \*연극<sub>i</sub>-은      존-이       $e_i$       좋아하-고      셰익스피어-가      유명하다.  
 \*yenkuk<sub>i</sub>-un    John-i     $e_i$     chohaha-ko    Shakespeare-ka    yumyenghata  
 play-Top          J-Nom            like-and            Shakespeare-Nom famous  
 ‘As for the play, John likes it and Shakespeare is famous for it.’

### 3. Similar Grammatical Properties of RCs and TCs

Unbounded dependencies in gapped RCs and TCs show similar grammatical properties in terms of semantics, island constraints, and strong crossover facts. This chapter discusses the similarity of the grammatical facts of RCs and TCs in detail.

#### 3.1. Semantic Relations

RCs and TCs show similar semantic relations; a relative clause provides a restriction on the set (or individual) specified by the head noun. In terms of topicalization, the comment phrase adds a restriction to the topicalized element, but not to others. Ever since Kuno (1973), an aboutness relation has been used to account for semantic and pragmatic dependencies between a topic and a comment in much of the literature. Kuno (1976) also defines a semantic restriction on the interpretation of relative clauses as the ‘aboutness condition,’ which derives from a condition on TCs. It requires that a relative clause be a statement about its head noun. A similar condition for RCs has also been provided by Yoon (1995) as follows.

(17) Condition for R-relation in Korean:

R-relation must be familiar and maximally salient

Na and Huck (1993) examine additional details of the aboutness condition and argue that it is a necessary condition of both RCs and TCs, but a sufficient condition only of

TCs given that the formation of an RC is restricted to a taxonomic relation as in (12). Furthermore, Kang (1988) and O’Grady (1991) have used an aboutness relation in order to capture the semantic relations in double nominative constructions (DNCs) in Korean. Lee (2004) argues that DNCs also license unbounded dependencies as TCs do; the aboutness relation holds between a salient subject and the following predicate in DNCs as well as between the topic and the comment phrase. Semantic and pragmatic properties between a relative clause and the head noun in RCs can also be captured by the aboutness condition.

### 3.2. Island Constraints

Now, let us consider island constraints for RCs and TCs. In the previous literature, it has been argued that island constraints are observed in Korean long-distance dependency constructions. The following examples seem to support this claim, where an element inside of an island cannot refer to the head noun in RCs and cannot appear in the topic positions in RCs.

#### [Complex Noun Phrase Constraint (CNPC)]

- (18) \* [지호-가 [NP [RC e<sub>i</sub> e<sub>j</sub> 기르-는 ] 개<sub>j</sub>]-를 좋아하-는 (그) 여자.  
 \* [Jiho-ka [NP [RC e<sub>i</sub> e<sub>j</sub> kilu-nun] kay<sub>j</sub>]-lul coaha-nun (ku) yeca  
 Jiho-Nom raise-REL dog-Acc like that woman  
 ‘the woman who Jiho likes the dog that (she<sub>i</sub>) raises e<sub>j</sub>’
- (19) \* 그 여자-는 [S 지호-가 [NP [REL e<sub>i</sub> e<sub>j</sub> 기르-는 ] 개<sub>j</sub>]-를 좋아한다].  
 \* ku yeja-nun [S Jiho-ka [NP [REL e<sub>i</sub> e<sub>j</sub> kilu-nun] kay<sub>j</sub>]-lul choahanta].  
 that woman-Top Jiho-Nom raise-REL dog-Acc like  
 ‘As for Mira<sub>i</sub>, Jiho likes the dog that (she<sub>i</sub>) raises e<sub>j</sub>’

#### [Sentential Subject Constraint]

- (20) \*? [S 유미-가 e<sub>i</sub> 살고있-는 것/음]-이 놀라운 현대 아파트  
 \*? [S Yumi-ka e<sub>i</sub> salkoiss-nun kes/um]-i nolaw-un Hyundai aphath  
 Y-Nom live-Rel thing/NML- Nom surprising-Rel Hyundai apartment  
 ‘Hyundai apartment where it is surprising that Yumi lives (there).’
- (21) \*? 현대 아파트- 는 [S 유미가 e<sub>i</sub> 살고 있-는 것/음]-이 놀랍다.  
 \*? Hyundai aphath-nun [S Yumi-ka salko iss-nun kes/um]-i nollapta.  
 Hyundai apartment-Top Yumi-Nom live-thing/NML-Nom surprising  
 ‘In terms of the Hyundai apartment, it is surprising that Yumi lives.’

[Adjunct Constraint]

- (22) <sup>?</sup>\* [s [s 선생님-이 e<sub>i</sub> 야단쳤-을 때 ] 모두 조용해지-ㄴ ] 학생<sub>i</sub>  
<sup>?</sup>\* [s [s sensayngnim-i e<sub>i</sub> yatanchyess-ul ttay] motwu coyonghayci-n] haksayng<sub>i</sub>  
 teacher-Nom scold-REL when everyone become-quiet-REL student  
 ‘the student<sub>i</sub> who everyone became quiet when the teacher scolded (him)’
- (23) <sup>?</sup>\* 그 학생<sub>i</sub>-은 [s [s 선생님-이 e<sub>i</sub> 야단쳤-을 때 ] 모두 조용해졌다.  
<sup>?</sup>\* kuhaksayng<sub>i</sub>-un [s [s sensayngnim-i e<sub>i</sub> yatanchyess-ul] ttay] motwu coyonghaycyessta.  
 that student<sub>i</sub>-Top teacher-Nom scold-REL when everyone become-quiet  
 ‘As for the student<sub>i</sub> everyone became quiet when the teacher scolded (him)’

However, there are counterexamples against the above island constraint facts. First, consider examples (24) and (25), which violate the Complex Noun Phrase Constraint. In contrast with (18) and (19), the following examples are grammatical even though a gap occurs inside of a complex noun phrase that refers to the head noun in (24) and even though the topicalized element refers to the gap inside of a complex noun phrase in (25).

- (24) [내-가 [NP [ e<sub>i</sub> 최근 e<sub>i</sub> 발표하-ㄴ ] 소설<sub>j</sub>]-을 잘 알고 있-는] 작가<sub>i</sub>  
 [nay-ka [NP [ e<sub>i</sub> choykun e<sub>i</sub> palphyoha-n] sosel<sub>j</sub>-ul cal al-ko iss-nun] cakka<sub>i</sub>  
 I-Nom recently publish-Rel novel-Acc well know-REL writer  
 ‘The writer who I know well the novel<sub>i</sub> which (he<sub>i</sub>) published e<sub>j</sub>’
- (25) 그 작가<sub>i</sub>-는 [s 내-가 [[ e<sub>i</sub> 최근 e<sub>i</sub> 발표하-ㄴ ] 소설<sub>j</sub>]-을 잘 알고 있다].  
 ku cakka<sub>i</sub>-nun [s nay-ka [ e<sub>i</sub> choykun e<sub>i</sub> palphyoha-n] sosel<sub>j</sub>-ul cal alko issta ].  
 that writer-Top I-Nom recently publish-Rel novel-Acc well know  
 ‘As for that writer<sub>i</sub> I know well the novel<sub>i</sub> which (he<sub>i</sub>) published e<sub>j</sub>’

There are numerous acceptable CNPC violations in Korean as in (26), as already noted in Na and Huck (1993).

- (26) [RC1 [RC2 e<sub>i</sub> e<sub>j</sub> 입고 있-는] 옷<sub>j</sub>-이 멋지-ㄴ ] 신사<sub>i</sub>  
 [RC1 [RC2 e<sub>i</sub> e<sub>j</sub> ipko iss-n ] os<sub>j</sub>-i mesci-n] sinsa<sub>i</sub>  
 wear-REL clothes<sub>j</sub>-Nom stylish-REL man<sub>i</sub>  
 (lit.) ‘the man<sub>i</sub> who the clothes that e<sub>i</sub> is wearing are stylish’
- (27) [RC1 [RC2 e<sub>i</sub> e<sub>j</sub> 발표하-ㄴ ] 소설-이 인기-가 있-는 ] 작가<sub>i</sub>  
 [RC1 [RC2 e<sub>i</sub> e<sub>j</sub> palphyo-n ] sosel<sub>j</sub>-i inki-ka iss-nun ] cakka<sub>i</sub>  
 publish-REL novel-Nom popularity-Nom have-RE writer<sub>i</sub>

(lit.) ‘the writer<sub>i</sub> who the novel that *e<sub>i</sub>* wrote *e<sub>j</sub>* is popular’

According to Na and Huck (1993), examples (26) and (27) are formed based upon the relationship between the referent of the head noun of the uppermost relative and that of the head noun of the lower relative; each relation of these RCs is conventional in terms of the information supplied by the lower relative. For example, the lower clause in (26) specifies the relationship that holds between the clothes denoted by the lower head and the member in question of the set denoted by the upper clause.

With respect to the above CNPC violation, Han and Kim (2004) claims that there is no violation. This is because the relativized element originated from relativising the subject of a double nominative construction. For example, the highest verb of the RC in (27) allows a double nominative construction in (28). Because no complex noun phrase intervenes, (27) does not violate CNPC.

(28) [S<sub>1</sub> 그 작가<sub>i</sub>-가 [ [S<sub>2</sub> *e<sub>i</sub>* *e<sub>j</sub>* 발표하-ㄴ ] 소설<sub>j</sub>]-이 인기-가 있다]  
 [S<sub>1</sub> ku cakka<sub>i</sub>-ka [ [S<sub>2</sub> *e<sub>i</sub>* *e<sub>j</sub>* palpyoha-n ] sosel<sub>j</sub>]-i inki-ka issta]  
 that writer<sub>i</sub> -Nom publish-REL novel<sub>j</sub>-Nom popularity have  
 ‘Speaking of the writer, the novel that he<sub>i</sub> wrote is popular.’

However, there are counterexamples against Han and Kim’s (2004) argument for relativization based upon double subject constructions. Consider the following examples.

(29) [RC<sub>1</sub> 내-가 [RC<sub>2</sub> *e<sub>i</sub>* *e<sub>j</sub>* 자주 다니-는] 카페<sub>j</sub>-를 알고 있-는 작가<sub>i</sub>  
 [RC<sub>1</sub> nay-ka [RC<sub>2</sub> *e<sub>i</sub>* *e<sub>j</sub>* cacwu tani-nun ] khapey<sub>j</sub>-lul al-ko iss-nun ] cakka<sub>i</sub>  
 I-Nom often go-REL cafe-Acc know-REL writer<sub>i</sub>  
 (lit.) ‘the writer<sub>i</sub> who I knows the cafe that he<sub>i</sub> goes to often’

(30) [S<sub>1</sub> 그 작가<sub>i</sub>-는 [[S<sub>2</sub> 내-가 [RC<sub>2</sub> *e<sub>i</sub>* *e<sub>j</sub>* 자주 다니-는] 카페-를 알고있어].  
 [S<sub>1</sub> ku cakka<sub>i</sub>-nun [ [S<sub>2</sub> nay-ka [RC<sub>2</sub> *e<sub>i</sub>* *e<sub>j</sub>* cacwu tani-nun ] khapey<sub>j</sub>-lul alkoisse]  
 that writer-Nom I-Nom often go-REL cafe-Acc know  
 (lit.) ‘Speaking of the writer<sub>i</sub>, I know the café that he<sub>i</sub> goes often.’

The examples (29) and (30) do not form a double nominative construction as in (31). Thus, relativization and topicalization out of a complex noun phrase cannot be based upon the double nominative constructions as claimed in Han and Kim (2004).

- (31) <sup>\*2</sup>[<sub>S1</sub> 그 작가가 [<sub>S</sub> 내-가 [<sub>RC2</sub>  $e_i$   $e_j$  자주 다니-는 ] 카페-를 알-고있어].  
<sup>\*2</sup>[<sub>S1</sub> ku cakka<sub>j</sub>.ka [<sub>S2</sub> nay-ka [<sub>RC2</sub>  $e_i$   $e_j$  cacwu tani-nun] khapeyj-lul al-ko isse]  
that writer-Nom I-Nom often go-REL cafe -Acc know

Furthermore, counterexamples violating the other island constraints including sentential subject constraint and adjunct constraint exist.

[Sentential Subject Violation]

- (32) [<sub>RC</sub> [<sub>S</sub> 메리가  $e_i$  전달했다-는 것/했음]-이 드러나-ㄴ] 선물  
[<sub>RC</sub> [<sub>S</sub> Mary-ka centalhayssta-nun kes/hayssum]-i tulna-n] senmwul  
Mary-Nom delivered-Rel thing/-did-NML-Nom exposed-Rel gift

‘The gift that it has been exposed that Mary delivered (it).’

- (33) 그 선물<sub>i</sub>-은 [<sub>S1</sub> [<sub>S2</sub> 메리가  $e_i$  전달했다-는 것/했음]-이 드러났다].  
ku senmul-un [<sub>S1</sub> [<sub>S2</sub> Mary-ka  $e_i$  centalhayssta-nun kes/hayssum]-i tulenassta.  
that gift-Top Mary-Nom delivered-Rel thing/-did-NML-Nom revealed

‘As for the gift, it has been revealed that Mary delivered it.’

[Adjunct Constraint Violation]

- (34) [<sub>RC</sub>[<sub>S</sub> 미라-가  $e_i$  연주하-면] [<sub>S</sub> 모두-가 기뻐하-는]] 곡  
[<sub>RC</sub>[<sub>S</sub> Mira-ka yencwuha-myeon] [<sub>S</sub> motwu-ka kippeha-nun]] kok  
Mira-Nom play-when everyone-Nom please-Rel song

‘the song<sub>i</sub>, that everyone becomes pleased when Mira plays (it<sub>i</sub>)’

- (35) 그 곡<sub>i</sub>-은 [<sub>S</sub>[<sub>S</sub> 미라-가  $e_i$  연주하-면] [<sub>S</sub> 모두-가 기뻐한다]].  
ku kok<sub>i</sub>-un [<sub>S</sub>[<sub>S</sub> Mira-ka yencwuha-myeon] [<sub>S</sub> motwu-ka kippehanta]].  
that song-Acc Mira-Nom play-when everyone-Nom please

‘As for that song<sub>i</sub>, everyone becomes pleased when Mira plays (it<sub>i</sub>)’

Szabolcsi and den Dikken (1999) argue that some island constraint effects are relevant to the semantic scope that an expression takes over certain operators. Also, Kluender (1998) takes a processing point of view with respect to CNPC violations and argues that semantic and pragmatic factors trigger island constraint violations.

### 3.3. Strong Crossover

RCs and TCs show similarity in terms of strong crossover. As discussed in Postal (1971), Wasow (1972), Hukari and Levine (1995) *inter alia*, strong crossover refers to a

that appear in the gap position are interpreted as overt traces with the nonlocal SLASH feature. The typological categories of gaps, pronouns, and reflexives in unbounded dependency constructions vs. other constructions are summarized in the following table.

Forms	[+ SLASH ] Trace (Gaps)	[-SLASH] Non-trace
Phonological Zero Forms	Trace ( <i>nonpro</i> )	<i>pro</i> ( <i>ppro</i> )
Phonologically Overt Pronouns	Resumptive Pronoun (Overt Trace)	(ordinary) Pronoun
Reflexive <i>caki</i>	Resumptive Reflexive (Overt Trace)	(ordinary) Reflexive

Table 1. Classification of UDC Trace vs. non-UDC Correspondents of Trace

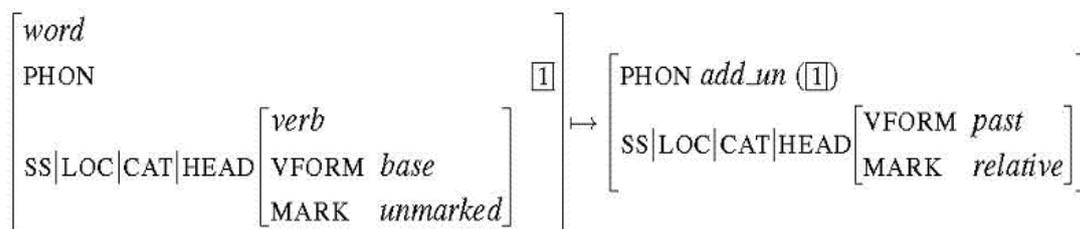

As shown in Table 1, resumptive pronouns (or reflexives) are overt traces corresponding to traces in unbounded dependency constructions, while they share lexical similarities with the corresponding ordinary pronouns (or reflexives). Lee (2004) also argues that logophoricity and contrastiveness are associated with interpretations of resumptive pronouns and resumptive reflexives in Korean UDCs as well as with their correspondents in non-UDCs.

#### 4. A Structural Representation of Korean RCs and TCs

Within the framework of Head-Driven Phrase Structure Grammar, a lexical analysis following Pollard and Sag (1994) properly captures the formation of RCs and TCs. Unbounded dependency between a gap and its antecedent can be simply handled by SLASH percolation.

In order to explain the formation of an RC, it is necessary to explain how a relativizing element combines with its stem. The formation of relativized predicates is a highly productive morphological process. A lexical rule analysis can properly capture this fact.

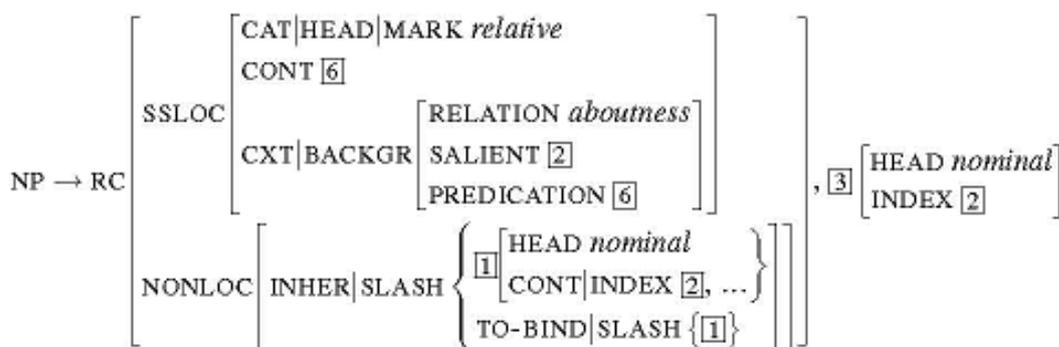

(41)

Korean has different relativizing complementizers including *-nun*, *-un*, *-ul* and *-ten* that add specific tense information to the stems, while representing sentence boundaries of RCs. The MARK(ING) feature has been added to the Head feature of a predicate. This is because in Korean the markedness of a sentence is represented by the predicate that is formed in combination with a complementizing suffix. This percolates up to the highest phrasal level.

The following schema is based on the lexical rule that forms the relative form of a predicate, and it provides the representation of the syntactic combination of a relative clause and the head noun.

(42) Schema for the Gapped Relative Clause-Head Noun

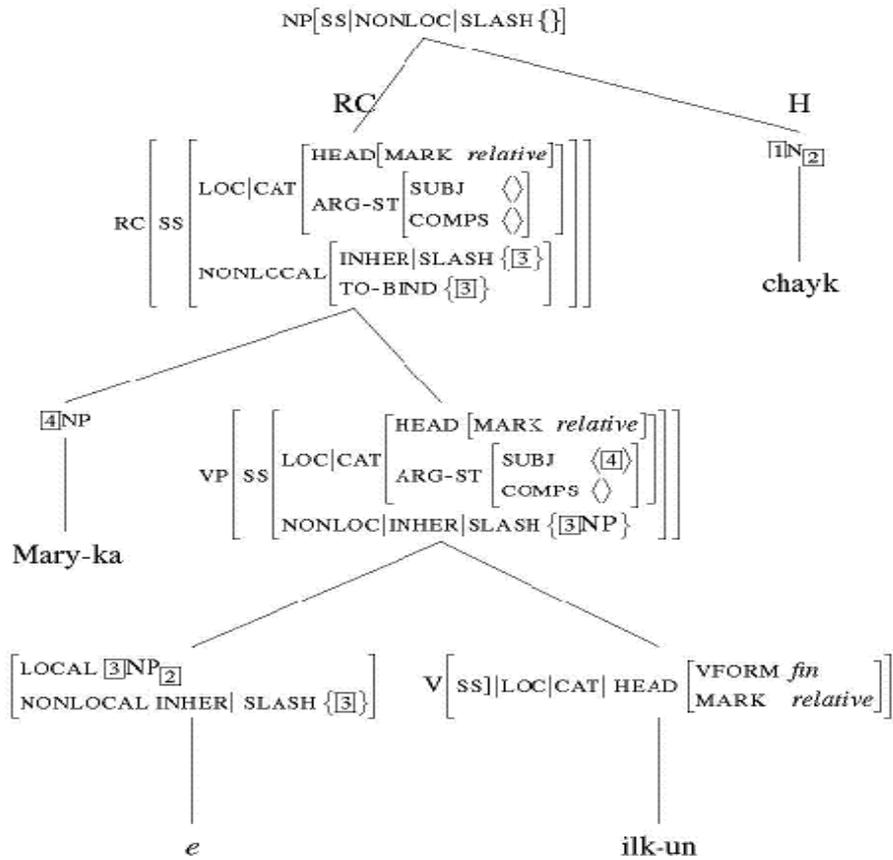

As we see in the given schema, the nonlocal SLASH feature of an RC is bound off when it meets the head noun. Unlike English, there is no overt filler for the inherited SLASH feature in Korean. Instead, coreference exists between the head noun and the trace of an RC. The TO\_BIND SLASH feature is introduced when an RC combines with a head noun, but there is only semantic coreference between a head noun and the SLASH value. In addition, the aboutness condition has been specified as the aboutness relation in the CONTEXT feature, which represents semantic and pragmatic relation between a relative clause and the following head noun. The head noun refers to a salient element in the context and the preceding relative clause provides predication for the

element. With the given schema and SLASH inheritance mechanism, the structure of an RC is shown in (43).

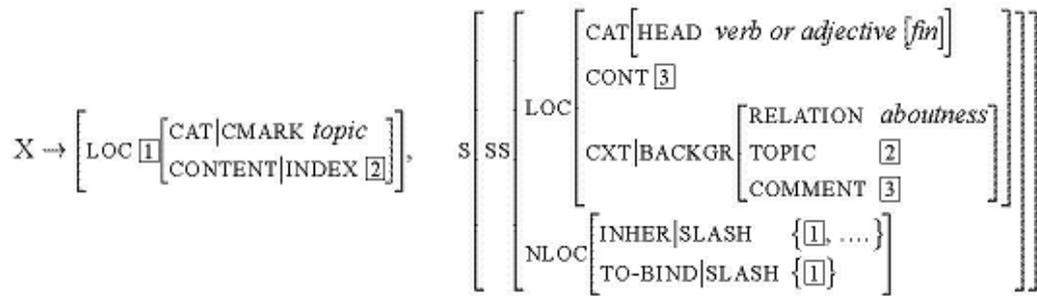

- (43) 메리-가 e<sub>i</sub> 읽-은 책<sub>i</sub>  
 Mary-ka e<sub>i</sub> ilk-un chayk<sub>i</sub>  
 ‘the book Mary read’

(44)

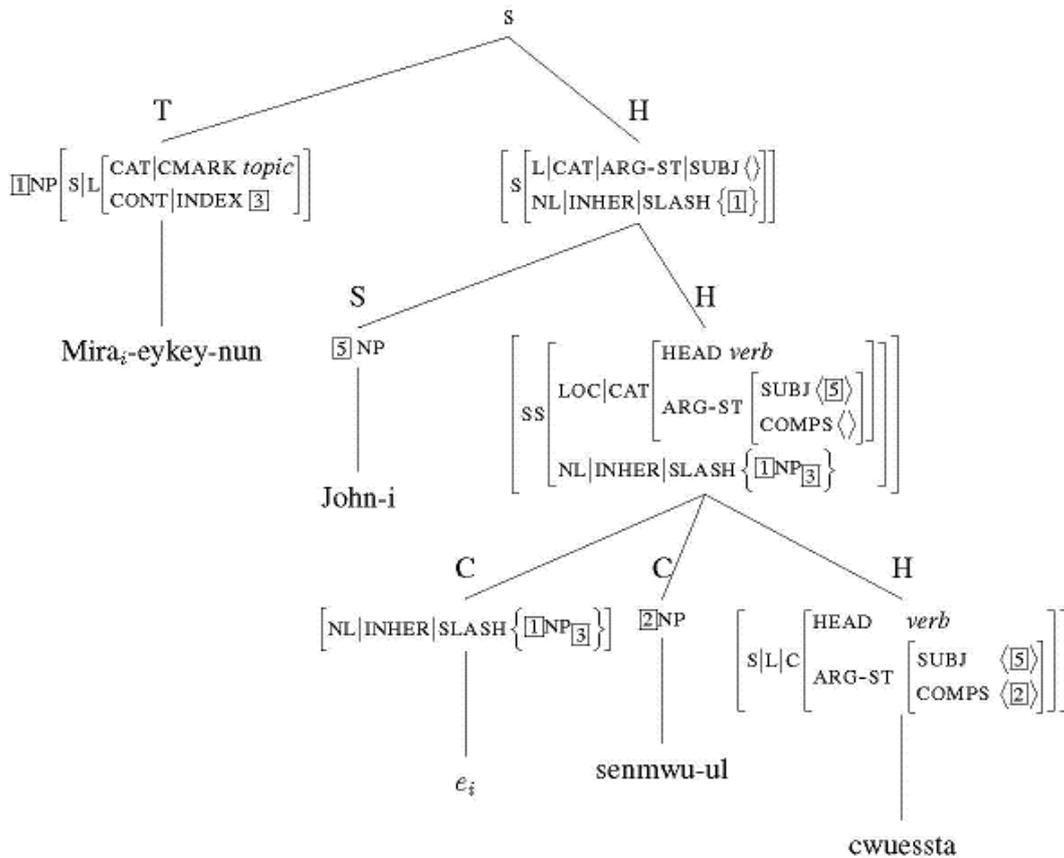

With respect to the gapped TCs, the schema in (45) captures unbounded dependency and can be provided with specification of the aboutness relation. Also in the given schema, a topic has the CASEMARKING (CMARK) value of *topic*. The CMARK feature is introduced when the nominal head combines morphosyntactically with a marker. The context feature provides the aboutness semantic relation with topic-comment roles. Furthermore, the structure of a TC in (46) can be represented as in (47). The semantic and syntactic dependency between a topic and the gap is properly captured in the given representation.

(45) Topic-Head Schema for Gapped Topicalization

- (46)  $\text{Mira}_j\text{-eykey-nun John-i } e_j \text{ senmul-ul cwuessta.}$   
 Mira-to-Top John-Nom present-Acc gave  
 ‘As for Mira, John gave a present.’

(47)

## 5. Conclusion

This paper examined similarities between gapped relative clauses and topic constructions in Korean by focusing on semantic and syntactic properties. Facts from island constraint violations for Korean RCs and TCs suggest that structure-based accounts of island constraints are less preferred to other accounts based upon pragmatic and semantic conditions. In line with this, the paper included a discussion of the aboutness conditions between a filler and a gap and strong crossover phenomenon in unbounded dependency constructions of RCs and TCs. The structure of these constructions and the relevant lexical representation were presented with the framework of HPSG. Finally, semantic and pragmatic conditions may serve as major factors licensing non-local linkage along the lines of processing cost according to the depth of embedding in these constructions, as suggested by Kluender (1998).

# The Light Verb Construction in Japanese and PF-LF Mismatch in Argument Linking\*

Toru Ishii

Meiji University  
1-1 Kandasurugadai, Chiyoda-ku, Tokyo, 101-8301 JAPAN  
tishii@kisc.meiji.ac.jp

## Abstract

This paper proposes a non-simultaneous Transfer analysis of the light verb construction in Japanese, arguing that the nominal phrase complement of a light verb functions only as an LF-phase but not as a PF-phase. It is shown that our non-simultaneous Transfer analysis accounts for a paradoxical PF-LF mismatch in argument linking which the light verb construction exhibits. Our proposed analysis receives further support from the fact that it accommodates various properties of the light verb construction. This paper presents evidence for the view of non-simultaneous Transfers, where a syntactic object can be transferred to a single interface during a derivation.

**Keywords:** Light Verb, Transfer, Phase, Argument Linking, PF-LF Mismatch.

## 1. Introduction

Since Grimshaw and Mester's (1988) seminal work, the light verb constructions in Japanese like (1) have drawn much attention in generative literature mainly due to a paradoxical PF-LF mismatch in argument linking they exhibit (see, among others, Hasegawa 1991, Kageyama 1991, 1993, Uchida and Nakayama 1993, Matsumoto 1996, and Saito and Hoshi 2000):

- (1) John-ga Bill-to aiseki-o site-iru  
John-Nom Bill-with table-sharing doing-be  
'John is sharing a table with Bill.'

In (1), the light verb *site-iru* 'doing-be', the present progressive form of *suru* 'do', is combined with the verbal noun *aiseki* 'table-sharing', which is marked by the accusative case particle *-o*. The term "light verb" refers to a verb which is semantically empty. Since the light verb is semantically empty, the arguments *John* and *Bill* are assigned  $\theta$ -roles, *i.e.* Agent and Theme, by the nominal head, *i.e.* the verbal noun *aiseki* 'table-

sharing'. These  $\theta$ -markings take place within the nominal phrase given the locality condition of  $\theta$ -marking proposed by Chomsky (1981). This suggests that the arguments *John* and *Bill* in (1) should be inside the nominal phrase as shown in (2a). Neither *John* nor *Bill*, however, is marked by the genitive case particle *-no*, *i.e.* the case marking of the nominal system. This suggests that *John* and *Bill* should be outside the nominal phrase as shown in (2b):

(2) PF-LF Mismatch in Argument Linking

- a. [NomP *John-ga Bill-to aiseki*]-o site-iru  
*John-Nom Bill-with table-sharing-Acc doing-be*  
 (Agent, Theme)
- 
- b. *John-ga Bill-to* [NomP *aiseki*]-o site-iru  
*John-Nom Bill-with table-sharing-Acc doing-be*

It has been widely assumed that  $\theta$ -marking is an LF-phenomenon. Case marking, on the other hand, is a PF-phenomenon, since Case features are irrelevant for LF, but only read and morphologically realized in the PF-component. The light verb construction exhibits a PF-LF mismatch in argument linking.

This paper proposes a non-simultaneous Transfer analysis of the light verb construction. The organization of this paper is as follows. Section 2 reviews previous analyses of the light verb construction. Section 3 proposes a non-simultaneous Transfer analysis, arguing that the nominal phrase complement of a light verb functions only as an LF-phase but not as a PF-phase. It is shown that our non-simultaneous Transfer analysis accounts for the PF-LF mismatch. Section 4 presents further arguments for our analysis. Section 5 makes concluding remarks.

## 2. Previous Analyses

Grimshaw and Mester (1988) propose an operation called Argument Transfer, which transfers the  $\theta$ -roles of a verbal noun to the light verb. Let us consider (1) again as an example. Under their analysis, the light verb *suru* 'do' and the verbal noun *aiseki* 'table-sharing' would originally have the argument structures in (3). In (3a), the parentheses are used to indicate that *suru* 'do' has a skeletal argument structure, and the notation <acc> indicates that *suru* 'do' assigns accusative case to the verbal noun *aiseki* 'table-sharing'. Argument Transfer applies to the arguments of the verbal noun *aiseki* 'table-sharing' in (3b). This operation produces the argument structure of the combination of the verbal noun and the light verb (4):

- (3) a. *suru* 'do' ( ) <acc>  
 b. *aiseki* 'table-sharing' (Agent, Theme)  
 (4) *aiseki* 'table-sharing' ( ) + *suru* 'do' (Agent, Theme) <acc>
- 
- Argument Transfer

The light verb *suru* assigns the transferred  $\theta$ -roles to *John* and *Bill*:

- (5) John-ga Bill-to [<sub>NomP</sub> aiseki-o] site-iru  
 John-Nom Bill-with table-sharing-Acc do-being  
 ( ) (Agent, Theme) <acc>
- 

Since *John* and *Bill* are outside the nominal phrase, they are not assigned the genitive case particle *-no*; this accounts for the PF-LF mismatch in argument linking. Although Grimshaw and Meter's analysis describes the PF-LF mismatch, Argument Transfer is a special additional mechanism only for the light verb construction, which is theoretically undesirable.

More recently, Hasegawa (1991), Kageyama (1991, 1993), and Saito and Hoshi (2000) analyze the light verb construction by making use of Incorporation, which is an independently motivated operation (see, among others, Baker 1988). Let us look at Saito and Hoshi's analysis as an illustration. Saito and Hoshi assume the minimalist program and propose an LF incorporation analysis, where a verbal noun is covertly incorporated into a light verb. Under their analysis, (1) would be analyzed as shown in (6):

- (6) a. John-ga Bill-to [<sub>NomP</sub> aiseki-o] site-iru  
 John-Nom Bill-with table-sharing-Acc doing-be  
 (Agent, Them)

- b. John-ga Bill-to [NomP  $t_i$ -o] *aiseki* <sub>$t_i$</sub> -site-iru  
 John-Nom Bill-with  $t_i$ -Acc *table-sharing* <sub>$t_i$</sub> -doing-be  
 (Agent, Theme)
- 

Before Spell-Out, (1) is assigned (6a). In (6a), the arguments *John* and *Bill* are outside the nominal phrase and thus not assigned the genitive case particle *-no*. Then, as shown in (6b), the  $\theta$ -role assigning verbal noun *aiseki* 'table-sharing' incorporates into the light verb *suru* 'do' at LF and assigns its  $\theta$ -roles to *John* and *Bill* at this level. Note that such LF  $\theta$ -markings are allowed under the minimalist assumption that the  $\theta$ -criterion applies only at LF. Saito and Hoshi's incorporation analysis captures the PF-LF mismatch in argument linking.

As pointed out by Fukui and Sakai (2006), however, such incorporation analyses have trouble in accounting for examples like (7). (7) involves coordination of a verbal noun and its internal argument by the conjunction particle *to*; *Amerika-ni ryokoo* 'travel to America' and *Doitu-ni ryuugaku* 'study abroad to Germany' are coordinated:

- (7) Taroo-ga kotosi-no natu [Amerika-ni *ryokoo*] to  
 Taro-Nom this year-Gen summer America-to *travel* Conj  
 [Doitu-ni *ryuugaku*](*-to*)-o sita  
 Germany-to *study abroad*(*-Conj*)-Acc did  
 Lit. 'This summer, Taro did a travel to the United States and a study abroad in Germany.'  
 (Fukui and Sakai 2006: 328)

Under the incorporation analyses, the verbal nouns *ryokoo* 'travel' and *ryuugaku* 'study abroad' would be incorporated into the light verb *suru*. This would violate the general constraint on movement (8); the incorporation analyses would wrongly predict that (7) is deviant:

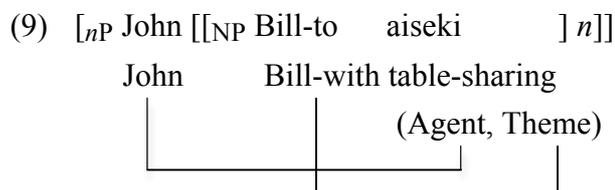

- (8) Constraint on an Across-the-Board Movement  
 An across-the-board movement of different elements into a single landing site is prohibited.

### 3. A Non-Simultaneous Transfer Analysis

Under the minimalist program proposed by Chomsky (1995) and further developed by, among others, Chomsky (2000, 2001, 2004, 2005, 2006), the syntactic component contains PF-Transfer and LF-Transfer operations, which transfer a syntactic object to the sensory-motor (S-M) and conceptual-intentional (C-I) interfaces, respectively. It is

still an open question when PF-Transfer and LF-Transfer should apply during a derivation. Chomsky (2004, 2005, 2006) assumes that phases are the same for both Transfer operations, and PF-Transfer and LF-Transfer apply simultaneously when structure-building completes a phase, which is CP and  $\nu$ P in his system. Since PF-Transfer and LF-Transfer are independent operations, however, there is no a priori reason to assume that they should apply simultaneously in a derivation. The idea of non-simultaneous Transfers, where a syntactic object can be transferred to a single interface (either only to the S-M interface or only to the C-I interface) has been advocated by, among others, Nissenbaum (2000), Megerdooimian (2002), Cecchetto (2004, 2005), Felser (2004), Marušič (2005), Matushansky (2005), and Ishii (2008). This section proposes a non-simultaneous Transfer analysis of the light verb construction, arguing that it accounts for the PF-LF mismatch. More specifically, I argue that the nominal phrase complement of a light verb functions only as an LF-phase but not as a PF-phase. I also propose "case domain fusion," arguing that when more than one "case domain" overlaps, "case domain fusion" must take place, where the notion of "case domain" is regulated by the Phase Impenetrability Condition.

Let us consider (1) again as an example. During its derivation, our analysis constructs the nominal phrase (9):

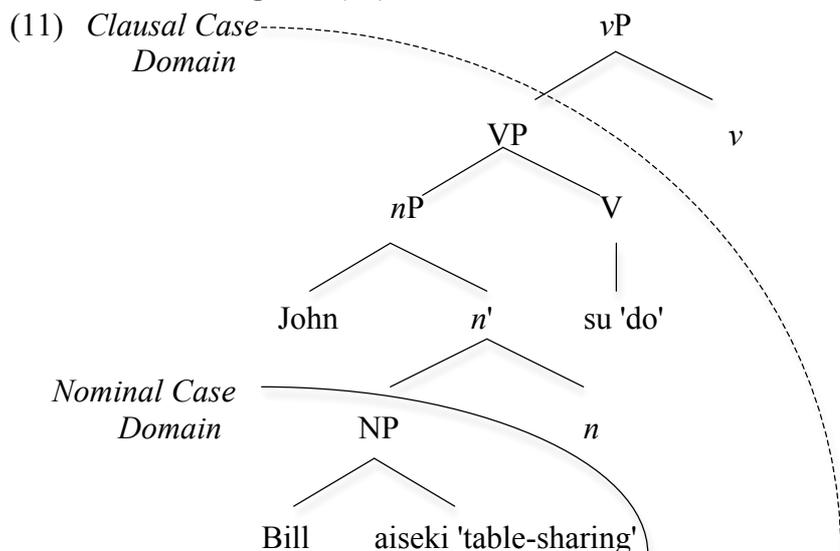

Essentially following, among others, Chomsky (2006), I assume that the nominal phrase contains the nominal functional category  $n$ , which is analogous to the verbal functional category  $\nu$ . The nominal functional category  $n$  is a light noun taking NP as its complement. In (9), the external argument *John* appears in the Spec of  $n$ P whereas the internal argument *Bill* is within NP. This is parallel to the widely accepted view of clausal structure, where an external argument appears in the Spec of  $\nu$ P whereas an internal argument appears within VP. In (9), both *John* and *Bill* are assigned  $\theta$ -roles by the verbal noun *aiseki* 'table-sharing' within  $n$ P, which satisfies the locality condition on  $\theta$ -marking. Following Chomsky's (1986) idea that inherent case is licensed in connection with  $\theta$ -marking, I claim that *Bill* is assigned the inherent case particle *-to* 'with' by its  $\theta$ -role assigner, *i.e.* the verbal noun *aiseki* 'table-sharing'. Note that given the diagnostic of an LF-phasehood (10),  $n$ P in (9) marks the completion of an argument structure (*i.e.* all the  $\theta$ -roles are assigned within  $n$ P). Hence,  $n$ P has the status of a

"proposition" just like  $vP$ ; it counts as an LF-phase (see, among others, Chomsky 2000, 2001, 2004, 2005, 2006, Matushansky 2005):

(10) LF-phasehood

LF phases have the status of a "proposition"; either a phrase in which all  $\theta$ -roles are assigned or a full clause including tense and force.

We then construct  $vP$  phase (11):

This paper adopts Miyagawa's (1991) view on Case. Miyagawa investigates the function of Case, arguing that Case of the clausal type including nominative and accusative has the function to identify an element as a member of a clause. For Case to license membership in the clause, Case itself must be licensed by the functional head INFL, which has the entire clause within its scope, *i.e.* its government domain in his analysis. Extending Miyagawa's idea, I argue that just as Case of the clausal type has the function to license membership in a clause, Case of the nominal type has the function to identify an element as a member of a nominal phrase. More specifically, I argue that there are two case marking systems in Japanese; the clausal case marking system, *i.e.* the lack of the genitive case particle *-no* including nominative and accusative, and the nominal case marking system, *i.e.* the presence of the genitive case particle *-no*. The clausal case marking system has the function to license membership in a clause whereas the nominal case marking system has the function to license membership in a nominal phrase. In order for clausal case marking to identify an element as a member of a clause, clausal case marking itself must be licensed within "the clausal case domain." The notion of "the clausal case domain" is defined as the accessible domain of  $C$  or  $v$ , which is the functional head of a clause (more precisely, a "proposition" in the sense mentioned in (10)). Nominal case marking, on the other

hand, must be licensed within "the nominal case domain" so that it can identify an element as a member of a nominal phrase. The notion of "the nominal case domain" is defined as the accessible domain of *n*, which is the functional head of a nominal phrase:

- (12) a. Clausal case marking, *i.e.* the lack of the genitive case particle *-no*, must be licensed within the clausal case domain, *i.e.* the accessible domain of *C/v*.  
 b. Nominal case marking, *i.e.* the presence of the genitive case particle *-no*, must be licensed within the nominal case domain, *i.e.* the accessible domain of *n*.

The notion of accessible domain is regulated by c-command and the Phase Impenetrability Condition (PIC) (13) formulated in Chomsky (2001):

- (13) The Phase Impenetrability Condition (PIC)  
 In [<sub>ZP</sub> Z ... [<sub>HP</sub> α [<sub>H</sub> YP]]], the domain of H, *i.e.* YP, is not accessible to operations at ZP; only H and its edge are accessible, where ZP and HP are phases. (adapted from Chomsky 2001: 13)

In (11), the nominal case domain, *i.e.* the accessible domain of *n*, is indicated by the solid line whereas the clausal case domain, *i.e.* the accessible domain of *v*, is indicated by the dotted line. Given that the nominal phrase complement of a light verb, *i.e.* *nP* in (11), is not a PF-phase, *Bill* is within the accessible domain of *v* for PF-phenomena including case marking. *Bill* is within the clausal case domain; our analysis can account for the fact that *Bill-to* 'Bill-with' may appear without the genitive case particle *-no* as shown in (1). In (11), *Bill* is also within the nominal case domain, *i.e.* the accessible domain of *n*. Our analysis therefore predicts that *Bill-to* 'Bill-with' may also appear with the genitive case particle *-no*. This prediction is born out, contrary to what has been claimed by, among others, Grimshaw and Mester (1988) and Saito and Hoshi (2000). As pointed out by Matsumoto (1996), although (14), where *Bill-to* 'Bill-with' is accompanied by the genitive case particle *-no*, sounds unnatural, its unnaturalness can be removed by some modification as shown in (15):

- (14)? John-ga Bill-to-*no* aiseki-o site-iru  
 John-Nom Bill-with-*Gen* table-sharing-Acc do-ing  
 'John is sharing a table with Bill.'  
 (15) John-ga Bill-to(-*no*) aiseki-o sita koto-ga nai  
 John-Nom Bill-with(-*Gen*) table-sharing-Acc did Comp-Nom Neg  
 'John has never shared a table with Bill.' (Matsumoto 1996: 116)

We should notice that there is an overlap between the nominal and clausal case domains in (11). I argue that when more than one case domain overlaps, "case domain fusion"

must take place:

(16) Case Domain Fusion

When more than one case domain overlaps, "case domain fusion" must take place.

I also argue that there is a constraint on "case domain fusion" (17):

(17) Constraint on Case Domain Fusion

"Case domain fusion" only takes place when two domain-defining functional heads are of the same type, *i.e.* they are either of the transitive/experiencer (T/E) type or of the unaccusative/passive (UA/P) type.

In (11), the functional head *n*, which defines the nominal case domain, has the external argument *John*; it is a transitive/experiencer (T/E) type. It then follows from (17) that the functional head *v*, which defines the clausal case domain, must also be of the same type, as shown below:

(18) [<sub>VP</sub> [<sub>VP</sub> [<sub>nP</sub> John [[<sub>NP</sub> Mary-to aiseki] *n*]] su] *v*  
           John       Mary-with table-sharing <T/E>   do <T/E>

Hence, *v* has the accusative Case feature, which is inherited by V as argued by Chomsky (2006). The nominal phrase complement *nP* moves to the Spec of VP, where it is assigned the accusative case particle *-o* by the verb *suru* 'do' as shown in (19):

(19) [<sub>VP</sub> [<sub>VP</sub> [<sub>nP</sub> John Mary-to(-no) aiseki]-*o*            [<sub>nP</sub> su]] *v*]  
           [John Mary-with(-Gen) table-sharing]-Acc       do

We then construct TP (20):

(20) [TP John-ga [[<sub>VP</sub> [<sub>VP</sub> [<sub>nP</sub> *t*John Mary-to(-no) aiseki]-*o*  
           John-Nom                    [<sub>nP</sub> *t*John Mary-with(-Gen) table-sharing]-Acc  
           [<sub>nP</sub> su]] *v*] T]]  
           do

According to the PIC (13), *John*, which is the Spec of *nP*, is accessible from T. *John* moves to the Spec of TP, where it is assigned the nominative case particle *-ga*. Hence, our analysis correctly yields (1), explaining the PF-LF mismatch in argument linking. It should be noted that if *John* were assigned the accusative case particle *-o* in the Spec of VP and *nP* were assigned *-ga* in the Spec of TP, the resultant structure would be (21):

(21) \*[TP [<sub>nP</sub> *t*John Mary-to-no aiseki]-ga            [[<sub>VP</sub> [<sub>VP</sub> John-*o*  
           [<sub>nP</sub> *t*John Mary-with(-Gen) table-sharing]-Nom       John-Acc  
           [<sub>nP</sub> su]] *v*] T]]  
           do

(21) is correctly ruled out by the Proper Binding Condition, because *t*John, the trace of

*John*, is not c-commanded by its antecedent.

The nominal phrases in the light verb constructions are in contrast with ordinary nominal phrases like (22):

- (22) [TP Mary-ga [[vP [VP [nP [NP John-no Amerika-e-no ryokoo]  
 Mary-Nom John-Gen America-to-Gen travel  
 [n]-o [t<sub>nP</sub> kyakkasita ]] v]T]]  
 -Acc turned-down

'Mary turned down John's trip to the United States.'

In (22), the nominal case domain, *i.e.* the accessible domain of *n*, is indicated by the shaded area whereas the clausal case domain, *i.e.* the accessible domain of *v*, is indicated by the closed box. Following Grimshaw (1990), I claim that *John* in (22) is not an external argument but an adjunct; *John* is not in the Spec of *nP* but adjoined to NP. This is supported by the fact that *John* does not have to be Agent. For example, (22) may have the interpretation that Mary turned down the trip to the US which John planned. Unlike *nP* in the light verb construction, the ordinary *nP* in (22) counts as a PF-phase (though it is not a "proposition" and hence does not function as an LF-phase). For PF-phenomena including case marking, therefore, *John* and *Amerika-e* 'America-to' are within the nominal case domain (the shaded area), but not within the clausal case domain (the closed box). They must be assigned the genitive case particle *-no*.

### 3. Consequences

First, the proposed analysis can account for Grimshaw and Mester's (1988) observation that an external argument never receives the genitive case particle *-no* as shown in (23):

- (23) \**John-no* Mary-to-no aiseki-o sita koto-ga nai  
*John-Gen* Mary-with-Gen table-sharing-Acc did fact-Nom Neg  
 'John has never shared a table with Mary.'

Recall that in our analysis, the external argument *John* originates in the Spec of *nP* and thus remains outside the nominal case domain, *i.e.* the accessible domain of *n*, throughout the derivation. Hence, *John* can never be assigned the genitive case particle *-no*.

Second, our analysis can account for the ergativity constraint, which states that a verbal noun in the light verb construction cannot be ergative (see, among others, Miyagawa 1989, Tsujimura 1990, and Kageyama 1991, 1993). For example, the ergative verbal nouns *meityuu* 'strike' and *tootyaku* 'arrival' cannot be assigned the

accusative case particle *-o* as shown below:

- (24) a. \*?Ya-ga mato-ni meityuu-o sita  
 arrow-Nom target-Dat *strike-Acc* did  
 'The arrow hit the target.' (Miyagawa 1989: 659)
- b. \*Ressya-ga Tookyoo-kara tootyaku-o sita  
 train-Nom Tokyo-from *arrival-Acc* did  
 'The train arrived from Tokyo.'

Let us consider (24b) as an example. Under our analysis, the *vP* phase structure of (24b) is (25):

- (25) [<sub>vP</sub> [<sub>VP</sub> [<sub>nP</sub> [<sub>NP</sub> Tookyoo-kara ressyia tootyaku] *n*] *su*] *v*]  
 Tokyo-from train arrival <UA/P> do <UA/P>

It should be noted that since *tootyaku* 'arrival' is an ergative noun, it only assigns its  $\theta$ -role to its internal argument; the surface subject *ressya* 'train' originates within NP as an internal argument in (25). In (25), given that *nP*, *i.e.* the nominal phrase complement of the light verb, is not a PF-phase, there is an overlap between the nominal case domain, *i.e.* the accessible domain of *n* (the shaded area), and the clausal case domain, *i.e.* the accessible domain of *v* (the closed box). According to (16), "case domain fusion" must take place. Given the constraint on "case domain fusion" (17), since *n* is an unaccusative (ergative)/passive type, *v* must also be of the same type. It then follows that *v* in (25) does not have any accusative Case feature; there is no way of assigning the accusative case particle *-o* to the *nP* complement of the light verb; the ergativity constraint follows.

Our analysis can also account for the fact that although zero-place ergative verbal nouns like *jinari* 'underground-rumbling' and *sokobie* 'freezing' cannot be assigned the accusative case particle *-o*, they can be assigned the nominative case particle *-ga* and combined with the light verb *suru* 'do', as shown in (26) (cf. Kageyama 1993: 285):

- (26) a. *Jinari-ga/\*-o* suru  
 underground-rumbling-Nom/\*-Acc do  
 'We hear an underground rumbling.'
- b. *Sokobie-ga/\*-o* suru  
 freezing-Nom/\*-Acc do  
 'It is freezing.'

Let us consider (26a) as an example. Under our analysis, the *vP* phase structure of (26a) is (27):

- (27) [<sub>vP</sub> [<sub>VP</sub> [<sub>nP</sub> [<sub>NP</sub> Jinari ] *n*] *su*] *v*]  
 underground-rumbling <UA/P> do <UA/P>

Since there is an overlap between the nominal case domain and the clausal case domain, "case domain fusion" takes place. Since *n* is of the unaccusative/passive type, *v* must also be of the same type. It follows that *v* in (27) does not have any accusative Case feature; the *nP* complement *jinari* 'underground-rumbling' cannot be assigned the accusative case particle *-o*. We then construct TP (28):

- (28) [TP *Jinari-ga* [[<sub>vP</sub> [<sub>VP</sub> *tnP* *su*] *v*] T]]  
*underground-rumbling-Nom* do

*Jinari* 'underground-rumbling' moves into the Spec of TP, where it is assigned the nominative case particle *-ga*; (26a) follows.

Third, a verbal noun in the light verb construction typically assigns an Agent  $\theta$ -role to its external argument. As pointed out by Kageyama (1993), however, there are cases where a verbal noun assigns an experiencer  $\theta$ -role to its external argument as shown in (29):

- (29) a. *Ikaiyoo-no titi-ga i-no tiryoo/syuzuyutu-o sita*  
*gastric ulcer-Gen father-Nom stomach-Gen treatment/operation-Acc did*  
 'My father, who had been trouble with a gastric ulcer, had treatment/an operation of his stomach.'  
 b. *Kodomo-ga asi-ni kega-o sita*  
*child-Nom leg-Dat injury-Acc did*  
 'The child injured his leg.' (Kageyama 1993: 282)

Under our analysis, since *n* in (29) is of the transitive/experiencer type, the *v* must also be of the same type. Hence, *v* in (29) has the accusative Case feature; the *nP* complement of the light verb is assigned the accusative case particle *-o*. Our analysis can accommodate the light verb construction with an experiencer subject.

Fourth, our analysis can accommodate the fact that among intransitive verbal nouns, unergative verbal nouns like *syokuji* 'meal' and *kooen* 'lecture' can appear in the light verb construction:

- (30) a. *John-ga syokuji-o sita*  
*John-Nom meal-Acc did*  
 'John had a meal.'  
 b. *John-ga kooen-o sita*  
*John-Nom lecture-Acc did*  
 'John gave a lecture.'

Given Chomsky's (1995) assumption that unergatives are hidden transitives, *n* in (30) is of the transitive/experiencer type. It then follows that *v* must be of the same type. Hence, the *nP* complement is correctly assigned the accusative case particle *-o*.

Fifth, as pointed out by Kishimoto (2001), an internal argument in the light verb construction is inside the scope of the quantificational particle *-mo* attached to a verbal noun. Let us first consider (31), where the quantificational particle *-mo* is attached to the complement clause and the matrix verb is in the negative form (Fukui and Sakai 2006: 330):

- (31) a. Taroo-wa Hanako-ni [dare-ga warui]-to-*mo* iwa-*nakat*-ta  
 Taro-Top Hanako-Dat anyone-Nom fault-that-*MO* say-*Neg*-Past  
 Lit. 'Taro did not say to Hanako that anyone was wrong.'
- b. \*Taroo-wa dare-ni [Hanako-g warui]-to-*mo* iwa-*nakat*-ta  
 Taro-Top anyone-Dat Hanako-Nom fault-that-*MO* say-*Neg*-Past  
 Lit. 'Taro did not say to anyone that Hanako was wrong.'

In (31a), the indeterminate pronoun *dare* 'anyone' is inside the complement clause whereas in (31b), it is outside the complement clause. The contrast between (31a) and (31b) shows that the indeterminate pronoun *dare* 'anyone' must be in the scope of both the quantificational particle *-mo* and the negation. Bearing this fact in mind, let us next consider (32):

- (32) a. \*Taroo-wa *dare*-ni hon-*mo* wata-*nakat*-ta  
 Taro-Top *anyone*-Dat book-*MO* hand-*Neg*-Past  
 'Taro did not hand a book to anyone.'
- b. Taroo-wa *dare*-ni soodan-*mo* si-*nakat*-ta  
 Taro-Top *anyone*-Dat consultation-*MO* do-*Neg*-Past  
 'Taro did not consult anyone.' (Kishimoto 2001: 624)

In (32a), where the quantificational particle *-mo* is attached to the direct object *hon* 'book', the indirect object *dare* 'anyone' is not within the scope of *-mo*; (32a) is deviant. In (32b), on the other hand, the quantificational particle *-mo* is attached to the verbal noun *soodan* 'consultation'; the result is acceptable. This indicates that in (32b), although *dare* 'anyone' is not marked by the genitive case particle *-no*, it is inside the scope of the quantificational particle *-mo* attached to the verbal noun. Recall that under our analysis, *dare* 'anyone', which is the internal argument of the verbal noun, stays inside the *nP* complement throughout the derivation as shown in (33):

- (33) John-wa [<sub>nP</sub> *t*<sub>John</sub> *dare*-ni soodan]-*mo* si-*nakat*-ta  
 John-Top *anyone*-Dat consultation-*MO* do-*Neg*-Past

Hence, we can correctly predict that the indeterminate pronoun *dare* 'anyone' is properly licensed within the scope of both the negation and the quantificational particle *-mo*.

Sixth, our analysis can explain the fact that a "bare" verbal noun resists XP operations including topicalization, relativization, clefting, passivization, and

scrambling (see, among others, Grimshaw and Mester 1988, Kageyama 1993, Uchida and Nakayama 1993, Matsumoto 1996, and Saito and Hoshi 2000). Let us consider topicalization as an example (Matsumoto 1996: 114):

- (34) a. John-wa [Tokyoo-ni ryokoo]-o sita  
 John-Top [Tokyo-to trip]-Acc did  
 'John made a trip to Tokyo.'  
 b. \**Ryokoo<sub>i</sub>-wa* John-ga [Tokyoo-ni *e<sub>i</sub>*] sita  
*trip-Top* John-Nom Tokyo-to did

Recall that under our analysis, the internal argument of a verbal noun, even when it is not accompanied by the genitive case particle *-no*, stays within the nominal phrase complement of a light verb throughout a derivation. It follows that (34b) can be ruled out along the same line with (35b):

- (35) a. John-ga [kagaku-no ronbun]-o kaita  
 John-Nom [chemistry-Gen paper]-Acc wrote  
 'John wrote a paper on chemistry.'  
 b. \**Ronbun<sub>i</sub>-wa* John-ga [kagaku-no *t<sub>i</sub>*](*-o*) kaita  
*paper-Top* John-Nom chemistry-Gen(*-Acc*) wrote

Under our analysis, the verbal noun *ryokoo* 'trip' in (34b) is the head of the NP complement of *n* just like *ronbun* 'paper' in (35b); it is an  $X^0$  category. Hence, (34b) and (35b) are both excluded by the fact that topicalization, which is an XP operation, cannot target the head noun, *i.e.* an  $X^0$  category, within a nominal phrase.

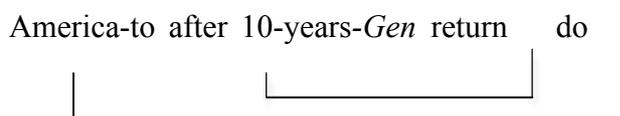

Finally, our analysis can account for the distribution of genitive case marked elements. When there are more than one elements within the nominal phrase complement of a light verb, an element without the genitive case particle *-no* can never intervene between a genitive case marked element and a verbal noun as shown below:

- (36) a. John-ga [amerika-e 10-nen buri-ni kikoku]-o suru rasii  
 John-Nom [America-to after 10-years return]-Acc do seem  
 'It seems that John will return to his country, the United States, after 10 years of absence.'  
 b. John-ga [amerika-e 10-nen buri-*no* kikoku]-o suru rasii  
 John-Nom [America-to after 10-years-*Gen* return]-Acc do seem  
 c. \*John-ga [amerika-e-*no* 10-nen buri-ni kikoku]-o suru rasii  
 John-Nom [Americak-to-*Gen* after 10-years return]-Acc do seem  
 d. John-ga [amerika-e-*no* 10-nen buri-*no* kikoku]-o suru rasii  
 John-Nom [America-to-*Gen* after 10-years-*Gen* return]-Acc do seem

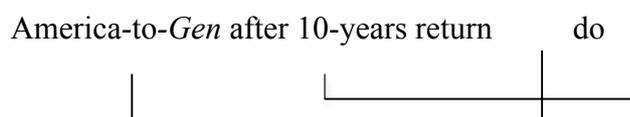

In (36c), *10-nen buri-ni* 'after 10 years', which is not marked by the genitive case

particle *-no*, intervenes between the genitive case marked element *amerika-e-no* 'Amerika-to-Gen' and the verbal noun *kikoku* 'return'; the result is deviant. Recall that under our analysis, the clausal and nominal case domains are defined as the accessible domains of *C/v* and *n*, respectively. I argue that there are dependencies between *C/v* and a clausal case marked (non-genitive case marked) element and between *n* and a nominal case marked (genitive case marked) element. Then, the above distribution can be accounted for by a crossing constraint (see, among others, Fodor 1978 and Pesetsky 1982). The relevant structures of (36b, c) are (37a, b), respectively:

(37) a. ...[[NomP Amerika-e 10-nen buri-*no* kikoku] *n*]] su ] *v*]

b. \*...[[NomP Amerika-e-*no* 10-nen buri kikoku] *n*]] su ] *v*]

Unlike (37a), (37b) violates the crossing constraint; the deviancy of (36c) follows.

#### 4. Conclusion

This paper has dealt with the light verb construction in Japanese, arguing that the nominal phrase complement of a light verb functions only as an LF-phase but not as a PF-phase. It was shown that the proposed analysis straightforwardly accounts for the paradoxical PF-LF mismatch in the light verb construction. I have also argued that the various properties of the light verb construction follow from our analysis. This paper presents evidence for the view of non-simultaneous Transfers, where a syntactic object can be transferred to a single interface during a derivation.

#### Notes:

\*This is a revised version of the paper presented at CIL 18. I would like to thank the audience at the conference for helpful comments and discussions on earlier versions of this paper. Remaining errors and omissions are, of course, the sole responsibility of the author. ## Abstract

By conducting experiments on the acceptability judgments made by a substantial number of native speakers, and statistically analyzing their results, we will attempt to identify multiple factors and their interactions contributing to acceptability judgments. Our goals are, first, to demonstrate how and how much quantitative examination of acceptability judgments can resolve some of the seemingly irreconcilable issues of grammaticality judgments, especially concerning the discrimination between ungrammaticality and unacceptability, and, second, to contribute to the task of data mining in the research conducted by generative syntacticians.

**Keywords:** Acceptability judgments, Japanese causatives, Multivariate statistical analyses, Experimental syntax

## 1. Introduction:

Since its inception, researchers in generative syntax have devoted enormous energies to the elaboration of theoretical concepts and devices, yielding a remarkable progress of the field. Compared to such vigorous pursuit of theoretical sophistication, however, much less attention has been paid to the advancement of research methodology. As a result, some serious problems have arisen concerning the main research tool in this field, namely, an appeal to speakers' introspective judgments based upon their native intuition.

Until fairly recently, virtually no methodology of measuring and assessing acceptability judgment had been developed in the field of generative syntax.<sup>1</sup> As a result, researchers continued to develop theoretical hypotheses based upon mere contrast of the relative unacceptability of sentences. Sentences have often been called ungrammatical (usually in accordance with the prediction made by the researchers' hypotheses) when they are relatively less acceptable than others. This practice has been indicated on example sentences, standardly, with fuzzy, unconstrained use of question marks, where two question marks, for instance, may indicate ungrammaticality on some sentences while they may still indicate grammaticality on others. When discrepancy in judgment arises and researchers disagree about the grammaticality of sentences, it is often ascribed to dialectal/idiolectal variations, usually without much serious investigation of the alleged variations. As a result, researchers' disagreement is often left irreconcilable, leaving behind a state of chaos.

A remedy for this problem often dubbed "experimental syntax," has emerged since the mid-1990s, which emphasizes the importance of precise, formal experimental

- (3) a. <sup>ok</sup>Taroo-ga [IP **kooen-e** kodomo-*o* **ik**] ase-ta.  
 Taro-NOM park-to child-ACC go CAUSE-PAST  
 |-----ok-----|  
 'Taro made his child go to the park.'
- b. <sup>???</sup>Taroo-ga [VP **kooen-e** kodomo<sub>i</sub>-*ni* [IP [e]<sub>i</sub> **ik**] ase]-ta.  
 Taro-NOM park-to child-DAT go CAUSE-PAST  
 |-----x-----|  
 'Taro let his child go to the park.'

(From Miyagawa (1999: 249) including translation and judgments)

The argument here was actually a little more complex. Based upon the claim made in Miyagawa (1996) and Miyagawa (1997), it was assumed that a VP-adjoined position cannot be the final landing site of movement in general and hence that the V-Ajct 'to the park' in (3b) cannot be analyzed as having been moved from the complement clause and adjoined to the matrix VP. Note that such an analysis would have permitted the intended verb modification established within the complement clause. In (3a), on the other hand, movement of the V-Ajct is permitted since it would involve adjunction to the complement IP.<sup>iii</sup> It was also assumed that (3b) "is not completely out due to the fact that there is a focus position above the VP, which is a legitimate landing site for 'to the park.'" (p. 249)

Let us point out here that the ACS-analysis inevitably makes another prediction, although it is not discussed in Miyagawa (1999). When "an adjunct meant to modify the matrix causative predicate *sase* (henceforth C-Ajct)" appears to the right of the *o*-causee at surface, it should be analyzed as being located within the complement, and hence not be permitted to establish the intended modification, as illustrated in (4) below. Two typical examples of C-Ajcts are *kyooseetekini* 'coercively' and *mite-minuhuri-o site* 'pretending not to be watching.'<sup>iv</sup>

- (4) *o*-causative: Causer-ga [IP Causee-*o* C-Ajct V] sase  
 -NOM -ACC | CAUSE  
 |-----x-----|

We will refer to these predictions (inevitably) made by the ACS-analysis as \*[V-Ajct ... *ni*] and \*[*o* ... C-Ajct], respectively.

## 2.2 Discrepancy in judgment:

We now would like to provide a brief summary of our purely linguistic conjectures on the issue raised in the previous section. First, we find it not too difficult to identify counter-examples to the ACS-analysis:

- (5) a. Kooti-wa **hiraoyogi-de** sensyu-tati-*ni* **oyog** aseta  
 coach-TOP breaststroke-in swimmers-DAT swim caused  
 'The coach had the swimmers swim in the breaststroke.'
- b. Kariforunia-syuu-wa subeteno huhoonyuukokusya-*o* **kyooseetekini** kikokus aseta  
 California-state-TOP all illegal.alien-ACC coersively return caused  
 'The State of California forced all illegal aliens to return to their home countries.'

The V-Ajct appearing to the left of the *ni*-causee in (5a) and the C-Ajct appearing to the right of the *o*-causee in (5b) seem to comfortably modify the complement verb and the matrix predicate *sase*, respectively, *with or without the focalization* of these adjuncts. If those speakers who provided the judgment indicated by three question marks on (3b)

(henceforth, the ACS-judgment) find any of the examples in (5) acceptable, that would suggest that the ACS-analysis was proposed prematurely based upon insufficient empirical investigation. If those speakers continue to reject these and similar examples, on the other hand, we do witness variation across speakers that is worthy of further investigation. With the assumption that the latter case indeed arises, we now proceed with our investigation.

### 3. Research questions and experiment

Several important research questions arise at this point. First, does the reported discrepancy in judgment reflect a difference in grammar? Is it, in other words, what is often referred to as dialectal or idiolectal variation in grammar? We are particularly interested in finding out whether or not the ACS-judgment is replicable in a larger-scale examination. Second, if some causative sentences are indeed lower in acceptability than others as claimed in the ACS-analysis, what exactly causes it? And to what extent are they awkward? In particular, are the predictions made by the ACS-analysis supported? To answer these questions, we have conducted an experiment and applied two distinct types of statistical analyses to its results, one theory-driven and the other data-driven.<sup>v</sup>

#### 3.1 Test sentences:

We prepared three different groups of example sentences for our experiment, which we will describe briefly in this subsection.

##### 3.1.1 Pre-test sentences:

First, we created "pre-test" sentences. Each pre-test sentence contained either V-Ajct or C-Ajct in a syntactic construction we labeled as V-frame or C-frame. V-frame refers to a sentence in which a V-Ajct easily succeeds in modifying a verb while a C-Ajct fails. C-frame has the opposite property — a C-Ajct is expected to succeed while a V-Ajct is expected to fail.<sup>vi</sup> The four possible combinations of the two adjunct types and two syntactic frames are exemplified as follows — V-Ajct in V-frame ((6a)), V-Ajct in C-frame ((6b)), C-Ajct in C-frame ((6c)), and C-Ajct in V-frame ((6d)).

- (6) a. *Watasi-wa batahurai-de oyoida.*  
 I-TOP butterfly.stroke-in swam  
 'I swam in the butterfly stroke.'
- b. *#Isya-ga watasi-ni batahurai-de sase-nakat-ta-koto-ga aru.*  
 doctor-NOM I-DAT in.butterfly.stroke CAUS-NEG-PAST-matter-NOM exist  
 'There is something the doctor would never let me do in the butterfly stroke.'
- c. *Sono-isya-ga itumo kanzya-ni kyoosee-teki-ni sase-ru.*  
 that.doctor-NOM always patient-DAT coercively make-PRES  
 koto-ga aru.  
 thing-NOM exist  
 'There is something that doctor always makes his patients do coercively.'
- d. *#Syuzu-yutu-no-yokuzitu sono-kanzya-wa kyoosee-teki-ni ugoki-mawat-ta.*  
 next.day.of.surgery that.patient-TOP coercively moved.around  
 'On the day after the surgery, that patient moved around coercively.'

We used six different adjuncts of each type in these four different combinations, making 24 pre-test sentences in total. Half of these sentences were expected to be accepted and the other half to be rejected.

By conducting a "pre-test" involving these sentences, we examined if the speakers participating in our experiment properly distinguish V-Ajcts and C-Ajcts, and also if the particular adjuncts we adopted can be safely used in the causative sentences we will examine in our main experiment. We examined in this pre-test, in other words, if all of the participating subjects as well as the target materials used in our main experiment can be reliably appealed to.

### 3.1.2 Experimental causative sentences

The causative sentences in our main experiment involved: (i) two types of adjuncts (V-Ajct vs. C-Ajct), (ii) two distinct particles to mark the causee NP (*ni* vs. *o*), and (iii) two distinct locations of an adjunct (to the left vs. right of the causee). With six distinct lexicalization of each adjunct type, we created 48 test sentences in total. (7a-b) exemplify two of the four possible combinations of these conditions — V-Ajct to the left of the *ni*-causee ([V-Ajct ... *ni*]) in (7a) and C-Ajct to the right of the *o*-causee ([*o* ... C-Ajct]) in (7b).

- (7) a. [<sub>Background</sub> Ziyuugata-no kyoogi-nanoni **hiraoyogi-de** sensyu-tati-**ni**  
           free.style-GEN race-despite breaststroke-in swimmers-DAT  
 oyog-aseta-no-wa ] [<sub>Focus</sub> **ANO KOOTI** ]-desu.  
 swim-CAUSED-NZR-TOP that coach-COP  
 'It was that coach who made the swimmers swim in the breaststroke in a free-style race.'
- b. [<sub>Background</sub> Subete-no huhoo-nyuukokusya-o **kyooseetekini**  
           all illegal.alien-ACC coercively  
 kikokus-ase-ta-no-wa ] [<sub>Focus</sub> **KARIFORUNIA-SYUU** ]-desu.  
 return.home-CAUSED-NZR-TOP California-state-COP  
 'It was California that coercively deported all illegal aliens.'

Note here that both adjunct and causee are placed in the background portion in a pseudocleft construction in each example. Since the focus of a sentence shows up in the precopula position, the adjunct or the causee cannot be, or at least is highly discouraged to be, interpreted as a focus. Constructing our test causative sentences in this fashion, we can eliminate a possibility for them to be secretly rescued by the application of a focus movement even when these constructions turn out to be judged highly acceptable by the subjects in our experiment. (Recall the account of the judgment associated with (3b) under the ACS-analysis presented above in Section 2.1.)

### 3.1.3 Filler sentences:

Finally, we also prepared a total of twenty-four filler sentences. They served not only as distractors but also as the stimuli that provide baseline judgments for clearly acceptable or clearly unacceptable sentences. Six of them are grammatical causative sentences (three each of the *ni*- and *o*-causatives) which either do not involve any V- or C-Ajcts at all, or at least do not involve any potential ordering problem between an adjunct and the causee, as exemplified in (8a-b).

- (8) a. Okyaku-**ni** kegas-**ase**-ru-yoodewa ii tokoya-to-wa iemasen.  
 customer-DAT get.injured-CAUSE-such-TOP good barber-that-TOP can't.be.said  
 'Any barber who injures his/her customer cannot be called "a good barber."  
 b. Yooyaku ame-ga agatta-node sotoni detagatteita inu-**o** sanpos-**ase**-ta.  
 at.last rain-NOM stopped-since outside wanted.to.go.out dog-ACC walk-CAUSED  
 'Since it finally stopped raining, I let the dog walk who was eager to go out.'

Eighteen of the fillers are ungrammatical non-causative sentences, as exemplified by (9a-b).

- (9) a. Ima, kodomotati-ga **nidoto ninsikisita**-no-wa, ningen-no yasasii inoti-wa  
 now children-NOM twice realized-NZR-TOP human gentle life-TOP  
 harikitte modotte-konai-to-iu-koto-desu.  
 enthusiastically will.not.return  
 "What the kids have realized now is that gentle human lives will never return again with vigor."  
 b. **Sensyuumatu-ni** doositemo tabe-**tai**-no-wa, **raisyuu** kat-**ta**-bakarino  
 last.weekend-on definitely eat-want-NZR-TOP next.week bought-just  
 puramoderu-o kumitateru-koto-desu.  
 plastic.model-ACC assembling.is  
 'What I definitely would like to eat last weekend is to assemble the plastic model kit that I bought next week.'

The causes of ungrammaticality involved in our filler sentences are varied and sometimes compound. Some involve a problem that is clearly syntactic in nature. Example (9a) involves a negative polarity item *nidoto* 'twice (= (never) ... again)' which remains unlicensed, (9b) involves incompatibility of tense between verbs and adjuncts (*sensyuumatu-ni* ... *tabe-tai* 'want to eat last weekend' and *raisyuu kat-ta* 'bought next week'). Some of them involve improper modification, as illustrated in (10).

- (10) Boku-ga [**teeneeni** hara-o-tateteiru]-no-wa aitu-ga [**hidoku** ayamarooto-sinai] koto  
 I-NOM politely am.angry-NZR-TOP s/he-NOM badly wouldn't.apologize fact

|-----x-----| |-----x-----|  
 'What I am politely angry at is that he wouldn't badly apologize.'

These sentences involve a similar type of improper modification to that which is expected to arise in the ungrammatical pre-test sentences. The same problem is also predicted to arise in the experimental causative sentences when they involve the order [V-Ajct ... *ni*] and [*o* ... C-Ajct] under the ACS-analysis, as in (11).

- (11) x  
 Taroo-ga **kooen-e** kodomo-**ni** [IP [e]<sub>i</sub> **ik**] **ase**-ta.  
 Taro-NOM park-to child-DAT go CAUSE-PAST  
 |-----x-----|

'Taro let his child go to the park.'

The ungrammatical filler sentences as in (10) therefore would provide the base line judgment for 'clearly unacceptable' sentences involving improper modification when we examine the acceptability judgment of pre-test sentences and experimental causative sentences.<sup>vii</sup>

The number of grammatical and ungrammatical fillers in our experiment was not equal. This is because we expected (as discussed in Section 2.2) that many of the experimental causative sentences would not be judged ungrammatical, and it has been

known that experiments with unbalanced design (in grammaticality) may result in judgment instability due to subjects' implicit bias toward counterbalancing their judgments (Snyder (2000), Sprouse (2007)).

### 3.2 Procedure:

All of the test sentences were randomized in order — among the pre-test sentences and among other sentences. Fifty-eight native speakers of Japanese, all college students, ages 18~20, 18 females, 39 males and 1 unidentified, were involved. They participated either as part of a class or were paid for participation. To the best of our knowledge, none of them have received any serious training in linguistics. Both pre-test and main test were conducted on the same day in this order.

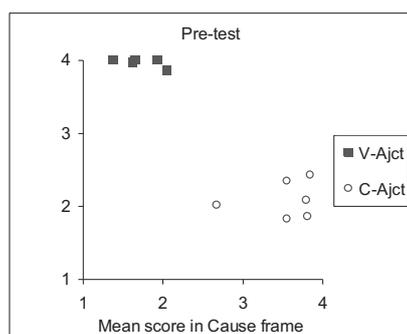

The subjects were asked to judge sentences in silent reading and select one of (a-d) below for each sentence, both in the pre-test and the main test: (a) It is a decent sentence in Japanese, (b) It may not be perfect, but I can admit it as a basically decent sentence in Japanese, (c) We may be able to guess the intention of the sentence if we try, but I do not think the way it is stated is permissible in Japanese, and (d) The way the sentence is stated is never permitted in Japanese, or we can hardly interpret the sentence. We translated each of the subjects' answers provided in the ordinal scale (a~d) into the interval scale (4~1), respectively, 4 being the maximal and 1 being the minimal score.

## 4. Experimental results and discussion:

### 4.1 Adjunct discrimination in the pre-test:

The graph in (12) visualizes the result of the pre-test.

(12) Pre-test results — Mean acceptability of Adjuncts:

Each data point in (12) represents the mean score of each of 12 adjuncts (6 V-Ajcts (■) and 6 C-Ajcts (○)). The horizontal axis shows the score when they are used in a C-frame, while the vertical axis shows the score when they are used in a V-frame. No speaker showed totally opposite or totally inconsistent reactions. Except for one sentence (— See Footnote viii below), the acceptability/ unacceptability of all sentences with all combinations of adjunct types and frames showed the clear tendency in the expected direction — the proper combination leaned toward high scores and the improper combination toward low scores. The pre-test, in other words, was by and large successful in confirming that the majority of the involved speakers distinguish V-Ajcts from C-

Ajcts and can be regarded as reliable Japanese speakers for our experiments. At the same time, this pre-test confirms that those particular adjuncts we have selected can be used safely in our main experiment.<sup>viii</sup>

#### 4.2 *The grammaticality status of causative sentences:*

We first examine the judgment scores in our experiment, i.e., the acceptability range of all 6 distinct types of sentences involved in the pre-test and the main test labeled as follows: **G-fil** = Grammatical filler sentences, **U-fil** = Ungrammatical filler sentences, **U-fil** = Ungrammatical filler sentences, **G-pre** = Pretest sentences expected to be grammatical, **U-pre** = Pretest sentences expected to be ungrammatical, **ni-caus** = Experimental causative sentences with *ni*-causee, **o-caus** = Experimental causative sentences with *o*-causee. Among them, the grammatical filler sentences (G-fil) and ungrammatical filler sentences (U-fil) exhibit a clearly high mean score and low mean score, respectively, and provide us with the baseline judgments in our investigation — **G-fil**: Mean acceptability = 3.79, Standard deviation = 1.001 **U-fil**: Mean acceptability = 1.30, Standard deviation = 1.000. The acceptability range of grammatical pre-test sentences (G-pre) (mean = 3.75) mostly overlaps with that of G-fil. The acceptability range of ungrammatical pre-test sentences (U-pre) (mean = 1.88) is also considerably low although it is slightly higher than that of U-fil. It does not seem to be overly brash, therefore, to state that those sentences that we expected to be deemed grammatical indeed seem to have been judged as grammatical and clearly acceptable, and those sentences expected to be judged ungrammatical as ungrammatical and sufficiently unacceptable.

The experimental causative sentences as a whole exhibited the mean acceptability score of 3.52 and patterned with G-fil and G-pre rather than U-fil and U-pre, although *ni*-causative sentences (*ni*-caus) and *o*-causative sentences (*o*-caus) exhibited some asymmetry — *o*-caus (mean = 3.79) had virtually the same acceptability range as G-fil and G-pre, while *ni*-caus (mean = 3.26) had a somewhat wider distribution. As will be reported and discussed directly below, among the *ni*-caus sentences, those involving the order [V-Ajct ... *ni*] received the lowest mean acceptability score, but even that score was 3.05, which is well into the upper half of the acceptability scale. (We will examine and discuss in Sections 4.3 and 5.2 below the nature and cause of the somewhat lower acceptability exhibited by some of the *ni*-cause sentences.)

Thus, the examination of the acceptability scores in our experiment suggests, first, that G-fil and G-pre clearly make up a group of grammatical sentences (henceforth G-sentences), and U-fil and U-pre, a group of ungrammatical sentences (henceforth U-sentences), and second that all the experimental causative sentences belong to the group of G-sentences rather than U-sentences.

#### 4.3 *Acceptability of causative sentences — ANOVA:*

Despite our impression that all the experimental causative sentences are to be regarded as grammatical, it was also observed that some *ni*-causative sentences are noticeably lower in acceptability than other causative sentences, being located toward the middle of the acceptability scale rather than its high end. Since this observation has potential to go along the prediction \*[V-Ajct ... *ni*] made by the ACS-analysis, it requires further scrutiny.

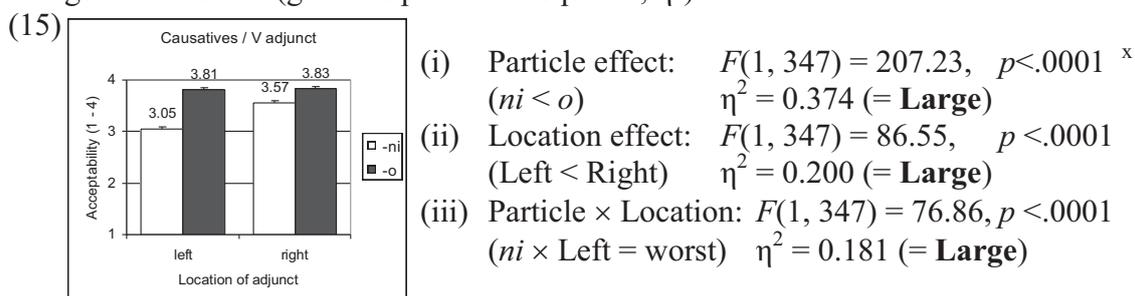

We ran the two-way ANOVA (Analysis of Variance) in order to measure how the acceptability judgments of *ni*- and *o*-causatives were affected by the syntactic conditions listed in (13).

- (13) (i) Difference in adjunct type — V-Ajct vs. C-Ajct  
 (ii) Difference in particle type — *ni* vs. *o*  
 (iii) Difference in the location of adjuncts — to the left vs. right of the causee  
 (iv) The interaction of (i)-(iii)

We conducted the analysis for V-Ajcts and C-Ajcts separately, with the obtained acceptability scores 4~1 as dependent variables and the conditions (13 ii) and (13 iii) as independent variables. In each set of four sentences we compared, we used one and the same adjunct, with the only difference among the sentences being the conditions (13 ii) and (13 iii). We therefore carried out ANOVA of repeated measures with conditions (13 ii) and (13 iii) as within-subject factors. The chart in (14) summarizes the conditions involved in the 2-way ANOVA conducted for the V-Ajct test.

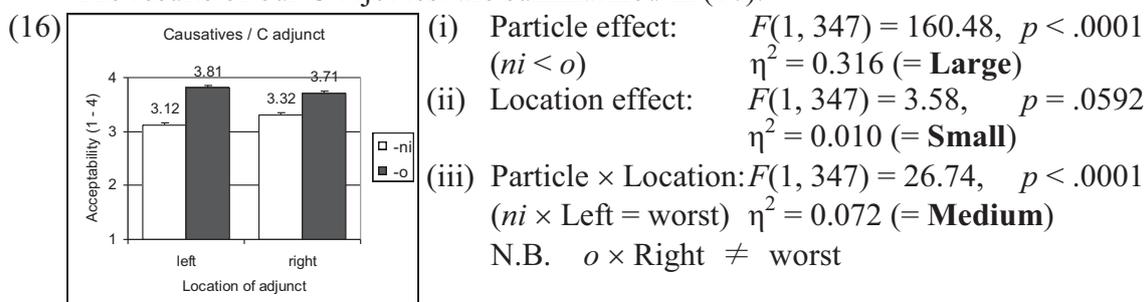

(14) V-Ajct Test		Location	
		(A) Left	(B) Right
Particle	(i) <i>o</i>	V-Ajct ... <i>o</i>	<i>o</i> ... V-Ajct
	(ii) <i>ni</i>	V-Ajct ... <i>ni</i>	<i>ni</i> ... V-Ajct

As summarized in (15), the main effect of locations, that of particles, and the interaction of locations and particles can be observed, all with statistical significance ( $p < .0001$ ) and a large "effect size." (given as partial eta-squared,  $\eta^2$ ).<sup>ix</sup>

Among these results, the interaction ( $ni \times$  Left) inducing the lowering of acceptability strikes us as a phenomenon in line with one of the predictions made by the ACS-analysis, namely, \*[V-Ajct ... *ni*]. It therefore gives us the impression that our experimental result supports the ACS-analysis. When we extend our investigation to the analysis of the C-Ajct test, however, this initial impression proves to be wrong.

The results of our C-Ajct test are summarized in (16).

Here, a significant main effect of particles ( $ni < o$ ) similar to that we saw in the V-Ajct test is observed ( $p < .0001$ ) while no significant location effect is observed ( $p = .059$ ). Even more important and crucial to us is that we do find the statistically significant

interaction (particle  $\times$  location,  $p < .001$ ), which lowers acceptability in [Ajct ... *ni*], not only in the V-Ajct test but also in the C-Ajct test, contrary to what is expected in the ACS-analysis. Recall that the ACS-analysis predicts the ungrammaticality of [V-Ajct ... *ni*] but not that of [C-Ajct ... *ni*], which should be permitted as illustrated in (17).

(17) *ni*-causative: Causer-ga C-Ajct Causee-*ni* [IP [e]<sub>i</sub> V] sase  
 -NOM | -DAT CAUSE  
 |-----ok-----|

Finally, and again crucially, the "particle  $\times$  location" interaction obviously does not lower acceptability in the case of "*o*  $\times$  Right."

To sum up the results of our ANOVA in (15) and (16), we have observed the following: (a) "*ni*  $<$  *o*" holds for both V-Ajcts and C-Ajcts, whether they are located on the left or right of the causee, (b) "Left  $<$  Right" holds for V-Ajcts for both *ni* and *o*, (c) "*ni*  $\times$  Left" is least acceptable not only with V-Ajcts but also with C-Ajcts, and (d) "*o*  $\times$  Right" for C-Ajcts is highly acceptable. None of these are predicated by the ACS-analysis, and (d) directly contradicts with it. The observations in (a-c) suggest that [V-Ajct ... *ni*] is the lowest in acceptability, first, because there generally are less number of *ni*-causative sentences that are effortlessly accepted than *o*-causative sentences, and second, because V-Ajcts are in general less comfortably used when they appear to the left of a causee rather than to their right, and finally because their effects are most robust when they interact with each other.

To sum up our investigation in Sections 4.2 and 4.3 so far, it is claimed in the ACS-analysis that causative sentences are ungrammatical and sharply rejected in all and only cases in which a specific type of adjunct and a specific causee-marking particle appear in a specific relative order, but neither of such predictions (\*[V-Ajct ... *ni*] and \*[*o* ... C-Ajct]) is supported, its expected results not having been replicated in a larger scale experiment we conducted. Thus, we are led to our interim conclusion that the ACS-analysis as a grammatical hypothesis cannot be sustained, at least based upon the behavior of adjuncts.

One question that remains is what are the sources of the two main effects ("*ni*  $<$  *o*" and "Left  $<$  Right") of ANOVA observed above. Let us briefly speculate on them based upon what we know about Japanese syntax. There is good reason to believe that the first main effect "*ni*  $<$  *o*" is induced by the extra pragmatic restrictions imposed on the *ni*-causative. It has long been noted by many researchers that the *ni*-causative tends to be more severely restrained pragmatically than the *o*-causative. Kuroda (1965), for instance, proposed the condition that the causer must assume that the *ni*-causee must be willing or has consent to do the action being caused, while the causer is indifferent or disregards such factors for the *o*-causative. Whether this or other proposed conditions ultimately survive against strictest empirical tests aside (cf. (8)), they collectively demonstrate the repeated efforts by Japanese syntacticians, who have long noted and craved to depict the asymmetry between the *ni*- and *o*-causatives concerning their pragmatic restrictedness. We find this to be a good circumstantial evidence that the asymmetry "*ni*  $<$  *o*" is induced by some "extra" pragmatic restrictions imposed on the *ni*-causatives. The wider distribution of *ni*-caus than *o*-caus mentioned in Section 4.2 above is also well in accordance with the variation and fluctuation that pragmatic factors are known to exhibit when they influence the interpretation of sentences. (Kitagawa and Yoshida (2008) discusses the possible source of the location main effect "Left  $<$  Right.")

## 5. Subgroups of sentences and speakers — Factor Analysis:

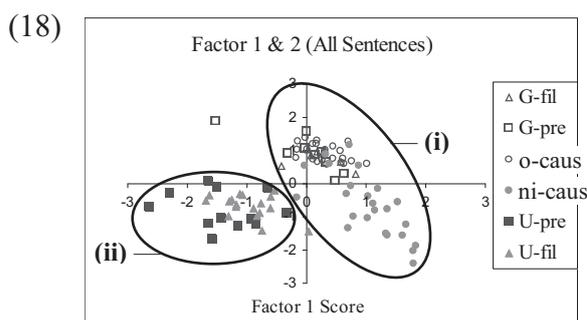

While our investigation in the previous section led us to reject the ACS-analysis, the fact remains that some variation across speakers has been observed as to the acceptability judgment of the causative sentences in Japanese (cf. Section 2.2). The next questions we would like to answer therefore is how exactly such variation arose. We are interested in discovering in particular if there are any structured properties involved in the variation.

Typically, the experimental approach to speakers' variation thus far has treated acceptability judgment as a function of the language users' grammaticality judgment, appealing only to a unidimensional scale going from low to high. We have, on the other hand, decided in this work to treat acceptability judgment as the amalgam of multidimensional factors, adopting the hypothesis that the variation across speakers is caused by the linear combination of such multiple factors. In pursuit of this idea, we re-examined all the data obtained in our experiments, applying Factor Analysis. Factor analysis is a procedure that is used to seek a set of latent factors that cannot be directly observed from multivariate observations. In our case, it explored possible latent factors underlying the speakers' judgments based upon the data set consisting of acceptability judgments (4 ~ 1) of all 96 sentences and those of all 58 speakers in our experiments.<sup>xi</sup> Appealing to this multivariate statistical method, we compared the patterns of acceptability responses concerning distinct sentence types by each speaker in the hope that it would allow us to investigate: (i) if the speakers participated in our experiment are divided into any subgroups, and if so, (ii) whether there is any "structure" or "dimension" within their acceptability patterns.

Because the number of sentences is larger than that of speakers in our experiment, we put the speakers in columns and the sentences in rows in the data set for our factor analysis. (See Section 6 below.) In this analysis, three factors were extracted which explained the three largest proportions of variance in the data.<sup>xii</sup> In accordance with the load of these three factors (to be called Factors 1-3), the speakers could be divided into three subgroups (Groups 1-3). Group 1 consists of those speakers with high Factor 1 load (32 speakers), Group 2 with high Factor 2 load (19 speakers), and Group 3 with high Factor 3 load (7 speakers). Our task now is to find out the identity of these latent factors which explain the partition of the speakers — and the partition of sentences, as we will see below. (Kitagawa and Yoshida (2008) examine if the subgrouping of speakers by the factor analysis here reflects the variation in regional dialects, and dismisses that possibility.)

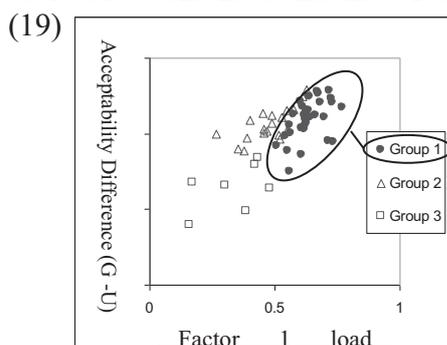

### 5.1 *The first dimension of acceptability — Factor 1:*

In pursuit of the identity of Factors 1-3, we performed several correlation analyses, starting with the examination of the factor score of all the experimental sentences. Although this perhaps deviates from the common practice, we believe that it helps us elucidate what is implied in the data. Factor 1 splits sentences into two separate subgroups (i) and (ii) indicated in (18) below, in which all the sentences were plotted with the Factor 1 score (i.e., the size of the influence of Factor 1 on sentences) indicated on the horizontal axis and the Factor 2 score on the vertical one.

Roughly, we observe here the following sub-grouping.<sup>xiii</sup> The group (i), which basically has the positive Factor 1 load, consists of G-fil, G-pre and all *ni-* and *o-caus* sentences. Note that all of these sentences can be identified as G-sentences, as pointed out in Section 4.2. The group (ii), which has negative Factor 1 load, on the other hand, consists of U-fil and U-pre sentences, i.e., U-sentences.

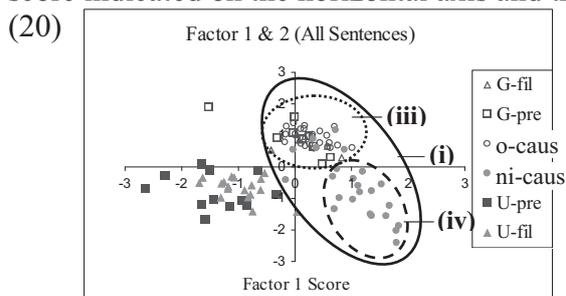

Recall here that the speakers were divided into three subgroups (Groups 1-3) in accordance with the load of Factors 1-3. In (19) below, all these speakers are plotted with Factor 1 load on the horizontal axis and the difference between the mean acceptability score of G-sentences and that of U-sentences (G - U) on the vertical axis.

What we can observe here is the correlation that the higher the Factor 1 load of a speaker is, the more clearly she distinguishes grammatical sentences from ungrammatical sentences. When we put together these observations on both sentences and speakers, we find it reasonable to identify Factor 1 as representing clear discrimination of grammaticality and ungrammaticality.

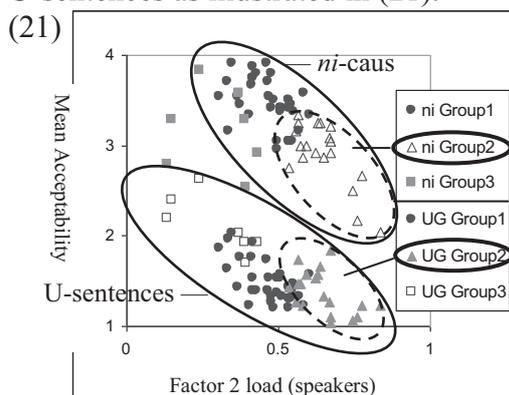

### 5.2 The second dimension of acceptability — Factor 2:

Factor 2 splits G-sentences (i) into two separate subgroups (iii) and (iv), as indicated in (20) below ( $\approx$  (18)), in which all the sentences were plotted with the Factor 1 score indicated on the horizontal axis and the Factor 2 score on the vertical one.

Here, we observe the following sub-grouping. The subgroup (iii), which has the positive Factor 2 load, consists of G-fil, G-pre, all *o*-caus sentences together with those *ni*-caus sentences with high acceptability (5/24 of *ni*-caus, mean acceptability scores 3.47~3.84). The subgroup (iv), which has the negative Factor 2 load, on the other hand, consists of those *ni*-caus sentences with lower acceptability (18/24 of *ni*-caus, mean acceptability scores 2.94~3.78). Factor 2, in other words, splits grammatical sentences into two groups — a subgroup consisting of sentences with relatively higher acceptability and one consisting of those with relatively lower acceptability.<sup>xiv</sup>

Turning now to the factor load of the speakers, we can also find out how Factor 2 characterizes speakers when we examine the way speakers judge *ni*-caus sentences and U-sentences as illustrated in (21).

Here, all the speakers are plotted in accordance with their judgment of *ni*-caus sentences (upper half) and U-sentences (lower half). The Factor 2 load is indicated on the horizontal axis and the mean acceptability score of these sentences provided by the speakers on the vertical one. Note first that, with respect to the judgment of the *ni*-caus sentences, the Group 2 speakers ( $\Delta$ ) show up in (21) not only toward the right end, reflecting their high Factor 2 load, but also toward its bottom, indicating that they have a tendency to judge these sentences notably lower in acceptability compared to other speakers. We can observe here, in other words, the correlation that the higher the Factor 2 load of a speaker is, the lower she judges the *ni*-causative sentences.<sup>xv</sup>

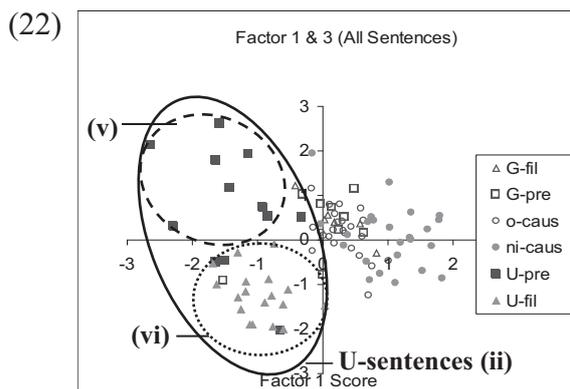

What is interesting and important is that Factor 2 is also correlated with the speakers' judgment of U-sentences in (21) — the higher the Factor 2 load of a speaker is, the lower she judges the U-sentences. Note also that even the Group 2 speakers rate the *ni*-caus sentences much higher than the U-sentences. Crucially, in other words, *this Factor 2 effect cuts across and hence is independent of grammaticality.*

Recall here what we reported in Section 4.2 above — some of the *ni*-caus sentences tend to be deemed somewhat less acceptable than other *ni*-caus sentences and the *o*-caus sentences, which we ascribed to the pragmatic restrictions more severely imposed on the *ni*-caus in general. Moreover, with our analysis of sentences in terms of Factor 1 and 2 scores in (20), we have observed that such "less acceptable" *ni*-caus sentences with the low Factor 2 score make up their own subgroup (iv) within the G-sentence group (i). When we put together all these observations on sentences and speakers, we find it reasonable to identify Factor 2 as representing susceptibility to extra-grammatical influence which degrades acceptability of sentences. We also note that the sentence groups (i) and (ii) (G-sentences vs. U-sentences) in (18) are rather clearly split while the groups (iii) and (iv) in (20) overlap in the type of membership, and make up a continuum.

This asymmetry comfortably corresponds to the traditional view of the asymmetry between grammaticality contrast ("all or nothing") and extra-grammatical deviance of sentences ("gradual degrading").

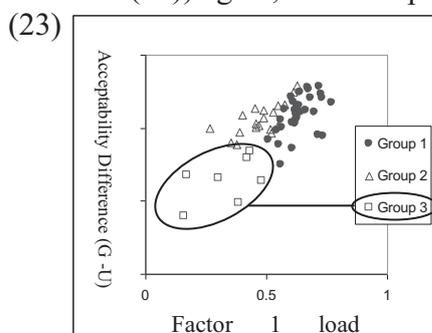

### 5.3 The third dimension of acceptability — Factor 3:

Factor 3 splits U-sentences (ii) (see (18) above) into two subgroups (v) and (vi) as in (22) below, in which all the sentences were plotted with the Factor 1 score indicated on the horizontal axis and the Factor 3 score on the vertical one.

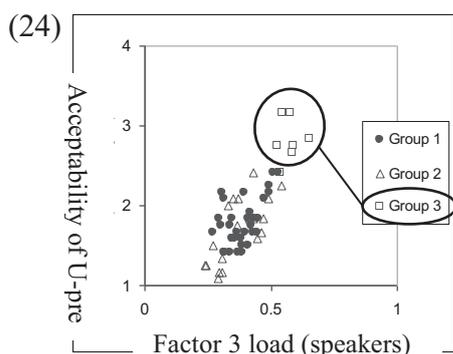

Here, we observe the following sub-grouping of U-sentences. The group (v), which has the positive Factor 3 load, consists most of the U-pre sentences, while the group (vi), which has the negative Factor 3 load, consists of all U-fil and a few U-re sentences.

We can learn how Factor 3 characterizes speakers when we examine (19) (repeated below as (23)) again, this time paying attention to the Group 3 speakers.<sup>xvi</sup>

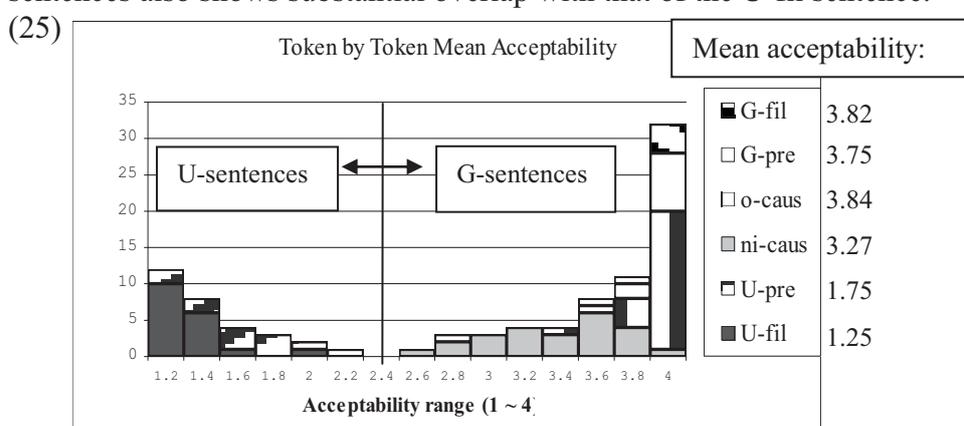

We can see here that the Groups 3 speakers, who are characterized by their high Factor 3, appear toward the bottom of the graph, indicating that they do not distinguish G-sentences and U-sentences as clearly as the other (Groups 1 and 2) speakers.

We can identify the partial cause of this tendency of the Group 3 speakers when we examine the judgment patterns of U-pre sentences by the speakers in terms of Factor 3, as in (24) below. Here, all the speakers were plotted with the Factor 3 load indicated on the horizontal axis and the mean acceptability score they assigned to U-pre sentences on the vertical one.

In (24), we find the Groups 3 speakers toward the right-top of the graph, which indicates that the higher the Factor 3 score of a speaker is, the higher she rates the U-pre sentences. The mean acceptability scores of U-pre sentences by the Group 3 speakers in fact ranged from 2.42 to as high as 3.17, the score well within the range of grammatical sentences. The Group 3 speakers, in other words, did not rule out some of the U-pre sentences, which were regarded as ungrammatical by the Groups 1 and Group 2 speakers (scores range from 1.08 to 2.42). This suggests that the Group 3 speakers were unable to rule out improper use of V-Ajcts and C-Ajcts, which was to play a crucial role in our main experiment to identify ungrammatical causative sentences, and thus failed to pass our pre-test. Based upon this observation, we have decided to regard the Group 3 speakers as unreliable subjects for our main experiment and to eliminate their judgments from our consideration. In the histogram (25) below, from which the judgments by the Group 3 speakers have been excluded, the split between G-sentences and U-sentences shows clear bimodal distribution (delimited at both ends). The acceptability range of the U-pre sentences also shows substantial overlap with that of the U-fil sentence.

When we revise the results of ANOVA in (15) and (16) excluding the judgment by the Group 3 speakers, the contrast between Group 1 and Group 2 as well as the nature of this contrast we discussed in Section 5.2 comes to be even more clearly illustrated as follows. First, the *ni*-causatives are more sharply degraded irrespective of the location of the adjunct for Group 2 than Group 1 for both V-Ajcts and C-Ajcts. Nonetheless, the mean acceptability judgments provided by the Group 1 and 2 speakers combined are well within the range of grammaticality for all cases including 3.07 for [V-Ajct ... *ni*] and 3.75 for [*o*... C-Ajct].

To sum up the results of our factor analysis, we have identified three major subgroups of speakers in our experiment characterized as follows. The Group 1 and 2

speakers provided clear grammaticality judgment. Among them, the Groups 2 speakers were more susceptible to extra-grammatical degrading of sentences (e.g., the severe pragmatic restrictions on the *ni*-causatives) than the Group 1 speakers. Finally, the Group 3 speakers did not provide clear grammaticality judgment, and failed to pass our pre-test. One important result of our factor analysis is that while these subgroups of speakers can be identified, there does not seem to exist any factor characterizing their distinction as stemming from distinct grammars.

## 6. Some methodological issues:

One methodological issue that may arise in our work is the use of the ordinal 4-point scale in our experiment. One obvious alternative approach would have been to use a similar scale with more degrees like a 5- or 7-point scale, which are popular in experimental syntax. We can imagine that the use of a finer ordinal scale may excite more insights into finer extra-grammatical influences in minute difference in acceptability judgment. It is harder to imagine, however, that it would lead us to the conclusion contrary to ours concerning grammaticality distinction of our causative sentences. There may in fact exist some advantage in adopting a 4-point scale, which does not have a middle point. Although the middle point of acceptability is theoretically conceivable, the literature reports a study which suggests its potential problem. Oda (1970) (as cited by Kamahara, et al. (1998: 17)) reports an experiment in which a choice intended to be middle in the scale like "neither ... nor" actually came below another choice intended to be lower in that scale like "not very ..." when the subjects' subjective intervals among various types of choices in a 5-point scale were measured. The middle point in a scale, in other words, may not necessarily behave as 'middle.' The choice we could have adopted as the middle point of the scale like "neither legitimate nor illegitimate as a sentence in Japanese," or "not sure whether this is a legitimate Japanese sentence or not" therefore may have fallen into this problem. Thus, our use of a 4-point scale may actually have been felicitous even if it was somewhat coarse and may have failed to catch some finer extra-grammatical factors influencing acceptability judgment.

Another possible approach would involve an appeal to magnitude estimation (ME), as advocated by Bard, et al. (1996), Cowart (1997) and Sprouse (2007), among others. At this point, however, we are not ready to appeal to this method, partly due to our inexperience in this method, and partly because there seem to exist several unresolved issues on ME which make us hesitate to dive in. One question that remains to be unanswered for us is the acceptability of what exact phenomenon involved in what type of sentence we should adopt as the reference point. Should it be a perfectly acceptable sentence, acutely rejected sentence (for what reason), or somewhere in between? Unlike most psychophysical measures, in which a meaningful 0 point or perfectly stable intervals in the scale can be independently and physically defined, we have no such perfectly reliable reference point in dealing with acceptability judgment. Even if we regard the acceptability judgment of some specific sentence as 100 (or 0, or whatever) in the scale and call it the reference, what must be sought from our subjects in the experiment still is relative acceptability difference from this arbitrary anchor, which may not be guaranteed to make up truly stable intervals. Determination of a reliable reference

therefore seems to remain to be an unresolved issue. See also Sprouse (2007) for relevant discussion on the advantages and potential problems of ME.

Another possible technical issue involved in our work is the ratio of speakers to sentences involved in our factor analysis. Generally speaking, an ideal ratio for the item (number of observation) against category (number of variables examined) is more than 2. In our case, it was about 1.66 (96 sentences divided by 58 speakers). We are, however, still comfortable with maintaining our discussion and conclusions in Section 5 intact, since, first, the results of our factor analysis came out so clear and were well in harmony with the results of our ANOVA as well as what we know of Japanese causative sentences in general, and second, the essence of its results was replicated also in the cluster analysis (Kitagawa and Yoshida (2008)).

## 7. Summary and conclusions:

We conducted two different types of statistical analysis of experimental results, combining them with our knowledge on Japanese linguistics. First, the results of ANOVA confirmed that one result of the "particle  $\times$  location" interaction, i.e., "*ni*  $\times$  Left" lowers acceptability not only for V-Ajcts but also for C-Ajcts, and that "*o*  $\times$  Right" does not lower acceptability for C-Ajcts. Combining these results with the sufficiently high mean acceptability scores of the causative sentences (3.07 for [V-Ajct ... *ni*] and 3.75 for [*o*... C-Ajct]), we confidently concluded that neither of the predictions made by the ACS-analysis \*[V-Ajct ... *ni*] and \*[*o* ... C-Ajct] are sustained.

Multivariate analysis of the acceptability judgment by Factor Analysis also allowed us to confirm that while some speakers (identified as Group 2 speakers) report somewhat lower acceptability of some *ni*-causative sentences, they do in fact judge them as "grammatical sentences with somewhat lowered acceptability" and clearly distinguish them from ungrammatical sentences. Based upon the results of our ANOVA and factor analysis, we concluded that the ACS-analysis should be rejected as a hypothesis which was constructed based upon the confusion between ungrammaticality and "grammaticality with lowered acceptability." One possible explanation is that all of the informants consulted in the construction of this hypothesis were the speakers who belong to Group 2.<sup>xvii</sup> We believe that this case study clearly demonstrates how dangerous it can be for generative syntacticians to construct a theoretical hypothesis based upon the grammaticality determination relying solely on the mere acceptability difference of sentences, especially when the involved judgments are subtle.

Through the research presented in this work, we hope to have shown that experiments conducted on a substantial number of native speakers and the statistical scrutiny of its internal structure (or dimensions) can be highly informative and useful in identifying the nature of sentences as well as informants in the generative syntactic study. We believe that such an approach has potential to resolve controversy over acceptability judgments, making explicit the distinction between ungrammaticality and "grammaticality with lowered acceptability," and proves to be useful especially when the validity of syntactic analyses rests on the acceptability judgments disagreed among researchers.

We consider it particularly effective to appeal to two different types of statistical analyses, combining them with careful linguistic considerations — *theory-driven*

*analyses* like ANOVA to evaluate the validity of specific grammatical hypotheses, and *theory-neutral analyses* like factor analysis to investigate into the nature of variation across linguistic expressions and their users. We believe that incorporating such a fine-grained experimental approach into our research will also be highly beneficial for the purpose of data mining.

## Notes

\* *Acknowledgments*: This is a somewhat shortened version of Kitagawa and Yoshida (2008). We are grateful to: Katsuo Tamaoka for his useful advice on statistical issues, Leslie Gabriele for reading the entire draft and providing us with invaluable comments, and Yuki Hirose for providing experimental resources. We are also grateful to the participants of *WPSI III*, *CIL 18* and *the Workshop on Syntactic Research and Acceptability Judgment* at Reitaku University. The usual disclaimer applies. This paper is based upon work supported by the National Science Foundation under Grant No. BCS-0650415.

<sup>i</sup> See Schütze (1996) and Cowart (1997), for some general critique of this tradition. See also Bard, et al. (1996) and Sprouse (2007), among others, for a proposal for an experimental approach involving some specific statistical method.

<sup>ii</sup> Another serious problem that needs to be resolved is how grammatical and extra-grammatical (or syntactic and extra-syntactic) causes of unacceptability can be properly distinguished so that we can distill the native intuition directly reflecting grammaticality from enormously heterogeneous acceptability judgments. See Kitagawa (2005) for a case study on Japanese syntax in pursuit of this issue. See also Wasow and Arnold (2005) for much relevant discussion on all of the major issues mentioned above.

<sup>iii</sup> Alternatively, we may consider that the V-Ajct in (3a) was base-generated at its surface position within VP.

<sup>iv</sup> The labeling V-Ajct and C-Ajct are not intended to indicate any categorial distinction. Since the causative predicate *sase* is a verb, what we label as C-Ajcts do modify verbs. They can perhaps modify even non-causative verbs if one succeeds in imagining appropriate contexts. We are using these two labels simply to indicate that the particular adjuncts involved in our particular examples are highly attuned to strictly modify the complement non-causative verbs and the matrix causative verb, respectively, while the opposite type of modification seems difficult without special effort.

<sup>v</sup> We would like to make it clear here that we have taken up the ACS-analysis merely as a test case, whose shutdown is not our primary goal. As stated in the introduction, our goal is to propose and argue for what we believe is a reliable and commendable research method in generative syntax.

<sup>vi</sup> These expectations hold with respect to the particular sentences we created.

<sup>vii</sup> One issue that we will not pursue in this work is whether the ungrammaticality caused by improper modification as in (10) (and (11a-b) according to the ACS-analysis) should be regarded as a purely semantic problem or it should be regarded as inducing a problem in syntax as well. The latter situation, for instance, may arise when the adjunct appearing in a sentence fails to find an appropriate item to modify and remains uninterpreted and

illegible at the interface, thereby failing to satisfy the Principle of Full Interpretation (Chomsky (1986), Chomsky (1995)).

<sup>viii</sup> One supposedly acceptable example involving a C-Ajct in a C-frame below showed poor performance, though it was still deemed basically acceptable (mean = 2.672):

- (i) Kokoro-yasasii taityoo-ga watasi-*ni* mite-minu-huri-o-site  
kind-hearted commander-nom I-DAT pretending.not.to.notice  
sase-te-kure-ta koto-ga-aru  
let there.is.something

'There is something the commander let me do, pretending not to have noticed.'

The following are some possible causes we can think of. It was the very first example the speakers encountered in the pre-test, and hence they may have been yet to figure out the task and yet to adjust the standard for their judgments. Besides, (i) contains the C-Ajct *mite-minu-huri-o-suru* 'pretend not to notice/close one's eyes,' which may have been somewhat unfamiliar to the young subjects (ave. = 18.8 years old) involved. It probably did not help that the sentence required them to imagine a mentality typical in the (old-fashioned) military, which they are totally unfamiliar with and may even have a hard time imagining. This problem in fact did not arise in the antecedent pilot study, which involved subjects who were somewhat older (ave. = 30.8 years old). We will treat this example as an outlier and exclude it from our analysis below.

<sup>ix</sup> Here we adapt Cohen's Convention to evaluate the effect size for partial eta-squared ( $\eta^2$ ):  $< .14$  = Large,  $< .06$  = Medium,  $< .01$  = Small (Aron, et al. (2006: 422))

<sup>x</sup> Some of the actual p-values are in fact smaller than indicated. However, we rounded them up to 4 decimals to avoid long numbers, and because practically there is no great difference when p-value gets very small. Readers can refer to the effect size ( $\eta^2$ ) to appreciate the difference in the effect of factors.

<sup>xi</sup> As for the internal consistency of the judgments from 58 subjects, we checked Cronbach's Alpha, which was very high (.993). We chose Unweighted Least Square Method with Varimax Rotation with Kaiser Normalization. With the general cutoff criterion of 'eigenvalues  $> 1.0$ ', three factors were extracted, with total variance explained by the three factors ( $R^2$ ) as .766, i.e., about 77% of the total variance within the data.

<sup>xii</sup> % of variance explained was: Factor 1  $\approx 31.8$ , Factor 2  $\approx 27.5$ , Factor 3  $\approx 17.4$ .

<sup>xiii</sup> The analysis below was performed excluding two outliers, the G-pre in the left upper end (mean = 2.67) and the *ni-caus* near sentence group (ii) (mean = 3.64). The former is the very first example presented in the experiment, which we discussed in Footnote viii above. At this point, we have no explanation to offer as to why the latter deviated from the trend of other *ni-caus* sentences.

<sup>xiv</sup> Factor 2 and the acceptability score of the *ni-cause* exhibit high correlation ( $r = .634$ ) in (iv), but no correlation ( $r = .057$ ) in (iii).

<sup>xv</sup> The mean acceptability of *ni-caus* in (iii) of

(20) is "3.66" for Group 1, "3.59" for Group 2, and "3.58" for all three groups. In (iv), it is "3.43" for Group 1 and "3.15" for all three groups, while it comes down to as low as "2.69" for Group 2.

<sup>xvi</sup> This graph excludes two sentences as outliers. See Footnote xiii above.

<sup>xvii</sup> We could consider that what is involved here is a type of idiolectal variation which concerns the speakers' susceptibility to extra-grammatical influence rather than their grammar.

## **Abstract**

This paper concerns ideologies underlying practises relating to curriculum planning, management and the hiring of teachers to be found in ELT in East and Southeast Asia – and the denaturalisation of such ideologies through parody. Specifically, the paper argues that parody and parodic insights are useful in exposing and denaturalising embedded ideologies. The paper provides examples of how this can be done – through the use of parodies of lectures, ELT job advertisements among other texts. It gives some attention to ELT in East and Southeast Asia which provide the background setting to most of the parodies but the ideas of language, ideology and power and how these come to bear on ELT are generalisable in other contexts.

**Keywords:** language, ideology, power, deconstruction

## **1. Introduction**

### *1.1. The Call to Unmask*

This paper owes its form to several sources of inspiration. First is the author's real life experience of engaging ideological pressures that often come to bear on non-native English teachers in East and Southeast Asia, be these from the way ELT jobs are advertised to the palpable inequalities in power relations among third world development workers engaged in ELT projects from native and non-native speaking backgrounds. Second is that not too long ago, an email from a noted academic in the area of language, ideology and power relations observed that it was important to "unmask, unmask and unmask" embedded ideologies in ELT. This particular email has inspired the 'unmasking' work in this paper as has the paper "Local Creativity in the Face of Global Domination: Insights of Bakhtin for Teaching English for Dialogic Communication" (Lin & Luk 2004). It was, in particular, the way Lin and Luk look at parody as a powerful and practicable way to provide language learners a creative (and sometimes) subversive voice to express their thoughts, that set me thinking about how parody can also be effectively deployed elsewhere in ELT. Another source of inspiration were the subversive glosses found in student marginalia captured in Canagarajah (1999). Discussing marginalia in students' textbooks, Canagarajah (1999:93) describes how "discursive data from the margins of the textbook" capture "everyday manifestations of...oppositional behaviour in the classroom." Capturing student cheek, parody and subversion, Canagarajah has this to say: "By communicating through secretive whispers, exchanging notes and messages among themselves,

deviating from the classroom agenda, and cheating the teacher, students enjoy a secret community life and a dimension of curriculum and culture that means a lot to them.” (Canagarajah 1999:93).

In this paper, I look at parody as a way to subvert and unmask embedded ideologies in Asian ELT and hopefully capture the experience of teachers and students vis-a-vis the excesses of ideologically laden encumbrances that have existed in the industry for this long.

The ELT enterprise is a hugely monied industry capitalising often on the many faces of global and regional development aid, the socio-historic winds of old and new imperialism and agendas as well as intricate systems of cronyship and power mongering. The parodies included here are an inroad into ideological deconstruction and in heightened awareness-raising – awareness of the way ideology chooses to talk and write, and awareness of the way ideology chooses to operate in ELT both in Asia and beyond.

### *1.2. Contention and Contestation*

It need not be said that ELT already embroils itself in many areas of contention and contestation where much is to be lost and won, whether it be in terms of language ecology (and consequently survival), social-politico-cultural influence, money and/or intellectual turf. Indeed, no apologies need to be made for violations of innocence when young language teachers-in-training in their first semester of a course in language and society or sociolinguistics are told that ELT is not just about language teaching and its prescribed panaceas for helping students master the language, including some more ardently touted ones like CLT (which in itself is ideological). Least of all, the language concerned here is one that had its origins many miles and eons removed from present day Asia (or many other ESL, EFL and ESOL bazaars for that matter). All a bona fide first-year tutor in any sociolinguistics related course needs to do is to pose some simple questions to her class of pre-service trainees about where this particular language originated and how it managed to slither its way (language spread) to Asia. Group work seems the best for this because the correct answers are not that obscure or beyond teacher trainees who need but to be given a chance to voice them. Some prompts may still be needed with some but this too depends on the extent of hegemonic infiltration in their situation (Toh 2003a).

## **2. Literature Review**

### *2.1 Ideology*

J. B. Thompson provides a useful definition of ideology. Ideology refers to “ways in which meaning (or signification) serves to sustain relations of domination” (Thompson 1987:519). He points out that relations of domination are a form of power relations where “particular agents or groups are institutionally endowed with power in a way which excludes, and to some significant degree remains inaccessible to, other agents or groups” (Thompson 1987:519). Domination results in power relations that are what he calls, “asymmetrical” (Thompson 1987:519). Two other definitions of ideology are also useful: ideology consists of “ideas which help legitimate a

dominant political power” (Eagleton 1991:1) and ideology is “the indispensable medium in which individuals live out their relations to a social structure” (Eagleton 1991:2).

Thompson’s definition of ideology moreover provides the answer to what mediates in a set of power relations apart from brute force: ideology. Ideology ‘sustains’ in relations of domination, where the dominant group need not resort to raw strength. Of the two definitions in Eagleton (1991), the first very clearly links ideology with power: once again, it is dominant power. The second definition is useful because it not only highlights the indispensability of ideology, it also captures succinctly the fact that ideology is linked to individuals faced with the lot of living out social relations in real life situations. Apple (1979) and others provide perceptions on how ideology also pervades curriculum choices and is closely intertwined with reproduction of cultural and other inequalities.

In addition, what is important too is the question of how ideology manages to wield such potency. This can be understood as a series of action words listed in the following. Giddens (1979:193-195) describes how ideology:

- a. Represents sectional interests as universal ones
- b. Denies or Transmutates contradictions
- c. Naturalises or Reifies the present, preserving the status quo

Terry Eagleton (1991:5-6) describes how ideology:

- a. Promotes beliefs and values congenial to a dominant power
- b. Naturalises and Universalises such beliefs so as to render them self-evident and apparently inevitable
- c. Denigrates ideas which might challenge it
- d. Excludes rival forms of thought, perhaps by some unspoken but systematic logic
- e. Obscures social reality in ways convenient to itself.

## *2.2. Parodic Insights and Sociohistoricity*

Parody is particularly useful tool where there is a need for greater probity - in order to better understand the intricacies and workings of ideology and power relations. It selects, targets, imitates and as a tool of dialogisation, criticises and illuminates (Rose 1993). As a tool of deconstruction, it probes, prods, decentres and exposes, providing insights into the nether workings and out-workings of existing monolithic entities and bastions of reductive and reductionist dominance. As a tool of dialogisation, it simultaneously captures, imitates and exposes the parodied voice, underscoring ideological struggle (Maybin 2003).

The bite of parody is essentially in the elements of travesty and daring - to make fun of a stodgy or inelastic original. Parodies succeed through outrageon, charadery, histrionics, baldness, burlesque even, as a way of curing inelasticity (Rose 1993) – which that much characterises the workings of power and ideology.

In this connection, Bakhtin is useful when he notes strong links between parody, ideology, academia and learning.

The Latin parody or semiparody was widespread. The number of manuscripts belonging to this category is immense. The entire official ideology and ritual are here shown in their comic aspect. Laughter penetrates the highest forms of religious cult and thought...There were other parodies in Latin: parodies of debates, dialogues, chronicles...these forms demanded from their authors a certain degree of learning, sometimes at a high level...(These) brought the echoes of carnival laughter within the walls of monasteries, universities, and schools.

(Bakhtin 1994a:202-203)

Also, viewed in terms of discourse and discursive practices, Lillis' (2003) call for shifts in traditional discourses in academic discussion can in many ways be met through parody. One example can be found in how Toh (2003b) deploys parodic strategies to expose inconsistencies in Berns (2003) and Brutt-Griffler (2003) through comic dislocation. Here, Rose (1993) is informative – in how parody succeeds through citing from an original but having it recontextualised in an environment of incongruity and dislocation. By way of process, Rose notes that the parodist may choose to (1) use words from the parodied original (2) substitute or insert one or more new words from the original and/or (3) paraphrase the original – but always with the aim of highlighting incongruity. Hence, in pitting Brutt-Griffler (2003) and Berns (2003), both part of a forum discussion on critical pedagogy and ELT in the developing world, Toh (2003:569) deploys Bern's metaphor of time and space and Brutt-Griffler's metaphor of historical stodginess epitomised in the notion of what is Victorian, to show (send) up the flaws in presumptuous attempts by non-participants of the 'former' world to critique the learning and teaching of English in the emerging world:

Of course, Berns' impatience for matters to hurry along, it having been "20 years" since, seems refreshingly more forward looking than any suggestion "to turn the clock back." Thus, without giving credence unduly to Brutt-Griffler, the suggestions that "there is no longer any need to conduct this postmodern exercise" (Berns) would regrettably, have to be relegated to a time when such optimism would at least appear to be less misplaced. (Toh 2003b:569)

The send-up concludes like this: "Thankfully, Brutt-Griffler's thoughts were betrayed in English, exposing just enough of a "privileged" few to such Victorian removedness" (Toh 2003b:569).

In keeping with Rose's points about the work of the parodist, the notions of privilege, naiveté, removedness, credibility, proselytisation (Brutt-Griffler 2003) and time and (Berns 2003) are parodied, through the ventriloquistic and replete use of similar words, paraphrasing and word substitution in the Toh (2003) parody. Also, in keeping with Rose (1993), Toh also uses elements of the burlesque to be found in depictions of clumsiness, crudeness, 'dark humour' and in Bakhtin's carnival characters like the Perkies – Leki's (2003) version of "post-pubescent" Christian proselytes who teach English as a way to preach "the word of freedom, salvation, vindication and deliverance from darkness" (Toh 2003:569) – and the Pricklies, the clumsily self-opinionated teachers of English who believe that they and theirs are Providence's answers to the woes of Brutt-Griffler's (2003:561) "underprivileged". One is quickly

reminded of Stone's 1914 take on how "parody explodes the pompous, corrects the well meaning eccentric, cools the fanatical, and prevents the incompetent from achieving success" (cited in Rose 1993:26). Along with this comes a challenge and taunt concerning parody dating from the early part of the last century – "Truth will prevail over it, falsehood will cower under it" (Stone cited in Rose 1993:26).

Moving on to research, parody functions in kindred spirit to current interest in sociohistoric approaches to academic research. Sociohistoric approaches probe, trace, explore and expose causations, motives, interactions and inner workings (Prior, 1998). Parody quickly and often intuitively senses and understands the inner workings of sociohistoricity and sociohistoric activity and brings the more obtuse of these to notice through magnification and through caricature.

Furthermore, in terms of composition and sociohistoricity (Prior 1998), one is reminded of how a piece of writing is a tapestry depicting vivid scenarios of its construction, and how sociohistoric triggers precipitate composition. So here again, parodies are essentially sociohistoric precipitates, revealing much of the reticulate of activity and ideology surrounding the piece. They dig (pun intended) up "views that privilege disembodied knowledge fixed in abstract centralized systems" and celebrate views that uphold "embodied action dispersed across places, time, and persons" (Prior 1998:21). They send-up "an intolerant one-sided tone of ...petrified seriousness" and celebrate "the gaiety, laughter and jests...eliminated from canonized ritual and etiquette" (Bakhtin 1994c:208). In so doing, parody, like sociohistoric approaches, allows (1) closer scrutiny of one-sided disembodied knowledge, in this case, concerning ELT in Asia (2) discovery of inconsistencies and contradictions resulting from ideologised assumptions, which in turn become fodder for parody. When linked to learning, parody in its celebration of embeddedness and situatedness, encourages (3) a pedagogy, in this case of ELT, which encourages a "formation of a (learner's) consciousness through participation in social practices, a theory that stresses affect, motivation, perspective, embodied ways of being in the world, and identity as well as conceptual development" (Prior 1998:22), rather than one which encourages the swallowing of fixed meanings and monolithic boluses.

### **3. Precipitated Parodies**

ELT in Asia fascinates with its diversity of veracities and voices, whether these be within the clammy portals of university English departments, at seminars and conferences at five-star hotels with their 'famous' invited speakers (otherwise known as 'big-names) or in the modest corner language school tucked in some busy back lane. Speaking perceptively about the dangers of co-optation and hence dilution of critical discourse by the fossilised dominant, and the importance of critical analyses in the exposure of hidden agendas and contradictions, of which parody is that much an instrument, Leki (2003) notes that "critical and theoretical generalisations" are more readily co-opted than "the unruly specifics of local knowledge" (2003:563). To avoid such co-optation, Leki suggests that "it is time to establish better access to the local knowledge and practices which critical analyses index" (2003:564). Hence, also in answer to Leki's call, the following parodies are borne of close-encounters with practices in ELT in East and Southeast Asia.

### 3.1. Situations Vacant

Position Number: XO-EN1101

Post: Lecturer in English and English Language Education (only one position)

Our venerated institution is one of the institutions in the forefront language learning, language education and language teacher training. We are at present frantically looking for a suitable candidate to fill the post of lecturer in English and English Language Education. The candidate will be a Native-Native Speaker of English. She should preferably be monolingual in English - the more smugly, resolutely, arrogantly and ignorantly so, the better. Demonstrations of such coveted qualities can be through genetic extract (for some it would also be through pigmentation or the want of it), temperament test, birth, education and indoctrination in notably (please read notoriously) monolingual English speaking countries, proven idiocy in any second or subsequent (please read *subservient*) language, or through references from famous names, authorities, professorial chairs (or stools) noted for their monolingual predilection. In this connection, experience in monolingual (English) classrooms in similarly monolingual socio-cultural and sociolinguistic contexts, is mandatory. The candidate will be eminently able to demonstrate manifest obsession for and fixation over the absolute Truth that the wonderful English language is the only answer to a better world, a better world order and a better cosmic order, where all forms of inequalities, exploitation, imperialism, subjugation and dialogisation will be obliterated through the mellifluity of lucidly enunciated English, and where all exploiters and non-sympathisers of the poor (in English) will be unmasked, exposed and expunged. Furthermore, the candidate will have post-graduate and ELT qualifications, a proven research record and publications, preferably in the areas of (English) language policy, planning, purification, promulgation, propagation and linguo-piracy. The candidate will be an independent and motivated worker capable of supervising post-graduate students and running undergraduate programmes. The candidate will also be clumsy and muddle-headed enough to take parodies (such as this very advert) with puerile earnestness, and actually respond with some semblance of a response.

Incidental Details: Accommodation - Accommodation will be provided in an exclusive suburb guaranteed to be exclusive to foreigners and diplomats working in foreign legations. The only locals one will encounter will be the maids, gardeners, chauffeurs and such like. Pubs and bars, country clubs, swimming pools, saunas, massage parlours and supermarkets stocking the finest imported products are guaranteed to be within a stone's throw. For singles, a maid service will be made available. This will come in the form of a cash-strapped student who wants to learn English from, and practice English with, a live native-speaker specimen. Please note however that a live-in maid will not be provided to male staff so as to maintain a certain level of decency and to protect the institution's reputation. Airfares - First class airfare to and from home complete with qualifying air miles will be provided the successful candidate.

Contact Details:

(e-mail: ucharanimit@useem.edu.mln)

Personal Assistant to the Worshipful Master of Neo-Graduate Studies  
University of Easterly Euroasiatic Manifestations (UEEM)  
666, Bussawa Road  
Peoples' Hypocratic Republic of Hyland  
Website: [www.gross.edu.hd](http://www.gross.edu.hd)  
(please note however that this website is still under self-deconstruction)  
Deadline for applications: 29 February 1853 – time(d) warp

Position Number BO-EN0001  
Post: Instructor in English

Applications are invited for the post of Instructor in English. The candidate must have a proven track record as an entertainer, and preferably have documented connections with the circus, for example, as a clown or if not, at least as a stand-up comedian in a respectably sordid nite-club (note deliberate mis-spellings to prove authenticity). The candidate must also have a proven track record of incompetence in matters to do with classroom and course administration, be a lazy haphazard or at least incompetent marker and an inveterate late-comer. A demonstrated ability at firing cynical remarks at and complaining against school administration, school councils, and local governments would be an advantage. The candidate must be Native-Native speaker of (what else?) English and should very preferably be clean-shaven (i.e. in the armpits) on the day of the interview, and at all times when front(al)ing students. Qualifications do not matter, as lesson preparation will be done by the students themselves, but proof of inmateship (meaning at least 8 weeks) in at least one eminent psychiatric research reformatory (in a country where English is perceived to be spoken as a homogenously and quintessentially monolingual language) will be an advantage from the viewpoint that the candidate will have some record of ability to communicate co-operatively and communicatively with various (non-English speaking) spirit voices. Respect for local culture and religion is totally irrelevant, as the candidate is expected to be an exemplary model of English culture (of whatever form or ilk). The candidate must never have visited Southeast Asia in this or previous lives, have a fear (or better still, disdain and abhorrence) for local food (e.g. dog meat) culture and language, and should be vouched for as being politically incorrect and inept. Salary will commensurate with sanity and sanitisedness (using Lux or Palmolive soap).

### *3.2. Listening Exercises for ESOL Learners (pronounced in some crisp thick-lipped old world English)*

#### *3.2.1. Listening Exercise One*

Listen carefully to the recorded monologue and answer the questions that follow.

The ultimate measure of success of ELT as an enterprise is for learners to ape native speakers. They will need to speak, think and behave like the quintessential native speaker. Those unlucky enough to be born in non-English-speaking environments, choosing wrong parents and geneticity should be given the chance to learn English to enrich their lives and embalm their future. Then their lives will be better than ever before – to deny them English will be to deny them their salvific lifeline, their mental virility, and their ultimate deliverance from the darkest of colonial oppressions and exploitations.

Now listen carefully to the following questions and answer them in the blank spaces provided in your worksheet. Leave the spaces blank if you understood nothing from what you have just heard, or if you think what you have just heard can be summarised in the key words, “gutter rubbish”.

1. What is the ultimate success of ELT as an enterprise?
2. Who does a learner need to think, speak and behave like?
3. Who should be given the chance to learn English?
4. What does will mean if learners are denied the English language?

#### *3.2.2. Listening Exercise Two*

Listen carefully to the recorded passage and answer the questions that follow.

The huge and famous Noda Language School has closed down and it owes its foreign English teachers a lot of money. The foreign English teachers launch a big protest in front of the Nosaka Mayoral office saying that the Nosaka Prefecture should pay for their expenses to fly home or they should re-employ them in other full-time jobs. The foreign English teachers have been paid 260,000 every month and the Noda Language School also paid 130,000 a month for housing. One of the teachers speaks to the press, “The Noda Language School has done a very great disservice to the public, to the students and to their parents. We English teachers do a great service to society by teaching children a very important world language. English is the key to the future of this country and a key to the children’s future. By closing down and not paying the foreign teachers, this means that the school has short-changed the parents and children of this country. Some of my colleagues employed by Noda do not have enough money to fly home. Some of us only have 8,000 left in our bank accounts. We want the prefectural government of Nosaka to pay for our airfares home or to re-employ us to teach English. We are very important people.”

Now listen carefully to the following questions and answer them in the blank spaces provided in your worksheet. Leave the spaces blank if you understood nothing from what you've just heard.

1. What happened?
2. What are the foreign teachers saying about themselves?
3. What do the foreign teachers want?
4. How much were the foreign teachers paid?

### *3.3. Professor Crabtree's Lecture on Syllabus Design and Curriculum Planning – A Soporific Journey*

Language teaching must be linked to corpora. Corpora are the ultimate key to language syllabus design. Without corpora, there will be no syllabus. In fact, corpora constitute a manifest syllabus. So our language boasts of a syllabus of 10,000,000 words. If there is no syllabus, what do you teach? Corpora provide authentic data, data that is extracted from real-life utterances, the speech (and also writing) of the aboriginal speakers of the language. Where else would you get a syllabus as authentic and as original as this? Corpora hold the key to meaning, and meaning is the key to communication, and communication is the key to understanding, and understanding is the key to wisdom, knowledge and persuasion. Imagine, if you are asked to think of the meaning of "Don't you dare feed parsnips to lemming!" what would you do without corpora studies incorporated into a university linguistics programme? And what is more, without corpora, there would be no dictionaries, and without dictionaries, there would be no language. And without language, there would be no communication. And empirical research provides the final irrefutable word on corpora. It is that simple. All right, that is all for today. In our next lecture, we will be continuing along a parallel theme – our expose of copula, copularity, copulolinguistics and copulolinguicism. Our semester 2 examination will require at least cranial knowledge of these vital areas. Thank you and see you next week.

### *3.4. Conclusion of an 18-hour Certificate in English Language Teaching Programme*

Go ye, go ye. Teach and multiply. If not the English language, what else would qualify as a language of globalisation? Spanish? German? Dutch? Double Dutch? Greek? Or Afrikaans? It is in the interests of everybody to learn English. It is convenient; everybody speaks the language almost everywhere you go these days. From the beaches of the Cocos Keeling to the Australian bush, everybody speaks English. And everywhere people go, signs are in English too. So learning English is one's passport to the world, one's passport out of oneself, out of the prison of obliviousness. So we are about to unleash you as red-haired monkeys among bananas. So remember to savour, savour and savour your experiences.

### *3.5. Sponsors Needed*

World Mission Inc. Sponsors are needed for Anglicisation. World Mission Inc. is launching a money drive to sponsor underfed, undernourished and under-anglicised

children in the developing world. Enclosed are lovely pictures of happy children beside their happy native speaker English teachers as well as their happy mothers and happy fathers (for those who still have not lost their mothers and fathers to dreaded diseases like Aids or feline influenza) who have been fed, watered and anglicised. For a modest amount of \$50 a month, you will sponsor a child to learn English from well-qualified native speakers of English, people who gallantly volunteer to endanger their own precious lives and live in high ultraviolet environments in order to bring English and happiness to these less-than-fortunate children who have had no choice about not being born into native English speaking Families.

If you are a native English speaking person yourself, you may want to volunteer to be one of these noble native English speaking teachers and have your picture taken with these happy children and their happy mothers and their happy fathers after they have been happily delivered by your English teaching from their squalor. Volunteer and grab the chance to change the world.

### *3.6. Call for Papers*

28<sup>th</sup> TAESOT (Teaching Asian Englishes to Speakers of Other Tongues) Conference

Venue: Throne Room  
Imperial Hotel and Serviced Apartments  
Cooliwong Road, Beachhead  
People's Burrowcratic Union of Haadnoy

Theme of Conference: Language Mutationability in a Mutating Global Contestual Climate: Priorities, Possibilities, Premises, Promises, Perversions and Presumptions

Paper proposals can either be for parallel sessions (30 minutes of non-stop of talking and 10 minutes for questions) or workshops (30 minutes of real-life demonstration of a useful technique and 30 minutes for practicals using the attendees as guinea pigs). Paper proposals are invited along the following themes:

1. Language Mutationability: Implications for Pigeons, Quails, Lingua Cockarachas
2. Languages in Interface: Implications for Classroom Privacies and Practices
3. Languages and Interphase: Vocabularial Malformations and the Misanthropic Learner
4. Transformational Malfoliation in the Language Pendulum: Generically Mollified
5. Staging of Texts in Real World Contexts
6. Teaching Altercational Englishes to Xenophobic Learners (Workshop only)

Selected papers will be published in the refereed conference proceedings. The following are the invited speakers:

1. Rosemary Rhododendron – University of North Promontia, World Renowned Authority on CDE (Controlled Discourse Expogenesis)
2. Marge White – University of South Protrudom, World Renowned Authority on CLA (Crude Language Acquisition)
3. Lola Smith – East Harbour University of Technology, World Renowned Authority on Hole-text Approach to Teaching Reading, Writing and Aromatics

4. Christine Primworth – Estuary Institute of Educational Research, World Renowned Authority on (AML) Acquisition of Mutoid Languages
5. Peter Primworth – WEtuary Institute of Educational Research, World Renowned Authority on Language Ecology and Obliterology

All keynote sessions will be in the Throne Room and parallel sessions and workshops will be in the adjoining closets. Video projectors, transparencies, tissue paper and chamber pots are available for all presenters. Conference sponsors are:

1. Imperial Hotel and Serviced Apartments
2. Global Banking Dissolutions, Hoodwinker Publishing
3. Quian's Rent-a-Cart Service
4. Rumbles Private Limited - the Ultimate in Catering
5. Poo and Pong Tissue and Toilet Roll Manufacturers
6. Society for Linguistically Challenged Learners of Udder Languages (SLCLUL)

### 3.7 *WMD (Words of Mass Delusion)*

The following constitutes part of an essay written by a top first-year student and awarded a good grade by her tutor, Assistant Professor Amnesia Myo-Spectapopulos

We must understand that the spread of WMD is never a deliberate act. This is the plain truth of the matter. Anyone who has read any history will tell you that. WMD spread of themselves and spread by themselves – WMD are self-propagating, self-propelling. There is no agency and therefore no agenda. Anyone who has read any history will tell you that. Those who say that the spread of WMD is a deliberate act of some agencies in the Inner Circle do not know what they are talking about. They are a grossly mistaken lot. Anyway, such a spread is needful, neutral and natural. In conclusion, it is the users of WMD themselves who are responsible for their spread – there is no mystery about it. Grade Awarded: A+ (Comment from Tutor: Good points have been raised in this essay, but you forgot to acknowledge that your ideas have all been drawn from my academic papers. Please be more careful the next time.)

### 3.8 *Communicative Language Teaching*

A robot English teacher-trainer speaks and each full stop is followed by a robotic twitch of the robot's metallic upper lip.

The students are not talking. They are very quiet. They don't talk in class. Use CLT with them. Get them to talk. Give them communicative tasks. Give them problem-solving activities. The students are not talking. Give them tasks. Tell them to talk. Students learn through oral communication. Not just yes-no answers. Provide opportunities for meaningful communication. Get them to solve problems. Get them to chat with each other using info-gap tasks. If that fails, give them more tasks. The above is repeated endlessly until it is time for the robot ELT teacher-trainer to be recharged or rewired.

## **4. Food for Further Reflection and Conclusion**

Before concluding, it would be worthwhile revisiting prior discussion on the call for alternative of discoursing in academia. Like Lillis (2003), Lea in an earlier paper (Lea 1999:105) highlights the importance of challenging “supposedly ‘academic ways of knowing’”, and encouraging “new and unfamiliar literacy practices”. The obvious point here is that such various discourses are not for their own sake, but for facilitating other facets of reality and experience.

In this instance, there needs to be a way to counterpoint the reductionism and monolithicism behind smugness, glibness and hence deceptiveness of dominant ideologies and their resultant practices – those ideologies embedded behind the veils of slick ELT textbooks and honey-lipped conference keynotes. The “everyday knowledge” (Lea 1999:105) of parody, the earthiness of carnival laughter (Bakhtin 1994a:200) help counterpoint prevailing discourses and promote the fresh air and “renewal” that Bakhtin (1994a) describes. The need for this within the clammy chambers of ELT in Asia and beyond, cannot be overstated. So, even if they are not welcome by the parodically-challenged, parodies, as ways of seeing, perceiving and counteracting, will like Bakhtin’s carnival laughter, need to be “tolerated” as part of a necessary “becoming, change and renewal” (Bakhtin 1994a:199).

Finally, parody is but one way of highlighting ideology – through showing up what ideology does, how ideology speaks, and how ideology behaves. Ideally, it should be done with considerable rigour and menippean variety – “novellas, letters, oratorical speeches, symposia...prose and poetic speech” (Bakhtin 1994b:192) and possibly, repetition. Each time some ideologically laden statement comes through with self-assumed finality it can be unmasked for what it is - like Patriot after Scud. The work of unmasking ideologies continues.

# The Use of Singlish Particles in the Singapore Classroom

Gwee Susan,

Hong Huaqing, Aman Norhaida

Nanyang Technological Univeristy

## ABSTRACT

The use of Singlish particles has been extensively studied in everyday interactions. However, to date, there is little research on its daily use in the classroom. From the study of 91 transcripts from science, mathematics, English and social studies lessons, it was found that Singlish particles were used across the curriculum, but most frequently in science and mathematics classes. It was also found that the particle *ah* was by far the most frequently used particle in the Singapore classroom.

**Keywords:** Singlish particles, classroom.

## INTRODUCTION

Singlish, one of the New Englishes of the post-colonial world, has quite a large number of particles and this topic has been the subject of much discussion in the literature on Singlish (Richards and Tay, 1977; Kwan-Terry, 1978, 1991; Platt and Ho, 1989; Gupta, 1992, 1994; Wee, 2002, 2004; Low and Deterding, 2003; Wong, 2004, 2005; Low and Brown, 2005). These particles occur typically in phrase-final positions and do not affect the grammaticality of the utterances. These particles have been shown to mark discourse functions in everyday speech. For example, they have been used to express solidarity, annoyance, impatience, objection or doubt. As early as 1977, Jack Richards and Mary Tay investigated the use of the *lah* particle in Singlish which has been found to be a code marker serving to mark informality, solidarity and rapport among the participants.

The particle *ah* has been one of the most prevalent particles seen in the preliminary transcripts examined. Teachers seem to use this pragmatic particle quite often compared to the other particles. Platt and Ho (1989) found that a rising *ah* or *a* is associated with the proposition being questioned being true. Kwan-Terry (1991) noted that her pre-school subject used the particle *ah* in the interrogative sentence to seek confirmation or in an echo question. Gupta (1992) also found that this particle was the most common one used in her data with pre-

school children and that it was used for checking propositions and Lim (2004) found that *ah* uttered with a rise may be used to check whether the interlocutor is following. She also noted that the particle *ah* serves to soften a command when it is used with an imperative. Lim (2004) noted that when the particle *ah* used for checking purposes, the listener is expected to respond whereas if the particle has a rise, the speaker usually uses it to reiterate a fact and does not expect a response from the listener.

Although the use of Singlish particles has been extensively studied in everyday interactions, to date, there is little research on its daily use in the classroom. Thus, to fill in the gap, the purpose of this study is to investigate the teachers' use of Singlish particles in the Singapore classroom where English is the medium of instruction. Specifically, this study focused on its use in twenty primary school classes. It sought to find out the patterns of particle usage across subjects and across pedagogic functions.

## **DATA ANALYSIS**

The data were drawn from a larger study of the CORE Research Program of the Centre for Research in Pedagogy and Practice (CRPP), whose key objective was to measure, map and model classroom pedagogy and student outcomes in a large representative sample of Singapore primary and secondary schools in 2004 and 2005. For this study, only recordings from primary schools were used. There were altogether ninety-one transcripts: twenty-one lessons from five mathematics units, sixteen lessons from five science units, eighteen lessons from five social studies units, and thirty-five lessons from five English units. Lessons were taken from whole units so that the data would be representative of the way teachers use particles in the classroom. There were altogether twenty units, i.e., five units for each subject. The total duration for all the transcripts is 3932.6 minutes altogether. The duration for English, mathematics, science and social studies transcripts are 1 589.1 minutes, 891.8 minutes, 815.9 minutes and 635.8 minutes respectively.

In this study, we used an annotation tool to annotate the occurrences of particles and other Singlish features and their pedagogic functions in the classroom such as curriculum access, class management, and interpersonal relations. These pedagogic functions are the ones which have been proposed by Ferguson (2003). In this study, code-switching for curriculum access serves to help students understand the content of the lessons taught and includes the following pedagogic functions: scaffolding knowledge construction, emphasizing, reiterating, checking of understanding, assenting and pointing out of the obvious. Code-switching for classroom management discourse is used for functions such as encouraging students, inviting

student participation, disciplining students, focusing students' attention, giving directions (includes clarifying and emphasizing directions) and confirming students' propositions. Code-switching for interpersonal relations serves to build rapport for the students. For the purposes of this conference paper, only the data of the broad pedagogic functions, curriculum access, classroom management and interpersonal relations will be discussed.

To analyze the data across subjects, the number of occurrences was divided by the duration in each subject and the result was multiplied by 30 minutes. To analyze that data across the pedagogic functions, the number of occurrences of particles was divided by the total word count and the result was multiplied by 30 minutes. The duration of 30 minutes was chosen because each period in the Singapore classroom is about half an hour.

## RESULTS AND DISCUSSION

The results (see Table 1) suggest that the science teacher used particles most frequently (27.6) compared to the mathematics teacher (21.7), English (14.6) and social studies teachers (14.2). The use of particles was similar for English and social studies teachers. These results were consistent with the expectation that science and mathematics teacher had to use more Singlish particles to ensure that the students understand the subject matter and that since more science and mathematics lessons were task-based rather than English and social studies lessons, the science and mathematics would have to use Singlish more often to ensure that students remain on task. That is, on the one hand, science teachers seemed to spend more time ensuring that students know how to conduct experiment or complete science worksheets, and mathematics teachers used a lot of particles to ensure that students were following their explanation of how problem sums were solved. On the other hand, social studies teachers had fewer tasks to complete, social studies being a non-examination subject. The English teachers are expected not to use Singlish particles or other Singlish features in the classroom, so it is not surprising that few particles were used in the English classroom compared to science and mathematics classroom.

*Table 1: Particle frequency across subjects (per 30 minutes)*

Science	Mathematics	English	Social Studies
27.7	21.7	14.6	14.2

In terms of pedagogic function (see Table 2), particles were most often used by teachers for classroom management (10.9) and for curriculum access (7.2). In contrast to the use of particles for curriculum and classroom management, the use of particles for interpersonal relations was minimal (0.4). This suggests that Singaporean teachers are very much on task when they use particles. The teachers had a lot of ground to cover in terms of the requirements of the syllabus, and their talk centered on the curriculum and the activities were connected to the curriculum. They do not use Singlish particles much for building rapport with their students as they do not engage in informal talk with their students. This finding is non-congruent with the existing literature where the use of particles in non-classroom contexts seems to concentrate on its use of building solidarity among the interlocutors.

However, the preponderance of particles for the function of classroom management may be the Singaporean's teacher way of building interpersonal relationships with their students given the limited time that they have in the classroom as teachers are required to finish the syllabus and to prepare their students for school assessments. That is, the Singaporean teacher may want to build rapport with her students, but she does not have the time to engage in informal talk with them. Therefore, she may resort to using Singlish particles for the pedagogic function of classroom management to create a warmer climate in her classroom while making sure that the students stay focused on the task at hand.

Table 2: Particle frequency across pedagogic functions (per 30 minutes)

Classroom Management	Curriculum Access	Interpersonal Relations	Others
10.9	7.2	0.4	0.2

Teachers used nine different particles: *ah*, *hor*, *lah*, *leh*, *lor*, *mah*, *one*, *orh*, and *what*. One of the most commonly used particles by teachers was *ah*. The particle *ah* was used much more frequently than all the other particles (see Tables 2 and 3). Out of 10.9 particles used in classroom management, for instance, 10.2 of the particles, or 94% of the particles, was the particle *ah*. In the same vein, 6.4 out of 7.2 particles, or 89% of the particles, used for curriculum access was the particle *ah*. Thus, the particle *ah* accounted for a very high percentage of the particles used for pedagogic functions.

Table 3: Particle *ah* frequency across pedagogic functions (per 30 minutes)

Classroom Management	Curriculum Access	Interpersonal Relations	Others
10.2	6.4	0.4	0.2

However, the particle *ah* was very seldom used for the interpersonal relations function although it accounted for all the particles used for this function. The particle *lah* which is usually used for establishing solidarity in everyday discourse is seldom employed by the Singapore teachers in this study for establishing interpersonal relations in the classroom.

#### *CURRICULUM ACCESS*

Some examples of its use are described below. In the phrase-final position, it was often used to emphasise what the teacher wanted to say. For example, in one of the science lessons, which focused on the topic of genes, the teacher wanted to make sure that the pupils knew that her students understood what she was pointing at was the cell nuclei, so she used the particle *ah* to emphasise a proposition for the pedagogic function of curriculum access. Earlier on, she had talked about how traits were inherited from different families. She discussed about how our cells came from our parents. She also emphasised that she would be discussing the topic of genes especially on why we inherited genes from our parents (see excerpt (1) below).

#### *EXCERPT 1*

Teacher: She has different cells, very good. Now where does her cell come from?

Student: Mother, mother.

Teacher: Hmm?

Student: Father and mother, both parents.

Teacher: Oh, right, some of our traits ah, most of our traits come from both parents, okay? Now, you will learn about reproduction in human beings, ah, later on in second term, right? Now today, we just do very briefly on ah, why, ah, the, the genes that you inherit from your parent, ah, all right, put it that way, right? And how does it come from? I'll just do the very brief one on that, okay? We are going to look at the cell nuclei, okay? This will be our cell nuclei.

(Score\_Sci\_031, turn 60)

In the utterance-initial position, in the unit *How to Make a Dinosaur*, English teacher used the particle *ah* to acknowledge what the student had said. This English unit was a form of science fiction where scientists were trying to recreate dinosaurs. This was done specifically in the room called hatchery. In the earlier part of the transcript, the English teacher asked the students what a hatchery was and she told them to read the text first before answering her question. A few turns later, the student replied that the word *hatchery* came from the word *hatch*. The teacher then used the particle *ah* to acknowledge her response. Below is a short excerpt from the English transcript.

#### *EXCERPT 2*

Student: Come from the word hatch.

Teacher: Ah. Come from the word hatch. So what place is this?

(Score\_Eng\_025, turn 391)

#### *CLASSROOM MANAGEMENT*

Particles were used most frequently for the pedagogic function of classroom management. This could be due to the teacher trying to soften commands when giving directions. Particles were used for giving directions, seeking confirmation, encouraging, inviting student participation and focusing students' attention. For example, in one of the English lessons (see Excerpt 3), the teacher used the particle *ah* for giving directions to ensure that students not read the advertisement.

#### *EXCERPT 3*

Teacher: Who has not finish reading?

Class: Background noise

Teacher: Please do not read the advertisement yet, ah.

Class: Background noise

Teacher: Okay, Jeremy, can you please start us off

(Score\_Eng\_019, turn 356)

In Excerpt 4, the mathematics teacher used the particle *ah* to confirm whether the students have finished their work on tessellation before she had their work printed out.

*EXCERPT 4*

Student: Miss Lim, can you print out for me?

Teacher: Finished ah? Have you completed?

Class: Background noise

Teacher: Anyone who needs me to print?

(Score\_Math\_085, turn 111 )

From the above excerpts, it can be seen that the particle *ah* has similar functions in the classroom as the everyday functions described in the literature above except for the function of emphasis in classroom discourse. The function of emphasis can be particularly important in the classroom because it is important for the teacher to convey the importance of certain facts or concepts to her students.

Why as the particle *ah* used significantly more often than the other Singlish particles? One possible reason could be that the teachers were not aware that the particle *ah* was a Singlish particle and were blithely using it without realizing that they were using the Singlish particle. The particle *ah* does not receive much coverage in the print media compared to its cousin *lah* which was the first Singlish particle to be studied.

*USE OF OTHER PARTICLES*

The particle *lah*, which is used to mark informality and solidarity in everyday speech, has different functions in the classroom. It was used for pointing out the obvious to the students as in shown in the last turn of Excerpt 5. In this unit, the social studies teacher explained to her students that due to the rising population in Singapore in the nineteen seventies, there was traffic congestion in the city area and thus the government imposed the rule of car pools for cars heading towards the central business district. She proceeded to give an example of how a mother and a daughter would have to pick up two other passengers to form to a group of four in the car before they could drive into the city area. When a student asked her what if the passengers that the mother picked up were to vomit in the car, she replied that it was obvious that these passengers should be chased out of the car by using the particle *lah!*

*EXCERPT 5*

Teacher: Okay. They built a lot of car pools in your housing estate. Say maybe one, one day your mother wanted to take, want to take you. Imagine you are living at that time ah. One day your mother want to take you to Orchard Road, but in the car only your mother and you. So can you go

to Orchard Road?

Student: No.

Teacher: Cannot. So what do you do? Hold on ah. What did you do? You would drive your car to the car pool, and there will be people waiting in the queue, the taxi queue. And they would go into your car. They would sit your car. It benefit both party you see? The people can take your car for free. They no need to pay for [taxi].

Student: [How] they vomit?

Teacher: Huh?

Student: How they vomit later ah?

Teacher: What if they vomit? Of course vomit then we chase them out lah ah. Okay. First of all, they have free transport. They don't have to take taxi.

(Score\_Soc\_038, turn 88)

The particle *what* was used by a mathematics teacher in the utterance 'Only one shape *what*' to tell as student that her work needed to be changed because she drew one shape instead of two (see the first turn in Excerpt 6). The teacher pointed out that it was obvious that there was only one shape drawn, not two. She told the student that the student had not followed her instructions of drawing two shapes. This finding is congruent with Wee's (2004) assertion that the particle *what* is used to point out something being obvious.

#### EXCERPT 6

Teacher: Only one shape what.

Student: I know.

Teacher: It's only one shape. One shape.

Student: I know.

Teacher: So? I want two shapes. You give me one shape only. Okay, so go and give me two shapes. I know you know.

(Score\_Math\_032, turn 72)

The particle *lor* was used by the same mathematics teacher in the utterance 'Just leave it *lor*' to give directions for classroom management (see the third turn in Excerpt 7). The teacher told the student to fill up the page with the same shapes. The student sought

clarification whether he should even fill up the blank side of the paper. The teacher gave instructions on leaving the blank side alone.

In everyday speech, the particle *lor* conveyed the obviousness of the action required. However, in classroom discourse, the particle *lor* had the additional pedagogic function of giving directions to the student so that the student work may be completed in a satisfactory manner.

#### *EXCERPT 7*

Teacher: Fill up whatever you can

Student: Teacher, you mean even the blank side.

Teacher: No. Just leave it lor. Just leave it half there

Student: Okay.

(Score\_Math\_032, turn 319)

## **CONCLUSION**

In summary, the data analysis offers some empirical support that teachers in Singapore use Singlish particles mainly for classroom management and curriculum access in the classroom but they do not use them very negligibly for interpersonal relations. It is perhaps a reflection of the Singapore education system where the teacher is very focused on “covering the syllabus” and thus most of the talk in the transcripts was centered on the curriculum and on classroom management. The teacher’s priority is to get job done, to finish the syllabus rather than to create a warm relationship with the students through informal talk.

The use of Singlish particles is found across the curriculum, but most frequently in science and mathematics classes. It was also found that the particle *ah* was by far the most frequently used particle in the Singapore classroom. Since there is not talk about the particle *ah* in the Singapore media compared to the other Singlish particles, the teachers might not actually know that they were using Singlish particles. This might open up a new area of research regarding teachers’ perceptions of their use of Singlish particles.

## **Abstract**

The issues of the perception-production relationship in L2 acquisition are dealt with in the present study. The results are comparable to Bohn & Flege (1990)'s findings that the relationship between perception and production changes with time or with L2 experience. Korean ESL beginning learners could not distinctively produce the English sibilants /s-ʃ/ but they showed excellent perception scores. As L2 learners gain experience in the L2, perception and production abilities develop for an L2 contrast that is allophonic in L1. The mean production scores of Korean advanced ESL learners were not as good as their perception scores, but longer exposure to English enabled Korean ESL learners to improve their production ability.

**Keywords:** production, perception, English, sibilants, Korean ESL learners

## **1. Introduction**

This paper investigates several issues in second language (L2) phonetics and phonology: 1) how L2 learners produce and perceive an L2 contrast which is allophonic in their native language, 2) how speech perception affects production, and 3) how the relation between production and perceptual abilities changes over time. It has been claimed by most researchers that in L2 acquisition, perceptual mastery leads to accurate production of L2 sounds. However, the claim that accurate perception is a prerequisite to good production has not always been supported by experimental studies. Some experimental studies found that while L2 learners are able to produce non-native contrasts accurately, they are not able to distinguish them perceptually (Goto 1971; Kang 1999; Sheldon & Strange 1982). It is argued that production can precede perception in L2 acquisition depending on L2 proficiency level. For instance, in the study of English liquids /r/ and /l/ by Japanese learners of English, Sheldon & Strange

(1982) found that experienced Japanese learners of English have demonstrated more accurate performance in production than in perception, particularly in the prevocalic position. Flege, Takagi & Mann (1995) also found that in both reading and spontaneous speech, production of English /r/ and /l/ by experienced (or advanced) Japanese learners of English was identified correctly by native speakers of English. However, Smith (2001) goes so far as to argue that production can proceed independently of perception. She claims that factors like kinesthetic feedback during articulation facilitate the independent development of production from perception. This means that although some L2 learners may be advanced in terms of production of new L2 contrasts, they are beginners in terms of perception of those same contrasts. In fact, according to Wode (1997), the tendency to model exclusively in terms of production is one of the most critical weaknesses in phonological theories. To address this, over the last two decades, a small number of experimental studies have critically examined the relationship between production and perception (Cheon 2007; Flege 1992, 1995, 2003; Toda 2003; Wode 1997).

This paper deals with the issues of the perception-production relationship in L2 acquisition. The L2 English sounds chosen for this study are /s/ and /ʃ/. Korean and English both make use of two voiceless sibilant fricative phonemes. Korean has /s/ and /s\*/, while English has /s/ and /ʃ/. However, despite the fact that the IPA symbol /s/ is used to represent a sibilant in both languages, English /s/ is not the same as Korean /s/. In fact, it has been observed by most Korean phonologists that English /s/ is more similar to Korean /s\*/ than to Korean /s/, in spite of the use of different phonetic symbols. Recently, foreign accent has been assumed to be closely related to the degree of articulatory, acoustic, and perceptual similarities between L1 and L2 sounds.

Table 1 shows a breakdown of the two English sibilants /s/ and /ʃ/ using Jakobson, Fant, & Halle's distinctive feature system (1963).

Table 1. Jakobson et al. (1963)'s distinctive feature values for English sibilants /s-ʃ/

	[±cons]	[±diffuse]	[±grave]	[±nasal]	[±cont]	[±strid]	[±tense]
s	+	+	-	-	+	+	+
ʃ	+	-	-	-	+	+	+

As shown in Table 1, /s/ and /ʃ/ are distinguished only by the feature [diffuse]. In articulation, the feature value [+diffuse] is associated with sounds in the anterior portion of the oral cavity. Labials, dentals, and alveolars are usually diffuse consonants, while palato-alveolars, palatals, and velars are non-diffuse. /ʃ/ is made by a narrowing of the

vocal tract between the blade of the tongue and the back part of the alveolar ridge, while /s/ has a constriction in the middle of the alveolar region or the forward part of the alveolar ridge (Stevens 1998; Ladefoged 2001). Ladefoged & Maddieson (1996) and Ladefoged (2001) have all contrasted the acoustics of the English sibilants /s/ and /ʃ/. These studies produced similar results (as follows). The voiceless sibilant fricatives /s/ and /ʃ/ have relatively strong acoustic intensity as compared to labial or interdental (non-sibilant) fricatives. The difference between /s/ and /ʃ/ in the spectrograms in Figure 1 is that /s/ has its greatest energy concentration (i.e., higher pitch frication noise) above about 6,000 Hz, while /ʃ/ shows most intensity at a lower frequency, between about 3,000 Hz and 5,000 Hz (Ladefoged 1962). English [ʃ] is produced with some lip protrusion, which presumably enhances the low frequencies in the frication noise.

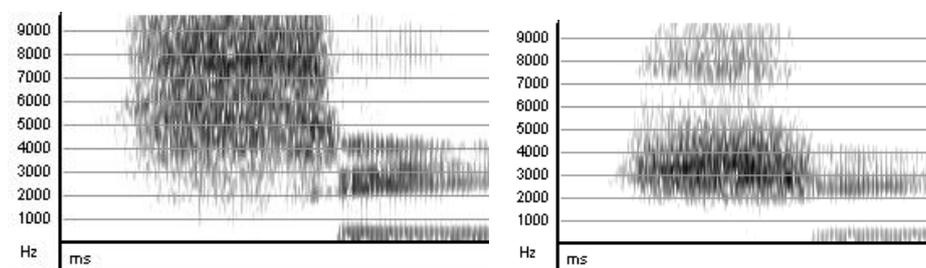

Figure 1. Spectrograms of “see” (left) and “she” (right) as produced by one of the American English speakers who participated in the present study.

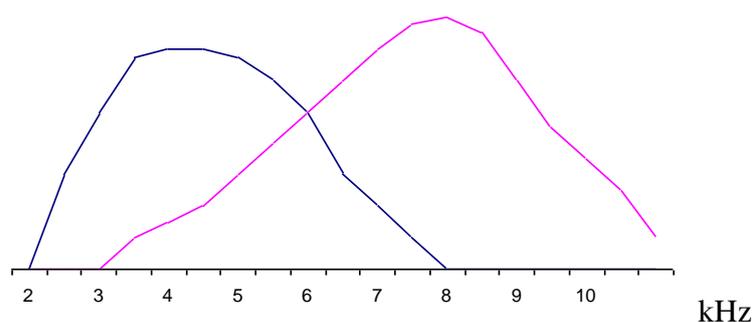

Figure 2. Spectra of the English sibilants /s/ (right) and /ʃ/ (left). The horizontal scale gives the frequency in kHz; the vertical dimension represents the amplitude of the sounds at given frequencies (Adapted from Ladefoged 1962: 53)

Figure 2 shows sample spectra of English /s/ and /ʃ/, showing that the /ʃ/ is has its energy concentration at lower frequencies than /s/. English sibilants /s/ and /ʃ/ are taken to be allophones by Korean speakers (Eckman & Iverson 1997). This present study includes two experiments that examine how Korean ESL learners perceive and produce

the L2 English contrast /s-ʃ/ which is allophonic in Korean, along with the relation between production and perceptual abilities.

## **2. Experiment 1: Production Task**

### *2.1. Method*

#### *2.1.1. Subjects*

Thirty paid volunteers participated in Experiment 1. They comprised three groups: 1) ten Korean ESL advanced learners, 2) ten Korean ESL beginning learners, and 3) ten American English speakers. Korean ESL learners who had studied English in the U.S. for less than one year belonged to the beginners' experimental group (on average, 11 months); those who had studied English in the U.S. for more than five years belonged to the advanced-learners' experimental group (on average, 5.6 years) at the time of recording. The approximate average age for the two experimental groups was 30.3 and 36.1 years, respectively. The average age of ten native speakers of American English in the control group was 22. All subjects were male undergraduate and graduate students at the University of Hawai'i at Mānoa. Twenty native Korean speakers are from Seoul or Kyunggi province. None of the subjects had a history of speech or hearing disorders.

#### *2.1.2. Stimuli and procedures*

In Experiment 1, stimuli were constructed from sibilant-vowel sequences that began with one of the initial sibilants in the English sibilant contrast /s, ʃ/ and were followed by one of the three vowels /i, a, u/. Each stimulus was composed of contrasting sibilant pairs (i.e., /si/ *see* or /ʃi/ *she*). Most of the stimuli were syllables rather than words in order to minimize the effect of individual word familiarity (even though some syllables were words per se). The stimuli were spoken in connected speech, with each speaker repeating five times a randomized list of six tokens in a carrier phrase, I'm saying \_\_\_\_\_ now) written in English on a notecard.

In order to evaluate the accuracy of the subjects' production performance on each L2 sibilant contrast, judgments of the subject's L2 speech as correct or incorrect <sup>1</sup>

---

<sup>1</sup> Each stimulus was judged by three Korean raters as 1) correct, 2) unclear but acceptable or 3) incorrect; "unclear but acceptable" stimuli were considered as correct here.

were carried out with the aid of acoustic analyses by three Korean raters: 1) a phonetically trained listener, 2) a naïve listener, and 3) a bilingual speaker of Korean and English. In total, the raters judged 900 sentences (2 sibilants x 3 vowels x 5 repetitions x 30 speakers).

## 2.2. Results

Each subject's scores for the five repetitions were averaged prior to statistical analysis. An alpha level of .05 was used to determine significance for all statistical tests. To examine the production of the sibilants in the three vowel contexts by the three groups, one three-way repeated measures ANOVA also tested the effects of Group, Sibilants, and Vowels on correct production response in Experiment 1. The scores yielded a value between 0 and 1, where 0.5 represented chance response and 1 represented perfect production (five correct responses out of five).

Figure 3 shows the mean correct production scores of English sibilants /s/ and /ʃ/ in the three vowel contexts by ten native AE speakers, by ten Korean ESL advanced learners, and by ten Korean ESL beginning learners. Overall, Korean beginning learners of American English seemed to have more difficulty producing English /sa/ and /su/ (0.1 & 0.34) and English /ʃa/ (0.36) than any other sibilant-vowel sequences.

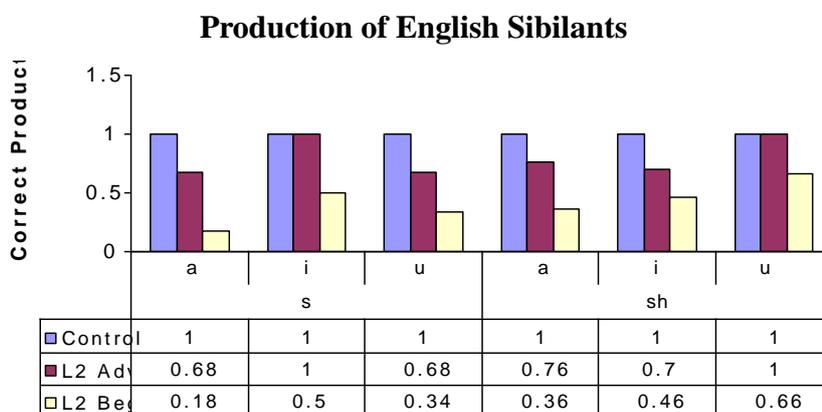

Figure 3. Mean correct production score of English fricatives /s/ and /ʃ/ "sh" in the three vowel contexts by AE speakers, by Korean ESL advanced learners, and by Korean ESL beginning learners.

A three-way repeated measures ANOVA that tested the effects of *Group*, *Sibilant contrast*, and *Vowel context* on the production of English /s/-/ʃ/ yielded two significant

main effects (*Group* and *Vowel context*)<sup>2</sup> and one significant interaction (*Sibilant contrast x Vowel context*).

A main effect of *Group* and a subsequent Tukey post-hoc test indicated that the mean production scores were significantly higher for native AE speakers than they were for Korean ESL learners ( $F [2, 27] = 38.124, p < .0001$ ). Korean ESL advanced learners were significantly higher in their mean production scores than were Korean ESL beginning learners (L2 Beg < L2 Adv < L1 Control). L2 experience made a difference in the production of English sibilants by Korean ESL learners. A main effect of *Vowel context* and a Tukey post-hoc test indicated that there was a statistically significant difference between /a/ (0.7) and /u/ (0.8), but there were no statistically significant differences between /a/ and /i/ and between /i/ and /u/ ( $F [2, 54] = 3.292, p = .0448$ ).

There was a *Sibilant contrast x Vowel context* interaction. Subsequent post-hoc tests revealed that there was a statistically significant difference between /s/ and /ʃ/ in the context of /u/, but there were no statistically significant differences between /s/ and /ʃ/ in the context of /a/ and /i/ ( $F [2, 54] = 7.923, p = .0010$ ). Figure 4 shows the mean production scores of English sibilants /s/ and /ʃ/ in three vowel contexts.

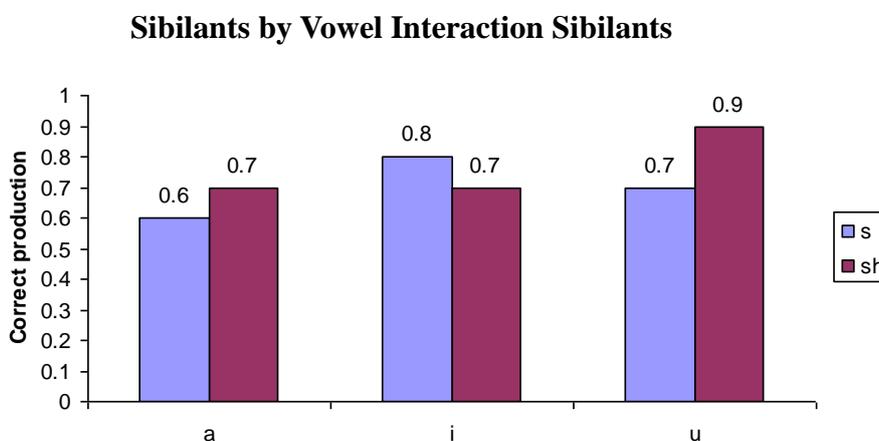

Figure 4. Mean production scores of English /s/ and /ʃ/ "sh" in three vowel contexts.

The English /ʃ/ was more accurately produced in the context of /u/ than the English /s/

---

<sup>2</sup> In Experiment 2, listeners were also presented with the vowel, and their reactions to the sibilants might have been influenced by non-native vowel productions. I regret that the potential factor like a vowel environment was not taken into consideration for data analyses.

was. Both /ʃ/ and /u/ in English are made with some lip rounding. It seems that lip rounding of /u/ enables Korean ESL learners to produce /ʃ/ more accurately than in any other vowel contexts.

### **3. Experiment 2: Identification Task**

#### *3.1. Method*

##### *3.1.1. Subjects*

The same thirty subjects from Experiment 1 participated: twenty Korean ESL learners in the experimental groups (specifically, ten beginning and ten advanced learners of English) and ten native speakers of American English in the control group.

##### *3.1.2. Stimuli and procedures*

The English stimuli in Experiment 2 were the same as those in Experiment 1. The stimuli were syllables rather than words in order to minimize the effect of individual word familiarity. One male American English speaker produced the stimuli. The speaker was instructed to read a list of isolated words. Recordings for Korean stimuli were made in a sound-attenuated booth at the University of Hawai‘i at Mānoa. Each of the two sibilants before the vowels /i/, /a/, or /u/ was repeated five times. The recorded stimuli were digitized onto PCquiner at a 22.05 kHz sampling rate and edited from a waveform display with the aid of a spectrogram at the University of Hawai‘i Phonetics Laboratory. A total of 6 tokens was chosen to create stimuli. Each token was digitally repeated five times, and the resulting 30 tokens were randomized. Experiment 2 was conducted on a Power Macintosh G4 running PsyScope with a button-box.

The subjects in Experiment 2 were tested individually in a sound attenuated booth of the Language Analysis and Experimentation General Laboratory at the University of Hawai‘i at Mānoa. The experiment began with a familiarization test. Subjects were asked to listen to the stimuli and then to identify the sound by pressing one of the two sibilant buttons displayed on the button box. Two color buttons were used for each stimulus: a red button on the left and a green button on the right. The subjects heard the stimuli over headphones. Each subject was instructed to press the button as quickly as possible, but the following stimulus was not initiated until they pressed one of the buttons. That is, they could take as much time as they wanted in making a decision. Subjects did not get any feedback regarding whether the answer was

correct or not while they were participating. Natural speech stimuli rather than synthesized stimuli were used in Experiment 2.

### 3.2. Results

Correct identification scores were computed from the proportion of correct and incorrect responses for all subjects on each of the sibilants. Each subject's scores for the five repetitions were averaged prior to statistical analysis. To examine the perception of the sibilants in the three vowel contexts by the three groups, one three-way repeated measures ANOVA also tested the effects of *Group*, *Sibilant contrast*, and *Vowel context* on correct identification scores in Experiment 2. The scores yielded a value between 0 and 1, where 0.5 represented chance identification and 1 represented perfect identification (five correct responses out of five). Figure 5 shows the mean correct identification scores of three groups on English sibilants /s-ʃ/ in the vowel contexts.

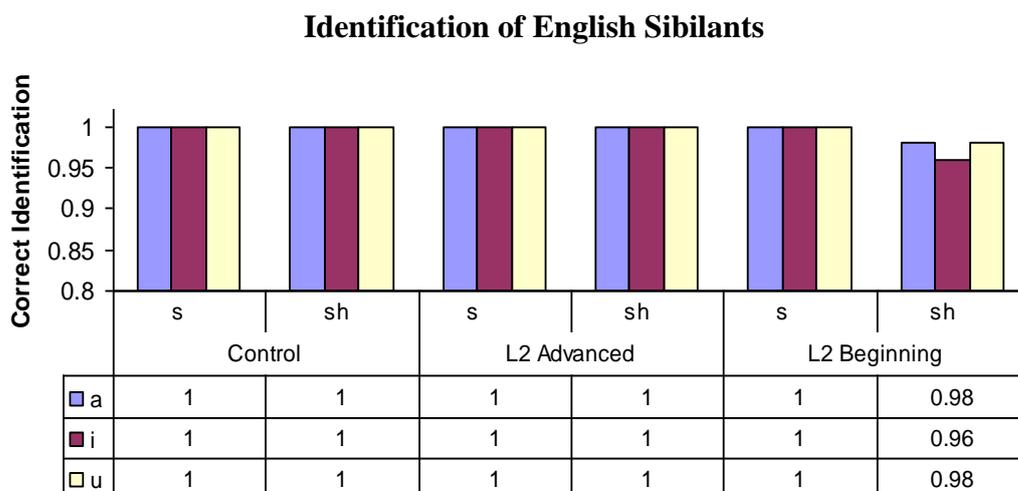

Figure 5 Mean correct identification scores of three groups on the English contrast /s/ and /ʃ/ "sh" in three vowel contexts.

The mean identification score was 1 for AE speakers, 1 for Korean advanced ESL learners, and 0.98 for Korean beginning ESL learners. English native speakers and Korean advanced learners of English showed perfect identification scores in all three vowel contexts, while Korean ESL beginning learners showed higher identification scores in the context of /a/ than in the context of /i/, and then /u/. All subjects in each group showed 'excellent' identification scores.

A three-way repeated measures ANOVA that tested the effects of *Group*, *Sibilant contrast*, and *Vowel context* on the production of English /s-/ʃ/ yielded two significant main effects (*Group* and *Sibilant contrast*) and one significant interaction (*Group x Sibilant contrast*). A main effect of *Group* on the correct identification scores and a subsequent Tukey post-hoc test showed that Korean advanced learners of English did not differ significantly from the native AE speakers ( $F [2, 27] = 6.000, p = .0070$ ). This suggests that Korean ESL advanced learners were just as accurate as AE speakers. L2 experience made a difference in perceptual improvement in second language acquisition ( $L2\ Beg < L2\ Adv \equiv L1\ Control$ ). English native speakers and Korean ESL advanced learners did better than Korean beginning learners of English. But surprisingly, Korean ESL beginning learners' identification scores were all higher than 93 percent. The results occurred despite the fact that Korean contains no phonemic contrast /s-ʃ/.

The main effect of *Sibilant contrast* and a subsequent Tukey post-hoc test indicated that English /s/ (1) was better perceived than English /ʃ/ (0.991). There was a *Sibilant contrast x Group* interaction, indicating that there were no significant differences among three groups in the perception of /s/. On the other hand, in the perception of /ʃ/, there was a significant difference between AE speakers and Korean ESL beginning learners and between Korean ESL advanced and beginning learners, but there was no statistically significant difference between AE KSL learners and Korean ESL advanced learners. All three groups got a perfect identification score (1) in /s/. AE speakers and Korean ESL advanced learners got perfect' identification scores (1) in /ʃ/, and Korean ESL beginning learners got an excellent score (0.97) in /ʃ/ as well. There was a *Group x Sibilant contrast* interaction. Subsequent post-hoc tests revealed that there was a statistically significant difference between /s/ and /ʃ/ in the beginners' group, but there were no statistically significant differences between /s/ and /ʃ/ in other groups ( $F [2, 27] = 6.000, p = .0070$ ), assuming that one beginning ESL learner did not discriminate /s/ from /ʃ/ perceptually.

#### **4. Discussion and conclusion**

The present study examined the production and perception of L2 English contrasts /s-ʃ/ which is allophonic in Korean by Korean ESL learners. This paper started with the issues of the perception-production relationship in L2 acquisition: 1) Can L2 learners perceive L2 sounds that they do not adequately pronounce, and can L2 learners produce sounds adequately that they do not perceive well?; 2) As L2 learners gain

experience in the L2, do perception and production abilities develop for an L2 contrast that is allophonic in L1? The results show that 1) L2 learners can perceive L2 sounds that they do not adequately pronounce and 2) perception and production abilities with longer L2 experience develop for an L2 contrast which is allophonic in L1.

As for the relationship between production and perception, Korean ESL learners showed improvement in perceptual ability with L2 experience (L2 Beg < L2 Adv  $\equiv$  L1 Control), and not only advanced ESL learners of Korean, but Korean beginning ESL learners reached a native level of perception (i.e., 100% and 98% accurate identification scores, respectively). They showed improvement in production ability as well after long exposure to English (L2 Beg < L2 Adv < L1 Control), even though they did not reach a native level of production. Tukey post-hoc test results indicated that Korean ESL learners did show statistically significant difference in performance between perception and production. Korean ESL learners generally showed better scores in perception than in production regardless of their length of L2 exposure (Production < Perception). Table 2 is a summary table of results of post-hoc tests of Group and Task interaction.

Table 2. Summary of results of Tukey post-hoc tests of Group and Task interaction.

Task	Perception	L2 Beg < L2 Adv $\equiv$ L1 Control
	Production	L2 Beg < L2 Adv < L1 Control
Group	Advanced	<i>Good</i> production < <i>Excellent</i> Perception
	Beginning	<i>Poor</i> Production < <i>Excellent</i> Perception

In sum, Korean ESL learners could perceive L2 English sounds that they did not yet adequately pronounce and greater L2 experience eventually had an impact on the production improvement of English sibilants.

Similarly, Bohn & Flege (1990) claim that the relationship between perception and production changes with time or with L2 experience – e.g., there is better perception than production in early stages of acquisition, but, over time, improved production, which is comparable with findings in the present study. Based on listener judgment of production data, Korean ESL beginning learners showed poor production scores (in fact, scoring near “chance production accuracy”). However, Korean ESL advanced learners were significantly higher in their mean production scores than were Korean ESL beginning learners (L2 Beg < L2 Adv < L1 Control), indicating that L2 experience made a difference in production improvement in second language acquisition

Thus, it is assumed that the production and perception of L2 contrasts that are not found in L1 are related in various and different ways. Recent research studies with various minimal segmental distinctions (Brown 2000; Cheon 2007; De Jonge 1995; Larson-Hall 2001; Toda 2003) also reveal that L2 learners' failure to acquire L2 contrasts differs according to the age of exposure to L2, to the class of L2 sounds, or to other factors. In a production-perception study of Korean voiceless sibilants which is allophonic in English by American English (AE) learners of Korean, Cheon (2007) found *poor* perception and *poor* production in the speech of AE beginning learners of Korean; *good* or *improved* perception but still *poor* production in the speech of AE advanced learners of Korean. In the study, L2 experience did not make any difference in production improvement, but Korean language experience made AE learners of Korean improve their performance in perception, even though they did not yet reach a native speaker level of perception. The results differ from Bohn & Flege (1990)'s findings. There was no improvement in production even after a long period of L2 learning or training in L2 speech learning by AE learners of Korean. Probably, they did not know the exact phonetic nature of the differences needed to produce the contrast authentically, while AE advanced learners of Korean were able to notice differences between /s/ and /s\*/ perceptually. On the other hand, the present study supports Bohn & Flege (1990)'s findings, showing the following results: 1) *excellent* perception and *poor* production in the speech of Korean ESL beginning learners; *excellent* perception but *improved* production in the speech of Korean ESL advanced learners.

In a study of the effects of phonetic similarity and L2 experience on the production of English /s-ʃ/ by adult Korean ESL learners, Cheon (2007) found that production of a dissimilar L2 sound /ʃ/ by ESL learners was perceived better by raters who were native speakers of American English than was production of the similar L2 sound /s/. Cheon (2006) also found that in an acoustic study of Korean sibilants by AE learners of Korean, AE advanced learners of Korean acoustically produce more-similar L2 Korean sounds with greater exactness than they do less-similar L2 Korean sounds,<sup>5</sup> while both L2 advanced and beginning learners poorly produced less-similar sounds; this suggests that L2 learners produce L2 sounds differently depending on the degree of phonetic similarity between L1 and L2 sounds and their L2 experience.

It seems that L2 learners' ability to acquire L2 contrasts differs according to the age of exposure to L2, class of L2 sounds, degree of phonetic similarity between L1 and L2 sounds, or other factors so that the relationship between production and perception in L2 acquisition is not easy to establish. Although perception scores were generally better than production scores in the present study, the relationship between the production and

perception of L2 contrasts that are not found in L1 were found to be more complicated, varying with the nature of the contrast or with L2 experience.

# The (perceived) authenticity of Irish accent in film

Shane Walshe

shane.walshe@uni-bamberg.de

## Abstract

This paper explores the (perceived) authenticity of accents assumed by actors for their roles in film. Focusing on Irish film in particular, it examines the processes involved in accent acquisition by non-Irish actors, and addresses the factors which influence their success. In addition, it finds that even in cases where successful accent acquisition has taken place, performers may nevertheless be judged as not having authentic accents due to their use of stereotypical expressions, due to their appearance or simply due to accent hallucination by audiences who already know that the actors are not really Irish.

**Keywords:** accent acquisition, Irish English, dialect coaches, Irish film, authenticity.

## 1. Introduction

In the introduction to his seminal book *The Cinema and Ireland* (1988), Anthony Slide wryly observed how to many readers the idea of a book devoted to Irish cinema would be comparable to a volume on the snakes of Ireland, in that there were “none of the latter and little of the former” (1988: vi.). According to Luke Gibbons, this lack of indigenous productions could be attributed to the lack of an economy of scale and an appropriate industrial base, to a general hostility towards mass culture, to the existence of an Anglophone audience which made a fledgling Irish cinema extremely vulnerable to Anglo-American influence, and, especially, to Ireland’s lack of a strong visual tradition. (cf. 2005: 207)

In the late 1980s and early 1990s, this situation began to change and Ireland experienced somewhat of a boom in film production. This surge may be attributed to two major factors. The first was a series of tax incentives which were introduced by the Irish government from 1987 to encourage investment in film production in Ireland.<sup>1</sup> The second was the unexpected success of Jim Sheridan’s *My Left Foot* at the Academy Awards in 1990, where the film garnered awards for both best actor and best supporting actress. This film’s achievement, and the subsequent nominations for *The Field* (Jim Sheridan, 1990), *The Crying Game* (Neil Jordan, 1992), and *In the Name of the Father* (Jim Sheridan, 1993), put the Irish film industry on the map and inspired future film-production, which again probably would not have been possible without the aforementioned incentives.

However, the very tax incentives which were designed to encourage investment in

the Irish film industry from the early 1990s were also ironically instrumental in ensuring that it was actually non-Irish actors who, more often than not, received leading roles in Irish films. In *Power in the Eye*, Terry Byrne explains that compromises had to be made to guarantee financial support from abroad. Such compromises usually involved decisions in casting. According to Byrne, Hollywood backers tried to reduce their risk by ensuring that a film shot in Ireland had a number of actors in the cast who were “bankable” in the US market (cf. 1997: 189).

The consequence has been that Irish actors are often overlooked and are replaced by stars whose box-office appeal far outweighs their lack of Irishness, with producers believing that they can compensate for the latter by engaging the services of a dialect coach to make their Irish accents believable.<sup>2</sup> Unfortunately, audiences do not always agree, with actors’ attempts at Irish accents often being exposed to severe criticism:

The casting of Kevin Spacey – one of America’s finest screen actors – was nothing short of disastrous: he looks as if he had strayed in from Los Angeles just for the day and makes no attempt at a Dublin accent. (Farren, *Sunday Independent*, 16 January, 2000: 5)

In light of such judgements, this paper aims therefore to examine 1) how exactly actors go about learning these accents, 2) which factors can influence their success and, finally, 3) whether it is indeed the accent which is being criticised by audiences or whether perhaps other linguistic or non-linguistic factors might be at play.

## **2. How do actors learn accents?**

Actors who have to perform a role with an accent other than their own usually seek the assistance of specially-trained coaches, known alternatively as voice coaches, dialect coaches or dialogue coaches. While there are slight shades of meaning between these terms, all three are used interchangeably in the industry.<sup>3</sup> For the purposes of this study, however, rather than using the terms interchangeably or coining the title “accent coach”, which, in fact, would be more accurate, I will continue to use the more popular term “dialect coach”. Furthermore, in the interest of brevity, rather than giving an in-depth description of how exactly dialect coaches teach actors to perform an accent, I will instead present a brief summary of the methods used by these coaches, and encourage the reader to consult Bonnie Raphael’s excellent article “Preparing a Cast for a Dialect Show” (1984) for the definitive description of the processes involved.<sup>4</sup>

When it comes to teaching somebody a new accent, the work of the dialect coach is not too dissimilar to that of the foreign-language teacher, insofar as they both try to equip their students with a range of completely new sounds, or combinations of sounds, which differ from those of the students’ own sound system, irrespective of whether that system stems from a different language or merely a different variety. Much of the terminology and the techniques used by EFL/ESL teachers can thus be applied to the work of dialect coaches.

One approach to teaching actors a foreign accent is the intuitive-imitative approach, which involves providing the actor with a model pronunciation and having him imitate it. This method “depends on the learner’s ability to listen to and imitate the rhythms and sounds of the target language [or, in this case, accent S.W.] without the intervention of

any explicit information” and it “also presupposes the availability of good models to listen to” (Celce-Murcia 2000: 2). These good models can take a couple of forms. Either the dialect coach himself will be the model, or he can provide the actor with recordings of some other speaker speaking with the accent. Both options have their positive and negative sides, with the authenticity of the models playing a key role.

If the dialect coach himself happens to speak with the accent he is teaching, then the student has a perfect living model. However, if the dialect coach is, for example, American and is teaching an actor an Irish accent, then this may lead one to question how accurate the end-product will be. After all, a photocopy of a photocopy is quality-wise usually a couple of steps removed from the original. On the other hand, some actors may find having a “non-native” dialect coach encouraging, as he is likely to know the potential stumbling blocks which the learner will face, and his own ability to imitate the new accent shows that it can indeed be done.

Alternatively, the dialect coach can furnish the actor with a recording of the required accent, the advantage of this being that the student has a model to imitate, even in the absence of his teacher. Here again, however, one should distinguish between recordings which themselves are imitations of accents, such as dialect coach David Alan Stern’s *Acting with an Accent* series (1979), and the real thing. Many dialect coaches tailor their recordings to the exact needs of the actor, collecting speech samples from authentic speakers of the same gender, age and social class as the character to be portrayed, thus giving the actor the most accurate input possible.<sup>5</sup>

The other major approach adapted by dialect coaches from the world of foreign-language teaching is the analytic-linguistic approach, which employs teaching aids, such as the International Phonetic Alphabet (IPA), articulatory descriptions, diagrams of the vocal apparatus, contrastive information, and a host of other materials to supplement listening, imitation, and production. This approach is not designed to take the place of the intuitive-imitative approach, but rather to be employed in tandem with it. The result is that learners are not only provided with a model pronunciation, but that they are also given detailed linguistic information about the sounds they have to produce (cf. Celce-Mercia 2000: 2).

The IPA is very useful for this purpose, as it is well-established and internationally recognised, and once actors have learned it they can apply it to all future accent work. The disadvantage is that many actors have never learned this alphabet. Even when given a chance to learn it from a dialect coach, many are not willing to do so, or due to a tight shooting-schedule cannot afford to invest the time in learning what for them may seem to be a system of strange symbols and dots. They much prefer to have an approximate orthographic representation of the lines they have to say, using the regular English alphabet. While dialect coaches are usually accommodating to such requests, they nevertheless need to continue to provide a model pronunciation for the actor. Failing to do this can lead to potential misreading of such respellings, as the following quotation from Evangeline Machlin’s text book for actors shows:

[...] you must always remember that respelling is suggestive rather than exact as to the pronunciation it represents. It is the best that can be done to show dialectal pronunciations using the letters of the alphabet. The dialect pronunciations that you must learn are those HEARD ON THE TAPE. There only can you discover exactly what the respellings stand for. Guiding yourself by what you *hear* rather than by what you *see*, you will safeguard yourself against mistakes in dialect reproduction. (Machlin 1975: 2)

Machlin's advice highlights once again the age-old problem which has always befallen dialectal respellings, namely the shortcomings of a twenty-six letter alphabet in representing the forty plus phonemes of the varieties of English.

In addition to offering actors a written model of what they have to say, either in IPA or literary dialect, dialect coaches also try to familiarise their students with the workings of the vocal apparatus, in the hopes that if they know where and how the sound is produced, they may be able to produce it themselves more easily. Again, it is often necessary for the coach to avoid using technical terminology, for the sake of actors who have no grounding in linguistics. Indeed, Scott Thornbury cautions against "explicit descriptions or models of voice setting features, on the premise that such descriptions, while useful for the teacher to refer to, are not very helpful for the learner. How, for example, does one lower one's larynx and palatize one's tongue position?" (1993: 131). In a similar vein, Judy Gilbert suggests that "explaining phonological stress rules might not be any more helpful to the pronunciation student than explaining the appropriate laws of physics to someone trying to learn a bicycle" (1980: 111). Thus, it is essential that dialect coaches pitch their knowledge at a level that is understandable for their students and, more importantly, easy to put into practice. In addition, it is desirable, even if it is not always possible due to financial or logistical reasons, that the dialect coach also be present on set during the shooting of the film. The reason for this is that even if the dialect coach has been very successful at teaching the actor the required accent, fossilisation often sets in. This means that while the actor has reached a certain level of attainment, he will not progress beyond this point, and, worse still, if he has begun to make mistakes, he may just reinforce them through repetition.

### **3. Factors which determine successful accent learning**

Much research has been conducted on the factors which are responsible for precise pronunciation among second and foreign language learners, and it is my contention that these factors are essentially the same as those which determine successful accent acquisition for the stage or screen. What follows is a summary of these determinants drawn from Celce-Murcia (2000) and Nunan (1995), which has been amended slightly for the purpose of this study, with the term "language" being replaced by "accent" or "dialect" where appropriate.<sup>6</sup> The factors include: the influence of the learner's first language (or, in this case, accent), the learner's age, the amount of exposure to the target accent, the amount and type of prior pronunciation instruction, the actor's phonetic ability, his attitude toward the target accent and his motivation to achieve an accurate accent.

#### *3.1 The influence of the learner's first language*

Just as a foreign-language student's native sound system will invariably influence his pronunciation in the target language, an actor's attempt at an accent will also be influenced by his own sound system. The contrastive analysis hypothesis holds that "second language acquisition is filtered through the learner's first language, with the native language facilitating acquisition in those cases where the target structures are similar, and "interfering" with acquisition in cases where the target structures are

dissimilar or nonexistent” (Celce-Murcia 2000: 20). This “interference”, which is now more commonly referred to as “negative transfer,” is thus supposed to be a determining factor in cases where accent acquisition is not so successful. As convincing as this hypothesis appears at first sight, it may not hold up to closer scrutiny.

There is, after all, a conflicting hypothesis, Flege’s Speech Learning Model (SLM), which suggests that rather than facilitating acquisition, similar target structures actually somewhat impede it. According to this model, all sounds being learned are categorised as ‘new’, ‘similar’ or ‘identical’ depending on the differences between them and sounds which already exist in the L1. Those sounds which are regarded as being similar to an existing L1 sound will only be produced as the L1 sound, but *never* as an authentic L2 sound. Those perceived to be new, however, will be learnt successfully (in a native-like manner) by learners, while sounds which are identical in both languages will pose no problem, as they will already have been mastered in the L1. (cf. Flege 1992)

The SLM would imply that it is exactly those target structures which are classed as similar which betray an actor by revealing his or her true origins. An example would be Wallace Ford’s American [æ] rather than the Irish English [a] when referring to the “Black and Tans” in *The Informer* (John Ford, 1935).

### 3.2. *The learner’s age*

A further factor in determining the success of accent acquisition is the learner’s age. The critical period hypothesis holds that there is an optimum time for language acquisition and that once learners pass a certain age, they lose their ability to learn new languages to anything close to a near-native level (cf. Scovel, 1988; Krashen, 1973). It is thought that neuroplasticity – “the ability of the young brain to program and process new patterns of behaviour quickly and efficiently, and to relocate this programming and processing to different areas of the brain if there is congenital damage or injury incurred after birth” (Scovel 1988: 62) – is greatest in the brains of young children but then diminishes with age. For our purposes, it is interesting to note that this hypothesis distinguishes between a critical period for acquisition of grammar, pre-puberty, with a steady decline between the ages of twelve and sixteen, and one for the acquisition of near-native pronunciation, merely up to the age of six (cf. Ellis 1997: 68). The theory would suggest that it would be therefore nigh on impossible for an adult actor to ever learn a new accent to such a degree that it would sound native, which echoes Lippi-Green’s assertion that a person’s accent “is fixed or hard-wired in the mind, and once past a certain age it can only be very laboriously changed, to a very limited degree, regardless of commitment, intelligence, and resources” (1997: 241). Having said that, there are conflicting opinions on the validity of this critical period hypothesis, as a number of studies have revealed instances of adult foreign language learners, and indeed actors, who have attained excellent pronunciation, thus somewhat discrediting the theory (cf. Neufeld, 1977, Kenworthy, 1987; Knight, 2000). Furthermore, as will become apparent, Lippi-Green may very well have underestimated the effects of “commitment, intelligence, and resources”, which, in one way or another, are components of the other factors which determine the degree of accent acquisition.

### 3.3. *Amount of exposure to the target accent*

One of these factors is the amount of exposure one has had to the target accent. It is generally agreed that learners acquire language primarily from the input they receive (cf. Postovsky, 1974; Krashen, 1982). Therefore the amount of exposure they have to the target accent will play a crucial role in the degree of their success, and accents which they have been regularly exposed to should be easier to learn. Even, in the absence of first-hand exposure to the target accent, the media can play a key role, ensuring that somebody, for example, who may never have been to Australia or never met an Australian, yet has had regular exposure to Australian television programmes, such as *Home and Away* and *Neighbours*, will nonetheless be able to imitate an Australian accent.

In cases where exposure to an accent is limited, so too will be the success. From an Irish perspective, therefore, the fact that so few Irish television programmes have been readily available to viewers in the UK and the US means that British and American actors lack the same degree of exposure to an Irish accent that an Irish actor who is exposed to many American and British movies and TV shows would have to those accents. This would support an argument made by Michael Dorsey in *Volta Movie Magazine* regarding the poor quality Irish accents on offer from non-Irish actors.

Why is it that the Hollywood Irish actors can effortlessly reproduce any number of European or American accents, but their British or American counterparts give an Irish accent all four provinces and a box of Lucky Charms wrapped up in forty shades of green? Be-da-hokey! Doff dat cap, Darby, tug dat forelock. (2000: 31)

Dorsey's comments would appear not only to criticise the quantity of exposure that British and American actors have to Irish accents, but also the quality of that exposure. The reference to "all four provinces" suggests that the accents assumed by foreign actors are often an amalgam of various regional Irish accents which when mixed together create an incredible whole. This opinion is corroborated by a review in the *RTE Guide* of Kevin Spacey's accent in the film *Ordinary Decent Criminal* (Thaddeus O'Sullivan, 2000). "Spacey's Irish accent is something else, ranging as it does from the walls of Derry to Cork and back again to somewhere in Dublin" (Doherty, 2000). Furthermore, "Lucky Charms", "forty shades of green" and "Darby" are all references to Irish American creations, which are erroneously thought to be Irish, and so if actors are using these questionable sources as their model input, then their Irish accents will be equally questionable.<sup>7</sup>

### 3.4. *The amount and type of prior pronunciation instruction*

In addition to the amount of exposure to the target accent, the amount and type of prior pronunciation instruction is also a determinant of how accurate an actor's new accent will be. Some actors may have had extensive accent training at drama school or may have already played roles in plays which were written in dialect, thus making learning new accents easier as their ear and vocal apparatus are attuned to hearing and producing new sounds. However, it often arises, just as in EFL settings, that the instruction comes from a teacher whose own pronunciation differs greatly from the target norm, meaning that the coach's own negative transfer is passed onto the students. Moreover, many drama schools use manuals compiled by dialect coaches which aim to teach actors how to acquire a variety of accents, or dialects, as the case may be, yet

which may be more detrimental to their acquiring a new accent than no prior instruction at all. These manuals are often poorly researched or so ambitious in their scope that they often unintentionally propagate completely erroneous or stereotypical features.<sup>8</sup>

### 3.5. *The actor's phonetic ability*

Another factor which influences an actor's ability to assume a new accent is his "ear" for accents, as it is often termed. This phenomenon has been variously called one's "phonetic coding ability" or "auditory discrimination ability" by Kenworthy (1987) and also "phonemic coding ability" by Carrol (1962). This ability is believed to have little to do with general intelligence or even language learning ability per se, and, indeed, there is a common belief among lay people, and even among dialect coaches, that this ability to learn accents may have more to do with the learner having, what they call, a "musical ear". For example, dialect coach, Ginny Kopf, suggests that those with an aptitude for music "will be better able to hear and copy the rhythms and pitch changes of different dialects" (2000: 14), while Machlin believes that "any actor who can sing a tune can learn to speak a dialect" (1975: 1). However, Howard Gardner's seminal work on multiple intelligences offers evidence from in-depth research on the workings of the human brain, which highlights that the information-processing mechanisms for phonology are in fact located "close to the core of linguistic intelligence" and that "investigators working with both normal and brain-damaged humans have demonstrated beyond a reasonable doubt that the processes and mechanisms subserving human music and language are distinctive from one another" (1983: 81, 117). Accordingly, in normal right-handed individuals, whose linguistic abilities are centred almost exclusively in the left hemisphere, and whose musical abilities, including sensitivity to pitch, are located in the right hemisphere, neural damage to the left hemisphere, through injuries or illness, will therefore affect a person's speech but not his musical ability (cf. Gardner 1983: 118).

While we may have disproved the connection between having a "musical ear" and the ability for phonology, this does not mean that there is no validity to the notion of an "ear" for accents, which was mentioned above. Indeed, Flege *et al.* (1996) suggest that one of the main obstacles people encounter when learning pronunciation in a second language is that they simply cannot hear the phonetic nuances of the new language. This condition of "incorrect perception" is explained as follows:

During L1 acquisition, speech perception becomes attuned to the phonetic elements of the L1. L2 learners may fail to perceive the phonetic details of L2 sounds and sound contrasts accurately owing to the assimilation of L2 sounds by L1 categories. Without accurate perceptual 'targets' to guide sensorimotor learning, production is destined to be inaccurate (Flege *et al.* 1996: 48).<sup>9</sup>

As one can see, this issue is closely related to the aforementioned factor of the influence of the learner's first language. What is more, the learner's age can also play a role in this issue. Schneiderman and Desmarais state that research on phonetic perception shows that "adults and older children are less able to discriminate between speech sounds than infants when these sounds are not distinctive in the older subjects' first language [...] and that adults discriminate on the basis of the phonetic categories of their first language" (1988: 111).

### 3.6. *The learner's attitude and sense of identity*

A learner's attitude and sense of identity can also play important roles in the acquisition of an accurate pronunciation. Indeed, Guiora (1972) argues that personality, or "language ego" as he calls it, is fundamental in the acquisition of a new language, and even more so with regard to pronunciation: "Speaking a foreign language entails the radical operation of learning and manipulating a new grammar, syntax and vocabulary and, at the extreme limits of proficiency, *modifying one of the basic modes of identification by the self and others, the way we sound*" [emphasis S.W.] (1972: 144). This means that the extent to which we believe that our voices and our sense of identity are linked will be a determining factor in whether we are willing to change our voices. Schumann echoes Guiora's comments and calls this measure of our willingness to change "ego permeability" (1975: 209-35). Based on this hypothesis, one could argue that actors should be good at learning new accents, as by the very nature of their job they should have a high degree of ego permeability, since they are constantly embodying new characters and assuming new personas.<sup>10</sup>

What is more, actors may have another personality-related factor of accent acquisition in their favour, as it has been claimed that individuals who show a basic strong sensitivity to emotion perform better in phonetic acquisition (cf. Markham 1997: 25). If that is indeed the case, then one could argue that actors should therefore be at an advantage, as they generally display this sensitivity to emotion, being able to call up feelings, and sometimes even tears, at will. Indeed, this notion of empathy leading to superior accent acquisition is supported to a certain degree by the findings of a study by Taylor et al. (1969). However, this applies only to a certain degree, as it is interesting to note that the same study also suggests that, while actors indeed are often very adept at accent acquisition, it may not necessarily stem from their greater sense of empathy but can often be the result of a greater sense of narcissism. Whether or not, one agrees with their opinion about actors, the notion of personality playing a key role in accent acquisition is nonetheless very interesting.

### 3.7. *The learner's motivation*

The final, and for some the most crucial, determinant of success both in language learning and accent acquisition is motivation. Schumann (1986) and Gardner and Lambert (1972) distinguished between various forms of motivation in language learning, which are generally related to acculturation, or the extent to which the learner wants to integrate in the foreign-language community.

The first of these types of motivation is "integrative motivation" in which a learner desires to be integrated socially into the target culture, and thus learns the language. The second is "assimilative motivation" and is like the first, in that it involves a longing to be integrated, but, in the latter case, this longing is even greater, with the learner desiring to become indistinguishable from other members of the target speech community. Neither of these forms of motivation are necessarily those which drive actors who accept accent roles. They may have no personal desire at all to integrate with the community represented in the film, never mind completely assimilate there. What is more, the film may not even be shot in the actual target speech community being depicted: "Irish" films, such as *Waking Ned* and *Darby O'Gill and the Little People*, for

example, were filmed on the Isle of Man and in Burbank, California respectively. Thus, the actors in those films would not even have had the chance to integrate or assimilate with the Irish people even if they had wanted to.

A better descriptor for an actor's motivation is perhaps "instrumental motivation", that is, the incentive involved when someone learns a new language (or accent) in order to attain a certain goal – to pass an examination or to get a job promotion. While this last type of motivation does not really involve acculturation, it does not mean that it is any less effective than the previous two. In fact, Celce-Murcia (2000) cites Lukmani (1972) as having argued that the intensity of motivation is often as important as the type of motivation at play. She even adds that "someone with extraordinarily high instrumental motivation (e.g., someone who wants to sound like a native speaker in order to function effectively as an actor or an espionage agent) may well achieve a better pronunciation than someone with integrative motivation that is quite positive yet less intense" (Celce-Murcia 2000: 19). What better motivation could there be for an actor than the fact that if he fails to perform the accent properly, he runs the risk of embarrassing himself in front of millions of people? After all, in film, unlike in theatre, one's performance is not ephemeral, but rather is captured forever on celluloid.

#### **4. Factors which influence the (perceived) authenticity of accents in film**

As has been shown there are a number of factors which can influence whether or not an actor is able to acquire an authentic accent. However, even in cases where an actor does succeed in achieving an accurate accent, it is still possible that his accented performance may, through no fault of his own, still be perceived as inauthentic by cinema audiences. There are a few intriguing reasons for this, yet these are generally not borne in mind when people judge a performance. These are as follows:

##### *4.1. Degree of standardisation to appeal to mass audience*

As one can imagine, perceptions of what an authentic accent is can be very different depending on an audience's experience and expectations. Therefore, filmmakers may run the risk of disappointing Irish audiences if the accents or dialects in Irish films are not accurate, or of alienating non-Irish audiences if they are, but are difficult to understand. Since films are generally produced to be exposed to as large an audience as possible, the last thing filmmakers want is to alienate audiences just because the actors are speaking some incomprehensible dialect and thus in order to ease comprehension for a wider audience, dialect and accent are often modified.<sup>11</sup> To that end, dialect coach Robert Blumenfeld offers the following words of advice to actors:

As an actor you must be understood by your audience. Do not, for instance, do such a thoroughly authentic Cockney or Glasgow accent that most of your audience will find everything you say utterly incomprehensible. Instead do an authentic-sounding version, and always keep your diction clear by articulating consonants strongly. (Blumenfeld, 2000: unpaginated)

These words are echoed by a fellow dialect coach who suggests that "sometimes you have to 'cheat' and do a lighter or more generic accent if you

think your audience would have trouble easily accepting the true one” (Kopf 2003: 51).<sup>12</sup> In these circumstances, it is no wonder that actors’ accents may be perceived as inauthentic.

#### 4.2. *Use of erroneous or stereotypical expressions*

Just as the insertion of lexical items typical of a dialect can lend a performance an extra degree of authenticity,<sup>13</sup> the use of erroneous or stereotypical expressions can undo even the best accent. Research for my doctoral thesis, (Walshe, forthcoming) has shown evidence of accents which are quite accurate on a segmental and/or suprasegmental basis, but yet have been unjustly criticised by both audiences and critics alike.

Indeed, it is my contention that very often audiences, and in this case Irish audiences in particular, deem an actor’s accent to be inaccurate not on the basis of the accent itself, but because they react negatively towards other linguistic or, as we shall also see later, non-linguistic features. The fact that these elements, and not necessarily accent itself, play a role becomes very clear when one analyses both film reviews and what Niedzielski and Preston (2003) describe as the “folk’s” comments on the accents. The first of these comments concern themselves with linguistic features, albeit ones which are not at all related to accent, namely stereotypical expressions or catchphrases.

Since the birth of the Stage Irish figure, the use of stereotypical expressions which are falsely deemed to be typically Irish has been one of the major gripes of Irish audiences. This stems from the fact that the speech of Irish characters is often “spiced up” by the addition of pat phrases which have developed Irish connotations, such as “Top o the morning”, “Faith” and “Begorrah”. Attention has been drawn to the inaccuracy of such expressions before, perhaps most famously by George Bernard Shaw in his satirical play *John Bull’s Other Island*, in which Doyle criticises Broadbent for giving money to the so-called “Irishman” Tim Haffigan. He berates him for being so gullible as to have believed that the man was Irish.

*Doyle:* [...] He’s not an Irishman at all.

*Broadbent:* Not an Irishman! [He is so amazed by the statement that he straightens himself and brings the stool bolt upright].

*Doyle:* Born in Glasgow. Never was in Ireland in his life. I know all about him.

*Broadbent:* But he spoke – he behaved just like an Irishman.

*Doyle:* Like an Irishman!! Man alive, don’t you know that all this top-o-the-morning and broth-of-a-boy and more-power-to-your-elbow business is got up in England to fool you, like the Albert Hall concerts of Irish music? No Irishman ever talks like that in Ireland, or ever did, or ever will. But when a thoroughly worthless Irishman comes to England, and finds the whole place full of romantic duffers like you, who will let him loaf and drink and sponge and brag as long as he flatters your sense of moral superiority by playing the fool and degrading himself and his country, he soon learns the antics that take you in. He picks them up at the theatre or the music hall.

(Shaw, 1907/1964: 80-1)

Doyle’s comments are all the more humorous if one knows that while Shaw’s wonderful critique of Stage Irishism was being performed in Dublin’s Abbey Theatre almost a decade later, a new musical entitled *Top o’ the Morning* was premiering down

the road in the Empire Theatre, today's Olympia Theatre.

However, somewhat surprisingly given their presence in the public consciousness, these Stage Irish expressions almost never appear in the 50 films examined in the film corpus compiled for my forthcoming PhD thesis. Indeed, as the examples below show, the expressions "Top of the mornin'", "Begorrah", "Faith" and "More power to your elbow" appear in only one film each. "Broth of a boy" does not appear at all.

(1) *Top o' the mornin'* Father.

(*Ryan's Daughter*, 00:38:43, MP1920W)<sup>14</sup>

(2) *Begorrah!* He wasn't far wrong.

(*Darby O'Gill and the Little People*, 00:28:25, MKB1800W)

(3) *Faith*, I know I can't sing a lick, but when I'm roarin like Doran's bull, it works up a killin' hunger in me.

(*Darby O'Gill and the Little People*, 00:48:54, MMB1800D)

(4) *More power to your elbow*, Frankie.

(*Angela's Ashes*, 01:18:55, MUP1930L)

However, despite the fact that these terms almost never appear in these Irish films, many of the comments on poor Irish accents in film still incorporate these very terms, especially "Top o' the mornin'" or "Begorrah", in their description of them, thus creating for their readers an impression of Stage Irish speech, which was not present in the actual film.<sup>15</sup> Comments on Tom Cruise's performance in *Far and Away*, for example, often employ such terms, although, as already mentioned these phrases do not appear in that film.

Below are some examples: the first comes from an interview by Sell which asked informants whether they had ever seen a film in which a non-Irish person assumes an Irish accent. The second is from an Internet forum which addressed the notion of the worst accents on film.

*Respondent* – It's just, we don't talk like that.

*Interviewer* – Is it exaggerated?

*Respondent* – Yeah, a little bit, yeah, it's the usual *Top o' the mornin' to you* kind of thing. It's just you're, like, no, we don't speak like that. So, there's a bit of a stereotype to the Irish accent in general." (Female, 25, Galway, in: Sell, forthcoming)

Has everyone forgotten about Tom 'Tommy Boy' Cruise in 'Far & Away ? Oh *begora* an' *begod*, sure isn't it a fantastic mornin' to be a lepracaun! (lazyink, August 22, 2007)<sup>16</sup>

The result is that even among those people who have never seen this film there is already an expectation that the accent must be terrible. This is again substantiated in some of the Internet comments discussing accents.

I haven't seen Tom Cruise's effort, but anyone who has seems to rate it among the very worst. (John 83, September 17, 2007)<sup>17</sup>

What is more, audiences appear to have picked up on one line of dialogue from the film *Far and Away* and focus on that as the justification for Cruise's poor accent. However, it is worth asking the question whether the problem is perhaps with the line itself rather than the accent.

Far and Away - when i saw it in the early Nineties in a cinema in Galway when Tom Cruise says "*Aye Shannon you're a corker*" the cinema exploded with laughter - comedy gold, i always end up watching it on Tv just to see that bit, Niall Tobins stage Irish *begorrah* accent is hilarious as well!!<sup>18</sup> (Tim Landers, January 16, 2007)<sup>19</sup>

A movie which manages to belittle the plight of the Irish immigrant, mangle the Irish accent and trivialise Irish history in one fell swoop. When Tom Cruise fixed his slightly creepy gaze on Nicole Kidman and pronounced "*Yer a corker, Shannon*", the groans from the audience were almost as loud as the sound of Joyce, Beckett and Yeats turning in their graves. (Declan McKenna, March 14, 2008)<sup>20</sup>

Ladies and gentlemen, I give you: "Far and Away". Oh. Dear. God. "*Aye Shannon, yer a corker*" - what? I mean, *what?* Tom Cruise and Nicole Kidman, you are found guilty of grievous bodily harm to the Irish accent. (Anacreon, January 23, 2001)<sup>21</sup>

Ironically, the line which grated so much with Irish audiences, was the very one which most struck a chord with the American film critic, Peter Travers, who works for *Rolling Stone*.

"*You're a corker, Shannon.*" says Joseph in rapt admiration. "*What a corker you are.*" The delicate sweetness of that moment, magnetically played by Cruise and Kidman, represents the movie at in (sic) best. (Peter Travers, December 8, 2000)<sup>22</sup>

This shows once again that, when it comes to expectations of authenticity, Irish and international audiences differ greatly. With regard to the controversial line from *Far and Away*, it would appear, based on my own enquiries and on the reaction of Irish audiences, that the word "corker" is not used in Ireland today<sup>23</sup>. That, of course, does not mean that the term might not have been popular at the time when the film was set, namely, in the late 1880s. Indeed, according to the OED, "corker" is first attested as appearing in 1882, and is a colloquial or dialect term which refers to "a person or thing of surpassing size or excellence, a stunner" (II: 934). The OED does, however, add that the term is "also used ironically" and this may be where the problem with Cruise's use of the term arises. He delivers the line so sincerely, "in rapt admiration" as Travers described it above, that it would appear to be his undoing. It is my contention that it was the line coupled with the sincerity of the delivery, and not his actual accent, which reduced audiences to groans and laughter.

#### 4.3. *Extra-linguistic factors*

While critics and audiences alike have drawn attention to the linguistic shortcomings of the aforementioned performances, there is also evidence to suggest that it may not necessarily be the accents or the use of Stage Irish expressions which detract from the perceived authenticity of the performance, but rather some other non-linguistic factors. For example, the *Historical Dictionary of Irish Cinema* (2007) features the

following criticism of *Circle of Friends*, and particularly of American actor Chris O'Donnell:

Inevitably, however, given the absence of Irish actors in lead roles, audiences were subjected to cringe-worthy attempts at local accents, some so bad as to obscure the dialogue. Chief among the culprits was Chris O'Donnell, clearly chosen to give the film international appeal, but always looking more like an American high school jock than what in the 1950s would have been a rare creature in Ireland – a university student.” (Flynn and Brereton 2007: 58-9)

At first glance, it appears to be a run-of-the-mill criticism of poor accents in Irish film; mentioning, as it does, the “cringe-worthy attempt at local accents”. However, if one looks at the choice of words a little more closely, there is another issue at play here. While Chris O'Donnell is singled out as the chief culprit, there is a strong suggestion that this could have more to do with his appearance than with his accent. After all, the complaint is not that he *sounds* like an American high school jock, but rather that he *looks* more like an American high school jock.<sup>24</sup>

Closer scrutiny of other film reviews reveals that writers may similarly be strongly influenced by an actor's appearance rather than by his accent per se. For example, based on the following review, the credibility of Tom Cruise's performance in *Far and Away* has less to do with accent and more to do with dentistry.

Any pretensions to plausibility are, however, fatally undermined by the presence of Tom Cruise's perfect teeth. (*O' Mahony, in: Film Ireland* (121), March/April 2008: 13)

It is significant therefore that, consciously or not, it is often non-linguistic elements which these reviewers make reference to when commenting on the elements which detract from the perceived authenticity of the actors' performances.

#### 4.4. Accent hallucination

The previous point is also strongly linked to the notion of “accent hallucination”, which also can play a significant role in accent perception. Accent hallucination occurs when “prejudice on the part of the hearer lead[s] to the perception of stigmatised forms (even where in reality these do not exist)” (Fought, 2006: 187-9). In *Language and Ethnicity*, Fought offers a number of examples, including experiments by Williams (1983) and Rubin (1992), to show just how endemic accent hallucination can be. In Williams' study, a group of European-American student teachers viewed videotapes of three children (1 European-American, 1 African-American and 1 Mexican-American) with the task of rating the level of English they heard. Unbeknownst to the respondents, the voice they were hearing was always that of the same standard English-speaking child. Nonetheless, the speech of the African-American and Mexican-American children was consistently regarded as significantly more “non-standard” than that of the European-American. The same applied to Rubin's study which had students listen to a lecture while looking at a photograph which they were informed was of the speaker. Half of the group were shown a picture of a European-American, while the other half were given a picture of an Asian woman. As in Williams' experiment, the speaker was actually the same for all visual stimuli and again was a native speaker of English with

no marked regional accent. However, as before, the students who were shown the picture of the Asian woman were more likely to rate her as having an Asian accent. Bearing such results in mind, it is worth considering the question of whether audiences who know that an actor is not Irish are perhaps also susceptible to accent hallucinations, thus projecting their preconceived notions onto the actor's perhaps impeccable performance.<sup>25</sup>

The implication here is that when audiences are aware that the stars of these Irish movies are not Irish, they imagine that they can hear traces of a non-Irish accent. Indeed, such hallucination was already proven to exist (above) with regard to stereotypical expressions, such as "Top o' the mornin'", "begorrah" etc. which are projected onto actors' performances by audiences, even though the terms are never used by the actors nor appear in those films.

## 5. Conclusion

In conclusion, one can say that although numerous factors, such as age, motivation, training etc, can certainly influence an actor's success in acquiring a new accent for a role, these are not the sole determinants in whether audiences perceive the performance as being authentic. Such decisions can also be influenced by what the actor says, by how he looks, by the audience's accent hallucination, and by the degree of standardisation of the accent for a global audience. It is important that these additional factors also be borne in mind, lest we make rash judgments regarding an actor's accented performances.

## Notes

---

<sup>1</sup> Under Section 481 of the Finance Act (formerly Section 35), a tax deduction is available to Irish investors who buy shares in Irish film production companies, with 80% of the amount invested being written off for tax purposes. For further information on these tax incentives, see [http://www.filmboard.ie/section\\_481.php](http://www.filmboard.ie/section_481.php) (19 June, 2005)

<sup>2</sup> A quick glance at the casts of Irish movies in the last two decades reveals a "who's who" of some of the film industry's most prominent names: Tom Cruise, Nicole Kidman, Kevin Spacey, Cate Blanchett, Daniel Day-Lewis, John Hurt, Julia Roberts, Alan Rickman, Joan Allen, Jon Voight, and Kate Hudson. All of these actors have assumed Irish accents with varying degrees of success.

<sup>3</sup> Technically, a voice coach is normally responsible for teaching proper breathing, voice projection and other elocution techniques, whereas a dialogue coach, in the early days of sound cinema in America, was traditionally somebody who helped actors to learn their lines and who ran dialogue with them. This role later developed into that of the dialect coach, who assisted actors in learning how to approximate various accents. The title, of course, is actually a misnomer and should really be "accent coach", as it is pronunciation which the coaches teach and not the grammar or other features of the dialects, which are already provided in the screenplay.

<sup>4</sup> Further insights into the work of the dialect coach were gained by consulting a number of works written by dialect coaches, such as Evangeline Machlin (1975), Lewis and Marguerite Herman (1997), Robert Blumenfeld (2000) and Ginny Kopf (2003).

<sup>5</sup> Actors often also request recordings of somebody saying the actual lines they will have to perform, and dialect coaches generally reluctantly oblige. However, they are quick to stress that their job is not

---

interpretive and that, while they will happily say the lines with an accent, it is outside of their remit to interpret how these lines should be delivered. Such work is the responsibility of the actor and director. It was exactly this reluctance “to select a particular interpretation of a line, at the expense of others” (Crystal 2005: 33) which initially deterred David Crystal from providing actors with a recording of him reading the lines from *Romeo and Juliet* in his experiment to recreate Shakespearean pronunciation for the stage. As is often the case, he too later acquiesced and furnished the actors with the auditory material.

<sup>6</sup> In the direct quotations that follow, I shall leave the word “language” intact, in the interest of fidelity to the original. The reader should, however, insert the word “accent” in its place.

<sup>7</sup> “Lucky Charms” is an American breakfast cereal which uses a leprechaun figure with a faux Irish accent in its advertising campaigns. “Forty Shades of Green” is a sentimental song written by American Country singer, Johnny Cash, about an emigrant reminiscing about the old sod, while “Darby” is a reference to a character created by Hermione Templeton Kavanagh, which appears in a series of books written in dubious literary dialect. The figure is best known from the Disney film *Darby O’Gill and the Little People* (Robert Stevenson, 1959), which was loosely based on Kavanagh’s books and again features some debatable Irish accents.

<sup>8</sup> One such manual, *Foreign Dialects. A Manual for Actors, Directors, and Writers*, by Lewis Herman and Marguerite Shalett Herman, for example, ambitiously professes to teach actors all of the following “dialects”: Cockney, British, Australian, Bermudan, Indian, Irish, Scottish, German, French, Italian, Spanish, Mexican, Filipino, Portuguese, Japanese, Chinese, Chinese pidgin English, Hawaiian, Beche Le Mar, Australian pidgin, Swedish, Norwegian, Russian, Lithuanian, Yugoslav, Czech, Finnish, Hungarian, Polish, Greek, and Yiddish (Herman and Herman, 1997). The same authors have also published a separate volume on the various American dialects. However, these “dialects” are never accompanied by a recording, and to make matters worse, the authors do not use the IPA, but instead offer faux transcriptions written in undecipherable respellings, such as “dUHd uhEE kUHI UHm, sEHzuhEE” which apparently is “‘Did I kill him?’ says I” in an Irish accent (Herman and Herman 1997: 68).

<sup>9</sup> Flege *et al.* go on to state that due to the fact that adults are language-specific perceivers of speech, it is their assumption that “a larger proportion of production errors in a second language may have a perceptual basis” (Flege *et al.* 1996: 66). It should be reiterated, however, that even if one is able to “hear” the nuances of a new language or accent, that does not necessarily mean that one will be able to accurately reproduce those sounds. As outlined already in 3.2., once pre-established patterns of articulation have been ingrained by the vocal apparatus, it is very difficult to modify them in order to learn new ones. Further discussion of the interplay between perception and production (or rather reproduction) can be found in Postovsky (1974).

<sup>10</sup> It might be worth noting, however, that, etymologically speaking, the words “embody” and “persona” only refer to the visible outward transformation of the actor, and do not necessarily suggest an audible change. If actors therefore lack the necessary degree of ego permeability and are not willing to also change the voice behind the mask, then their success with the new accent will be limited.

<sup>11</sup> Of course, this is less of a problem in certain film markets, such as the German one, which tend to dub films into the audience’s mother tongue. Nevertheless, problems can still occur when trying to translate dialect or heavily accented pronunciation into a foreign language for the purposes of dubbing or subtitling. Indeed this is even evident in the English subtitling of some Irish films. For example, compare the two versions of the following exchange from *When the Sky Falls* (John MacKenzie, 2000). It takes place between a drug addict and some Dublin thugs, one of whom is named Keegan, but called Keego, the familiarizing suffix ‘o’ being common in colloquial Dublin speech. It appears on the soundtrack as follows (my transcription):

*Thug 1:* Ah look who it is.

*Thug 2:* Go on, ya waster!

*Drug Addict:* Alright, Keego?

*Thug 1:* You alright, tinfoil head?

*Thug 2:* Ya scumbag ya, keep walkin’.

The subtitles, however, read as follows:

*Thug 1:* Look who it is.

*Thug 2:* On your ways.

*Drug Addict:* All right, Keego.

*Thug 1:* You are, rude tinfoil head.

---

*Thug 2*: You scumbag, keep walking.

Clearly, the person responsible for subtitling had difficulty understanding the Dublin pronunciation and thus two of the five lines of the exchange are incorrect.

<sup>12</sup> A fine example of this school of thought is evident in the case of the Newcastle-set film *The One and Only* (Simon Cellan Jones, 2002). According to the local newspaper *The Northern Echo*, the producers were so worried about foreign audiences not understanding the dialogue in the movie that they hired a dialect coach, Majella Hurley, “to create the ‘Geordie Light’ accent. Producer Leslie Udwin said: ‘We’re sorry, but we believed we could either please local people and lose an international audience, or make it accessible to everyone.’” <http://archive.thenorthernecho.co.uk/2003/2/20/103201.html> (10 June, 2008)

<sup>13</sup> One way of compensating for a poor Irish accent may be to incorporate numerous Irish expressions or turns of phrase into the film script, as these automatically create a more authentic impression. After all, according to Ives (1950: 171), “the easiest and one of the most effective methods of giving regional flavor to speech is the use of local expressions and names for things”. These can very often be used in place of Standard English expressions or names and involve very little reworking of the script. For example, in an Irish context, one only has to substitute the words “Ma”, “Mam” or “Mammy” for the standard terms “Mum” “Mummy”, “Mom” and “Mommy”, to already lend the speech a certain air of Irishness. Similar substitutions can be done with any number of terms, ranging from “Da” for “Dad” or “Daddy”, “grand” for “fine”, “guard” for “police officer”, and “shite” for “shit”, with the cumulative result being a script which seems more Irish and which may thus compensate for any shortcomings in the actor’s accent.

<sup>14</sup> These examples show the film title, the time when the sentence is uttered, and the speaker’s initials with when and where the film is set. For more see Walshe (forthcoming).

<sup>15</sup> As Niedzielski and Preston (2003) have observed, the folk often include imitations of the accent to explain their point, and this is clearly what also happens in many people’s observations, whether written or oral. The quotes on the next few pages are taken from oral interviews conducted by my colleague Katrin Sell in the summer of 2007 in Galway City or from internet forums which have addressed the notion of accent in films. These quotes have been taken over verbatim from their sources and thus sometimes contain quite a number of spelling errors. However, in the interest of transparency, I have not amended them in any way.

<sup>23</sup> While Wright cites the term as being used in Ireland (as well as in Northumberland, the West Midlands, Lancashire, Yorkshire, Cheshire, Lincolnshire, East Anglia, and Warwickshire), it should be remembered that his dictionary was actually compiled between 1898 and 1905 when the term did enjoy popularity.

<sup>24</sup> It is interesting to note that the word “look” also appears in the critique of Kevin Spacey’s accent at the beginning of this article: “he *looks* as if he had strayed in from Los Angeles just for the day.”

<sup>25</sup> Fought does, however, cite a study by Atagi (2003) which revealed that race may play more of a role in accent hallucination than foreign origin. “Overall, then, it seems that the more ‘ethnically different’ a speaker is perceived to be by the hearer, the more likely the hearer is to perceive an accent where none is present” (Fought 2006: 189).

# **An OT Analysis of the Nasal Pronunciation Variability in Coda Position---Transfer Effect or Unmarkedness Constraint**

**Ya-Ting Yang**

National Kaohsiung Normal University (R.O.C.)

[yatingkristy@yahoo.com.tw](mailto:yatingkristy@yahoo.com.tw)

## **Abstract**

This study suggests one perspective in viewing the cause of difficulty in pronouncing English /m/ sound in coda position for Native Taiwanese English learners. The Contrastive Language Hypothesis and Contrastive Analysis Hypothesis may lead people to assume that it is easy for Native Taiwanese English learners to learn the nasal coda sound since Taiwanese sound repertoire contains /m/ sound in the coda position. Nevertheless, the subjects tend to pronounce /n/ instead of /m/ in the coda position in their English oral performance and it is postulated by the author of this paper that this pattern of speech failure can only be accounted for by Optimality Theory (OT) which succinctly shows the hierarchical relations among different constraints.

**Key Words:** Nasal Sound, Second Language Acquisition, Optimality Theory, Transfer Effect, Unmarkedness

## **1. Introduction**

In Lado's Contrastive Language Hypothesis (CLH), he stated that through comparing the L2 system with that of L1 of the learner, problems which were encountered by the learner could be predicted. He also argued that "Those elements that are similar to his native language will be simple for him, and those elements that are different will be difficult" (Lado, 1957). Aside from Lado, Weinreich (1953) also made a similar claim asserting that "The greater the difference between two systems, i.e. the more numerous the mutually exclusive forms and patterns in each, the greater is the learning problem and the potential area of interference." Furthermore, according to their Contrastive Analysis Hypothesis (CAH), Freeman and Long (1991) stated that "Where two languages were similar, positive transfer would occur; where they were different, negative transfer, or interference, would result." Nowadays, both Lado's

CLH and Freeman's CAH have been considered a vast overgeneralization, and it is the emergence of Optimality Theory (OT) (Prince & Smolensky, 1993) which makes a breakthrough on this mysterious area of L2 acquisition by providing a most in-depth explanation for some unsolved problems. One of the key notions in OT is the idea of "unmarkedness" and Kager (1999) had put it this way: "[All] types of linguistic structures have two values, one of which is 'marked', the other 'unmarked'. Unmarked values are cross-linguistically preferred and basic in all grammars, while marked values are cross-linguistically avoided and used by grammars only to create contrast" (1999). This idea of markedness/unmarkedness has been a major force conflicting with faithfulness constraints in OT. While the constraints of markedness and faithfulness are universal, the rankings are not. "[Differences] in ranking are the source of cross-linguistic variation" as Kager (1999) postulated it. Thus, some L2 acquisition phenomena which could not be fully explained by CLH or CAH could find the way out in the application of Optimality Theory.

## **2. Background**

In this paper, I dwell upon the pronunciation problem which many Taiwanese English learners encounter in their interlanguage. Some studies done in Taiwan have been based on CAH and made the point that the problem that Taiwanese English learners tend to pronounce /n/ sound instead of /m/ sound in the coda position originates from the interference of the learners' native language "Chinese", for its sound repertoire does not contain the sound /m/ in the coda position. At the first glance, it may sound legitimate, yet when Taiwanese speakers whose native language is Taiwanese but not Mandarin are tested in this experiment, a stunning discovery overrules this claim. According to CAH, through the facilitating effect, Taiwanese speakers who have /m/ in their sound repertoire should not have any difficulties in pronouncing the sound /m/ despite its position of emergence, i.e., onset or coda position. Yet, the result does not match with the postulation. In this study, these Taiwanese native speakers still have serious pronunciation error in pronouncing /n/ rather than /m/ in coda position. Thus, CLH or CAH are inept at providing any convincing explanation for this phenomenon and only OT can come to its rescue. The central idea of OT is that the most optimal candidate of the input is the one which violates the least serious conflicting constraints consisting of markedness and faithfulness constraints. Since /n/ is an unmarked and /m/ is a marked sound, at the beginning stage of Taiwanese English learners'

interlanguage, the ranking of unmarkedness will be higher than the faithfulness constraint. As a consequence, Taiwanese English learners thus tend to pronounce the unmarked /n/ instead of /m/ at this stage. Through strenuous practice in conquering the force of fossilization, the faithfulness constraint will eventually overcome the markedness constraint and the L2 learner will become more native-like in pronouncing /m/ sound when it appear in the coda position. In this study, according to OT, the ranking of constraints which explains the performance error of pronouncing /n/ rather than /m/ in the coda position in Taiwanese English learners' interlanguage will be derived to provide a new perspective on explaining this language learning problem.

### 3. Experiment

#### 3.1 Methodology

##### 3.1.1 Participants

The participants consist of 35 students whose native language is Taiwanese and they major in Information Management in Southern Taiwan University of Technology. The ages of this group vary from 26 to 42 as shown below in figure 1 and they all have worked for a few years. Among these 35 participants, 13 are female and 22 are male.

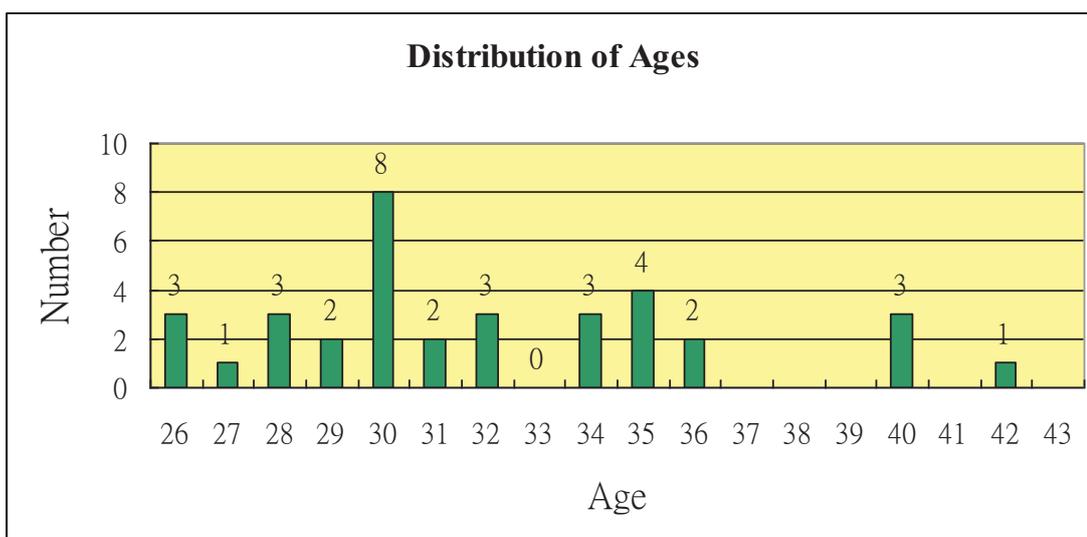

Figure 1: Distribution of Ages

### 3.1.2 Materials<sup>1</sup>

There are 53 sentences containing words with /m/ sounds totaling 126 tokens. The /m/ sound may occur in the onset or coda positions within these words. The sources of these sentences are from my originality and pronunciation textbooks including English Pronunciation in Use, Pronunciation Plus and Clear Speech.

#### *Recording and Measurement*

The recording process is carried out in a language lab in Southern Taiwan University of Technology. Each student is given plenty of time to do the reading and recording with an individual recording machine. They are also given specific instruction that they have to read the sentences without hesitation and their reading fluency is the priority in the recording. The recording of the students are later listened and analyzed by the researcher. Since there are 35 participants who read 53 sentences which contain 126 /m/ sounds, the total tokens analyzed are 4410 (35\*126=4410).

#### *Results*

The number and percentage of error produced by the participants are shown in the following tables.

Table 1: Erroneous Production of /n/ Instead of Correct Production of /m/

Word Position of Token & Percentage of /m/	Sentence Initial		Sentence Medial		Sentence Final	
	Onset 6*35=210 (Tokens in total)	Coda 7*35=245 (Tokens in total)	Onset 53*35=1855 (Tokens in total)	Coda 35*35=1225 (Tokens in total)	Onset 15*35=525 (Tokens in total)	Coda 9*35=315 (Tokens in total)
Token of Error	0	37	0	181	0	28
Percentage of Error	0	15.10	0	14.78	0	8.89
Total Count of Errors	Onset: 0 token 0% Coda: 246 tokens 13.78 % (246÷1785=0.1378)					

<sup>1</sup> Refer to Appendix A

In this table, none of the participants pronounce /n/ instead of /m/ when the /m/ sound appears in the onset position, regardless of the word position in the sentences. On the contrary, when /m/ sound appears in the coda position of the word, errors abound. There are 246 tokens of error and that take up 13.78 % of the total count of /m/ sound in coda position regardless of the positions of the word in the sentences.

### *Discussion*

Before moving on to the discussion section, findings from the experiment are summarized as the following.

- A. When /m/ sound appears in the onset position, participants do not erroneously pronounce it as /n/ sound.
- B. When /m/ sound appears in the coda position of the words (regardless of the position of the word in the sentence), participants tend to mistakenly pronounce it as /n/ sound.

The constraints involved in the process of producing /n/ instead of /m/, the correct pronunciation, are firstly listed below and then shown in the tableau.

1. MAX-IO  
Input segments must have output correspondents.
2. Two-level well-formedness  
If an input segment S is [ $\alpha$  round], then its output correspondent S' must be [ $\alpha$  round] and stand in an initial syllable.
4. Universal ranking for markedness constraints governing place of articulation \*[lab] >> \*[cor]
5. Ident-IO (Place)  
The specification for place of articulation of an input segment must be preserved in its output correspondent.

Table 2: The Ranking of Constraints Which Leads to the Pronunciation of /n/ instead of /m/ in Coda Position in the speech of Native Taiwanese English Learners—Unmarkedness prevails over Faithfulness constraint

/mam/	MAX-IO	Ident-IO (lab,[ $\sigma$ ])	*[lab]	*[cor]	Ident-IO (Place)
a. mam			**		
b. ma	*				
c. am	*				
d. nan		*			

e. na	*				
f. an	*				
☞ g. man			*		
h. nam		*			

First of all, MAX-IO, a faithfulness constraint, requires that input segments must have output correspondents. Thus, candidate b, c, e, and f are disqualified and are marked with a “\*” for each violation. As for the second faithfulness constraint “Ident-IO (Place, [σ])”, which requires that the place feature of the initial segment of each syllable in the input should have the same place feature in the output in the same position, candidates d and h are expelled under this constraint. Last but not least is the markedness constraints of “\*[lab] and \*[cor]”. It is a universal phenomenon that [lab] is more marked than [cor], so due to the higher positioned “\*[lab] >> \*[cor]” constraint than the faithfulness Ident-IO (Place) constraint, we derive the most optimal candidate “/man/”. Though the last constraint “Ident-IO (Place)”, a faithfulness constraint, can ensure the total correspondence between the input and the output segments, the ranking of this constraint is too low to influence the outcome. Thus, this table explains why many of the participants in this experiment erroneously pronouncing /n/ instead of /m/ in the coda position in a constant fashion at their interlanguage stage.

Throughout the interlanguage continuum, with much effort in practicing the coda /m/ sound, these participants may eventually overcome the markedness feature of the /m/ sound in the coda position and eventually they may correctly pronounce it in a stable fashion. When they proceed to this stage, the ranking of the constraints will be different from the above table and a new ranking of the constraints is shown table 3.

Table 3: The Ranking of Constraints Which Leads to the Correct Pronunciation of /m/ in both Onset and Coda Position of Native Taiwanese English Learners

/mam/	MAX-IO	Ident-IO (lab,[σ])	Ident-IO (Place)	*[lab]	*[cor]
☞ a. mam				**	
b. ma	*				
c. am	*				
d. nan		*			
e. na	*				
f. an	*				
g. man			*		

h. nam		*			
--------	--	---	--	--	--

In this table, the ranking of the faithfulness constraint “Ident-IO (Place)” has advanced to a position higher than the markedness constraint “\*[lab] >> \*[cor]”. Hence, the optimal candidate, according to this new ranking, is “a. mam” which is what native English speakers would pronounce for the word “mom”. In a word, when native Taiwanese English learners conquer the natural force of the more easily pronounced unmarked /n/ sound and stick to the /m/ sound under the faithfulness constraint of “Ident-IO (Place)” when the /m/ sound appears in the coda position, they will pronounce the /m/ sound in the coda position without any difficulty and sound more native like.

#### 4. Summary

Though Eckman (1981), Larsen-Freeman & Long (1991), Major (1999) and other linguists all consent to the interfering and facilitating effects of L1 over L2, CLH and CAH are still short of providing any solid explaining for some language learning problems -- such as the mispronunciation of /n/ instead of /m/ when /m/ appears in coda position of a syllable. In this study, I succinctly account for this pattern of performance error within the realm of Optimality Theory and a tentative ranking of constraints which leads to this error is also provided. The constraints which play a part in the ranking are first of all, markedness constraint: \*[lab] >> \*[cor] and secondly, faithfulness constraints: (1) MAX-IO (2) Two-level well-formedness and (3) Ident-IO (place). Throughout the continuum of the L2 learners’ interlanguage, at some point, fossilization may take place and the L2 learners may not be able to reach a stable state of pronouncing /m/ correctly when it takes place in the coda position. When this happens, the ranking of the constraints will fossilize as well and it will appear as the above second table shows. Nevertheless, if extra practice of coda /m/ sound has been done before the fossilization takes effect, the ranking of constraints may proceed from the second table to the third one. Consequently, the error of pronouncing /n/ as /m/ in coda position of a syllable will perish in native Taiwanese English learners’ speech performance.

## Appendixes

### A: Reading List

Please read the following sentences and record them.

1. I'm \_\_\_\_\_years old and I'm a student in Southern Taiwan University of Technology.
2. My name is \_\_\_\_\_.
3. My student number is \_\_\_\_\_.
4. Mum made me move my models.
5. There was no one on the moon on the ninth of June.
6. My friend likes Robin Banks.
7. Tom ran yesterday.
8. She had a swim in the garden.
9. The son warned me.
10. Mary likes window-shopping.
11. Her name is Nancy and she's gardening.
12. Listening to music is a lot more fun than cleaning the bathroom.
13. Living room is the place where we watch TV.
14. Linda combs her hair 100 times every single night.
15. Do you know where the washing machine is?
16. The alarm clock is set at six o'clock in the morning.
17. The blanket can keep you warm at night.
18. Jim is a student who comes from Canada.
19. Tom may not be able to come to the moon-festival.
20. Would you like to have some more milk?
21. Jim is here in Taiwan for more than nine months.
22. Can you tell me what time it is?
23. Sam and I will go to the movie theater to see a great film named "Mummy".
24. I miss the feeling of eating ice cream in the summer.
25. Since it is raining so hard, Tom may already go home.
26. Turn the alarm off!
27. The noise is killing me.
28. Sunny came much later because she missed the train.
29. I need to rent a room with a bathroom.
30. He needs more money to buy a diamond ring.
31. The sun was shining a minute ago, and now it's raining hard.
32. Look, Mom.

33. Those men are selling umbrellas.
  34. They are the same men who climbed the mountains with us yesterday morning.
  35. I am sorry to let you down, Dad.
  36. Timmy got down on his knees to ask Marian to marry him.
  37. He has millions of dollars to spend.
  38. The two of them live happily ever after.
  39. Small children enjoy watching Mickey Mouse on TV.
  40. Does your mother tell you bedtime stories when you were growing up?
  41. Kenny works in the department store.
  42. It sounds like somebody is crying.
  43. I lost the money Mommy gave me for the medicine.
  44. What is your home phone number?
  45. Sorry, ma'am.
  46. I have the wrong number.
  47. We'll meet at the same time and the same place.
  48. Do you like romantic movies?
- A: (49) I met a man near the monument this morning. (50) He was a singer and he sang a song for me. (51) I'll always remember that magic moment. (52) Like something out of a dream!
- B: (53) What, is that the moment, the monument or the man you meant?

# **Building temporal structure: Adverbs and times\***

**Aniko Csirmaz**

## **Abstract**

It is suggested that finite clauses in any language contain a number of obligatory and several optional time intervals. The paper explores the source of these time intervals, arguing that functional heads, aspectual operators and certain adverbs can all introduce specific times in a clause. Some types of time intervals can be iterated; this is suggested to follow from the iterability of adverbs, but not that of functional heads or operators. The adverbs relevant to time intervals are counting adverbs. The paper proposes a taxonomy for these adverbs and discusses how the adverbs are related to the time intervals present in a clause.

**Keywords:** times, clause structure, adverbs, operators, iteration

## **1. Introduction**

The paper addresses the following basic questions: (a) What time intervals can be identified in a finite clause? and (b) How are time intervals and counting adverbs (multiplicatives, frequency adverbs and adverbs of quantification) related? The answer to the first question helps to pinpoint the relevance of time in clauses and the distinct interpretations of those predicates that apply to the time intervals in question. The answer to the second question specifies the relation of counting adverbs on the one hand and multiplicity of situations, which are required by these adverbs, on the other. It also makes explicit the precise interpretation of the time interval which cooccurs with the counting adverb in question.

The main claims put forward in this paper are as follows. Clauses – specifically, finite clauses – have an articulated structure of time intervals, with the intervals

appearing at specific positions in the clausal skeleton. The times are introduced by distinct elements in the structure, a difference which accounts for the interpretation and the obligatory or optional nature of these intervals. Turning to the adverbs which interact with times, it is argued that counting adverbs do not behave as a homogeneous group; rather, three subgroups must be distinguished among these adverbs (multiplicatives, frequency adverbs and adverbs of quantification). Members of these groups of adverbs can differ, among others, in the temporal interpretation resulting after adverbial modification and in the specific requirements on time intervals or the availability of multiple events. Finally, counting adverbs – in contrast with other constituents which are capable of introducing time intervals – can yield the iteration of times, where a clause contains more than one time interval of a specific type.

In the following discussion, the term *event description* is reserved for the description of a single, non-iterated event or state. This description may be complex itself, if it contains causation or a distinct result subevent. The term *situation description*, in contrast, is used for all predicates of times, including iterative and habitual descriptions. The paper is structured as follows. Section 2 presents the basic assumptions concerning time intervals, the elements introducing these times and the structural position of times. Section 3 presents arguments for the distinctions among counting adverbs. Section 4 discusses the possibility of adverb iteration and the ordering of adverbs. Section 5 concludes the paper.

## 2. Time intervals

A finite root clause must contain at least three time intervals, and may contain a number of additional times. Taking Reichenbach 1947 and Klein 1994 as a departure point, the obligatory times are the *event time* (the runtime of the eventuality); the *topic time* or *reference time* (the time under discussion) and the *speech time* (the time of utterance).

The three times are normally distinct, with the relation between time intervals captured as precedence or containment. The speech time, which is instantaneous or atomic, is preceded by the topic time if the time interval under discussion is located in the past. The topic time is contained by the event time in an imperfective or progressive situation description; in this case, the situation has not culminated within the time under discussion, and it may or may not have culminated at a later time. This order of times is found in (1), for example:

(1) Zed was reading the book

In addition to these obligatory times, a number of optional time intervals can also be present in a clause. These include the following:

(2) a. Result time

The time interval during which the result state of a culminated situation holds

b. Iterative time

The time during which iteration (of a type of situation) occurs

c. Habitual time

The time during which a type of situation habitually obtains

d. Perfect time

The time interval between the times determined by tense (right boundary) and an overt or covert adverb (left boundary) (Iatridou et al. 2001, a.o.)

e. Modal time

The time during which modal evaluation obtains (Zagona 1990, Stowell 2004)

The differences in the interpretation of the time intervals are illustrated in the following paradigm. The paradigm exploits the fact that the predicates applying to the times can be homogeneous, and thus the times can be modified by a durative *for*-adverb. The *for*-adverbs measure distinct times in the following examples.

(3) a. (speech time; deictic, does not allow modification)

b. Zed could have escaped *for two hours* (modal time)

c. Zed has lived here *for fifty years* (perfect time)

d. Zed was writing that letter *for half an hour* (topic time)

e. Zed drank *for fifty years* (habitual time)

f. Zed coughed *for ten minutes* (iterative time)

g. Zed wrote *for two hours* (event time)

h. Zed opened the window *for an hour* (result time)

The speech time is the only time interval which does not permit *for*-adverb modification, or any type of modification, for that matter. This restriction follows from the deictic nature of the speech time; deictic expressions resist modification, in general (cf. Hornstein 1990).

Given that *for*-adverbs can measure almost all time intervals, durative adverb modification cannot be taken to diagnose (a)telicity by itself. It must be specified what predicate or what time interval homogeneity is defined for. Similarly, homogeneity itself cannot be taken to be a defining property of event descriptions only, since the property of homogeneity can be defined (among others) for any predicate that applies to a time interval.

The constituent that introduces the time intervals (more precisely, the constituent which requires a time interval argument) can be different for the time interval types noted above. The obligatory times are arguments of constituents that are obligatorily present in the structure: the speech time is an argument of T and the topic time is an argument of the Asp head, which encodes viewpoint aspect. The event time is the argument of the event predicate, usually a verb. The result time is not necessarily present; it appears in the structure whenever the event structure contains a result subevent.

The other times are introduced by constituents which are optionally present in the clausal structure. The functional head Mod, which encodes modality, takes the modal time as argument, and the perfect time is an argument of the Perfect head. The iterative and the habitual times can be introduced by an appropriate aspectual operator, ITER or HAB, which introduce the iterative and habitual interpretation, respectively.

The relative position of the appropriate functional heads largely determines the distribution of the time intervals; the time interval local to the argument-taking head receives the appropriate interpretation. The position of functional heads does not account, however, for the placement of the event, result, iterative and habitual times. Let us assume that the event time is an argument inside a verbal (or other predicative) projection and that the result subevent is a predicate contained inside the event predicate (with the result time being an argument local to the result subevent). The iterative and habitual operators appear above the event predicate and below AspP, with the habitual operator appearing in higher position. This yields the following hierarchy for time intervals:

- (4) [ ... [ speech time [ modal time [ perfect time [ topic time [ habitual time  
[iterative time [ event time [ result time ]]]]]]]]]

On the assumption that modification is local, the hierarchy of times predicts that if two or more time intervals are modified, then the relative position of the modifiers will correspond to the time interval hierarchy. This prediction is briefly explored in section 4.

In addition to the predicates, functional heads and operators noted above, certain adverbs can also introduce time intervals. Counting adverbs are sometimes characterized this way (cf. van Geenhoven 2004, 2005 for a comparable characterization of frequency adverbs). The following section explores the group of frequency adverbs; in addition to a taxonomy of these adverbs, their interaction with time intervals is also discussed.

### 3. Counting adverbs

Counting adverbs<sup>1</sup> appear with multiple situations of some type. Since there are several situations involved, the time interval where they occur is distinct from the event time. Consider (5):

(5) Zed coughed twice

The event time is the time of a single coughing event; there are (at least) two events of this type. The time during which Zed coughed twice is distinct from the event time, and contains both event time intervals.

Counting adverbs are all tied to time intervals. Section 3.1 presents a taxonomy of these adverbs and addresses their relation to times. Section 3.2 considers some previous proposals and argues that some of the characterizations proposed earlier cannot be upheld.

#### 3.1 Taxonomy of counting adverbs

As noted above, three groups must be distinguished among counting adverbs (cf. Csirmaz (submitted a, b) and also Csirmaz (submitted c) for a slightly different position). The three adverb classes are the following:

- (6) a. Multiplicatives (*twice, five times, many times*)
- b. Frequency adverbs (*frequently, rarely, daily*)
- c. Adverbs of quantification (*often, always, sometimes*)

*Multiplicatives* specify the cardinality of situations. These adverbs introduce iterative time. Accordingly, the time during which the complex situation of *Fred cough twice* in (5) holds is the iterative time (cf. section 4 for discussion).

It is the adverb itself that introduces the iterative time, and it does not modify a situation description that is iterated (\*multiplicative (ITER [event])). The claim that multiplicatives introduce, but do not require iterativity or multiplicity of situations is supported by the following examples.

The semelfactive verbs *nod* and *wink* express unique, non-iterated events (an iterative interpretation is available with the imperfective form (cf. *Zed was nodding / winking*)). While a unique event interpretation is the only possible reading in absence of a multiplicative or a counting adverb, a multiplicative is possible, and it requires multiple events of the cardinality specified:

- (7) a. Zed nodded / winked  
 (once / \*multiple times)  
 b. Zed nodded / winked twice

The same state of affairs holds in Hungarian. If a verb has a semelfactive suffix, as in (8a), then the description can refer to a single event only. However, if a multiplicative is present, then in spite of the presence of the semelfactive suffix, multiple situations are possible; there are as many situations as specified by the adverb.

- (8) a. *Zed*            *ból-int-ott*  
 Z-NOM    nod-SEMELFACTIVE-PAST,3SG  
 “Zed nodded once / \*multiple times”  
 b. *Zed*            *kétszer / többször*            *ból-int-ott*  
 Z-NOM    twice    many.times    nod-SEMELFACTIVE-PAST,3SG  
 “Zed nodded twice / many times”

*Frequency adverbs*, as the term suggests, specify the frequency of situations within a given time interval. Given this characterization, it is apparent that in addition to the event time, another time interval must be present, which is the time for which the frequency is specified.

Frequency adverbs can be distinguished according to whether the frequency is relative to a contextually determined standard (e.g. *frequently*) or is defined in terms of an absolute time interval (e.g. *daily*). Stump 1985 labels the two kinds of adverbs *relative* and *fixed frequency adverbs*, respectively. This distinction, since it does not play a role in the issues discussed in this paper, is ignored in the following discussion.

As noted above, frequency adverbs require a time interval argument, the time for which the frequency is determined. Languages show variability, however, in whether the adverb itself can introduce iteration, or whether it requires an event description which can denote multiple events. In English a frequency can introduce iteration, thus it can specify the frequency of a nodding or winking event. The additional contexts in (9b-d) highlight the episodic, non-habitual interpretation.

- (9) a. Zed nodded / winked frequently  
 b. Zed nodded frequently in agreement as Fred lectured  
 c. He nodded frequently and his face seemed contemplative  
 d. He looked in their direction and winked frequently

In contrast with English, Hungarian frequency adverbs do not yield multiple events. Given a verb with a semelfactive suffix, frequency adverb modification is impossible (10a). These adverbs become grammatical, though, if the verb bears an iterative suffix (10b); such a verb form denotes multiple, iterated events.

- (10) a. ??Zed            *sűrűn*            *ból-int-ott*  
           Z-NOM    frequently    nod-SEMELFACTIVE-PAST,3SG  
           “Zed nodded frequently”
- b. Zed            *sűrűn*            *ból-ogat-ott*  
       Z-NOM    frequently    nod-ITERATIVE-PAST,3SG  
       “Zed nodded frequently' / 'Zed was nodding frequently”

The markedness of frequency adverbs does not extend to quantificational expressions which contain a universal quantifier. The Hungarian quantificational *minden órákor* 'at every hour' or *minden órában* '(once) in every hour' is grammatical with a semelfactive verb:

- (11) Zed        ??*óránként* / *minden óra-kor* /        *minden órá-ban*  
       Z-NOM    hourly        every        hour-AT    every    hour-IN  
       *ból-int-ott*  
       nod-SEMELFACTIVE-PAST,3SG  
       “Zed nodded hourly / once every hour”

The lack of multiple event interpretations is thus due to the fact that in Hungarian, frequency adverbs do not introduce iteration. This contradicts the assumption that frequency adverbs are pluractional operators (cf van Geenhoven 2004, 2005 and section 3.2), since pluractional operators yield multiple entities – in this case, multiple events.

The third group, that of *adverbs of quantification*, includes adverbs such as *often* and *always*. These adverbs quantify over situations, and have a time interval restrictor which is usually covert.

This characterization of adverbs of quantification excludes proportional readings (cf. Swart 1993, for example), which are ignored here. Since proportional readings are not considered, several interpretations of sentences containing an adverb of quantification are disregarded. For instance, one of the interpretations of (12a) not discussed in given in (12b). It is only the reading in (12c) which is relevant for the present discussion.

- (12) a. Zed often drank mango juice  
       b. The proportion of situations of Zed drinking mango juice and of situations of Zed drinking (any kind of liquid) is higher than a contextually determined number  
       c. The number of situations of Zed drinking mango juice is higher than a contextually determined number

Adverbs of quantification can introduce iteration. Accordingly, these adverbs are grammatical in the following English example:

(13) Zed often nodded / winked (when ...)

Adverbs of quantification can also yield multiple events in Hungarian. Accordingly, these adverbs are grammatical with a semelfactive verb; what occurs often is the event of Zed nodding once ((14a), cf. (8), (10)). Naturally, an iterative suffix is also acceptable (14b); in this case it is the event of nodding several times which occurs often.

- (14) a. *Zed gyakran b6l-int-ott*  
Z-NOM often nod-SEMELFACTIVE-PAST,3SG  
“Zed often nodded (once)”
- b. *Zed gyakran b6l-ogat-ott*  
Z-NOM often nod-ITERATIVE-PAST,3SG  
“Zed often nodded (several times)”

The three adverb types, as shown above, can differ in whether they can introduce iteration. In addition to this difference, and a contrast in the time interval introduced (cf section 4), there are other properties which distinguish the groups of counting adverbs. For instance, adverbs of quantification can appear with individual-level predicates, but frequency adverbs are ungrammatical.

(15) Germans are often / \*frequently tall

This contrast follows from the time interval requirement of frequency adverbs; recall that these adverbs specify frequency within a time interval (cf Csirmaz (submitted c) for a more detailed discussion).

While a number of properties distinguish the groups of counting adverbs (discussed in more detail in Csirmaz (submitted a, b, c)), there are properties that were argued to be distinguishing characteristics, but fail to discriminate between the adverbs. Some of these properties are discussed below.

### 3.2 *Earlier characterizations*

Previously, van Geenhoven 2004, 2005 and Jóhannsdóttir 2005, 2007 have argued for a strict distinction between frequency adverbs and adverbs of quantification. In support of the distinction, they presented characterizations and test batteries (especially Jóhannsdóttir 2005, 2007). This section addresses some of these properties, showing that they fail to distinguish these groups of adverbs reliably.

The following characterizations are offered by either van Geenhoven or Jóhannsdóttir:

- (16) a. Frequency adverbs  
 Affect the event time  
 Can affect homogeneity (diagnosed by *for*-adverbs)  
 Are pluractional operators
- b. Adverbs of quantification  
 Affect the topic time  
 Cannot affect homogeneity

In support of the difference with respect to homogeneity, van Geenhoven 2005 and Jóhannsóttir 2005, 2007 offer the following examples:

- (17) Frequency adverbs (in the scope of a *for*-adverb)
- a. John was constantly discovering fleas on his dog for a whole month
- b. Joe discovered a flea on his dog every now and then for a month
- (18) Adverbs of quantification (cannot be in the scope of a *for*-adverb)
- a. \*John was often finding fleas on his dog for a whole month
- b. \*Mary always / usually discovered a flea on her dog for a month

Given the observation that all time intervals except for the speech time can be modified by a *for*-adverb (cf. section 2), and the fact that *always*, and arguably *often* and *usually* yield homogeneous predicates of times, it is unexpected that *for*-adverbs are ungrammatical in (18).

In fact, adverbs of quantification can yield homogeneity, as shown below:

- (19) For a (whole) month, Mary often / always discovered a flea on her dog  
 (when she checked)

A clause-initial *for*-adverb is acceptable, in contrast with the reported judgment for the clause-final *for*-adverb in (18). The preferred topicalization of the *for*-adverb licensed by adverbs of quantification is not addressed here.

(19) shows that adverbs of quantification can license homogeneity, as shown by the acceptability of the *for*-adverb. Concerning the position of the durative adverb, consider *for*-adverbs licensed by negation. Speakers vary in whether they prefer a topicalized or a clause-final position, but crucially, *for*-adverbs are licensed in at least one of these positions.

- (20) a. % Zed didn't finish the picture for two hours  
 b. % For two hours, Zed didn't finish the picture

If homogeneity is not licensed, then *for*-adverbs remain ungrammatical whether topicalized or clause-final (a possible result time modification of the *for*-adverb is ignored here):

- (21) (\*For two hours,) Zed finished the picture (\*for two hours)

Given that topicalized *for*-adverbs are acceptable with (some) adverbs of quantification, these adverbs can license homogeneity, contrary to (16).

Concerning pluractionality, van Geenhoven 2004, 2005 argues that frequency adverbs are pluractional operators. Recall from section 3.1 that this fails to hold for Hungarian, for instance: frequency adverbs cannot yield a description of multiple events on their own. Furthermore, it is more generally true that frequency adverbs cannot yield iteration for unique, once-only descriptions.

Consider (22), which van Geenhoven 2004 offers in support of the claim that frequency adverbs are pluractional operators.

- (22) a. Jim hit a golf ball into the lake for an hour  
(same golf ball; # different golf balls)
- b. Jim hit a golf ball into the lake *every five minutes* for an hour  
(same golf ball; different golf balls)

The *for*-adverb enforces an iterative interpretation (an interpretation that is available with the predicate *hit*), since (22a) would otherwise not contain a homogeneous predicate of times. In (22a) the iteration fails to have wide scope over the indefinite *a golf ball*; the resulting interpretation is that the same golf ball is hit into the lake repeatedly. The universally quantified expression *every five minutes* can take scope over the indefinite; thus an additional reading is available, where each hitting event involves a different golf ball. Based on these examples, van Geenhoven concludes that frequency adverbs are pluractional operators, and can yield multiple participants denoted by an indefinite expression.

Note, however, that it is a universally quantified expression which has wide scope over the indefinite in (22b). A frequency adverb, as in (23), does not allow the same interpretation (also cf (11)):

- (23) Jim hit a golf ball *frequently* into the lake for an hour  
(same golf ball; # different golf balls)

The adverb *frequently* can introduce iterative interpretation in some languages, as shown above in (9) for English. It cannot, however, take scope over an indefinite – an observation that also accounts for the markedness of (15), where the frequency adverb cannot scope over the subject. In this respect, *frequently* behaves similarly to the operator ITER, which can also introduce interpretation, but does not permit scope over an indefinite. ITER is present in (22a), for example; yielding iterative interpretation but taking narrow scope.

In sum, frequency adverbs can introduce iteration in some languages (e.g. English), but not in others (e.g. Hungarian). Even in the former languages, they do not take wide scope over indefinite arguments, contrary to the conclusions reached by van Geenhoven.

Finally, let us consider the times affected by the adverbs. Van Geenhoven 2005 suggests that frequency adverbs affect (operate on) the event time, and adverbs of quantification affect the topic time. It is not clear, however, that this is the case.

First, note that frequency adverbs can denote the frequency of either the event (24a) or that of a complex event involving iteration (24b). In other words, frequency adverbs can affect either of these two times.

- (24) a. Zed frequently arrived late
- b. Zed frequently knocked twice

There is a similar difference in the interpretation of adverbs of quantification. These adverbs specify the quantity of either simple events (25a) or that of iterated events (25b, c).

- (25) a. Zed often arrived late
- b. Zed often knocked twice
- c. Zed always spoke frequently (in class)

While the topic time can be argued to be related to the appropriate time interval in (25), and so yield the desired interpretation, the view that the adverbs operate on the topic time faces a considerable problem given (26).

- (26) Zed always interrupted often

Since adverbs of quantification can be iterated, it cannot be maintained that they affect the topic time, which is, by definition, the time interval that is ordered by tense with respect to the speech time. Only one such interval can exist; thus adverbs of quantification do not affect the topic time. Let us assume, given lack of evidence to the contrary, that these adverbs affect either the event time or the iterative time, just as frequency adverbs do.

With the range of time intervals and the basic properties of counting adverbs given, the next section considers the time intervals introduced by counting adverbs. The section also considers the ordering and possible iteration of these adverbs.

## 4. Times, adverb iteration and ordering

### 4.1 Time intervals and iteration

Among the time intervals identified in section 2, several can occur at most once within a clause. The speech time, as well as the topic, modal and perfect times are introduced by a functional head (T, Asp, Mod and Perf, respectively), which cannot be iterated. The result time is the time interval to which the result subevent is mapped. In a complex event description, there is a unique result subevent, and thus only one time interval that corresponds to this subevent. Finally, the time interval that the maximal (possibly complex) event description maps to is the event time. Again, as there is only one maximal event description, only one event time is possible.

Two other time intervals remain: the iterative and the habitual times. If these times are introduced by a covert operator, ITER and HAB, then no iteration is possible, a restriction which may be tied to recoverability. Accordingly, (27a) has four different interpretations – a semelfactive interpretation (27b), one with ITER (27c), HAB (27d), and ITER as well as HAB (27e). Iterations of either ITER or HAB are impossible (27f,g).

- (27) a. Zed jumped  
b. Zed jumped once  
c. Zed jumped multiple times (ITER)  
d. Zed jumped habitually (HAB)  
e. Zed jumped habitually, on each occasion multiple times (HAB (ITER))  
f. \*Zed jumped repeatedly, each time multiple times (ITER (ITER))  
g. \*Zed had the habit of jumping habitually (HAB (HAB))

The iterative and habitual times can be iterated, however, with counting adverbs. If there are multiple adverbs present which introduce time intervals with the same interpretation, then a single clause may contain more than one iterative or habitual time.<sup>2</sup>

One prerequisite of iteration is a coercion operation. All counting adverbs modify countable, non-homogeneous entities. A complex structure, which is modified by an adverb, may be non-countable, however. For instance, *Zed was late* or *Zed was often late* are both non-countable. In order for a counting adverb to modify these descriptions, a coercion operation must yield a countable interpretation for them.

Coercion operations aside, all counting adverbs may be iterated, as the following examples show for multiplicatives (28a), frequency adverbs (28b) and adverbs of

quantification (28c) (cf Ernst 2004 on the iteration of similar adverbs, and Cinque 1999, 2004, who restricts iteration to at most two adverbs of the same type).

- (28) a. Zed knocked twice three times on my door  
b. Zed frequently wrote to his cousin regularly  
c. The modem light usually always flickers

Counting adverbs appear along with a time interval. All counting adverbs can appear with iterative time. Alternatively, both frequency adverbs and adverbs of quantification (but not multiplicatives) can appear with habitual time. The iteration of counting adverbs can thus yield multiple iterative or habitual times within a given clause.

On the assumption that episodic events, which transpire within a short period, cannot be habitual descriptions, all adverbs in (29) appear with iterative rather than habitual time.

- (29) a. Zed frequently / often coughed yesterday  
b. Zed coughed twice yesterday

Both frequency adverbs and adverbs of quantification can introduce a habitual time, where the complex situation description characterizes a custom which recurs habitually over a(n appropriately long) time span:

- (30) a. Zed often ate a sandwich around four  
b. Zed frequently drank mango juice

In contrast, multiplicatives do not introduce a habitual time. (31) cannot describe a custom. If a habitual interpretation is enforced, then it is a situation of Zed drinking mango juice twice that recurs habitually. This contrasts with (30), where the habitually occurring situation is that of drinking mango juice, rather than that of drinking mango juice frequently of eating a sandwich often.

- (31) Zed drank mango juice twice

Assuming that these observations are correct, iterated counting adverbs can yield multiple iterative (and arguably multiple habitual) times. Coupled with the observations at the beginning of this section, it is only multiple counting adverbs which can introduce more than one time interval of a certain type.

#### 4.2 *Adverb ordering*

A clause can contain counting adverbs of different types, and also multiple tokens of a single type of counting adverb. The interpretation with multiple adverbs follows straightforwardly from the scope relations:

- (32) a. Zed often always drinks mango juice  
 = There is a period  $t$  during which there are many subintervals  $t'$  of  $t$  such that at all (relevant) subintervals of  $t'$  there is a situation of Zed drinking mango juice (often > always)
- b. Zed always drinks mango juice often  
 = There is a period  $t$  such that at all (relevant) subintervals  $t'$  of  $t$  there are many situations of Zed drinking mango juice (always > often)

The linear ordering of counting adverbs varies across languages. The variation is expected to arise because of two reasons. Coercion operations which yield the non-homogeneous descriptions required by these adverbs may not be equally available, but can vary across languages. In addition, languages impose varying constraints on the scope and the syntactic / linear position of adverbs.

As a case in point, consider (33). On the natural interpretation *daily* has wide scope, requiring a patient to take two capsules every day (daily > 2), rather than going through two regimens of taking a capsule daily for a certain number of days (2 > daily). With postverbal adverbs, English has rigid inverse scope, hence the contrast between (33a, b).

- (33) a. Take one capsule twice daily  
 b. ?? Take one capsule daily twice

In Hungarian, postverbal constituents have either surface or inverse scope (cf. Csirmaz (submitted a), É. Kiss (submitted)). This general property makes the natural interpretation available with either ordering of *naponta* 'daily' and *kétszer* 'twice':<sup>3</sup>

- (34) a. *EGY KAPSZULÁT kell be venni naponta kétszer*  
 one capsule-ACC must in take-INF daily twice  
 "It is a capsule that must be taken twice daily" (daily > 2)
- b. *EGY KAPSZULÁT kell be venni kétszer naponta*  
 one capsule-ACC must in take-INF twice daily  
 "It is a capsule that must be taken twice daily" (daily > 2)

The present approach makes it possible to treat the ordering of counting adverbs without appealing to restrictions specific to the adverbs. The relative order of these adverbs partially follows from independent, general considerations of ordering and scope in the given language. It is also expected that adverb ordering correlates with the time intervals that are introduced by the adverbs.

This prediction is corroborated by (35), taken to describe a habit, where there are few bouts of Zed complaining frequently. *Frequently* introduces an iterative time, and *seldom*, a habitual time, which is structurally higher than an iterative time. The ordering

between the two adverbs is fixed; *seldom* linearly precedes *frequently*:

- (35) a. Zed seldom complained frequently  
b. ?? Zed frequently seldom complained  
?? Zed frequently complained seldom

The issue of possible orderings and interpretations is not exhausted by these examples, but the observations point to the tentative conclusion noted above: the position (and ordering) of counting adverbs falls out from independent facts about syntactic structure and of the language in question.

## 5. Conclusion

The paper sketched an inventory of time intervals which can be present in a clause. In addition to the time intervals themselves, the position and source of these times was also considered. Counting adverbs (multiplicatives, frequency adverbs and adverbs of quantification) were argued to show diverging behavior. The adverbs differ in a number of properties, including the possibility of yielding (rather than requiring) multiple events. Multiplicatives and adverbs of quantification can introduce iteration of an event themselves, but frequency adverbs select iterated events in some languages, rather than introducing iteration themselves. In addition, counting adverbs differ in the time interval of which the complex description is predicated. Differences aside, situation descriptions with a counting adverb can be predicated of an iterative or a habitual time. It was suggested that these adverbs are the only source of time interval iteration, where a clause contains more than one time interval of a specific kind.

## Notes

\* The present paper builds on earlier discussions of related issues, which were presented at PLC 32, BLS 34 and CIL and published or submitted as Csirmaz (submitted a, b, c). For comments and discussions, I am indebted to the audience at CIL 18, as well as the audiences at the venues where other takes on this material were presented earlier. In addition, I also acknowledge comments and data supplied by H. Bartos, A. Bene, B. Gyuris, K. É. Kiss, C. Piñón, B. Santorini, and B. Ürögdi. I am alone responsible for any errors.

1 With the exception of *once*, *never* and comparable adverbs.

2 In using the terminology of *introducing a time interval*, I abstract away from the question of whether the adverb introduces the interval (e.g. adverb (x)), or it requires a situation description which contains an operator introducing that time (e.g. adverb (ITER (x))). What is relevant for the present purposes is the time interval that serves as the argument of the (minimal) complex description containing the adverb in question.

3 Capitalization marks focusing in the example; a focused constituent is necessary to ensure the postverbal position for the adverbs in these examples.

## Abstract

The grammaticalization literature notes the cross-linguistic robustness of a diachronic pattern involving the aspectual categories resultative, perfect, and perfective. Resultative aspect markers often develop into perfect markers, which then end up as perfect plus perfective markers. We introduce supporting data from the history of Old and Middle Indo-Aryan languages, whose instantiation of this pattern has not been previously noted. We provide a semantic analysis of the resultative, the perfect, and the aspectual category that combines perfect and perfective. Our analysis reveals the change to be a two-step generalization (semantic weakening) from the original resultative meaning.

**Keywords:** Aspect, Grammaticalization, Semantic Change, Indo-Aryan Perfect, Perfective

## 1. Introduction

Large-scale grammaticalization studies have produced a number of typological generalizations about shifts in the meaning of tense-aspect categories characterized by three properties: (a) The categories involved in the shifts are stable across cross-linguistic instantiations; (b) The paths of change are unidirectional; (c) The shifts are uniformly generalizing (Heine et al., 1991; Bybee et al., 1994; Haspelmath, 1999; Dahl, 2000; Traugott and Dasher, 2002; Hopper and Traugott, 2003; Kiparsky, 2005). A well known trajectory is the one in (1).

(1) RESULTATIVE  $\gg$  PERFECT  $\gg$  PERFECTIVE

The morphological marking denoting resultative aspect diachronically generalizes to denote the perfect, including the resultative perfect, and further, to encompass the perfective as well (Dahl 1985, 2000; Bybee et al 1994). Romance languages and Chinese are familiar instantiations of the successive changes in (1). Our own comparative study of distinct diachronic stages in Indo-Aryan, which we document here, reveals that Indo-Aryan also exhibits these two aspect shifts.

The trajectory in (1) naturally gives rise to three questions: What is the semantic content of the resultative, the perfect, and the perfective categories? What logical relation in the meanings of these categories allows the construal of these shifts as generalizations? What is the motivation for the shift from one stage to the next? In this paper we answer the first two of these questions through a close examination of the Indo-Aryan diachronic facts. Our analysis of the meaning of the resultative, the perfect, and the perfective enables an analysis of the diachronic pattern as a two-step generalization (semantic weakening) from the original resultative meaning.

Although the perfect to perfective shift has been taken to involve semantic bleaching with an extension in the range of uses across time (Schwenter, 1994; Schwenter and Cacoullos, 2008; Bybee et al., 1994, a.o.), this extension has not been explicitly treated as a systematic generalization. Specifically, previous accounts are compatible with an ambiguous meaning for the forms that participate in the grammaticalization shift. The precise mechanism which introduces this ambiguity between perfect and perfective meaning is left unspecified. The generalization analysis we propose is the first explicit proposal to our knowledge for the resultative to perfect and perfect to perfective shifts.

In Section 2 we describe the three distinct stages of Indo-Aryan with reference to the changing meaning of an originally (result) stative morphology, *-ta*, and establish that it systematically undergoes the resultative to perfect to perfective shift, a fact gone largely unnoticed in the vast literature on Indo-Aryan. In Section 3 we characterize the meanings of the aspectual operators that are involved in the analysis of *-ta* across the delineated stages. The first diachronic generalization effects a change such that one of the entailments of the resultative, namely that of the prior occurrence of an event of the type denoted by the lexical predicate, becomes part of the meaning of the operator at a later stage (the perfect stage). The second diachronic generalization associates with the aspectual operator a more general relation for instantiating eventuality descriptions within temporal intervals. In Section 4 we discuss the implications of our analysis for theories of language change.

## 2. Indo-Aryan Stages

The Indo-Aryan branch of Indo-European inherited a deverbal result stative adjectival participial form with the affix *-ta* (allomorph *-na*) attached to the verb root. The distribution and interpretation of this form undergoes systematic expansion across the history of Indo-Aryan, instantiating at three historical stages the three points in the trajectory in (1). We establish this by providing original data for the distinct readings available to the *-ta* form at each of these stages and distributional diagnostics, such as presence of overt agents, compatibility with particular temporal adverbials, use in narrative discourse, etc. The three stages of Indo-Aryan are given in (2). The rightmost column gives the texts representative of the delineated periods, from which we extracted the empirical data.

(2) **The Chronology**

TIMELINE	STAGE	LANGUAGE	SOURCE
1900BCE-1100BCE	I	<b>Early Vedic</b>	Ṛgveda (RV)
1000BCE-200BCE	II	<b>Later Vedic</b>	Baudhāyana Dharma Sūtra (BS) Bṛhaddevatā (BD) Bṛhadāranyaka Upaniṣad (BAU)
300 BCE-700CE	III	<b>Middle Indic</b>	Vasudevahimṇi (VH)

(Approximate dates from Witzel (1999); Jamison and Witzel (1992); Alsdorf (1936))<sup>1</sup>

In the earliest stages of Indo-Aryan (Early Vedic), *-ta* always attaches to the root of a change of state verb whose meaning makes reference to a result state. The *-ta* form is a predicate with two distinct but related readings. On the first reading, like English de-verbal adjectival participles, it predicates a stative property corresponding to the verb’s result state of the verb’s direct object argument in both attributive and predicative positions (e.g., *hide x* → *x is hidden*, *hidden x*). Despite the restriction to change of state verbal roots with an associated result state, the *-ta* form does not entail the existence of a prior event of the type denoted by the corresponding verb (just like *x is hidden*, *hidden x*). On the second, resultative reading, the *-ta* form is in a predicative position and the sentence entails the existence of a prior event of the type denoted by the corresponding verb (like *x has been hidden* on the resultative construal of the perfect). It is the second reading that is of primary concern to this paper because, as we view it, it is the one which undergoes the semantic change. The distribution of *-ta* forms on the first reading remains constant throughout. At stage II, *-ta* exhibits the resultative, the existential, and the universal perfect readings, patterning like a regular perfect marker. In stage III, while retaining its resultative, existential, and universal readings, *-ta* is also regularly used in narrative discourse and is compatible with past referring definite frame adverbials giving rise to the implication that the described eventuality occurred within the time specified by the frame adverbial.

(3)

READINGS	Resultative Stage I	Perfect Stage II	Perfective Stage III
Resultative perfect	✓	✓	✓
Existential perfect	∅	✓	✓
Universal perfect	∅	✓	✓
Eventive/Past	∅	∅	✓

Before we move on, let us summarize what the labels we use for the readings amount to, by relating them to the English perfect and perfective.<sup>2</sup> The resultative perfect applies to predicates of events with associated result states and asserts that the relevant state holds at the reference time as a result of an event of the type denoted by the verb having occurred. For instance, *John has put the cake in the oven* implies that the cake is now in the oven as a result of John’s putting it there. The existential perfect applies to predicates of any type and has a backshifting effect: it asserts that the predicate holds at some time before the reference time. For instance, *John has visited Korea many times* implies the past

occurrence of many separate visits to Korea by John. On the universal perfect reading, the predicate is understood to have continuously held throughout an interval stretching from some time in the past up to the reference time, as in *John has lived in Korea for the last three years*. With perfective aspect a predicate is asserted to hold within the reference time. Sentences with perfective aspect are typically used in narrative discourse to advance the reference time, contrasting with the perfect aspect in this respect. Compare *John iced the cake. He (then) went shopping* with #*John has iced the cake. He (then) went/has gone shopping*. The English perfect morphology, unlike the German or French perfect, does not express perfective aspect and cannot be used in narratives (de Swart and Molendijk, 2001; Pancheva and von Stechow, 2004).

## 2.1. Early Vedic: Stage I

### 2.1.1. Plain stative and result-stative readings of *-ta*

Much of the literature on Sanskrit treats *-ta* as used to refer to events occurring in an indefinite or proximate past time (e.g., Whitney 1889: 340, 362; Speijer 1886: 4), or as expressing exclusively the result state of an action (Jamison, 1990), or a completed action whose results persist in the present (e.g., Keith, 1909: 247). We agree with the latter authors that *-ta* does not have a past perfective reading at Stage I (Vedic), but we distinguish between two *stative* readings available to *-ta* – a distinction in use that has already been noticed by Vedic scholars focusing on the temporal and aspectual semantics of the Sanskrit verbal system (Wackernagel, 1954: 583; Delbrück, 1888: 385).<sup>3</sup>

These two readings — the plain stative and the result stative readings — are illustrated below.<sup>4</sup> In (4a), the *-ta* form predicates of the tree the state of being fixed/established in a certain location, and it certainly does not imply any event that resulted in the coming about of this state. (4b) is part of a characterizing description of Maruts (minor storm deities), which enumerates stable attributes of these deities rather than describing a result state obtaining from a prior event. The visors are understood as being in a spread-out position without there being a prior event by which they come to be in such a position. (4c) is an example of a prenominal attributive *-ta* form, derived from the root *su* ‘press’, that agrees in case and number with the head noun it modifies, *soma*.

- (4) a. *kāḥ svid vṛkṣó níṣṭh-ito mādhy-e árṇas-o*

 soma-ACC.M.SG drink-IMP.2.DU  
 ‘O Indra and Varuṇa, the pressed-juice (Soma) drinkers, drink this *pressed*  
 Soma.’ (RV 6.68.10a)

The plain stative reading of *-ta* forms contrasts with their result stative reading, asserting the existence of a prior event and the result state it brings about. This is the familiar resultative reading of the perfect aspect, where the result state of the event is understood to hold at the contextually salient reference time. This reading of *-ta* becomes salient in the presence of agentive and instrumental phrases, as well as adverbial modifiers of the underlying eventive predication. In (5a) the three short clauses with *-ta* are understood to describe three events essential to the preparation of the Soma drink and undertaken in order to offer the drink to Indra. In (5b) the result stative reading becomes salient because of the presence of the agentive phrase. In (5c) and (5d) the result stative reading is again made prominent by the presence of the benefactive dative-marked arguments.

 ‘For you, Maghavan, it (the Soma) *has been pressed*, for you, it *has been*  
*offered*.’ (RV. 2.36.5)

(6) illustrates the two readings of a *-ta* form with the same verbal root *yuj* ‘yoke’. In (6a) the state of being yoked is predicated of the bull and the dolphin (a prior yoking event is inferrable, but arguably not part of the meaning of the sentence.). In (6b) the state of being yoked is understood to be brought about by a prior event of yoking, which is clearly what the adverbial modifier *by means of prayer* is associated with.

### 2.1.2. -ta as the resultative operator

Having established that *-ta* has a result stative reading distinct from the plain stative reading, characteristic of its Indo-European origin as a deverbal adjective, we proceed to show that as an aspectual operator, it has only the result stative reading and not the larger range of readings associated with the more general perfect operator (specifically the existential and the universal perfect readings). This larger range of readings is available to the reduplicated perfect at this stage (Renou 1925; Dahl 2008). Nor does *-ta*, contra most standard grammars, have a perfective reading, with past eventive reference at this stage (contrast with the Aorist, whose perfective status is under no doubt (Delbrück, 1888; Hoffman, 1967; Dahl, 2008)).

A close survey of Vedic data by Jamison (1990) shows that predicative *-ta* forms are uniformly stative at this stage and overwhelmingly make reference to result states (see also Keith, 1909: 247). Jamison claims that the vast majority of instances of *-ta* forms without the copula at this stage refer to a present result state. We offer three empirical arguments to corroborate her finding that *-ta* forms do not have existential perfect or eventive readings at this stage.

First, we conducted a small study of Sanskrit verbs (n=92) for which the *-ta* form is first attested at Stage I.<sup>5</sup> The hypothesis was that the availability (as inferred from attestation) of the *-ta* form at this stage should vary with lexical subclasses, if *-ta* denotes result states. Result states are expected to be more easily accessible with change of state verbs. The study presented a striking asymmetry between predicates which encode a change of state and those which do not with respect to the attestation of *-ta* forms at Stage I. As (7) shows, the *-ta* participial form is attested for 80% of verb roots encoding change of state but only for 10.5% of simple verb roots. This distribution of *-ta* strengthens the case for it being associated with the resultative aspectual operator at this stage.

(7)

VERBS	CHANGE OF STATE			OTHERS
	BARE	PREVERBED	TOTAL	
Number of roots	44	10	54	38
<i>-ta</i> attested	33	10	43	4
% <i>-ta</i> forming roots	75%	100%	<b>80%</b>	<b>10.5%</b>

Second, we examined all instances of *-ta* forms for some very frequent change of state verbs in the R̥gveda in order to determine the readings they exhibited in context. This set of verbs is given in (8). None of the predicative instances of verbs in this set exhibited the existential perfect or past perfective reading. Although the set of verbs investigated is small, the consistent absence of an existential or past eventive reading for the *-ta* forms in context supports the case for its resultative status.

(8)

verb	<i>-ta</i> form	Count	Existential/Past reading
<i>su</i> ‘press out’	<i>suta</i>	58	0
<i>yuj</i> ‘yoke’	<i>yukta</i>	46	0
<i>idh</i> ‘kindle’	<i>iddha</i>	30	0
<i>badh</i> ‘bind’	<i>baddha</i>	15	0
<i>gr̥bh</i> ‘grasp’	<i>gr̥bh̄ita</i>	15	0
<i>vi+tan</i> ‘spread’	<i>vitata</i>	15	0

Third, we investigated the co-occurrence of *-ta* forms with indefinite past referring and frequency adverbials. The reasoning is that if the *-ta* form can trigger eventive reference for the sentence it occurs in, then it should be possible for the predicate to be modified by indefinite past and frequency adverbs. However, this expectation is not met in the textual data. Of all occurrences of three adverbials, *purā*, *pūrvam*, and *purudhā*, only one each appear with the *-ta* form, and two of these three instances occur in the part of the text known to be authored much later than the soriginal text (the 10th Book).

(9)

Adverbial	Occurrence	modification of <i>-ta</i>
<i>purā</i> ‘of old, earlier’	45	1 (RV 6.60.4)
<i>pūrvam</i> ‘before, in the past’	8	1 (RV 10.97.1)
<i>purudhā</i> ‘often’	9	1 (RV 10.27.21)

We take these facts, together with Jamison’s quantitative study, to show that *-ta* realizes the resultative aspect at Stage I. The next section discusses the generalization of *-ta* to the perfect category in Stage II, which is the language of Late Vedic (Vedic prose).

## 2.2. Late Vedic: Stage II

Two changes characterize Late Vedic: (a) the availability of the existential and the universal perfect readings for *-ta* forms; and (b) the extension of *-ta* to lexical predicates which do not encode change of state.<sup>6</sup> The original resultative perfect reading (ongoing result

state) is still available to *-ta*, indicating an expansion in the set of readings from Stage I to Stage II rather than a non-generalizing change.

The following examples illustrate the existential reading of *-ta*. In (10a), the verb *dr̥ś* ‘see’ does not imply a change of state. The *-ta* sentence with *dr̥ś-ta* simply makes reference to a prior seeing of the formulae (the formulae are considered divine, incapable of being written by human effort), not to any result state associated with such a seeing. This is a case where an existential reading is associated with a lexical predicate that does not encode change of state. The existential reading may also be available with lexical verbs that do encode a result state. In (10b) *smṛ* ‘teach’ can be associated with the result state of successful knowledge transfer. The context provides a description of barley (grains), which are being praised. (10b), in this context, only refers to the pronouncement on the part of the sages regarding the sin-banishing abilities of barley. There is no implication that any state has resulted from this event; the existential reading is salient. (10c) is another illustration of a *-ta* sentence with existential reading, where the form is built on the non-change-of-state predicate *vac* ‘speak’.

- (10) a. *mantrā*                      *nānāprakār-āḥ*                      *sy-ur*                      ***dr̥ś-tā***

*vidhi-ḥ*  
 rule-NOM.M.SG  
 ‘Thus, the general rule about these three (Gods) has been stated.’ (BD. 1.79)

(11) illustrates the use of *-ta* with stative predicates, where the relevant inference is that the state denoted by the lexical verb continues to hold throughout some interval from a time in the past until the reference time. The context before (11a) describes how the original father produced (*ajanayat* Imperfect) seven kinds of foods and how he apportioned (*abhājayat* Imperfect) them. One of these foods (viz. milk) he gave (*prāyacchat* Imperfect) to the animals. Since this apportioning, milk has been the basis for living and non-living beings. The *-ta* modified predicate *prati+sthā* ‘rest’ denotes the state which has held since the completion of the apportioning event.<sup>7</sup> (11b) is a similar example from a later text with the verb *man* ‘think’. In this case also, the belief or thought is considered to have held throughout an interval stretching from a past time up until the present.

### 2.3. Middle Indic: Stage III

The Middle Indic languages (illustrated here by Mahārāṣṭrī Prakrit) are characterized by a simpler past marking system, having lost most of the inflectional past tense morphology of Old Indic.<sup>8</sup> The result of this morphological loss is that *-ta* becomes the default morphology for past time perfective reference (This change is, in fact, evident from the period of at least the Epic Sanskrit texts within Sanskrit (Old Indic) as well). In addition to the perfect readings of *-ta* from Late Vedic, it exhibits a past perfective reading.

Every study of Middle Indic grammar recognizes the perfective use of the *-ta* form as central to its distribution (Pischel, 1900; Bloch, 1965; Bubenik, 1996, a.o.). In addition to relying on this observation from the literature, we use two distributional diagnostics to argue that *-ta* sentences refer to culminated past events. First, in contrast to earlier periods, *-ta* is the only form available for narrating sequences of past events. In simple narrative discourse, where consecutive sentences typically move reference time forward, verbs in these sentences inflect with *-ta*. Second, in contrast to the earlier period, *-ta* appears with definite past referring adverbials. Of course, because the change involves an expansion in the set of readings, the resultative, universal, and existential perfect readings remain available to the *-ta* form.

The narrative fragment in (13) illustrates the perfective readings available to *-ta*. The main predicate in each of the sentences in (13) is a *-ta*-inflected form. The story describes the events before the sacrifice of a goat, beginning with the departure of the family (with

their friends and relatives) to the sacrificial stake. Every following sentence is understood to describe an eventuality that took place later in time, each of them ordered with respect to each other.<sup>9</sup> Thus, the going (13a) is understood to occur prior to the goat-taking (13b), which is before the worshipping (13c), which is followed by the elders' announcement (13d) and the leaving of the son (13e).

 then his son-NOM.M/SG goat-ACC.SG bring-INF go-PERF.M.SG  
 'At that, his son... went to bring the goat.' (VH:D 29.25-28)

The other piece of evidence that the *-ta* form has past eventive reference is that it may be modified by definite past adverbials. Definite time adverbials specify particular intervals within which eventualities are realized. The *-ta* form, when modified thus, indicates that a completed event obtains in the time denoted by a definite time adverbial. The impossibility of modification by definite temporal adverbials is one of the defining features of the English present perfect. The *-ta* form (which may have present reference in the absence of tense auxiliaries), on the other hand, can be freely modified in this way. In this respect it patterns like the German or French perfect, which have been analyzed as having undergone some kind of a perfect-to-perfective shift.

- (14) a. **tato** *kaiva-esu divas-esu aikkan-t-esu... diṭṭhā me*

### 3. Analysis

In the previous section, we provided evidence for the instantiation of the resultative to perfect to perfective shifts in Indo-Aryan, through the changes in the interpretation of the *-ta* form from Vedic to Late Vedic to Middle Indic. In this section we characterize the meaning of the aspectual operators implicated in the analysis of predicative *-ta* forms across the three distinct stages and show how each shift involves a generalization of the meaning of the relevant aspectual operators. We are assuming that saturated clausal predications, sentence radicals, denote properties of eventualities which get instantiated by aspectual operators. Most of our assumptions are standard but we make a new proposal about the lexical denotation of change of state predicates with associated result states and the resultative perfect and about an aspectual operator whose meaning encompasses that of perfect and of perfective.

Let  $\mathcal{E}$  be a domain of eventualities, sorted into a set of events  $\mathcal{E}^E$  and a set of states  $\mathcal{E}^S$ , and  $\mathcal{T}$  a domain of non-null temporal intervals (with points as a special case) partially ordered by the relation of temporal precedence  $\prec$  and by the subinterval relation

$\sqsubseteq$ . A function  $\tau$  from  $\mathcal{E}$  to  $\mathcal{T}$  gives the time span of an eventuality. Basic eventive predicates have an eventuality argument of the sort  $E$  (event); basic stative predicates have an eventuality argument of the sort  $S$  (state). Sentence radicals arising out of such predicates then are either eventive or stative predicates. Aspectual operators, such as the perfect and the perfective that we discuss below, apply to such sentence radicals to yield predicates of times within which the properties denoted by sentence radicals are instantiated. Instantiation of properties of eventualities involves the familiar existential quantification over the Davidsonian event variable. In (16) we define instantiation for both predicates of eventualities and predicates of times.

(16) **Property Instantiation**

$$\text{INST}(P, i) = \begin{cases} \exists e \in \mathcal{E} [P(e) \wedge \tau(e) \sqsubseteq i] & \text{if } P \subseteq \mathcal{E} \\ P(i) & \text{if } P \subseteq \mathcal{T} \end{cases}$$

In the absence of overt morphosyntactic tense, we assume that a semantic tense operator, dependent on a contextually determined reference time, applies to a property of eventualities or times and instantiates it within/at that time. We use the operator  $\text{TNS}$  indexed to a time variable  $i$  whose content is given in (17). The time of utterance  $\text{Now}$  is always available as a potential reference time, i.e., as a value for  $i$ .

(17) Relative to context  $c$  and contextual variable assignment  $g_c$ ,

$$\text{TNS}_i = \lambda P \text{INST}(P, g_c(i))$$

We additionally define two notions that we will use in the discussion to follow: the notion of the temporal correlate  $P[i]$  of a predicate of eventualities  $P$ , given in (18), and the notion of non-final instantiation, given in (19).

(18) For any  $P \subseteq \mathcal{E}$ ,  $P[i] = \lambda i \exists e [P(e) \wedge i = \tau(e)]$

(19)  $\text{NFINST}(P, j, i)$  is defined only if  $i$  is a final subinterval of  $j$   
 $\text{NFINST}(P, j, i) = \exists k [\text{INST}(P, k) \wedge k \sqsubseteq j \wedge \neg(i \circ k)]$  if defined

3.1. *-ta: Lexical Stativizer and Resultative Perfect*

We take the non-ambiguity of attributive and the ambiguity of predicative *-ta* forms to show two distinct functions of *-ta*, one as a lexical, derivational operator operating on change of state verbs, the other as an aspectual operator operating on sentence radicals. The historical changes under discussion involve *-ta* as an aspectual operator. Below we briefly outline our view of *-ta* as a lexical operator and then go on to analyze its meaning as an aspectual operator.

Kratzer (2000), Piñón (1999) and von Stechow (2003), based on empirical evidence of different kinds, have made a convincing case that certain eventive verbs make result states accessible for phrasal semantic composition. Following this main idea, we assume that change of state verbs can make the result state property accessible for lexical and for phrasal semantic operations by projecting it into the lexicon in a particular way. We take verbs like *yoke* to have purely eventive denotations, such as those shown in (20), as

well as denotations that pair the eventive component with the stative component of their meaning, such as those shown in (21). We give the variants in (a) and (b) to illustrate that the descriptive term attached to the event determines the descriptive term attached to the state. For the sake of concreteness, we have chosen to associate the arguments of eventive predicates via thematic roles and the arguments of stative predicates via the ordered argument method but this is not essential to our analysis. We assume that meaning postulates regulate the identification of arguments across the two predications.

- (20) a.  $\lambda y \lambda x \lambda e \text{ put-yoke-on}(e) \wedge \text{Agent}(e,x) \wedge \text{Patient}(e,y) [x \text{ yokes } y]$   
 b.  $\lambda y \lambda z \lambda x \lambda e \text{ connect-to-with-yoke}(e) \wedge \text{Agent}(e,x) \wedge \text{Patient}(e,y) \wedge \text{Theme}(e,z) [x \text{ yokes } y \text{ to } z]$
- (21) a.  $\langle \lambda e \text{ put-yoke-on}(e), \lambda y \lambda s \text{ have-yoke-on}(s)(y) \rangle$   
 b.  $\langle \lambda e \text{ connect-to-with-yoke}(e), \lambda z \lambda y \lambda s \text{ connected-to-with-yoke}(s)(y)(z) \rangle$

As a lexical operator, *-ta* maps paired properties to their stative component. In that case the predicates projected to the syntax and entering semantic composition are as in (22). The eventive component of the meaning of the original predicate is not made available for semantic composition. Any implications about the existence of an event of the relevant type resulting in the truth of the stative predication are inferential.

- (22) a.  $\lambda y \lambda s \text{ have-yoke-on}(s)(y)$   
 b.  $\lambda z \lambda y \lambda s \text{ connected-to-with-yoke}(s)(y)(z)$

Pairs such as those in (21) are also projected to the syntax and enter semantic composition, where the arguments of the stative predicate will be saturated. The output will be paired eventive-stative property sentence radicals. *-ta* in its function as an aspectual operator applies to such sentence radicals to yield the temporal correlate of the stative property. We can thus identify the meaning of *-ta* with the aspectual operator RESPERF.

The resultative perfect RESPERF applies to paired property sentence radicals and instantiates the two properties via paired property instantiation, defined in (25). The logical form of sentences with a sentence radical  $\langle P, Q \rangle$  would be as in (23). The reference time  $r$  specified by tense has to be one of the elements of  $\text{RESPERF}(\langle P, Q \rangle)$ . Given that  $r \in \text{RESPERF}(\langle P, Q \rangle)$  only if  $r \in Q[i]$ , the characteristic entailment of the resultative perfect that the reference time is included in the time span of the result state is captured.

$$(23) \text{TNS}_i(\text{RESPERF}(\langle P, Q \rangle))$$

$$(24) \text{RESPERF} = \lambda R \lambda i \text{INST}^2(R, i) \text{ defined only if } R = \langle P, Q \rangle \text{ with } P \subset \mathcal{E}^E \text{ and } Q \subset \mathcal{E}^S.$$

(25) **Paired Predicate Instantiation**

$$\text{INST}^2(\langle P, Q \rangle, i) = \exists e \in \mathcal{E}^E \exists s \in \mathcal{E}^S [P(e) \wedge Q(s) \wedge \text{result}(e, s) \wedge i = \tau(s)]$$

We assume that for any event  $e$  and state  $s$  if  $\text{result}(e, s)$ , then  $\tau(e) \prec \tau(s)$ , and allow for multiple states, with different time spans, to be related to an event  $e$  via  $\text{result}$ , i.e., unlike many other treatments of the resultative perfect we do not take  $\text{result}$  to be functional

and thus avoid having to refer to maximal states. Otherwise, we remain agnostic here on how exactly result should be axiomatized, for instance, whether it involves the notion of causation.

To illustrate, let us consider a somewhat simplified resultative perfect variant of the Vedic (6a), rendered in English as in (26). Its sentence radical would be as in (27), and application of RESPERF would yield (28). Application of tense to (28) with the reference time set to Now would yield (29).

(26) The dolphin has been yoked to the chariot.

(27)  $\langle \lambda e \text{ connect-to-with-yoke}(e), \lambda s \text{ connected-to-with-yoke}(s)(d)(c) \rangle$

(28)  $\lambda i \exists e \in \mathcal{E}^E \exists s \in \mathcal{E}^S [\text{connect-to-with-yoke}(e) \wedge \text{connected-to-with-yoke}(s)(d)(c) \wedge \text{result}(e, s) \wedge i = \tau(s)]$

(29)  $\exists e \in \mathcal{E}^E \exists s \in \mathcal{E}^S [\text{connect-to-with-yoke}(e) \wedge \text{connected-to-with-yoke}(s)(d)(c) \wedge \text{result}(e, s) \wedge \text{Now} = \tau(s)]$

### 3.2. From Resultative Perfect to Perfect

For any pair  $\langle P, Q \rangle$  and any  $i \in \text{RESPERF}(\langle P, Q \rangle)$ , there is an interval  $j$  of which  $i$  is a final subinterval such that  $j$  contains an event  $e$  of type  $P$  which does not overlap  $i$ . In other words, the subset relation in (30) holds for the following two sets of times: the set of times in the temporal correlate of  $Q$  and the set of times that are final subintervals of intervals within which  $P$  is instantiated non-finally.

(30)  $\lambda i \exists e \exists s [R(e, P, Q, s) \wedge i = \tau(s)] \sqsubseteq \lambda i \exists j \text{NFINST}(P, j, i)$

We claim that this entailment of the resultative perfect gets conventionalized as the meaning of *-ta*, when it combines with verbs of any kind without restrictions. In Stage II then, *-ta* is identified with the aspectual operator RESPERF applying to paired property sentence radicals, as in Stage I, and also with the aspectual operator PERF applying to sentence radicals of the regular type. The meaning of PERF is given in (31).

(31)  $\text{PERF} = \lambda P \lambda i \exists j [i \sqsubseteq_{\text{final}} j \wedge \text{NFINST}(P, j, i)]$

This is, in effect, the ‘extended now’ analysis of the perfect (McCoard, 1978; Dowty, 1979; Iatridou et al., 2001, among others). If  $P$  is an eventive or stative sentence radical and the reference time is the time of utterance, the meaning of the sentence would be as in (32):  $P$  is asserted to be instantiated within intervals preceding Now.

(32)  $(\text{PERF}(P))(\text{Now}) = \exists j \exists k \exists e [P(e) \wedge \neg(\text{Now} \circ k) \wedge \tau(e) \sqsubseteq k \wedge k \sqsubset j \wedge \text{Now} \sqsubseteq_{\text{final}} j]$

The existential and universal readings are a consequence of the semantic properties of the predicate  $P$  to which PERF applies; these determine certain relations between elements of  $P$  and elements of  $\text{PERF}(P)$ . To show how the existential and the universal readings arise we will consider here only PERF applying to eventive and stative sentence

radicals, though the same point can be made for temporal properties as well. Take an eventive predicate  $P$ . For any  $t \in P[i]$ , there is a subset  $Sub_t(\text{PERF}(P))$  of  $\text{PERF}(P)$  such that for every  $t' \in Sub_t(\text{PERF}(P))$ ,  $t \prec t'$ . For any such  $P$ ,  $\text{PERF}(P)$  will yield the existential reading, involving backshifting from the reference time. Take a stative predicate  $P$  that holds over a given time. Given the divisiveness of stative predicates and their temporal correlates,<sup>10</sup> there are  $t \in P[i]$  and subsets  $Sub_t(\text{PERF}(P))$  of  $\text{PERF}(P)$  such that for every  $t' \in Sub_t(\text{PERF}(P))$  the convex interval  $[t, t']$ <sup>11</sup> is itself an element of  $P[i]$ . If the reference time  $r$  is assumed to be within such a subset of  $\text{PERF}(P)$ , then the universal reading arises. Otherwise, the existential reading arises.

### 3.3. From Perfect to Perfective

In the transition from Stage II to Stage III the condition for non-final instantiation is generalized to instantiation and *-ta* is identified with the aspectual operator  $\text{PERV}$ , whose meaning is given in (33).

$$(33) \text{ PERV} = \lambda P \lambda i \exists j [i \sqsubseteq_{\text{final}} j \wedge \text{INST}(P, j)]$$

$\text{PERV}$  subsumes the readings of  $\text{PERF}$  and in addition allows for instantiation within the reference time, the hallmark of a perfective reading. If  $i = j$  or if  $i \sqsubseteq_{\text{final}} j$  and  $P$  is instantiated within  $i$ , the perfective reading arises. If  $P$  is instantiated before  $i$  within  $j$ , the perfect reading arises. In case  $P$  is instantiated at some time within  $j$  that overlaps  $i$ , the eventuality instantiating  $P$  is taken to be culminating within  $i$ , hence within the reference time.

In this paper we do not work out the dynamics of reference time advancement but we can assume that in a narrative sequence like that of (13) each sentence is evaluated relative to the reference time set by the context thus far and then resets the reference time to a later time. That reference time is then given as an argument to the temporal abstract obtained by applying  $\text{PERV}$  to the sentence radical of the following sentence, with  $i$  and  $j$  identified.<sup>12</sup>

## 4. Comparisons and conclusion

We have characterized the meanings of *-ta* as an aspectual operator at the three diachronic stages and demonstrated the semantic relatedness of resultative ( $\text{RESPERF}$ ), perfect ( $\text{PERF}$ ), and perfect+perfective ( $\text{PERV}$ ). *-ta* undergoes successive generalization of its meaning. Our proposal rests on the conventionalization of entailed meaning and the generalization of the relation instantiating event descriptions in time. It, therefore, holds promise of application to other instances of this type of cross-linguistic shift.

### 4.1. Semantic generalization vs. invited inferences

Our semantically-rooted account may be contrasted with the pragmatic inferencing approach that has been invoked for explaining regular semantic change (Traugott and Dasher,

2002; Eckardt, 2006). On this view, pragmatically derived ‘invited’ inferences associated with an expression are diachronically *semanticized* or conventionalized as part of the meaning of that expression. For instance, Eckardt (2006) proposes that the emergence of the prospective aspect in English is the result of the conventionalization of the invited inference of imminent event occurrence available to a transparent *going to V* construction. The conventionalized meaning is distinct from the original compositionally available meaning and the form may be ambiguous between the diachronically former and latter meanings at some stage.

The pragmatic inferencing hypothesis and the meaning generalization hypothesis make distinct predictions about the meanings of the aspectual categories concerned. Specifically, it is only the latter that requires that the meaning of an expression at a diachronically earlier stage be a subset of the meaning at a later stage. In this regard, the semantic generalization hypothesis offers a more restrictive account of the set of changes in question.

#### 4.2. *Motivating semantic generalization*

Our account may explain how the diachronic changes involve semantic generalization, but it does not address the motivating factors for the occurrence of each shift. Here we offer some speculative remarks on why the shifts might have occurred. The Old Indo-Aryan finite verbal tense-aspect system (Stage I) contains a number of past aspectual categories, which overlap with *-ta* in some of their uses. The Aorist expresses the perfective, while the reduplicated Perfect realizes the more general perfect aspect, with stative present readings limited to some predicates. The Imperfect is a neutral past tense, and is often used in narrative contexts with eventive reading (Delbrück, 1888; Whitney, 1892). In the second stage, the reduplicated perfect generalizes to include the past perfective reading, overlapping in this domain with the Aorist and the Imperfect. By the time of Epic Sanskrit these three past referring categories have become interchangeable and there is an increase in the frequency of the *-ta* form.<sup>13</sup> These three finite categories are lost almost entirely by Stage III (Pischel, 1900) and their functions taken over by the *-ta* form. At Stage III, *-ta* realizes the complex aspectual category PERV (perfect+perfective) and has the entire range of readings available to the older, lost Perfect and Aorist.

A plausible motivation for the generalization of *-ta* is the diachronic loss of forms that express perfect and perfective meaning, respectively. The semantic shift, thus, may be seen as going hand-in-hand with a morphological change that affects the semantic categories expressed by the broader verbal paradigm of Indo-Aryan. We do not have spontaneous changes in the meaning of *-ta* but rather these changes are triggered by the need for morphology that can express the semantic categories previously expressed by older forms. This change is, of course, spread over several centuries and must have involved a period over which *-ta* increased in relative frequency over the Perfect and the Aorist. There is a clear morphological advantage that *-ta* enjoys over the Perfect and the Aorist: it is built on the root, and constructs an invariant stem that inflects with the set of adjectival endings. The Perfect and Aorist stems involve reduplication and other morphological changes to the root, and the perfect further involves a distinct set of personal endings. The case can be made that the increasing use of *-ta* is facilitated by its relative lack of morphological complexity and predictable derivation, but that remains a speculative point, and is

ultimately orthogonal to the purposes of this paper.

### 4.3. Conclusion

Our semantic analysis shows that the resultative to perfect to perfective shift is a generalization, which is consistent with the proposal that grammaticalization is non-exemplar-based analogical change (as has been argued by Kiparsky, 2005). A more ambitious goal would be to specify the factors that trigger the grammaticalization in a particular language at a particular time. We suggested some language-specific factors that might have triggered it in Middle Indic. Our proposal makes predictions that can be tested by textual research that traces changing the frequencies of *-ta* and its competitors across time.

## 5. Notes

1. These are approximate periods and the first of these, especially, only gives the broad window within which Northern and North-west India were settled (Jamison and Witzel, 1992, p.6). The composition of the texts that have been used for our research, for the most part, took place in the later parts of each of the three delineated chronological stages.
2. For a recent discussion of the descriptive issues and analytical choices pertaining to the syntax and semantics of the perfect see Alexiadou et al. 2003.
3. The Modern Greek cognate of *-ta*, the participle in *-tos/ti/to*, exhibits only the plain stative reading and contrasts with *-menos/meni/meno* participles which exhibit the result stative reading. For discussion and other references see Anagnostopoulou 2003.
4. We gloss *-ta* as PERF regardless of its distribution and readings at distinct stages of Indo-Aryan. The other glosses are as follows: PRES = present; PST = past; IMP = imperative; NOM = nominative; ACC = accusative; INS = instrumental; GEN = genitive; LOC = locative; M = masculine; F = feminine; N = neuter; SG = singular PL = plural; PRT = particle; FOC = focus particle.
5. The information for the first attested *-ta* forms for lexical roots and the roots themselves have been gleaned from Grassman, 1964 and Whitney, 1883.
6. It is difficult to precisely locate a line of clean separation between Stage I and Stage II corresponding to Vedic verse and Vedic prose. Specifically, there is no exhaustive study of Vedic lexical verbs that establishes that *-ta* appears only with change of state predicates in Early Vedic (Stage I), although, overwhelmingly *-ta* is used to describe result states. Early Vedic texts (the Mantras) were composed over a long period and represent multiple linguistic layers. What we are able to clearly show in this section is that Stage III (the period characterized by Middle Indic (and possibly Epic and Classical Sanskrit) is preceded by a period during which *-ta* functions as the perfect with existential, universal, and resultative readings. At this stage, covering the bulk of the Vedic prose, “the tendency is to assimilate the part.(iciple) to the present” (Keith 1909: 248). This tendency is much more visible in the *Dharmasūtras*, the youngest texts within Vedic prose.
7. Note that the universal reading of the perfect is absent in several languages, such as Greek and Russian. In these languages, the universal reading is expressed by the present tense forms. *-ta* forms with stative predicates occurring in Vedic prose may often be translated in the English present tense (e.g., Keith, 1909). However, the fact that this translation is possible with a form expressing resultative or perfect meaning provides evidence that the form licenses universal perfect readings.
8. The inflectional system of verbal contrasts in OI changed to a relatively morphologically impoverished inflectional system in MI with loss of most of the past referring categories. Pischel (1900), on the basis of careful textual study, reports that the Imperfect, the Aorist, and the Perfect occur in MI texts only as a few scattered forms for a few verbs. The single instance of the Imperfect retained in MI is the Imperfect form of the verb *as* ‘be’ (Pischel, 1900: 421-22). The Aorist occurs relatively more frequently (Pischel, 1900: 422-24), while the Perfect is preserved only as an archaism for a few verbs. Bloch (1965: 228-233) reaches the same conclusion. The only remaining past-referring paradigm from Epic Sanskrit is

the PERF paradigm and it is used regularly for past time reference, which is the reason for it to be considered the simple past tense in MI.

9. Also see VH:KH 3.10-17, VH:KH 7.7-11, VH:KH 23.8-12, Vh:D 29.19-23, VH:D. 31. 1-8, VH:D. 34. 18-25 as examples in support of the claims that *-ta* forms have eventive reference and are understood as causing an advancement of reference time.
10. A temporal predicate *P* is divisive iff its denotation is closed under the subinterval relation.
11.  $[t, t']$  is a convex interval with *t* as an initial subinterval and *t'* as a final subinterval.
12. In this version of the paper we use temporal adverbs as diagnostics for certain readings but we do not provide an analysis of them.
13. While this lack of distinction has been well-established in the literature, it is a puzzle why the Imperfect, the Aorist, and the Perfect are interchangeable at the Epic Sanskrit stage. It is conceivable that the writers of the Sanskrit Epics, are, in fact, speakers of a language with a Middle Indic (Stage III) type system, characterized by a single perfective form and no further distinctions within the perfective domain. We know that the MI Prakrits were the vernacular languages in the region at least since the 300 BCE (based on Aśokan inscriptions). On the other hand, Sanskrit was the learned language of prestige. MI native speakers, whose language was characterized by a single aspectual category that referred to past situations—the *-ta* form—may well have mapped the distinct Vedic paradigms onto this single category, when writing in Sanskrit. This can account for why the three paradigms appear to be undifferentiated in terms of their distribution. It also accounts for the increased frequency in the usage of *-ta* (Avery, 1875), an anticipation of the later MI system, where this is the only exponent of the perfective and perfect aspects.

## Abstract

This paper concerns a peculiar contrast between English and Dutch: in English, subject quantifiers are not allowed to scope over epistemic modals, whereas in Dutch, this is not problematic at all. I argue that this contrast relates to a difference in subjectivity of the modals involved: English modals are more subjective than Dutch ones. I will discuss various ways to implement this idea, settling in the end for a speech act modifier analysis of subjective epistemic modals. Such modals contribute to the illocutionary force, while quantifiers contribute to the truth conditional content. As illocutionary force is a 'higher' level of meaning, subjective epistemics always take wide scope.

**Keywords:** epistemic modality, wide scope, subjectivity, speech acts

## 1. A difference between English and Dutch

English and Dutch differ with respect to the scopal interaction between epistemic modals and nominal quantifiers. In English, nominal quantifiers are not allowed to take scope over epistemic modals, but in Dutch this is possible. I will first present the relevant English data, and then I will look at Dutch.

### 1.1 The English facts

As observed by von Stechow & Iatridou (2003), English epistemic modals take obligatory wide scope over subject quantifiers.<sup>1</sup> Among the evidence they present is the fact that (1) is reliably judged false in the given scenario:

Scenario:

*We are standing in front of a student residence. In some of the rooms the light is on, in other rooms it is off. Imagine that every room is equipped with a special device that automatically switches off the light if a student leaves his/her room. We thus know that some students are home, because some lights are on.*

- (1) Every student may have left.
- |    |                     |         |
|----|---------------------|---------|
| a. | may > every student | (false) |
| b. | every student > may | (true)  |

---

\* The research for this paper was in part made possible by a grant from the Stichting Fonds Doctor Catharine van Tussenbroek, which is hereby gratefully acknowledged.

<sup>1</sup> The same claim can be found in Leech (1971), Drubig (2001) and Gergel (2003), but none of these authors present any evidence for it. I therefore restrict myself to von Stechow & Iatridou's work.

It follows that (1) can only be interpreted with wide scope for the modal. That is, the sentence means that the speaker considers it possible that every one of the students has left. The reading that for every student  $x$  the speaker considers it possible that  $x$  has left is unavailable.<sup>2</sup> Further evidence is that the following sentence is contradictory:

- (2) #Every student may have left, but not every one of them has.  
a. may > every (inconsistent)  
b. every > may (consistent)

If the quantifier were allowed to scope over the modal, (2) should be consistent.

Strong and weak quantifiers are equally unable to scope over epistemic modals. For example, (3), containing the weak quantifier *two friends of John's* is inconsistent:

- (3) #Two friends of John's from Texas may have come to visit him this weekend, but they can't both have come (because they hate each other).

Again, this is explained if the modal takes obligatory wide scope.

It is indeed the epistemic nature of the modal which forces it to take wide scope. Expressions that are not interpreted epistemically may take both scope positions. The modal in (4) is deontic, and the sentence has two readings, which can be brought out by different continuations:

- (4) Most of our students must get outside funding,  
a. for the department budget to work out.  
must > most of our students  
b. the others have already been given university fellowships.  
most of our students > must

The continuation in (4a) corresponds to a wide scope construal of the modal. It doesn't matter which of our students get outside funding, as long as most of them do. In contrast, in (4b) the obligation is imposed on specific students: those who haven't already received a university fellowship. This interpretation goes with wide scope for the quantifier.

Though I agree with von Stechow & Iatridou that in the above examples the epistemic modals take wide scope, I take issue with their claim that epistemic modals *always* take scope over nominal quantifiers. Below in 2.2 I will present some counterexamples.

---

<sup>2</sup> Von Stechow & Iatridou (2003 fn. 7) note that some people claim that they can get the reading with wide scope for the quantifier, given the right intonation, but they have no explanation for this. Below I will point out further cases in which wide scope for the quantifier is possible, and my account of these might extend to the reported effect of 'prosodic acrobatics'.

## 1.2. The Dutch facts

The wide scope behavior that we just saw that English epistemics display is not something to be found in all languages. In Dutch, for instance, matters are entirely different. In the student residence scenario given above, (5) is undoubtedly true:

- (5) Iedere student kan vertrokken zijn.  
every student may left be  
'Every student may have left.'

As is expected, the following isn't contradictory at all:

- (6) Iedere student kan vertrokken zijn, maar niet iedere student  
every student may left be but not every student  
is vertrokken.  
be left  
'Every student may have left, but not every student has left.'

Being able to take scope over an epistemic modal is not the prerogative of the universal quantifier *iedere* 'every', but other quantifiers have the same ability. For example, the following sentences are fine. Yet, if the modal took obligatory wide scope, they should be odd, for in each sentence the predicate is such that only one individual can satisfy it:

- (7) Slechts weinig studenten kunnen de langste van de klas zijn.  
'Just a few students might be the tallest of the class.'
- (8) Minstens drie mannen kunnen de vader van mijn kind zijn.  
'At least three men might be the father of my child.'

In contrast to the English (3), the next sentence is not contradictory:

- (9) Twee van Jans vrienden kunnen gisteren bij hem op bezoek zijn gekomen, maar ze zijn in ieder geval niet allebei gekomen, want ze hebben een ontzettende hekel aan elkaar.  
'Two of Jan's friends may have come to visit him yesterday, but they sure haven't visited him both, because they hate each other.'

However, while it is easy for a Dutch quantifier to take scope over an epistemic *auxiliary*, it is difficult to scope over an epistemic *adverb*. Note that the following sentences only have one reading, and that this is the one where the modal takes wide scope, even though it appears below the modal at surface:

- (10) Iedereen heeft het misschien gedaan.  
everyone has it perhaps done  
'Perhaps everyone has done it.'

- (11) Slechts weinig studenten zijn waarschijnlijk geslaagd.  
 just few students are probably passed  
 ‘Probably only a few students have passed.’

In this respect, Dutch is like English. For instance, ‘Every student has perhaps left’ is clearly false in the student residence scenario above (cf. von Stechow & Iatridou 2003, fn. 8).

### 1.3 Interim Summary

In this section, we have seen that:

- in English, it is difficult for quantifiers to scope over epistemics
- in Dutch, it is quite easy for quantifiers to scope over epistemic auxiliaries, though not over epistemic adverbs

The aim of this paper is to account for this contrast between English and Dutch.

## 2. Subjective vs. objective epistemic modality

The first step in accounting for the above data is—I believe—to relate the above data to a traditional distinction found in the literature: that between *subjective* epistemic modality and *objective* epistemic modality (Lyons 1977). The same hunch can (independently) be found with Tancredi (2007), though he is not concerned with cross-linguistic differences. Why should it be relevant to distinguish these two senses of epistemic modality? First, it is known that subjective epistemic modals generally prefer wide scope, while this is not so for objective epistemics. It could thus very well be that the wide scope behavior we have just witnessed is a rather broad phenomenon, not restricted to the modal’s scope with respect to subject quantifiers. Second, it is usually assumed that (English) modals are ambiguous between subjective and objective readings (though the subjective reading is often preferred), which might explain why even in English scoping over an epistemic modal sometimes is allowed (recall footnote 2, and see 2.2 below). Finally, it is conceivable that languages differ in the expression types that they use for subjective epistemic modality. Indeed, this is what I propose in this paper: subjective epistemic modals take wide scope, both in English and in Dutch, but in Dutch, subjective epistemic modality is typically expressed by adverbs. The modal auxiliaries express objective epistemic modality, and items which express this kind of modality may scope under quantifiers.

In what follows, I will first discuss the difference between subjective and objective modality in detail. After that, I will demonstrate the relevance of the distinction with respect to quantifier-modal interactions. Finally, I will provide support for the idea that English and Dutch employ different strategies to express subjective epistemic modality.

## 2.1. The traditional distinction

The distinction between subjective and objective epistemic modality goes back to Lyons (1977: 797ff). The distinction has strong intuitive appeal, and has been widely adopted in the literature, yet I know of no clear definition. Lyons presents the subjective-objective distinction as relating to the quality of the evidence of which an epistemic claim is based. He discusses the following sentence:

(12) Alfred may be unmarried.

Assuming the modal is interpreted epistemically, the sentence has two readings. First, it might be understood as an expression of the speaker's personal belief state. This is the subjective epistemic reading. But the sentence also has a more objective reading. Lyons sketches the following situation to bring that reading out:

There is a community of ninety people; one of them is Alfred; and we know that thirty of these people are unmarried, without however knowing which of them are unmarried and which are not. In this situation, we can say that the possibility of Alfred's being unmarried is presentable, should the speaker wish so to present it, as an objective fact. (Lyons 1977: 798)

Thus, (12) can also be understood as a conclusion based on reliable, public facts, and if so, it is understood objectively. In contrast, understood subjectively, (12) involves a mere subjective hunch or guess.

Lyons' remarks should obviously be qualified further, since even on its subjective reading (12) is surely based on some sort of 'objective fact', say the fact that some people are unmarried. What rather seems to matter is the *quality* of the available evidence. The better or stronger the evidence is, the more objective the interpretation of the modal that depends on this evidence. Related to this is the accessibility of the evidence: strong evidence is typically accessible to a larger group of people, while more shaky evidence such as a personal guess is accessible only to the speaker, inscrutable by other people (cf. Nuyts 2001a;b).<sup>3</sup>

In Lyons' system, the distinction between subjective and objective epistemic modality is captured in terms of scope. The idea is that subjective epistemics act like illocutionary force indicators. In Lyons' terminology, they are part of the 'I-say-so' or 'neustic' component of the utterance, which is superimposed on the 'it-is-so' or 'tropic' component of the utterance, to which objective epistemics contribute. One might think of the latter component as the truth conditional content of the utterance. It follows that subjective epistemics do not contribute to this level of meaning. As such, they are similar to performatives:

[The function of subjective epistemic modality] is to express different degrees of commitment to factuality; and in this respect it qualifies the illocutionary act

---

<sup>3</sup> Note that it would be a mistake to correlate subjectivity with indirect, non-observable evidence, and objectivity to direct, observable evidence. Inferential evidence might be of impeccable quality, if the premises are based on good evidence and if the inference is valid.

in much the same way that a performative verb parenthetically qualifies, or modulates, the utterance of which it is a constituent in an explicitly performative utterance or a primary performative with a performative clause tagged on to it. Looked at from this point of view, *It may be raining* (construed as a subjectively modalized utterance) stands in the same relationship to *It's raining, I think* or *I think it's raining* as *Is it raining?* does to *Is it raining, I wonder?* or *I wonder whether it's raining*. (Lyons 1977:805)

Lyons backs up his proposal by pointing out that subjective epistemics resist embedding in the antecedent of a conditional and in the complement of a factive verb. The examples below are taken from Papafragou (2006):

- (13) a. ?If Max may be lonely, his wife will be worried.  
b. ?If Max must be lonely, his wife will be worried.
- (14) a. ?It is surprising that Superman may be jealous of Lois.  
b. ?It is surprising that Superman must be jealous of Lois.

In contrast, objective epistemics can be embedded in these positions:

- (15) If it may rain tomorrow, people should take their umbrellas.
- (16) It is surprising that it may rain tomorrow, since there was no sign of a cloud all day today.

Lyons also noted that subjective epistemic modals cannot be assented or dissented to, whereas objective modals can:

- (17) This professor may be smart.
  - a. ?Is that so?
  - b. ?I don't believe it.
  - c. ?I agree.
- (18) The weather forecast told viewers it may rain tomorrow.
  - a. Is that so?
  - b. I don't believe it.
  - c. I agree.

It seems that in (17), the replies target the utterance without the epistemic modal; i.e. they target the proposition embedded by the modal. In contrast, in (18) it is the modal claim that is agreed or disagreed with.

We now have some idea as to what the subjective-objective distinction pertains to. What is particularly relevant for the topic at hand is that subjective modals make solipsistic claims, dependent on evidence that is inscrutable by anyone other than the speaker, whereas objective modals depend on public evidence; on quantifiable facts. In the next subsection, I will address the relevance of this distinction.

## 2.2. Quantifier-modal interactions

The claim that it is the subjectivity of an epistemic modal, which influences its wide scope behavior, makes clear, testable predictions. By forcing an objective interpretation, it should be possible for quantifiers to scope over epistemics, even in English. How can we make sure that our modals are interpreted objectively? Given the above discussion, what seems to be important is that the context provides the facts on which the utterance is based. The prediction that quantifiers can scope over epistemic modals in such contexts seems to be borne out. Consider for instance:

Scenario (variation on an example by Tancredi 2007):

*I have 5 friends that visit me regularly; 2 of which are blond, 3 of which have dark hair. My boyfriend opens the door and tells me that there is one person at the door and that she has blond hair.*

- (19) Two of my friends may have come to visit me (but they can't both have come, since there is only one person at the door).

Contrary to what one might expect given von Stechow & Iatridou's paper, there is nothing contradictory about this sentence. This means that the *quantifier* takes wide scope, not the epistemic modal. What facilitates this reading seems to be the added context. Recall example (3), repeated below:

- (20) Two friends of John's from Texas may have come to visit him this weekend, but they can't both have come (because they hate each other).

Von Stechow & Iatridou report that we feel that the speaker is making an inconsistent claim. But apparently this results from the sentence being presented to us out of the blue. As soon as the context makes clear on which evidence the claim is based, we can understand utterances like (20) as consistent (for note that (19) is like (20) in all relevant aspects).

Another case in point is the following context plus sentence (capital letters indicate stress):

Scenario:

*Miss Marple is investigating a murder. She has found out that the murder has been committed between 7 and 9 pm last night. At this point, she has eight suspects. Two of them have provided a good alibi for the time of the murder: they were at home and their roommates confirm this. The others have all said that they were home alone. Naturally, no one can confirm that they were in fact home.*

- (21) Fewer than half of the suspects **MUST** have been home last night. But it is possible that they were all at home.

Again, if it were never possible for the quantifier to take wide scope, this should be contradictory. But it isn't.

In the above examples, the contexts seem to favor an objective interpretation, in the sense of Lyons, since the modals clearly depend on accessible, quantifiable evidence. This suggests the following reformulation of the situation that we want to explain: in English, *subjective* epistemic modals take obligatory wide scope.<sup>4</sup>

### 2.3. Subjectivity, expression type and language

The above considerations pave the way to an account of the difference between English and Dutch. According to Lyons, the subjective interpretation is the default for English modals. If so, it is expected that in isolation, speakers will prefer the wide scope reading for the modal, and this is indeed what we find (see section 1.1). However, in Dutch, epistemic auxiliaries have little trouble taking narrow scope. This follows if Dutch auxiliaries are not subjective by default. This claim, too, gives rise to clear predictions. It should be easier to embed Dutch auxiliaries than it is to embed English auxiliaries. This seems to be the case indeed:

- (22) Als Max wel eens eenzaam kan zijn, zal zijn vrouw zich wel zorgen maken.  
'If Max may be lonely, he wife will be worried'
- (23) Het is verrassend dat Superman wel eens jaloers kan zijn op Lois Lane.  
'It is suprising that Superman may be jealous of Lois.'

According to my intuitions, these sentences are pretty good. Yet, their English counterparts are usually considered to be odd.<sup>5</sup>

As said, Dutch epistemic adverbs do tend to take wide scope. From this I conclude that speakers of Dutch tend to employ adverbs if they want to convey subjective epistemic modality. Lyons already noted that adverbs are particularly subjective. The adverb *perhaps* even seems specialized as a subjective epistemic modal:

- (24) \*If it will perhaps rain, people should bring their umbrellas.

Something similar seems to hold for Dutch epistemic adverbs; they may not be specialized for subjective epistemic modality, but it is certainly true that they are the most natural choice when trying to communicate subjective modality.<sup>6</sup>

---

<sup>4</sup> At this point, the reader may wonder about the student resident scenario. Isn't this an objective context? And if so, then why does (1) seem false? I will address this objection below in 3.4.

<sup>5</sup> The Dutch modal *kunnen* differs from the English *may* in that allows both an epistemic reading and an opportunity reading (perhaps it is more like *could* than like *may*). In the example above, I have added the particle combination *wel eens* to force an epistemic reading. See Geurts & Huitink (2006) on the combination of *kunnen* and *wel eens*.

<sup>6</sup> Nuyts (2001a,b) offers some examples of objective uses of Dutch epistemic adverbs, yet he too concedes that the adverbs tend to be more subjective in their interpretation than adjectives or auxiliaries.

This diagnosis of the English-Dutch contrast is in line with the conclusions in van der Auwera et al. (2005): on the basis of an analysis of epistemic modals in translations of J.K. Rowling's *Harry Potter and the chamber of secrets* in various Slavonic languages, they suggest that there is an east-west cline, such that languages that are spoken more to the east often employ adverbs in cases in which more western languages employ auxiliaries. The findings by Aijmer (1999) point into the same direction. She studied translations of English modals in Swedish, and found that auxiliaries are often translated by an adverb.

#### 2.4. *Interim conclusion*

In this section, I have wanted to point out that providing good, public evidence has an effect on the scoping possibilities for epistemic modals: it makes it easier for them to take narrow scope. This suggests that objective epistemics can take both scope positions, and that only the subjective epistemics are the problematic items. This provides for an explanation of the contrast between English and Dutch: whereas in English modal auxiliaries are subjective by default, in Dutch there is a division of labor between auxiliaries and adverbs: typically, epistemic adverbs are chosen when subjective modal claims are made.

### 3. Analysis

Let me now consider various ways to capture the subjective-objective distinction. I will first discuss two proposals already on the market, and I will argue that these are not satisfactory. After that I will present my own account.

#### 3.1. *Previous proposals*

The two proposals on the market are by von Fintel & Iatridou (2003) and Tancredi (2007). Von Fintel & Iatridou conclude that the data follow from a constraint on Quantifier Raising:<sup>7</sup>

- (25)      *The Epistemic Containment Principle (ECP)*  
A quantifier-trace chain cannot cross a subjective epistemic modal  
\*Q<sub>i</sub> . . . [Subjective Epistemic Modal (. . . t<sub>i</sub> . . .)]

The ECP forces quantifiers to reconstruct, i.e. to be interpreted at the position of their trace. The main problem with this theory is that it isn't really an analysis, but merely a restatement of the facts. One is left wondering *why* there should be such a constraint. Moreover, the theory doesn't extend to epistemic adverbs, so this cannot be seen as a full explanation of our data.

An alternative analysis is proposed by Tancredi (2007). As the analysis is quite intricate, I will refrain from presenting it in detail. Essentially, the proposal is that

---

<sup>7</sup> In their paper, von Fintel & Iatridou do not restrict their claim to subjective epistemic modals, but I take it that section 2 has sufficiently made clear that such a restriction is necessary.

subjective epistemic modals are interpreted in a model attributed to the subject. Naturally, all the worlds in this model count as relevant for the modal's interpretation. This means that we do not need a world parameter to figure out the modal's contribution. Quantifiers, however, do need such a parameter, in order to fix their domain. 'Above' subjective epistemics, no such parameter is available.

The problem I have with this analysis is that the underlying intuition is doubtful. Tancredi ultimately proposes that in (1) the quantifier cannot take wide scope, because then we wouldn't know about which students we were talking. It is, however, perfectly clear about which students we are talking. After all, we are standing *in front of the student residence*.

### 3.2. Speech act modifiers

To capture the above patterns, I propose that subjective epistemics do not contribute to the truth conditional content of the utterance in which they occur. The basic idea is that (26), on its subjective reading, is used to offer a conjecture that it is raining/to raise the possibility that it is raining.

(26) It may be raining.

Then, what subjective *may* contributes to, is not the content of the sentence, but its illocutionary force. Assuming that the default speech act for declaratives is assertion, subjective *may* functions as a down-toner, which weakens that speech act into conjecture. The following table makes the gist of the analysis clearer. Here *may<sub>s</sub>* stands for subjective (epistemic) may, while *may<sub>o</sub>* stands for the objective interpretation. The diamond has its usual interpretation (explicated below in (29))

	FORCE	CONTENT
It is raining.	assert	rain
It may <sub>s</sub> be raining.	conjecture	rain
It may <sub>o</sub> be raining.	assert	◇rain

Following Krifka (2001), I assume that speech act modifiers relate commitment states. The subjective interpretation of *may* can then be implemented as follows, where *c* is a commitment state:

(27)  $[[\text{may}_s\phi]] = \lambda c. c + \text{the speaker is weakly committed to } \phi$

In turn, weak commitment can be explicated in terms of the beliefs of the speaker:

(28) an individual *x* is weakly committed to  $\phi$  iff  $\phi$  is compatible with *x*'s beliefs.

This makes the subjective interpretation of *may* close to its objective interpretation, the main difference being that objective *may* relates propositions and contributes to the truth conditions (here *b* represents the beliefs of the speaker or of a larger group of believers; *b* is of the type  $\langle s, t \rangle$ , a proposition):

(29)  $[[\text{may}_o\varphi]] = \lambda b. b$  is compatible with  $\varphi$

How does this account for the fact that subjective modals take obligatory wide scope? Since quantifiers contribute to the truth-conditional content (they just aren't illocutionary force indicators/modifiers), it follows that they can never scope over subjective epistemics.

### 3.3 Removing objections.

Papafragou (2006) argues against the idea that subjective epistemics fail to contribute to the truth conditions of the utterance.<sup>8</sup> One of her arguments is that this would wrongly predict that (30) is contradictory :

(30) Sally<sub>i</sub> may come, and (then) she<sub>i</sub> may not come.

But it is clear that on my analysis of speech act modification, this objection doesn't hold water. For (30) is contradictory only if the speaker both asserts that Sally comes and that she doesn't come. But I claim that the speaker is not asserting at all when uttering (30). She is merely making a conjecture that she comes, and then she is making a conjecture that Sally does not come.

Yet Papafragou does point out a nasty problem: subjective epistemics may fall in the scope of negation:

(31) a. John doesn't have to be the prime suspect.  
b. John can't be the prime suspect.

To deal with this kind of sentences, I will have to claim that *can't* doesn't involve a subjective modal in the scope of a negation, but rather than *can't* is one unit, expressing one negative speech act.

### 3.4. The case of every

The reader may have noted that I 'pulled a fast-one'. My claim is that epistemic modals that depend on objective, quantifiable evidence, may scope under subject quantifiers. This claim seems to be contradicted by example (1). It seems that the student residence context counts as an objective context. This is even more clearly the case for the next example by von Stechow & Iatridou:

Scenario:

---

<sup>8</sup> She presents an alternative analysis which centers around the idea that there is something indexical in the meaning of subjective epistemics: such modals depend on what the *current* speaker knows *at the time of utterance*. While this strikes me as plausible, it does not account for the fact that subjective epistemics take obligatory wide scope over nominal quantifiers. So it seems to me that her story is not the whole story about subjective epistemics.

*Imagine a group of people who were exposed to an infectious agent. From anonymous test results, we have concluded that half of the people are healthy, but we don't know which ones they are. For any given person, then, we don't know whether he or she is infected.*

(32) Half of you are healthy, but everyone may be infected.

My theory predicts that (32) is good, yet it is inconsistent. Still, the given context seems to be as objective as can be. How is this possible?

I submit that in case of *every*, a narrow scope reading for the modal is blocked, because of the existence of the free choice item *any*. Clearly, (33) is the preferred way of reporting our situation:

(33) Half of you are healthy, but anyone may be infected.

In general, the wide scope tendency for the quantifier is strongest with *every*, no matter how objective the context, this item just cannot take scope over an epistemic modal. Nevertheless, perhaps all that we are witnessing is a division of labor between *every* and *any*.<sup>910</sup>

#### 4. Conclusions and future research

To sum up, I have demonstrated that it isn't the case in all languages that epistemic modals take obligatory wide scope. In Dutch this is not true. Even for English, the claim needs to be further qualified, as in some cases, it is possible for epistemics to scope under subject quantifiers. I have argued that in these cases, the modal receives an objective interpretation.

So my claim is that subjective epistemics take obligatory wide scope. In English, it seems that modals are subjective by default, but not so in Dutch. In this language, only the adverbs tend to be subjective, which results in there being no problem with nominal quantifiers scoping over epistemic auxiliaries. I have argued that the best way to capture the subjective-objective distinction is by locating each sense at another level of meaning: objective epistemics contribute to the content, but subjective epistemics rather modify the speech act. I have tried to make sense of the subjective and objective meanings of *may* in such a way that they are still related. After all, it is probably not a coincidence that English uses the same item to express both meanings.

There are many issues left open for future research. One is how other languages behave. It seems that Japanese (Tancredi 2007) and Modern Greek (Iatridou p.c.)

---

<sup>9</sup> Unlike English, Dutch doesn't have a free choice item like *any*, but uses universal quantifiers in this case. Note that this fact alone is not enough to account for the English-Dutch contrast: quantifiers other than *iedereen* 'every' also scope over epistemics.

<sup>10</sup> Interestingly, *each* patterns with *any*, in that it can also scope over epistemics. Tancredi (2007) assumes that the use of *each* typically signals an objective context. The same line of defense is open to me.

behave like English, but that German and Mandarin Chinese (Ken Shan p.c.) are like Dutch. Another open question is whether we can make sense of the data without having to stipulate that subjective modals make non-truth-conditional contributions. On the one hand, I think that if such an analysis were available, it would be preferred over the one I presented here. On the other hand, I don't see how this can be achieved, and it really does seem to me to be the case that in subjective epistemic claims, the modal serves to merely mark the force of the speaker's commitment to the complement of the modal.

## Abstract

In this paper, we compare the semantics of Chinese and English aspect marking in the Reichenbachian (1947) time-relational framework. The temporal interpretation of a simple Chinese sentence with no time adverbials or aspect markers mainly depends on the Vendlerian (1967) class of the verbal predicate. For the four aspect markers *le*, *guo*, *zai* and *zhe*, we basically follow Klein *et al.*'s (2000) definition but abandon their use of the distinguished phase. We conclude that *zai* and *zhe* indicate the same time relation as the English progressive, while *guo* indicates the same relation as the English perfect, and *le* indicates a precedence relation between the initial point of event time and the final point of reference time.

**Keywords:** time-relational, verbal classes, zero marking, *le*, *guo*, *zai*, *zhe*.

Both English and Mandarin Chinese have grammatical aspect, while the former also has grammatical tense but the latter does not, just as is usually assumed. In this paper, we compute the semantics of Chinese aspect marking in simple isolated sentences in the Reichenbachian time-relational framework and compare it with that of English. In the first section, we introduce a time-relational definition of tense and aspect for English and discuss the interaction between aspect and Vendlerian classes of the verbal predicate in that language. Against this theoretic background, we move on to Chinese aspect. In the second section, we introduce the Chinese aspectual system, focusing on the combinational restrictions of aspect markers with verbal classes. In the third section, we discuss two recent papers on Chinese aspect marking that were both done in the time-relational framework, namely, Klein *et al.* (2000) and Lin (2006), and we make our own claim based on these studies. The last section offers some concluding remarks.

## 1. Introduction: The case of English

### 1.1. A time-relational definition of English tense and aspect

Reichenbach's (1947) philosophical work has had a tremendous impact on linguistic works about tense and aspect. He introduces three notions of time: speech time ( $T_S$  - the time when the utterance is made), event time ( $T_E$  - the time when the event described in the utterance takes place) and reference time ( $T_R$  - the time from which the event is seen). In his system, tense and aspect are represented in terms of positional relationships of these three times. More recent attempts at time-relational definitions of tense and aspect such as Johnson (1981) and Klein (1994) adopt the notion of intervals instead of Reichenbach's points of time. An interval of time has a beginning point  $t_1$  and an end point  $t_2$ . If the end point of an interval  $T_1$  is located before the beginning point of the other interval  $T_2$ , there is a relation of temporal precedence between the two intervals. Temporal overlap indicates that two intervals share some part in common. As a special case of temporal overlap, temporal inclusion means that one interval is included in the other one. They are defined below:

(1) Temporal relations (Carpenter 1997: 413)

Temporal precedence:  $T_1 < T_2$  iff  $t_1 < t_2$  for every  $t_1 \in T_1$  and every  $t_2 \in T_2$

Temporal overlap:  $T_1 \text{ O } T_2$  iff  $T_1 \cap T_2$  is nonempty

Temporal inclusion:  $T_1 \subseteq T_2$  iff  $T_1 \subseteq T_2$

For both Johnson and Klein, tense indicates a relation between reference time and speech time, while aspect points to a relation between reference time and event time.

(2) Table 1. Time-relational definitions of tense and aspect<sup>1</sup>

		Johnson (1981)	Klein (1994)
Tense	Past	$T_R < T_S$	$T_R < T_S$
	Present	$T_S = T_R$	$T_S \subseteq T_R$
	Future	$T_S < T_R$	$T_S < T_R$
Aspect	Simple	$T_E = T_R$	$T_E \subseteq T_R$
	Progressive	For some $t$ in $T_E$ , $T_R < t$	$T_R < T_E$
	Perfect	$T_E < T_R$	$T_E < T_R$

In the current analysis, we follow Klein's (1994) definitions, because there are two weak points in Johnson's definitions: first, Johnson's definition of present tense is problematic for statements such as *Mary has long hair*, which indicate that speech time is included in (not simultaneously with) reference time. In other words, there is a relation of  $T_S \subseteq T_R$  rather than  $T_S = T_R$ . Second, his definition of the simple aspect does not hold in sentences like *I worked* or *I work*, in which event time is not the same as reference time but is included in the reference time, that is,  $T_E \subseteq T_R$ .

Focusing on aspect, as Klein’s definition in Table 1 shows, the criterion for the simple/progressive distinction is whether event time is (properly or improperly) included in reference time or reference time is (properly) included in event time. The simple aspect in *Tom smiles / Tom smiled* indicates that the event of Tom’s smiling is located somewhere within or simultaneously with the interval of reference time (that is fixed by tense); with the progressive form such as in *Tom is smiling / Tom was smiling*, on the contrary, reference time is located within the interval of event time. For a sentence such as *Anna has graduated*, the event of Anna’s graduating takes place before the time about which the assertion is made, that is, before reference time. Table 2 presents the time relations due to tense and aspect in English simple sentences.

(3) Table 2. The English tense/aspect system

Aspect Tense			Time relations	Example sentences
	± Perfect	± Progressive		
Past	+	–	$T_R < T_S, T_E < T_R$	<i>Anna had met Peter.</i>
	–	–	$T_R < T_S, T_E \subseteq T_R$	<i>Anna met Peter.</i>
	–	+	$T_R < T_S, T_R \subset T_E$	<i>Anna was meeting Peter.</i>
Present	+	–	$T_S \subseteq T_R, T_E < T_R$	<i>Anna has met Peter.</i>
	–	–	$T_S \subseteq T_R, T_E \subseteq T_R$	<i>Anna meets Peter.</i>
	–	+	$T_S \subseteq T_R, T_R \subset T_E$	<i>Anna is meeting Peter.</i>
Future	+	–	$T_S < T_R, T_E < T_R$	<i>Anna will have met Peter.</i>
	–	–	$T_S < T_R, T_E \subseteq T_R$	<i>Anna will meet Peter.</i>
	–	+	$T_S < T_R, T_R \subset T_E$	<i>Anna will be meeting Peter.</i>

### 1.2. Aspect and inherent verb meaning

By aspect, we mean only grammatical aspect. The reason why some linguists group grammatical aspect and lexical aspect or “inherent verb meaning” (Comrie 1976) together under the one term ‘aspect’ (Ref. Smith 1991) lies in the fact that the two kinds interact greatly with each other so that it is not always easy to tell them apart. For the current discussion, we will introduce Vendler’s (1967) four verb classes and Klein’s (1994) three kinds of lexical contents (that are mainly relevant for the discussion about Chinese aspect), both of which take the interaction between aspect and inherent verb meaning into consideration.

#### 1.2.1. Vendler’s (1967) States/Activities/Accomplishments/Achievements<sup>2</sup>

Vendler (1967) observes that state verbs such as *know*, *love* and *recognize* do not occur in the progressive form. The verbs that do occur in the progressive can be divided into two groups, namely, those that have a set terminal point such as *run a mile*, *draw a*

*circle*, and those that do not such as *run*, *push the cart*. He calls the first kind accomplishments and the second activities. State verbs can be combined with durative adverbials such as *for three years* while achievements like *reach the hilltop* can only be combined with punctual adverbials such as *at 5 o'clock*. Accomplishments and achievements have in common that the eventualities they involve have natural terminal points, while this is not the case with states and activities. Both activities and accomplishments can be combined with the progressive aspect, while states and achievements cannot. Vendler's verb (or predicate) classes correspond to the telic/atelic distinction of verbal predicates.<sup>3</sup> His accomplishments and achievements correspond to telic verbal predicates. States and activities equal atelic verbal predicates.

### 1.2.2. Klein's (1994) 0-phase/1-phase/2-phase Lexical Contents

Klein (1994) distinguishes three kinds of lexical contents: 0-phase, 1-phase and 2-phase. 0-phase lexical contents are verb contents, "which, when applied to some argument(s) at some time T, are supposed to apply to the argument(s) at any other time T as well" (Klein *et al.*, 2000: 747). For example, if we say *The Rhine is in Europe*, it should hold true at any time. 1-phase lexical contents, for example, *sing*, *work*, describe situations that are "true for some argument(s) at some time T" with "a contrasting time T' at which they are not true". Klein claims that 0-phase contents describe situations without boundaries but 1-phase contents describe bounded situations, in other words, those with a beginning and an end. If we say *Tom loves Amy*, there is usually some time at which the described situation does not hold true in contrast to the time of reference (or time of assertion TT in Klein's term) at which the situation does hold true. This kind of contrast is what Klein calls a TT-contrast. Like 1-phase lexical contents, 2-phase lexical contents also involve a TT-contrast, but it is rather an internal one, that is, within the same TT there is "a change of state" such that "a situation first obtains" and then "does not obtain (or vice versa)" (Klein *et al.*, 2000: 748). 1-phase content / 2-phase lexical content pairs are, for instance, *stechen/erstechen* 'to stab'/'to kill by stabbing' in German or *eat/eat up* in English or *da/da-si* 'hit'/'hit-die' in Chinese. As we will discuss later, such constructions as *da-si* are called RVCs in Chinese.<sup>4</sup>

Roughly speaking, Klein's 0-phase lexical contents are atemporal in nature (often applied for factual statements). Both his 1-phase and 2-phase lexical contents are temporal as they hold true only for a certain stage of time. His 1-phase contents correspond to atelic predicates or Vendler's states and activities, while 2-phase contents correspond to both accomplishments and achievements, in other words, to telic predicates. At this point, we find Klein's classification problematic, because it neither

considers the common features of 1-phase and 2-phase lexical contents, both being temporal predicates, nor the distinctions between states and activities of 1-phase contents and between accomplishments and accomplishments of 2-phase contents. We will come back to this when talking about Chinese aspect marking.

### 1.2.3. A summary

The Vendlerian classes can be applied cross-linguistically, as verbal predicates in any language are used to express human conceptualization of what is going on in the world, that is, eventualities, which is ontology rather than linguistics. Linguistically speaking, eventualities involve much more than what verbs denote. Parsons (1990: 145) claims that “Most events and states are concrete entities, not abstract ones”, thus *Brutus’s stabbing of Caesar* is different from *Parson’s stabbing of his finger*. We neglect such differences, taking the compositional approach like Verkuyl (1972). His suggestion that the Vendler classes pertain to predicates and not to verbs means that *run*, *run a mile*, *run to the library* do not belong to the same class even though the same verb *run* is used. Among those languages with aspect, the nature of aspect is different in each language. For example, regarding the combination restrictions of verbs classes with aspect, there is variation, as we will see, between English and Mandarin Chinese.

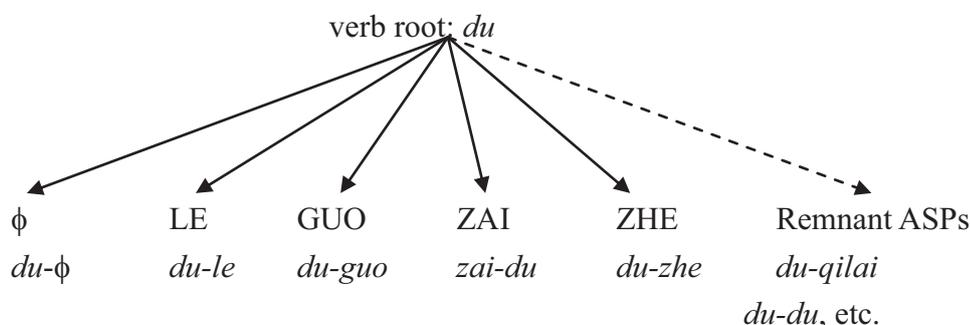

## 2. Chinese aspect marking

Except for the fact that English has tense and Mandarin Chinese does not, in either of the languages, time adverbials, aspect and inherent verb meaning all contribute to the temporal interpretation of the described situation in simple sentences. Lin (2006) proposes [CP...[IP...[ModalP...[AspP...[VP...]]]] as the Chinese phrase structure, with no TP above AspP. We assume that in a finite sentence, if the verb does not take any aspect marker, there is zero marking.<sup>5</sup>

Chinese is called an aspect-prominent language due to its very rich aspectual system, yet there is no consensus about how many aspect markers there are. Li and Thompson (1981: 185) categorize four types: “1. Perfective: *-le* and perfectivizing expressions, 2. Imperfective (durative): *zai*, *-zhe*, 3. Experiential: *-guo*, 4. Delimitative: reproduction of verb”. Chu (1998) adds one more, namely the inchoative aspect marker *qilai*. Since our present work does not aim at any exhaustive listing of all potential aspect markers, we concentrate on the four most discussed and well acknowledged ones, namely, *le*, *guo*, *zai* and *zhe*, leaving all the other potential ones in the category of ‘Remnant ASPs’ for

future study. Of the four aspect markers, *zai* is the only one that precedes the verb and receives a fourth tone, while the other three are all toneless verbal suffixes. The finite forms of the verb *du* ‘read’ are stated below:

(4) Chinese aspectual system

With zero marking, the temporal features of a sentence are usually expressed through time adverbials (if there is none, the reference time simply includes the speech time (now); in other words, time is located at the present) and the inherent temporal properties of the verbal predicate.<sup>6</sup> With aspect markers used, the temporal meaning can be conveyed by three elements, namely time adverbials, inherent verb meaning and aspect. In the following sections, we leave out time adverbials completely while discussing only simple isolated (in other words, without any context backgrounding) sentences to show how zero marking and the four aspect markers work, especially how they interact with Vendlerian verb classes in Chinese.

2.1. Zero marking

Concerning zero marking, we want to answer two questions: first, are aspect markers, as some linguists claim, optional in Chinese? Second, how do temporal interpretations obtain in sentences without aspect markers?

Smith (1991) claims that aspect markers are “syntactically optional” in Chinese and therefore that zero marking, or the “neutral viewpoint” as she calls it, is “in principle always available”. This is a problematic claim, as with achievement verbs such as *si* ‘die’, *dao* ‘arrive’ or *bi-ye* ‘graduate’, aspect markers are not optional if neither time adverbials nor RVC elements are present.

(5) a. *zhang-san si-le.*

Zhangsan die-LE  
‘Zhangsan died.’

b. \**Zhangsan si-φ.*

Zhangsan die.

- c. *zhang-san gang-gang si.*  
 Zhangsan just die  
 ‘Zhangsan just died.’
- d. *zhang-san si-diao.*  
 Zhangsan die-RVC  
 ‘Zhangsan died.’

In Lin’s (2006) attempt to decode the semantics of zero marking, which he calls “default viewpoint aspect”, he starts with the following example sentences:

- (6) a. *zhang-san hen mang.*  
 Zhangsan very busy  
 ‘Zhangsan is very busy.’
- b. *ni da lan-qiu ma?*  
 you play basketball Q  
 ‘Do you play basketball?’
- c. *zhang-san da-puo yi-ge hua-ping.*  
 Zhangsan break-RVC one-CL vase  
 ‘Zhangsan broke a vase.’
- d. *ta dai wo qu tai-bei.*  
 he take me go Taipei  
 ‘He took me to Taipei.’

For Lin, (6a) is interpreted as a present tense sentence and (6b) as a present generic one; (6c) and (6d) both have a past interpretation. This interpretation is quite problematic. First, as a native speaker, I do not think that the sentence (6d) necessarily indicates a past interpretation unless the aspect marker *le* is added. Nevertheless, it is also all right to interpret it with a future reading. If someone says *ta dai wo qu tai-bei*, it sounds more natural to ask *When are you leaving?* than *When did you go?* Thus, the temporal reference in (6d) is rather ambiguous.

The weakness of Lin’s proposal lies also in that he does not clarify how the past interpretation obtains in (6c) and (6d). It is obviously not random that these two sentences could have (although questionably) a “past interpretation”. Taking a closer look at the four sentences, we find that (6a) involves a state that is indicated by an AdjP (without any copula verb, as Chinese allows), that (6b) involves an activity and that (6c) involves an achievement indicated by a RVC. The last sentence is hard to define at first sight. What Lin terms as a past interpretation in (6c) seems to come from some kind of world knowledge: if an event such as *zhang-san da-puo yi-ge hua-ping* does not take place in the past (which means nothing has been achieved yet), it will sound odd to utter

such a sentence with all the detailed information, namely the agent of the event *Zhang-san*, and the existence of the undergoer of the event, *yi-ge hua-pin* in this case. Even in English, it sounds odd to say *Peter breaks a glass* (if we take the present tense/simple aspect as the default form in English corresponding to zero marking in Chinese) although it is a completely grammatical sentence. Moreover, *breaking a glass* can not be something ‘habitual’ so as to convey a present reading. The only possible factor that causes a “past interpretation” (if there were one) is the verbal predicate *da-pao* ‘hit-broken’, which is a RVC construction and an achievement in nature.

Since the other three sentences cover a state, an activity and an achievement, (6d) is probably supposed to an accomplishment. As Smith claims, accomplishment sentences without aspect markers are aspectually vague and the described situation “may be ongoing, terminated or completed” (1991: 364). This corresponds to our intuition.

In brief, aspect markers are not always optional in Chinese, especially those with non-RVC achievements. Accomplishments without any aspect marker are aspectually ambiguous. We have to mention again that we mean isolated accomplishment sentences, as often discourse or world knowledge, for example, can specify the aspectual property of the given situation, even when no aspect marker is present. With zero marking, the temporal meaning of a given situation comes mainly from inherent verb meaning, that is, whether it is a state, an activity, an accomplishment or an achievement.

## 2.2. The four aspect markers

### 2.2.1. *Le*

First of all, *le* marks a termination of an event, but not necessarily a completion. (7a) is ambiguous in that the homework can either be finished or not, which for whatever reason is not specified. (7b) makes the incompleteness explicit, whereas in (7c), the meaning of completion is marked through use of a RVC.

- (7) a. *ta zuo-le zuo-ye.*  
       he do-LE homework  
       ‘He did his homework.’
- b. *ta zuo-le zuo-ye, dan-shi mei zuo-wan.*  
       he do-LE homework but not do-RVC  
       ‘He did his homework, but didn’t finish it.’
- c. *ta zuo-wan-le zuo-ye.*  
       he do-RVC-LE homework

‘He finished doing his homework.’

However, the meaning of completion follows from the verbs sometimes. When *le* is used with atelic verbs or activities in Vendler’s term, the sentence does not indicate completion necessarily, while a sentence with *le* suffixing telic verbs or achievements has the meaning of completion. With accomplishments such as *zuo yi-ge dao-gao* ‘make a cake’, it remains unclear to us whether the completion follows necessarily or not and therefore we leave this issue for future research.

State verbs usually do not appear together with *le*. When they do, there are two possibilities. We observe that with verbs like *xiang* ‘think’, the sentence indicates a state without *le* but an activity with *le*, similar to the verb *think* in English. When *le* follows state verbs such as *zhi-dao* ‘know’ or adjectives such as *pang* ‘fat’ without anything following it, the sentence denotes a meaning of inchoativity.

- (8) *nana pang-le*.  
Nana fat-LE  
‘Nana gained weight.’

### 2.2.2. *Guo*

*Guo* means that some event takes place at least once, which requires the event indicated by the predicate to be repeatable.

- (9) *?ta si-guo*.  
he die-GUO  
‘He died once.’

*Guo* is often called an experiential aspect marker due to the pragmatic principle governing its use, namely, it should be applied to things that can be called an experience. This leads to the contrast in (10), as rice eating can hardly be called an experience in most cultures.

- (10) a. *ta chi-guo kimchi/?mi-fan*.  
he eat-GUO kimchi/?rice  
‘He has eaten kimchi/?rice (once).’

### 2.2.3. *Zai* and *zhe*

It is easier to understand both *zai* and *zhe* by comparing them with each other. As ‘imperfective’ aspect markers, they cannot co-occur with states or achievements.

- (11) a. *\*ta zai zhi-dao*.  
he ZAI know  
b. *\*ta yin-zhe*.

he win-ZHE

*Zai* differs from *zhe* in that the former only modifies dynamic durative events, whereas the latter usually modifies stative durative ones. *Zhe* indicates continuation either of an action or a resultant state from an action. As (12) shows, with the same verb such as *chuan* ‘put on / wear’, the difference whether it is meant to be an action or a result state is made clear through the use of *zai* or *zhe*. With the former, an action is expressed and with the latter, a resultant state from the action. In other words, *zai* is action-oriented while *zhe* is result-oriented.

- (12) a. *ta zai-chuan yi-jian da-yi.*  
 he ZAI-wear one-CL coat  
 ‘He is putting on a coat.’
- b. *ta chuan-zhe yi-jian da-yi.*  
 he wear-ZHE one-CL coat  
 ‘He is wearing a coat.’

### 2.3. A Summary

(13) Table 3. Combinational restrictions of aspect and Vendlerian verb classes

	$\phi$	<i>le</i>	<i>guo</i>	<i>zai</i>	<i>zhe</i>
States	+	?	+	?	+
Activities	+	+	+	+	+
Accomplishments	?	+	+	+	+
Achievements		*	+	*	*
	RVCs	+	+	*	*

Table 3 summarizes the restrictions on the combinations of aspect marking and verbal classes in Mandarin Chinese. To clarify, firstly, some but not all state verbs can be combined with *le* to indicate inchoativity. State verbs with *zai* are not completely unacceptable, but often they are switched into activities in the meantime. Secondly, activities are available with both zero marking and all the four aspect markers. Thirdly, accomplishments are available with both zero marking and all the four aspect markers. However, they are aspectually ambiguous with zero marking. Last, non-RVC achievements are incompatible with zero marking. Achievements, in general, can occur with *le*, but not *guo*, *zai*, or *zhe*.

### 3. A time-relational definition of Chinese aspect marking

More recently, linguists working on Chinese aspect have taken efforts to approach

it in a more formal way, such as Smith's (1991) schematic statements of the four aspect markers in her two-aspect theory, Klein *et al.*'s (2000) time-relational definitions of the four aspect markers and Lin's (2006) formal analysis of zero marking and aspect markers. In the following paragraphs, we will discuss the latter two works that are both done in the time-relational framework in order to make our own claim.

### 3.1. Klein *et al.*'s (2000) definitions of the four aspect markers

It must be noted that “‘perfective aspect’ in one language is not necessarily the same as ‘perfective aspect’ in another language” and for example, “Chinese ‘perfective’ and English ‘perfective’ are similar in many ways, but they also differ in some respects” (Klein *et al.* 2000: 744). This is why we do not use the perfective/imperfective distinction but rather the simple/progressive one for English. For the same reason, instead of using the terms perfective/imperfective/perfect for Chinese aspect markers, we simply stay with the original Chinese words and discuss the time relations indicated by them respectively, in order to respect and thus convey the language-specific properties of Chinese aspect.

To understand Klein *et al.*'s definition of Chinese aspect markers, it is necessary to mention that according to them, “a situation described by a 2-phase expression such as <Adam fall asleep> includes two distinct time intervals, a source phase which can be described by <Adam not be asleep>, and a target phase which can be described by <Adam be asleep>” (Klein *et al.* 2000: 751). They further claim that languages must choose one of the two phases to which the reference time (in Klein's term, topic time or time of assertion) is related. The chosen phase in a language is called “the distinguished phase (DP)”, which is “(a) the only phase in the case of 1-phase contents, and (b) either the source phase or the target phase in the case of 2-phase contents” (Klein *et al.*, 2000: 751). They assert that DP is the source phase in English but the target phase in Chinese, as “English is more ‘action-oriented’ while Chinese is ‘result-oriented’” (754).

In the time-relational framework, they define the four Chinese aspect markers as in (14): all of them indicate a relation between event time and reference time. This is exactly what aspect is defined to do.

- (14) Klein *et al.*'s (2000) time-relational definition of Chinese aspect markers<sup>7</sup>
- le*:  $T_R \text{ O PRETIME } T_{DP} \text{ and } T_{DP}$
- guo*:  $T_{DP} < T_R$
- zai*:  $T_R \subset T_{DP}$

*zhe*:  $T_R \subset T_{DP}$

We propose revising this definition on the basis of the following three points:

### 3.1.1. *Guo* is a perfect marker

*Guo* is in fact more of a perfect maker than a perfective one, although it is usually given the latter term. According to Klein *et al.*, DP in Mandarin Chinese is the single phase for 1-phase lexical contents and the target phase for 2-phases contents. Therefore, for 1-phase contents or in more general terms, states and activities, the relation of ‘ $T_{DP} < T_R$ ’ that *guo* is defined to indicate is a relation of ‘ $T_E < T_R$ ’. For 2-phase contents or for accomplishments and achievements, the relation ‘ $T_{DP} < T_R$ ’ says nothing more than a relation of ‘ $T_E < T_R$ ’, since DP, in Chinese, that is, the target phase is evidently the latter part of a 2-phase content. This means that more generally speaking, whatever content is involved, *guo* indicates a precedence relation between event time and reference time, which is exactly what the English perfect does.

### 3.1.2. Redefinition of *le*

As defined in (14), *le* indicates that reference time overlaps with DP and part of the time before DP. Observe the following examples with some simple diagrams according to Klein *et al.* (2000). +++ stands for DP, ---for the source phase of 2-phase contents and [] for reference time that corresponds to Klein’s topic time or time of assertion, that is, “the time about which an assertion is made” (Klein *et al.* 2000: 742).

- (15) a. *zhang-san tiao-wu-le.* [ +++]+++ or  
[ ++++++]  
Zhangsan dance-LE  
‘Zhangsan danced.’
- b. *zhang-san pang-le.*  
[ ++++++]  
Zhangsan fat-LE  
‘Zhangsan became fat.’
- c. *zhang-san hua-le yi-fu hua.* ---[---+++]+++ or ---[---  
+++++]  
Zhangsan draw-LE one-CL picture  
‘Zhangsan drew a picture.’
- d. *zhang-san si-le.* ---[---+++++]  
Zhangsan die-LE  
‘Zhangsan died.’

In (15a), with the activity verb *tiao-wu* ‘dance’, *le* does not necessarily indicate

any completion. The interpretation is left open. In (15b), combined with a state predicate, the adjective *pang* ‘fat’ without any copula verb, as is allowed in Chinese, together with *le* conveys an inchoative reading. In (15c), with an accomplishment, the sentence is also ambiguous as to whether it indicates completion or not, since we can say, for example, *zhang-san hua-le yi-fu hua, dan-shi mei-you hua-wan* ‘Zhangsan drew a picture, but didn’t finish it’. This ambiguity can be avoided by using a resultative verb complement added to the verb, in which case completion is indicated. In the last sentence, with the achievement verb *si* ‘die’, *le* marks the realization of DP. Obviously, all the four cases fall into Klein *et al.*’s definition of *le*, namely, ‘ $T_R$  O PRETIME  $T_{DP}$  and  $T_{DP}$ ’.

However, we claim that the use of DP is totally redundant to define *le*. To back up this claim, let’s check Klein *et al.*’s definition with 1-phase contents and with 2-phase contents separately.

For 1-phase contents such as in the first two sentences of (15), the time of DP is simply the time of event; thus it is all right to translate Klein *et al.*’s definition of *le* into ‘ $T_R$  O PRETIME  $T_E$  and  $T_E$ ’.

“For 2-phase contents in Chinese, the target phase is the distinguished phase DP, and as a consequence, the source phase is the pretime of DP” (Klein *et al.*, 2000: 757). If it is possible to take <Zhangsan be not dead> and <Zhangsan be dead> to be the source phase and the DP for <Zhangdan die> in (16d), we find it difficult to tell what is the source phase and what is the target phase of <Zhangsan draw a picture> in (15c).

To avoid the sort of confusion stated above, we suggest giving up the concept of DP, and coming back to the notion of event time. In this case, we only have to switch ‘--for the source phase of 2-phase contents’ in (15c) and (15d) into +++ and combine it with DP to stand for event. Thus, (15c) involves four kinds of temporal relations, namely, [ +++]+++, [ +++++], +++[+++]+++ and +++[+++]. As we mention in the first section, with notions of intervals,  $T_E$  and  $T_R$  can be defined with two endpoints as  $[t_1, t_2]$  and  $[t_3, t_4]$ <sup>8</sup>. Then, the four time relations presented by the four sentences in (15) can be translated into  $t_3 < t_1 < t_4 < t_2$ ,  $t_3 < t_1 < t_2 \leq t_4$ ,  $t_1 < t_3 < t_4 < t_2$  and  $t_1 < t_3 < t_2 \leq t_4$ . All of them include a relation of ‘ $t_1 < t_4$ ’, in other words, that the initial point of event time precedes the final point of reference time. Thus, we can redefine *le* as below:

(16) Redefinition of *le*: InitialPoint  $T_E <$  FinalPoint  $T_R$

In fact, all the four time relations also involve a relation of  $t_3 < t_2$ , that is, ‘InitialPoint  $T_R <$  FinalPoint  $T_E$ ’. The reason why we pick the relation in (16) is that it can perfectly explain all the behaviors of *le* shown in (15), especially the fact that *le* does not indicate completion itself. As our redefinition shows, the focus of *le* is put on

the relation between the initial point of event time and the final point of reference time while the final point of event time, which determines the completion of an event, is left unspecified. Moreover, such a definition also seems to be in line with the definition of *guo* in that both concern a precedence relation between event time and reference time (although not in exactly the same way). Hence we can claim that *le* and *guo*, which are traditionally called perfective markers, are better defined as perfect markers, as Klein *et al.* themselves almost claim: “*le* and *guo* express a ‘perfective’ (or perhaps ‘perfect’ aspect)” (2000: 1-2). As we will see later in this section, our claim even brings the accounts of zero marking into our framework.

### 3.1.3. *The redundancy of DP*

As we show in 3.1.1. and 3.1.2., DP is not necessary for the definitions of *le* or *guo*. In this part, we will show that it is not necessary for the definition of *zai* and *zhe*, either.

Most often *zai* and *zhe* appear with states or activities. States and activities are called 1-phase contents by Klein (1994, 2000) and for them, the time of DP equals event time. In this case, we can switch Klein *et al.*'s (2000) definition of *zai* and *zhe* into ‘ $T_R \subset T_E$ ’. Achievements in Chinese can not occur with *zai* or *zhe*, while accomplishments like *hua yi-fu hua* ‘draw a picture’ can be combined with either of them. However, then they rather behave like activities because the resulting state (remember that an accomplishment involves an activity and a state resulting from the activity), that is, DP, is not relevant or realized, although it is there naturally. Thus, we do not think it necessary to distinguish the source phase and the target phase (DP). In short, we can abandon the use of DP for the definition of *zai* and *zhe* as well. A relation of  $T_R \subset T_E$  is sufficient to define both of them.

## 3.2. *Zero marking*

The semantics of zero marking is often neglected in the research on Chinese aspect. Some accounts on it can be found in Smith (1991), Klein *et al.* (2000) and Lin (2006). Smith (1991) claims that aspect markers in Chinese are optional and without them, the sentences have a so-called neutral aspect that needs the context and world knowledge to specify whether an imperfective or a perfective meaning is intended. We agree with Klein *et al.* that “it is rarely the case that the same sentence can have both a perfective and an imperfective reading: discourse or situational contexts almost always disambiguate the two interpretations” (Klein *et al.* 2000: 766). As we have argued in the

last section, aspect markers are not always optional, especially with non-RVC achievements. Furthermore, the aspectual meanings of a sentence without aspect markers basically come from the inherent meaning of the verb predicate.

In the following, we will discuss Lin's (2006) accounts of zero marking, which he calls "default viewpoint aspect", arguing against his claim that "the temporal interpretation of sentences without any temporal adverbs or aspectual markers is determined via their viewpoint aspect. Namely, a sentence with imperfective viewpoint aspect has a present interpretation, whereas a sentence with perfective viewpoint aspect has a past interpretation" (Lin 2006: 4). Without clarifying how, the default perfective is distinguished from the default imperfective aspect when no aspect marker is present, Lin proposes a definition for Chinese perfective aspect (both in his default sense and also for the two aspect markers *le* and *guo*), which "is functionally like the past tense in English" (Lin 2006: 6):

(17) Lin's (2006) temporal semantics of Chinese 'perfective' aspect

Perfective aspect =  $\lambda P_{\langle i, t \rangle} \lambda t_{\text{Top}} \lambda t_0 \exists t [t \subseteq t_{\text{Top}} \wedge P(t) \wedge t_{\text{Top}} < t_0]$

$\| \text{guo} \| = \lambda P_{\langle i, t \rangle} \lambda t_{\text{Top}} \lambda t_0 \exists t [P(t) \wedge \text{IStage}(t, P) \subseteq t_{\text{Top}} \wedge t_{\text{Top}} < t_0]$

$\| \text{le} \| = \lambda P_{\langle i, t \rangle} \lambda t_{\text{Top}} \lambda t_0 \exists t [P(t) \wedge \text{IStage}(t, P) \subseteq t_{\text{Top}} \wedge t_{\text{Top}} < t_0 \wedge t_{\text{ana}} \subseteq \text{Rstate}(t, P)]$

To explain (17), we have to mention Lin's claim that "(the time of) an eventuality canonically breaks down into (the time of) Inner Stage and (the time of) Result State" (2006: 8). According to him, the time of Inner Stage equals event time for atelic events, that is, for states and activities, whereas for telic ones, that is, for accomplishments and achievements, the time of Inner Stage is the time of event time minus its final point. For states and achievements, the time of Result State is the time following the interval of event time, and for accomplishments and achievements, it is the time at which the result state holds. In (17), 'IStage' stands for Inner Stage and 'Rstate' for result state. Furthermore,  $t_{\text{Top}}$  stands for topic time or reference time,  $t$  for event time,  $t_0$  for "local evaluation time", which I understand as speech time, and  $t_{\text{ana}}$  for "an anaphor-like variable that needs to be bound or given a value from context" (Lin 2006: 14), the function of which is still vague for me.

Lin argues that *le* and *guo* incorporate into their temporal meaning "an extra relation between the topic time and the evaluation time" indicated as  $t_{\text{Top}} < t_0$  (equals  $T_R < T_S$  in our terms) so that *le* and *guo* are not pure aspectual markers but "a mixture of tense and aspect". However, observe the sentences in (18):

(18) a. *ming-tian zhe-ge shi-hou, ta yi-jing zou-le.*  
 Tomorrow this-CL time he already leave-LE  
 'He will already have left by this time tomorrow.'

b. *mei-tian ba-dian, ta yi-jing qi-chuang-le.*

every day 8 o'clock he already get up-LE

'Every day at 8 o'clock, he has already got up.'

c. *ming-nian zhe-ge shi-hou, ta yi-jing qu-guo mei-guo.*

next year this-CL time he already go-GUO America

'He will have already been to America (once) by this time of next year.'

If Lin's claim was accurate, the sentences in (18) could not be grammatical, for the time adverbials, either indicating a present or future time reference, would be in conflict with the past interpretation that Lin supposes *le* and *guo* to indicate. This is to say, if *le* and *guo* indicated a past interpretation, the combination of them with any present-locating or future-locating time adverbials should be totally ruled out, just as we cannot say in English *\*He now worked* or *\*He will worked*. Thus, it is unconvincing to say that what Lin still calls the 'perfective' in Chinese, whether 'default' or with aspect markers, denotes a past interpretation. Rather, like in English, it just expresses a relation between event time and reference time.<sup>9</sup>

At this point, we assert again that the present or past interpretation claimed by Lin actually comes from the inherent temporal meanings of verbal predicates. In Mandarin Chinese, a language without tense, states and activities in finite sentences without time adverbials nor aspect markers indicate a meaning of the simple present, while achievements in finite sentences without time adverbials nor aspect markers (if they can appear at all without any aspect marker) indicate a meaning of the present perfect. As we have claimed earlier in this paper, accomplishments are aspectually vague, that is, a meaning of either the simple present or the present perfect is possible, being further specified by other contextual or pragmatic factors. Below, we give each verbal class one example sentence (with neither time adverbials nor aspect-markers) and the time relations they indicate.

(19) Table 4. Semantics of zero marking

Verbal classes	Example sentences	Time relations
States	<i>ma-li hen gao.</i> Mary very tall 'Mary is very tall.'	$T_R \subseteq T_S, T_E \subseteq T_R$
Activities	<i>ma-li tiao-wu.</i> Mary dance 'Mary dances.'	$T_R \subseteq T_S, T_E \subseteq T_R$
Accomplishments	<i>ma-li hua yi-fu hua.</i> Mary draw one-CL picture 'Mary draws/has drawn a circle.'	$T_R \subseteq T_S, T_E \subseteq T_R$ or $T_R \subseteq T_S, T_E < T_R$

Achievements		* <i>ma-li si.</i> Mary die	
	RVCs	<i>ma-li si-diao.</i> Mary die-RVC 'Mary has died.'	$T_R \subseteq T_S, T_E < T_R$

To sum up, in Mandarin Chinese, before any aspect marker is added, temporal meanings of a simple finite sentence can be interpreted through both time adverbials and inherent verb meaning. When no time adverbial is present, a relation of  $T_R \subseteq T_S$ , that is, a present time location, is taken by default. Inherent verb meaning, whether states/activities or achievements, further denotes a relation between event time and reference time, the former ' $T_E \subseteq T_R$ ' and the latter ' $T_E < T_R$ '. With accomplishments, both interpretations are available for isolated sentences, while one of the interpretations is usually specified by the larger context. In brief, without time adverbials, zero marking in Mandarin Chinese has the semantics of either the simple/perfective or perfect aspect, as defined in the first section for English.

#### 4. Conclusion

With Klein's time-relational definition of English aspect and our definition of Chinese aspect, we arrive at the comparative schemata below:

(21) Time-relational definitions of aspect

Chinese	English
zero marking: $T_E \subseteq T_R$ or $T_E < T_R$	Simple: $T_E \subseteq T_R$
<i>le</i> : InitialPoint $T_E < \text{FinalPoint } T_R$	Perfect: $T_E < T_R$
<i>guo</i> : $T_E < T_R$	
<i>zai</i> : $T_R \subset T_E$	Progressive: $T_R \subset T_E$
<i>zhe</i> : $T_R \subset T_E$	

To conclude, with the addition of the semantics of zero marking, our definition of Chinese aspect marking is more complete than Klein *et al.*'s. In both Mandarin Chinese and English, aspect indicates a relation between event time and reference time, either of temporal precedence or of temporal inclusion, with the exception of some minor language-driven differences.

---

#### Notes

This paper is based on my 2006 master thesis titled *The Semantics of Aspect Marking: A*

---

*Comparative Study of Mandarin Chinese and English* at University of Göttingen. I owe above all to my supervisor Regine Eckardt for numerous fruitful discussions. I realized how patient she was when I look back upon the time. I am also very grateful to Götz Keydana as my second ‘Gutachter’ for very helpful comments and especially for his encouragements and advice on my study of general linguistics in Göttingen. I thank Janina Radó for helping me work through the presentation that I was to give at CIL18 and I thank the commentators there at the workshop *Formal Approaches to the Relation of Tense, Aspect and Modality* organized by Yukinori Takubo and Stefan Kaufmann. Many thanks also to Lucas Ogden for proofreading this paper. All remaining errors and limits are of course my own responsibility.

<sup>1</sup>We apply the simple/progressive distinction for English, instead of the more general perfective/imperfective one, because the latter does not take language-driven differences into consideration. That is to say, what is called perfective in one language is probably (more or less) different from the perfective in another language, as we will show later with regard to Mandarin Chinese and English. The same is true with the imperfective. For example, the French imparfait should have different representations from the English past progressive.

<sup>2</sup>Vendler’s (1967) philosophical work actually targets ‘time schemata’. However, it has been widely applied by linguistics to verbs at first and then to predicates since Verkuyl (1972) suggested that the four classes pertain to predicates rather than to verbs.

<sup>3</sup>Garey’s (1957) telic/atelic distinction was the first attempt to classify verb predicates according to their inherent temporal meanings. The word ‘telic’ is from ancient Greek word *télos* ‘end’. For telic verbs such as *die*, *make a cake*, a terminal point at which the death is realized or the cake is ready is naturally presupposed, while there is no natural termination of *dancing* for instance, which can stop at any point. The latter kind of verbs are atelic and by definition, they “do not have to wait for a goal for their realization, but are realized as soon as they begin” (Garey 1957: 106).

<sup>4</sup>RVCs stand for Resultative Verb Compounds/Complements/Constructions, whose second element (after the verb), either simple or complex, also contributes to temporal (often resultative) properties of verb predicates. They are achievements in nature.

<sup>5</sup>The existence of such a zero is hard to prove empirically. In order not to incite any argument, we want to make clear that by zero marking, we mean nothing more than sentences without aspect markers. However, we believe intuitively that at least in one sense, the use of zero marking is meaningful here and for the Chinese language. As we have argued so far, Mandarin Chinese is a tenseless but aspectual language. Some

---

linguists assume that all languages have both TP and AspP nodes and if some language does not have tense or aspect, there is a zero form. In contrast to them, we take the position that Chinese does not have TP-nodes instead of saying that there is a zero under the TP-node. Further, concerning aspect, we maintain that it has a zero form in relation of complementary distribution to non-zero forms, namely, sentences that have aspect markers.

<sup>6</sup>Sometimes even world knowledge is needed to capture the temporal nature of a situation.

<sup>7</sup>In Klein *et al.* (2000), TT and T-DP are used for what we label as  $T_R$  and  $T_{DP}$ .

<sup>8</sup>We neglect the bounded/unbounded difference here.

<sup>9</sup>We have already pointed out that *le* and *guo* are rather perfect markers than perfective ones. Analogously, if there is no aspect marker present, since we understand Chinese to be a tenseless but aspectual language, there might probably be aspectual relations implied, that is relations between event time and reference time, rather than between reference time and speech time.

# Aspect markers in two dialects of Japanese and Korean: Variation and division of labor

Saeko Urushibara

saeko@kitakyu-u.ac.jp

## Abstract

This paper first shows that the well-known ambiguity of *-te i-ru* in the Tokyo dialect is disambiguated by two distinct morphemes *-yor-u* and *-too* in the Hakata dialect. I argue that the Hakata Dialect is closer to English with respect to the relation between verb classes and aspectual interpretation. Then I argue that the “event” position associated with some nominals causes variation in the usage of *ar-u* ‘exist’ in those dialects. Finally, I compare the above dialects and Korean and show that division of labor is observed depending on existence or absence of double forms, evidential markers, etc. In particular, I argue that if there are distinct morphemes for evidentiality, “invasion” of tense markers into the region of aspect occurs.

**Keywords:** progressive, perfect, event, evidentiality.

## 1. Introduction

This paper seeks to show the following three theses by comparing two dialects of Japanese, the Tokyo and Hakata dialects, and Korean. First, division of labor among tense, aspect and modality is subject to typological and/or parametric variation. Second, in Japanese and Korean, realization of tense, aspect and modality is often done in a way one specific morpheme that bears one meaning in either one of these grammatical categories can play the role of signifying a different meaning in another, adjacent category. Finally, to better understand these natures in Japanese, dialects other than the Tokyo dialect should be investigated.

The structure of the paper is as follows: In Section 2 I will discuss Japanese data. In particular, Section 2.1. reviews well-known cases of *-te i-ru* in the Tokyo dialect (henceforth TD). In Section 2.2. I will show a striking contrast observed between TD and the Hakata dialect (henceforth HD). Section 3 summarizes the facts and raises questions, answers to which will be given in Section 4. Then we turn to Korean *-ko*

*iss* in Section 5. Section 6 is a brief discussion of evidentiality markers in Korean and the Goshogawara dialect (henceforth GD). Specifically, 6.1. shows interesting patterns of “double-past” forms in Korean. In comparison, a seeming Japanese counterpart found in the Goshogawara dialect is discussed in 6.2.

In discussing these markers and their interactions with verbs, I assume verbal classification by Vendler (1967) and Dowty (1972).

## 2. Japanese data

### 2.1. Tokyo Dialect (TD) of Japanese: the sole form *-te i-ru*

It is well-known among Japanese linguists that a TD aspectual morpheme *-te i-ru* attaches to a verbal stem and expresses the aspect of progressive or perfect.<sup>1</sup> The meaning depends on the class of verbs that the main predicate belongs to. When *-te i-ru* attaches to activity verbs, it bears the meaning of progressive, as in (1). Note in passing that another morpheme *-ta* is ambiguous between perfect and simple past ((2)):

- |     |                     |   |   |
|-----|---------------------|---|---|
| (1) | Mina-ga<br>Mina-nom | hasit-te i-ru.<br>run- <i>te-i-ru</i> ([-past]) | ‘Mina is running.’<br>*‘Mina has run.’ <sup>2</sup> |
| (2) | Mina-ga<br>Mina-nom | hasit-ta.<br>run-[+past]                        | ‘Mina ran/has run.’                                 |

In the case of accomplishment verbs, ambiguity is observed:

- |     |                                    |  |   |
|-----|------------------------------------|--|---|
| (3) | Mina-ga hon-o<br>Mina-nom book-acc | yon-de i-ru.<br>read- <i>te-i-ru</i> ([-past]) | ‘Mina is reading a book.’<br>or ‘Mina has read a book.’ |
|-----|------------------------------------|--|---|

---

<sup>1</sup> The form itself is morphologically complex: *-te* is a connective morpheme between a verbal stem and another verbal element. *I-ru* is originally an independent verb meaning “(a mobile subject) exist”. *-te* undergoes the phonological change of voicing and surfaces as *-de* when it attaches to a verbal stem whose ending is nasal or voiced obstruent.

<sup>2</sup> In some cases this sentence can also express the perfect aspect. But in those cases, there must be a preceding context referring to the object of the act of running, such as ‘the track’ or ‘along the river’. That is, the sentence should be glossed as ‘Mina has run *pro*’. In other words, such cases are instances of ‘aspectual shift’ whereby a phonologically-null object *pro* causes the verb class to shift from activity to accomplishment.

This is disambiguated by the choice of locative postposition. When the locative NP is marked with *de*, *-te i-ru* is interpreted as progressive, while it has the perfect reading when the locative NP is *-ni*-marked. I will return to this in Section 4.

- (4) a. Mina-ga niwa-de sentakumono-o hosi-te i-ru.  
 Mina-nom garden-in laundry-acc dry- *-te-i-ru*([-past])  
 ‘Mina is putting the laundry in the garden.’
- b. Mina-ga niwa-ni sentakumono-o hosi-te i-ru.  
 Mina-nom garden-in laundry-acc dry- *-te-i-ru*([-past])  
 ‘Mina has put the laundry in the garden.’

When it comes to achievement verbs, *-te i-ru* has the perfect interpretation only. Again, perfect can also be expressed by *-ta*.:

- (5) Kisha-ga Seoul-ni tochaku-si-te i-ru  
 train-nom Seoul-dat arrival-do-*te i-ru*  
 ‘The train has arrived in Seoul.’
- (6) Kisha-ga Seoul-ni tochaku-si-ta.  
 train-nom Seoul-dat arrival-do-[+past]  
 ‘The train (has) arrived in Seoul.’

## 2.2. *Hakata Dialect (HD) of Japanese*

Let us now turn to HD, which is spoken in Fukuoka in Kyushu Island, southern part of Japan. A striking difference from TD is that HD has two distinct aspectual morphemes *yor-u* and *too*, which exactly correspond to English *-ing* and *-en*, respectively.

### 2.2.1. *yor-u*

When this morpheme attaches to activity and accomplishment verbs, it yields progressive meaning:

- (7) Mina-ga hasiri-yor-u. ‘Mina is running.’  
 Mina-nom run-*yor-u*

- (8) Mina-ga hon-o yomi-yor-u. 'Mina is reading a book.'  
 Mina-nom book-acc read-*yor-u*

As in the case of TD, a locative P *-de*, but not *-ni*, is compatible with the progressive:

- (9) Mina-ga niwa-de/\*-ni sentakumono-o hosi-yor-u.  
 Mina-nom garden-in laundry-acc dry- *yor-u*  
 'Mina is putting the laundry in the garden.'

Turning to achievement verbs, however, *-yor-u* expresses neither progressive nor perfect: Instead, it refers to so-called 'proximate future', or the event about to take place in the near future. This is parallel to English *-ing*:

- (10) Densha-ga Seoul-ni tuki-yor-u.  
 train-nom Seoul-dat arrive-*yor-u*  
 'The train is arriving in Seoul.'

#### 2.2.2. *too*

On the other hand, another morpheme *-too* signifies the meaning of perfect.<sup>3</sup> Since, as we saw in the case of TD (1), activity verbs are only compatible with progressive, attachment of the perfect morpheme *-too* yields ungrammaticality:<sup>4</sup>

- (11) Mina-ga hasit-too. \* 'Mina has run.'  
 Mina-nom run-*too*

With accomplishment verbs, it is interpreted as perfect:

- (12) Mina-ga hon-o yon-doo. 'Mina has read a book.'  
 Mina-nom book-acc read-*too*

And since *-too* exclusively means perfect, only P *-ni*, but not *-de*, is allowed:

<sup>3</sup> There seems to be a variation among speakers. Namely, while *-yor-u* bears the meaning of progressive for all speakers, *-too* is ambiguous between progressive and perfect for younger generations. I will not go into this matter here.

<sup>4</sup> Again, it is grammatical under the interpretation with the object *pro* 'Mina has run *pro*.' See Note 2.

- (13) Mina-ga niwa-ni/-de sentakumono-o hosi-too.  
 Mina-nom garden-in laundry-acc dry- *too*  
 ‘Mina has put the laundry in the garden.’

Finally, when *-too* appears with achievement verbs, it is interpreted neither as progressive nor near future but as perfect:

- (14) Densha-ga Seoul-ni tui-too.  
 train-nom Seoul-dat arrive-*too*  
 ‘The train has arrived in Seoul.’

### 2.3. Summary

The above facts are summarized in (15). Note in particular that the behaviors of HD *-yor-u* and *-too* are parallel to those of English *-ing* and *-en*:

(15)

	English		Tokyo Dialect		Hakata Dialect	
	<i>-ing</i>	<i>-en</i>	<i>-te i-ru</i>		<i>yor-u</i>	<i>-too</i>
State	*	*	*prog	*perf	(*)prog	(*)perf
Activity	ok	*	<sup>ok</sup> prog	*perf	<sup>ok</sup> prog	*perf
Accomplishment	ok	ok	<sup>ok</sup> prog	<sup>ok</sup> perf	<sup>ok</sup> prog	<sup>ok</sup> perf
Achievement	n.f.	ok	*prog/*n.f.	<sup>ok</sup> perf	*prog/ <sup>ok</sup> n.f.	<sup>ok</sup> perf

### 2.4. Progressive and perfect of some state verbs

Let us now take a look at yet another striking difference between TD and HD. It is well-known that in TD state verbs cannot co-occur with *-te i-ru*. The fact has been pointed out by many scholars, Kindaichi (1950), among others:<sup>5</sup>

<sup>5</sup> In TD, there is an alternation between *ar-u* and *i-ru*, which is sensitive to whether the subject of the sentence is capable of moving by any internal mechanism. Namely, if

- (16) a. \*Tana-ni hon-ga at-te i-ru.  
 shelf-dat book-nom exist-*te i-ru*  
 ‘There is (temporarily) a book on the shelf.’
- b. \*Ima kaigi-ga at-te i-ru.  
 now meeting-nom exist-*te i-ru*  
 ‘There is a meeting being held now.’
- c. \*Moo kaigi-ga at-te i-ru.  
 already meeting-nom exist-*te i-ru*  
 ‘There has already been a meeting.’
- (17) a. \*Taro-ni-wa ani-ga i-te i-ru.  
 Taro-dat-top elder brother-nom exist-*te i-ru*  
 ‘Taro has an elder brother.’
- b. \*Ima ie-ni tomodati-ga i-te i-ru.  
 now house-dat friend-nom exist-*te i-ru*  
 ‘There is a friend of mine in my house now.’

One might argue that (17a) is ungrammatical because “having an (biological) elder brother” is an inherent property of the subject, or it is an individual-level predicate in the sense of Diesing (1992). However, as the rest of the examples in (16) and (17) show, it is not the individual/stage distinction that determines grammaticality. As I will show through examples from HD below, I argue that what is relevant is “eventhood” of the subject nominals.

To see this, let us now turn to HD. The HD counterparts of these verbs, on the contrary, allow attachment of *-yor-u* and *-too* in some cases:<sup>6</sup>

- (18) a. \*Tana-ni hon-ga ari-yor-u.  
 shelf-dat book-nom exist-*yor-u*  
 ‘There is temporarily a book on the shelf.’

---

the subject is [-mobile], *ar-u* is used, while if it is [+mobile], *i-ru* is used. Note that this is different from the “animacy restriction” well-observed in many languages. For instance, artifacts such as ‘elevator’ and ‘taxi’ can be predicated of either by *ar-u* or *-i-ru* depending on the context, or the speaker-hearer’s cognitive process.

- (i) Kono biru-ni-wa elevator-ga 3-ki ar-u. “There are 3 elevators in this building.”  
 this building-in-top elevator-nom 3-nc exist-[-past]
- (ii) Ima elevator-wa 3-kai-ni i-ru. “The elevator is at the third floor now.”  
 Now elevator-top 3-floor-at exist-[-past]

<sup>6</sup> The same alternation as in TD is observed in HD, though its realization is *a-ru* [-mobile] and *o-ru* [+mobile].

- b. Ima kaigi-ga ari-yoo.  
now meeting-nom exist-*yor-u*  
'A meeting is being held now.'
- (19) a. \*Taro-ni-wa ani-ga ori-yor-u.  
Taro-dat-top elder brother-nom exist- *yor-u*  
'Taro has an elder brother.'
- b. \*Ima ie-ni tomodati-ga ori-yor-u.  
now house-dat friend-nom exist- *yor-u*  
'My friend is in my house now.'
- (20) a. \*Tana-ni hon-ga at-too.  
shelf-dat book-nom exist-*too*  
'There has been a book on the shelf.'
- b. Moo kaigi-ga at-too.  
already meeting-nom exist-*too*  
'A meeting has already been held.'
- (21) a. \*Taro-ni-wa ani-ga ot-too.  
Taro-dat -top elder brother-nom exist-*too*  
'Taro has an elder brother.'
- b. Moo ie-ni tomodati-ga ot-too.  
already house-dat friend-nom exist-*too*  
'My friend has already been in my house.'

As the above examples show, attachment of *yor-u* and *-too* is allowed only if the subject denotes an event. In other words, (18b) and (20b) are grammatical because "meeting" is an event. *Yor-u* and *-too* cannot attach to *or-u*, a mobile variant of the verb "exist", since the mobile subject cannot be eventive. Thus, the determining factor is not the nature of predicates, i.e. stage/individual distinction, but the nature of the subject nominals.

### 3. Questions

The above observation leads us to the following questions:

- (21) a. How can we capture the distribution and interpretation of TD *-te i-ru*,

HD *-yor-u* and *-too*?

- b. Why can some state verbs co-occur with *-yor-u* and *-too* in HD, while it is utterly ungrammatical under any reading in TD?

A composite mechanism will be proposed below to answer these questions.

#### 4. Proposal and analysis

##### 4.1. Compositional organization of grammar

I argue that aspect of the predicate is determined by combining the inherent property of the main predicate and other elements in the sentence. This compositional view on aspectual interpretation is not new at all. Many researchers have observed that aspect of the sentence is influenced by singularity/plurality of the object (22), existence/absence of prepositional phrases denoting a goal (23), type of durational prepositional phrases (24), and so on:

- (22) a. John is drawing a circle. (accomplishment)  
b. John is drawing circles. (activity)
- (23) a. John is pushing a cart to the car. (accomplishment)  
b. John is pushing a cart. (activity)
- (24) a. John read a book in an hour. (accomplishment)  
b. John read a book for an hour. (activity)

In order to capture this composite nature of aspect, I will introduce the following two mechanisms: inherent specification of boundedness for each predicate in the lexicon, and syntactic projections for encoding aspect and event.

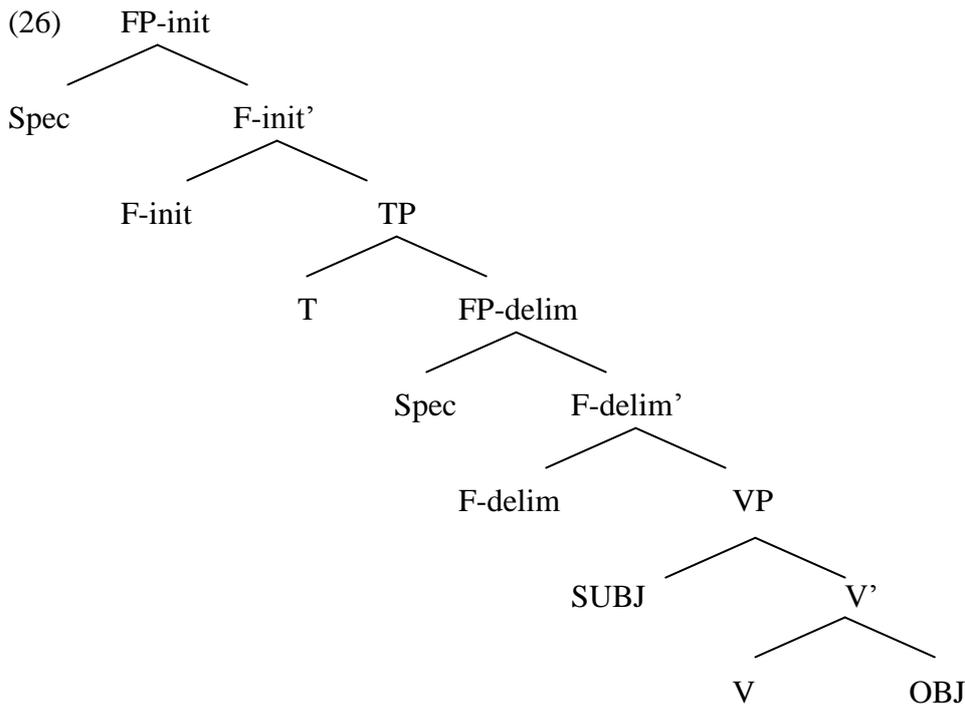

First, assuming that an event is cognitively differentiated by boundedness of its initial and terminal points, I argue that each verb is inherently specified for its boundedness for these two points as in (25). The similar view has been presented in Ritter and Rosen (2000:195) and also by Kudo (1995):

(25)

Class	Initial point	Terminal point
States	[-bound]	[-bound]
Activities	[+bound]	[-bound]
Accomplishments	[+bound]	[+bound]

Achievements	[-bound]	[+bound]
--------------	----------	----------

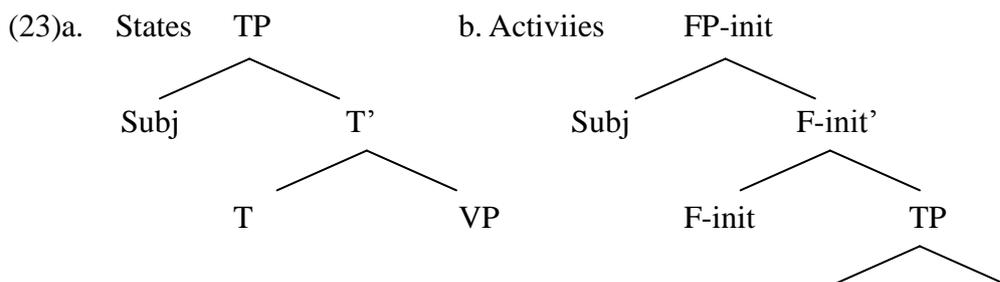

Second, adopting from Ritter and Rosen (2000:197), I assume that there are two functional heads F-init(iator) and F-delim(iter), which are licensed by [+bound] feature of the initial and terminal points specified for the main predicate, respectively. The full structure looks like (26):

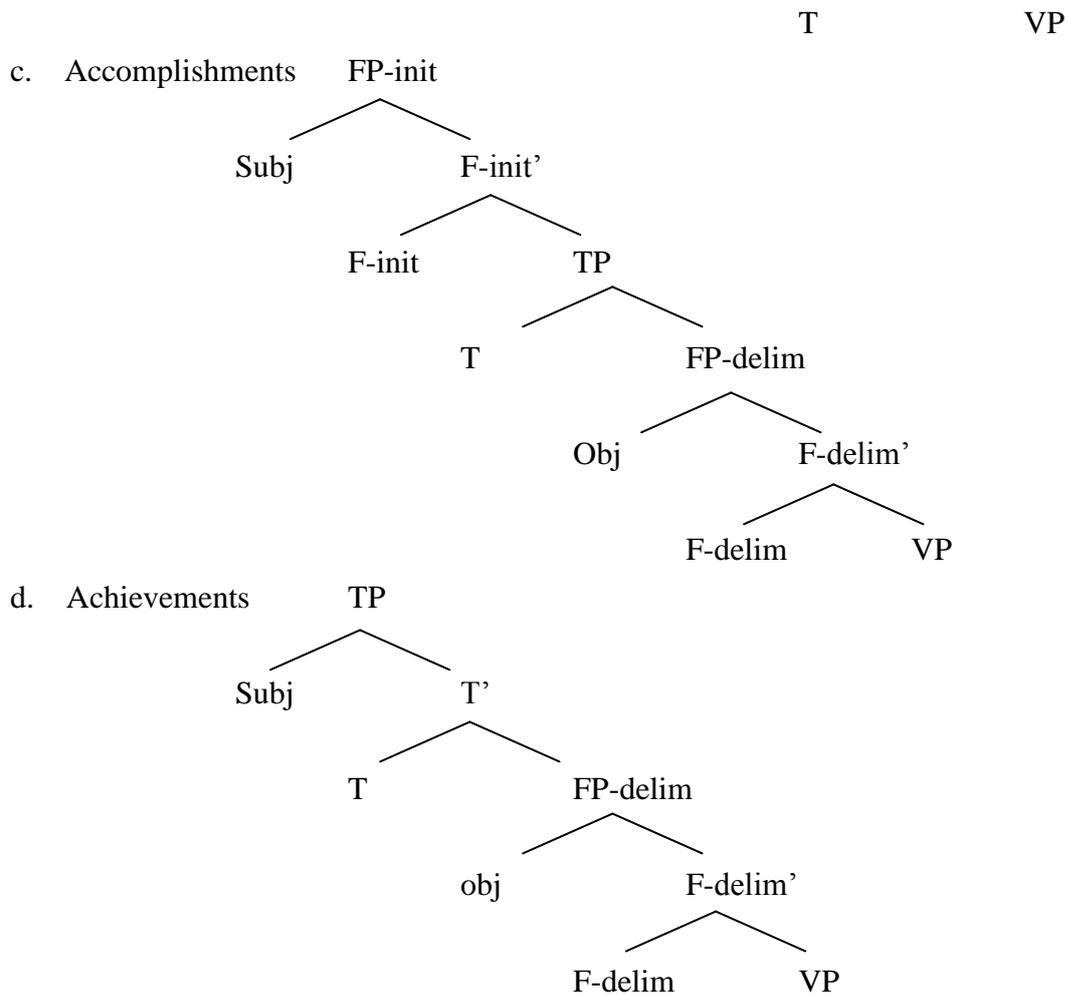

As mentioned above, the licensing mechanism for F-init and F-delim are as follows:

- (27) Licensing mechanism of F-init and F-delim
- a. If [+bound] for initial point → then F-init is projected
  - b. If [+bound] for terminal point → then F-delim is projected

This way, the fundamental structure for the four classes of verbs is projected as follows:

For realization of these aspectual heads, I take the view of Distributed Morphology proposed by Halle and Marantz (1993). Following their system, actual morphemes are inserted under heads at Morphological Structure through the following Vocabulary Insertion Rules:

(25) Vocabulary Insertion

- TD) {F-init, F-delim} ⇔ *-te i-ru*  
 HD) a. F-init ⇔ *-yor-u*  
       b. F-delim ⇔ *-too*

These mechanisms will derive ambiguity of *-te i-ru* in TD, while capturing the exclusive nature of HD *yor-u* and *-too* in their interpretation, which constitutes an answer to (21b). Given the space limitation, I will not demonstrate them in details.

#### 4.2. *Event transfer*

Now let us tackle the second question (21b), namely, why can some state verbs co-occur with *-yor-u* and *-too* in HD, while it is utterly ungrammatical under any reading in TD?

First, let us recapture the generalization within HD. As I indicated in Section 2.4., even in HD not all instances of *ar-u* plus *-yor-u*(progressive) or *-too*(perfect) are allowed: it is only when the subject denotes an event.

In order to explain this HD fact, I extend the notion of the “event positions” proposed by Davidson (1967) and adopted by Grimshaw (1990) and others, and propose that nominals denoting event have an event position. Then, I argue that in HD this event position is transferred to its head V via spec-head relation. Presumably state verbs do not have event positions inherently. Therefore, when the event position is transferred from the subject nominal to the state verb, *ar-u* in particular, this transfer changes the aspect of *ar-u* from state to accomplishment, projecting F-init and F-delim. That is why *ar-u* plus progressive and perfect morphemes are grammatical in HD.

Then a natural question is, why this option is unavailable in TD, which is the latter half of (21b). I propose that there is a parametric variation with respect to the way the event position associated with the subject nominal affects the main predicate. Whereas the mechanism of the “actual” event transfer occurs in HD, thereby changing the aspect of the main predicate itself, this is unavailable in TD for some reason. Yet, since the subject nominal in the specifier position of the main predicate has <e>, it percolates up to the maximal projection of VP to supplement the privative feature <e>. This is in accordance with the “feature percolation convention” proposed by Lieber (1982). This mechanism of event transfer is summarized below:

(26) { meeting, lecture, conference, festival, demonstation, exam(ination) } = <e>

(27) Event transfer: If the subject of a state verb has <e>,

a. in TD, it percorates up to VP and changes the VP into an eventive predicate.

(cf. Lieber (1982))

b. in HD, it is transferred to V and changes the V into an accomplishment verb.

→ licenses F-init and F-delim

If the above analysis is correct, we should expect indication of the percolated event position even in TD. In the following two subsections, I will show two pieces of

evidence supporting this.

#### 4.2.1. Evidence 1: Choice of locative postpositions

In Japanese, the postpositions associated with locative NPs are either *-ni* or *-de*. Yet there is a correlation between the choice of the preposition and whether the locative NP is an argument or an adjunct of the predicate:

- (28) a. Mina-ga Tokyo-ni (sun-de) i-ru.  
 Mina-nom Tokyo-*ni* (live-*te*)exist [-past]  
 ‘Mina is (lives) in Tokyo.’
- b. Mina-ga tana-ni hon-o oi-ta.  
 Mina-nom tana-*ni* book-acc put-[+past]  
 ‘Mina put the book on the shelf.’
- c. Mina-ga Tokyo-de hon-o kat-ta.  
 Mina-nom Tokyo-*de* book-acc buy-[+past]  
 ‘Mina bought a book in Tokyo.’

Now, both in TD and HD, the locative NP appearing with *ar-u* takes *-ni* or *-de* depending on the eventhood of the subject:

- (29) a. Tana-ni hon-ga ar-u.  
 shelf-*ni* book-nom exist-[-past]  
 ‘There is a book on the shelf.’
- b. Tokyo-de kaigi-ga ar-u.  
 Tokyo-*de* meeting-nom exist-[-past]  
 ‘There is a meeting in Tokyo.’

I take this to be the indication that in TD the event position associated with the subject NP *kaigi* ‘meeting’ is percolated up to the VP dominating the subject NP itself, the verb *ar-u* and the locative PP. This means that *ar-u* is no longer a stative verb which takes the locative PP as an argument, but is a eventive verb where the locative PP behaves as an adjunct. That is why *-de*, not *-ni*, is used on the PP.

The same holds for HD, the only difference being that the event position is not percolated to the VP, but transferred to the head V.

#### 4.3.2. Evidence 2: Interpretation of some modal elements

The second evidence is concerned with the interpretation of some modal

elements. *-Soo-da* takes VP and expresses the modality of likelihood in either present or future. When this modal element is attached to stative predicates, the only available interpretation is that the state expressed by the VP is likely at present, and the sentence is unambiguous. If, on the other hand, *-soo-da* appears with eventive predicates, both present and future interpretations are available and the sentence is ambiguous:

- (30) a. Mina-ga kasiko-soo-da.  
 Mina-nom smart-likely-copula  
 ‘Mina seems to be smart.’  
 \* ‘Mina is going to be smart.’
- b. Mina-ga hon-o yomi-soo-da.  
 Mina-nom book-acc read-likely-copula  
 ‘Mina seems to read books (Mina seems to like books.)’  
 or ‘Mina is going to read a book.’

Now, when *-soo-da* co-occurs with *ar-u*, the sentence is unambiguous if the subject is a simple noun, but is ambiguous with an eventive nominal as the subject:

- (31) a. Tana-ni hon-ga ar-i-soo-da.  
 shelf-*ni* book-nom exist-likely-copula  
 ‘There seems to be a book on the shelf.’  
 \* ‘There is going to be a book on the shelf.’
- b. Tokyo-de kaigi-ga ar-i-soo-da.  
 Tokyo-*de* meeting-nom exist-[-past]  
 ‘There seems to be a meeting in Tokyo.’  
 or ‘There is going to be a meeting in Tokyo.’

The reason is that while *ar-u* is inherently a stative verb, it is turned into an eventive predicate by virtue of the event position associated with the subject nominal.

This also supports the existence of the event transfer mechanism.

## 5. Korean data

### 5.1. *-ko iss-ta*

In this section we take a look at Korean morphemes expressing progressive and perfect. *-ko iss-ta* is a morpheme that shares characteristics TD *-te i-ru* in some respects and HD *-yor-u* in others. When this attaches to activity verbs, it means progressive, which is the same with both *-te i-ru* and *-yor-u*:

- (32) Mina-ka talli-ko iss-ta. 'Mina is running.'  
 Mina-nom run-ko iss-ind

In order to express perfect, a different morpheme *-ess* is used:

- (33) Mina-ka talli-ess-ta. 'Mina ran/has run.'  
 Mina-nom run-perf-ind

With accomplishment verbs, *-ko iss-ta* behaves like *-te i-ru* in that it induces ambiguity between progressive and perfect:

- (34) Mina-ka chayk-ul ilk-ko iss-ta.  
 Mina-nom book-acc read-ko iss-ind  
 'Mina is reading a book.'  
 or 'Mina has read a book.'

Thus, just like TD example (4), the sentence is disambiguated by the choice of locative postpositions:

- (35) a. Yenghi-ka mantug-eyse ppallay-lul  
 Yenghi-nom garden-in laundry-acc  
 nel-ko iss-ta.  
 dry-ko iss-ind  
 'Yenghi is drying the laundry in the garden.'  
 b. Yenghi-ka mantug-ey ppallay-lul  
 Yenghi-nom garden-in laundry-acc  
 nel-ko iss-ta.  
 dry-ko iss-ind  
 'Yenghi has put the laundry in the garden.'

(Kim (2006: 11))

In the case of achievement verbs, *-ko iss-ta* patterns with HD *yor-u*, as the sentence means near future:

- (36) Kicha-ka Seoul-ey tochak-ha-ko iss-ta.  
 Train-nom Seoul-to arrival-do-ko iss-ta  
 ‘The train is arriving in Seoul.’

5.2. *-ess-ta* vs. *-ess-ess-ta*

Let me draw attention to a less-known case of the “double past” form for perfect. This form is used if and only if the main verb belongs to the class of achievement verbs:

- (37) Mina-ka talli-ess-ta/\*-ess-ess-ta.  
 Mina-nom run-perf-ind  
 ‘Mina ran/has run.’
- (38) Mina-ka chayk-ul ilk-ess-ta/\*ess-ess-ta.  
 Mina-nom book-acc read-perf-ind  
 ‘Mina read/has read a book.’
- (39) a. Kicha-ka Seoul-ey tochak-ha-ess-ta.  
 Train-nom Seoul-to arrival-do-ess-ta  
 ‘The train (has) arrived in Seoul.’
- b. Kicha-ka Seoul-ey tochak-ha-e-iss-ta.  
 Train-nom Seoul-to arrival-do-e-iss-ta  
 ‘The train has arrived in Seoul.’

This presents a rather complex situation, which is shown in the tables below:

(40) Activity verbs

	Korean	TD	HD
progressive	-ko iss-ta	-te i-ru	-yor-u
perfect	-ess-ta	-ta	-ta
past			

## (41) Accomplishment verbs

	Korean	TD	HD
progressive	-ko iss-ta	-te i-ru	-yor-u
perfect			-too
past	-ess-ta	-ta	-ta

## (42) Achievement verbs

	Korean	TD	HD
progressive (near future)	-ko iss-ta	-(r)u or -soo-da	-yor-u
perfect	-ess-ess-ta	-te i-ru	-too
past	-ess-ta	-ta	-ta

## 6. Evidentiality Markers

Finally, let us take a look at evidentiality markers in Korean and the Gohogawara Dialect of Japanese.

### 6.1. Korean

There is a Korean sentence-final particle *-te-la*, which means that the speaker of the sentence has actually seen the event denoted by the sentence. If, on the other hand, when *-ess* is inserted between the verbal stem and *-te-la*, the sentence indicates that the speaker did not actually see the event, but infers from some evidence. Furthermore, if the “double past” observed above is used regardless of the verb class, then, the sentence is about indirect report. Thus, in (43a), the speaker has actually seen Mina’s reading of the book, while (43b) is inferential and (43c) is reported speech:

- (43) a. Mina-ka chayk-ul ilk-te-la.  
Mina-nom book-acc read-*te-la*  
‘Mina read/has read a book.’ (direct evidential)
- b. Mina-ka chayk-ul ilk-ess-te-la.  
Mina-nom book-acc read-perf-*te-la*

- ‘Mary read/has read a book.’ (indirect-inferential)
- c. Mina-ka chayk-ul ilk-ess-ess-te-la.  
 Mina-nom book-acc read-past-*ess-te-la*  
 ‘Mary read a book.’ (indirect-reported)

6.2. *Goshogawara Dialect of Japanese (spoken in Goshogawara, north of Aomori, northern part of Japan)*

Interestingly, a similar pattern is found in the Goshogawara dialect:

- (44) a. Mina-ga hon-o yon-de-ra.  
 Mina-nom book-acc read-*te-ra*  
 ‘Mina is reading a book.’ (direct evidential)  
 or ‘Mina has read a book.’ (direct evidential)
- b. Mina-ga hon-o yon-da.  
 Mina-nom book-acc read-[+past]  
 ‘Mina read/has read a book.’ (indirect-inferential)
- c. Mina-ga hon-o yon-dat-ta.  
 Mina-nom book-acc read-past-*ta*  
 ‘Mina read/has read a book.’ (indirect-reported)

Correspondence between Korean and the Goshogawara dialect is shown in (45). We can attain a generalization which is stated in (46):

(45)

	progressive	perfect	direct evidential	indirect evidential	
				inferential	reported
Korean	-ko iss-ta	-ess-ta	-te-la	-ess-te-la	-ess-ess-ta
Goshogawara	-te-ra			-ta	-tat-ta

(46) Generalization

Doubling of “tense” morphemes causes a shift in aspect and mood toward more “perfect” and “remote”.

- Korean) ess-ess-ta > ess-ta: past vs. perfect  
 ess-ess-ta > ess-te-la: reported vs. inferential
- Goshogawara) tat-ta > ta: past vs. perfect

tat-ta > ta: reported vs. inferential

## 7. Conclusions and residual problems

In this paper I mainly analyzed the form and meaning of *-ko iss-ta* in comparison with HD *-yoo/-too* and their much-discussed TD counterpart *-te ir-u*. Doing this line of research reveals interesting questions which have been concealed by the ambiguity of *-te i-ru*. Specifically, difference between TD and HD in aspectual realization stems from two factors. First, there is a difference in the number of morphemes available: while HD has two morphemes, TD has only one. Naturally, the overall pattern of progressive and perfect aspect of HD is closer to English than that of TD is. Second, I argued for the mechanism of event transfer. Furthermore, I proposed two different modes of that mechanism: percolation of the event position to VP in the case of TD and the actual transfer of that event position to the head V.

In actual analysis I adopted the compositional view on the interaction between the lexical information and syntactic structure proposed by many researchers, Ritter and Rosen (2000) in particular. By implementing their theory with the correlation with inherent feature specification and functional projection, the questions addressed on the otherwise mysterious facts are partially solved.

In particular, event transfer from subject nominals is an addition to compositional aspect. This is particularly interesting because the findings thus far have been limited to aspectual shift caused by elements within the maximal domain of the main predicate, most typically VP.

Extending the range of analysis, I took into consideration some evidentiality markers in Korean and Goshogawara Dialect of Japanese and reached the following generalization. Namely, doubling of “tense” morphemes causes a shift in aspect and mood toward more “perfect” and “remote”. This indicates that tense, aspect and modality are not isolated categories but adjacent, interactive categories.

There are, however, still some stipulations, as well as more interesting generalizations. Among them are how to derive near-future interpretation and details of vocabulary insertion and interpretation. Hopefully these will be cleared in future studies.

# The interpretation of a “contrast-marking” particle

Beáta Gyuris

Research Institute for Linguistics, HAS  
Benczúr u. 33. Budapest, H-1068, Hungary  
gyuris@nytud.hu

## Abstract

The paper discusses the interpretation of the accented *csak* discourse particle in Hungarian that is often referred to in the literature as a marker of contrast. It is argued that this particle has the function of an adversative context marker (Zeevat 2003, 2006). The discourse particle use of *csak* is contrasted to its older use as an exclusive particle, whose interpretation is described in terms of Beaver and Clark’s (2008) theory. It is shown that the meaning change in the course of which *csak* acquired its adversative particle interpretation can be accounted for in terms of semantic reanalysis, along the lines of Eckardt’s (2006) theory.

**Keywords:** adversative context marker, discourse particle, exclusive particle, ordered alternatives, semantic reanalysis.

## 1. Aims

The paper analyses the interpretation of the accented *csak* discourse particle in Hungarian, which has been claimed by some authors to be a marker of contrast (Kocsány 1986).<sup>1</sup> In the first half of the paper, we will provide an empirical characterisation of the necessary and sufficient conditions for the appearance of this particle in Hungarian sentences, and then we will try to formalize them in the framework of Zeevat (2003, 2006), relating the use of accented *csak* to the use of accented *toch* in Dutch and *doch* in German. The particle *csak* in Hungarian has a much more prominent and older use as a focus sensitive particle with an exclusive (scalar) interpretation analogous to English *only*. In the

---

<sup>1</sup> Research for the paper was supported by project No. F 68139 of the Hungarian Scientific Research Fund (OTKA). I thank the participants of the CIL18 workshop *Contrastiveness in Information Structure and/or Scalar Implicatures*, particularly Hans-Martin Gärtner, Laurence Horn, Manfred Krifka and Chungmin Lee, as well as audiences in Berlin (ZAS), Budapest (RIL HAS) and Szeged (SZTE) for criticism and suggestions.

second half of the paper we will look at the contribution of this exclusive *csak* to the presuppositions and truth conditions of Hungarian sentences, proposing that they are best accounted for in the framework of the theory recently proposed by Beaver and Clark (2008). It will then be argued that the latter approach also leads naturally to an explanation of the meaning change in the course of which *csak* acquired its discourse particle use in terms of semantic reconstruction that took place in order to avoid pragmatic overload (cf. Eckardt 2006). The paper ends with a summary of the conclusions. In what follows, to avoid confusion, we refer to the obligatorily accented discourse particle as *CSAK*.<sup>2</sup>

## 2. The discourse particle *CSAK*

### 2.1. Data

Example (1) below illustrates a context where a sentence containing an obligatorily accented *CSAK* particle can appear in Hungarian:

- (1) A: *I don't think John will be invited.*  
 B: *I've just heard Mary invite him.*  
 A: (*Szóval*) *CSAK meghívták Jánost.*  
 so            *CSAK VM:invited:3pl John:ACC*  
 "(So) John got invited after all."

Although leaving the particle *CSAK* out from A's second utterance would not make the sentence ungrammatical or alter its truth conditions, it would definitely make the sentence inappropriate in the context, since the speaker would have to be attributed contradictory beliefs (given that he would be taken to utter two declarative sentences whose propositional contents are incompatible with each other).<sup>3</sup> Thus, (1) suggests that the contribution of the particle to the interpretation of the sentence is to mark that the speaker is aware that the propositional context of his present utterance is incompatible with the propositional content of a previous utterance of his. The above

---

<sup>2</sup> There are other discourse particle uses of (non-accented) *csak* in addition to the one discussed in this paper, most of which are analogous to the discourse particle uses of German *nur* 'only' (cf. Gyuris 2007).

<sup>3</sup> Note that the propositional contents of the first and the second utterances by A in (1) are not contradictory, since the first one is of the form 'I don't think that *p*', whereas the second is of the form *p*.

example is thus a typical case where the use of a particle serves the aim of making the discourse coherent, or, more specifically, as Zimmermann (to appear) puts it, indicates the “speaker’s epistemic attitude” towards the truth of the proposition. The latter interpretational features have been attributed in the literature to the so-called *modal* or *discourse particles* (cf. Kiefer 1988, Thurmair 1989, Meibauer 1994, Zimmermann, to appear, among others), whose characteristic features on the formal side include that they cannot be negated, do not answer any questions, cannot be coordinated, and do not form a constituent with other expressions. In the rest of this section we will specify what the presence of *CSAK* can signal about the context and in what cases it is necessary for the coherence of the discourse.

First, as (2) illustrates, *CSAK* can also appear in a sentence *S* that is uttered by a speaker different from the one who previously uttered the sentence expressing a proposition felt to be incompatible by the speaker of *S* with the propositional content of *S*:

- (2) A: *I think John will be invited.*  
 B: *I don’t think so, Mary does not like him.*  
 C: *I’ve just heard Mary invite him.*  
 A: *Szóval (CSAK) meghívták Jánost.*  
 so CSAK VM:invited:3pl John:ACC  
 “(So) John got invited after all.”

Note that in the context of (2), as opposed to that of (1), the presence of *CSAK* is not obligatory. In both contexts, however, a German sentence containing the accented particle *DOCH*, illustrated in (3), would be just as acceptable as the corresponding Hungarian sentences with *CSAK*:

- (3) *(So,) Hans ist DOCH eingeladen.* (German)  
 so John is DOCH invited:PTCP  
 “(So) John got invited after all.”

The following contrast between the acceptability of accented Dutch *TOCH* and *CSAK* in parallel contexts shows that it is not enough for *CSAK* to be properly licensed in a context where a sentence attributing some kind of attitude to somebody towards the negation of the propositional content of the *CSAK*-sentence has been uttered:

- (4) *Jan droomde dat hij was gezakt voor het examen, maar hij had het TOCH gehaald.* (Dutch)  
 “John dreamt that he would pass the exam but he failed after all.”  
 (Zeevat 2000:14)

- (5) #*János azt álmodta, hogy megbukik a vizsgán, de CSAK átment.*  
 John that:ACC dreamt that fail the exam:on but CSAK passed  
 Intended: “John dreamt that he would pass the exam but he failed after all.”

There are two further important facts to be observed about the use of *CSAK*. The first one is that, as (6) shows, it is not a necessary condition for the use of this particle in a sentence *S* that there be precisely one sentence *S'* in the preceding discourse that expresses a proposition felt to be incompatible with the propositional content of *S*:

- (6) *Zsuzsi: Hisz' ez azé a kis tolvajé! oly kegyetlen volt but this that:POSS the small thief:POSS so cruel was nagyságod, hogy elvette tőle? your:majesty that VM:took from:him*  
 “But this belongs to that small thief! Was your majesty so cruel as to take it away from him?”

*Countess: CSAK nem hagyhattam a karján!*<sup>4</sup>  
 CSAK not leave:could:1sg the arm:POSS:on  
 “I could not leave it on his arm after all!”

Note that there is nothing incompatible between the propositional content of the second speaker’s sentence and those of the first speaker’s first or second sentences individually. What the propositional content of the second speaker’s sentence is incompatible with is the proposition expressed by the first speaker’s first sentence, the presuppositions introduced by her second sentence, and default inferences based on the latter two. The second fact is that the acceptability of discourses with *CSAK* is a gradual matter, and depends not only on the content of utterances but also on the shared beliefs of the interlocutors. For example, the acceptability of (7) depends on how important B thinks A was in the campaign of János, and how efficient B thinks A is in performing the tasks related to the campaign:

---

<sup>4</sup> From the Hungarian Historical Corpus (<http://www.nytud.hu/hhc>).

- (7) A: *I campaigned hard for John.*  
 B: *CSAK nem választották meg.*  
 CSAK not elected:3pl VM  
 “He was not elected after all”

If B thinks A is a good campaigner and has a great influence on the campaign, then the fact that A worked hard in the campaign leads him to conclude that John was likely to be elected. B then marks the incompatibility between the latter inference and information pertaining to the actual outcome of the election by using *CSAK*. (Sentence (7B) can, naturally, also be meant ironically, to express the belief on the part of the speaker that the fact that A participated in the campaign does not legitimate an inference that John will be elected.)

The *yes-no* interrogative in (8) below, which would be coherent way to continue the discourse in (1) above, and the second, imperative sentence of the discourse in (9) illustrate that *CSAK* is not only possible in declaratives:

- (8) A: (*Szóval*) *CSAK meghívták Jánost?*  
 so CSAK VM:invited:3pl John:ACC  
 “(So) did John get invited after all?”
- (9) A: *I don't think John would come to the party if he got an invitation.*  
 B: *CSAK hívjuk meg!*  
 CSAK invite:IMP1pl VM  
 “(So) John got invited after all.”

As the parallel between the third sentence of (1) and (8) also shows, the conditions under which *CSAK*-sentences belonging to any of the latter two sentence types can or must appear in a discourse are analogous to those under which the corresponding declaratives are licensed.

Having illustrated the basic facts about the use of the *CSAK* discourse particle, in the next section we will try to capture its meaning in terms of Zeevat's (2000, 2003, 2006) proposals.

## 2.2. *CSAK as a context marker*

Zeevat (2000, 2003, 2006) argues that a number of discourse particles in various languages, including English *indeed*, Dutch *immers*, *toch*, *wel*, or German *ja* and *doch*, serve as so-called *context markers*, that is, they mark whether the propositional content of the sentence they are situated in is viewed by the speaker as being part of the *common ground*, as having been suggested to be false in the context, as having been denied in the common ground, or as addressing a topic that has been addressed before. Zeevat assumes that context markers have to be present due to functional necessity, since in the lack of them, the hearer is determined to interpret any new sentence as carrying information to be added automatically to the common ground, independently of its previous content. In case the relevant information was already present in the common ground, the latter strategy results in having to view the incoming information as superficial, and in case the negation of the propositional content of the sentence was already part of the common ground, the strategy results in having to think that the speaker has contradictory beliefs.

Zeevat (2000, 2003, 2006) argues that German accented *doch* and Dutch accented *toch* are *adversative context markers*, which are defined by him as in (11) below. The definition of adversative context markers uses, assuming that  $\varphi$  is a proposition, the proposition *suggested*( $\varphi$ ), which is defined by Zeevat in a recursive fashion, shown in (10), and the proposition *normally*( $\varphi$ ), the truth of which in an information state requires, according to Zeevat, that  $CG \models \psi_1, \dots, \psi_n$ , where  $\psi_1, \dots, \psi_n$  together constitute a reason for thinking that  $\varphi$ , while at the same time the *CG* does not support a similar argument for  $\neg p$  (Zeevat 2006:141).

(10) *suggested*( $\varphi$ )  $\leftrightarrow$  *may*  $\varphi \wedge (\varphi \vee O_1 \varphi \vee \dots \vee O_n \varphi \vee \textit{suggested}(\varphi))$   
the set  $\{O_1, \dots, O_n\}$  contains operators like *x dreams that, x suggests that, x believes that.* (Zeevat 2003:182)

(11) *adversative*(*CG*,  $\varphi$ ) holds iff  $CG \models \textit{normally}(\neg\varphi)$  or  $CG \models \textit{suggested}(\neg\varphi)$   
(Zeevat 2003:182)

The data presented in the previous section suggest that Hungarian *CSAK* should be analyzed as an adversative marker analogous to Dutch accented *toch* and German accented *doch*. The approach seems to run into two problems, however. The first one is illustrated by (12)–(13) below, which contain the prosodically prominent particles *doch* and *csak*, respectively:

- (12) A: *John wasn't invited.*  
 B: *Hans war DOCH eingeladenet.* (German)  
 John was DOCH invited:PTCP  
 "John WAS invited."
- (13) A: *John wasn't invited.*  
 B: #CSAK *meghívták Jánost.*  
 CSAK VM:invited:3pl John:ACC  
 Intended: "John WAS invited."

The pair of sentences above point to an asymmetry between the behaviour of the two particles: although the propositional content  $p$  of sentences (12B) and (13B) satisfies the first requirement of adversativity in the relevant contexts, since there is a set of propositions in the common ground, namely the unit set  $\{\neg p\}$ , such that its elements constitute a reason for thinking that  $\neg p$ , the two sentences differ in acceptability. In Zeevat's framework, however, it is possible to find an explanation for this problem: in addition to the adversative markers, he also distinguishes so-called *corrective markers*, which mark the content of the sentence to be false in the common ground. The correction relation is an extreme case of adversativity, therefore, whenever the propositional content of a sentence is viewed as also satisfying this stronger relation to the common ground in addition to that of adversativity, it is a natural requirement that a context marker marking this stronger relation be chosen if available in the language. He argues that the prosodic realization of *doch* in (13B) is different from that of *doch/toch* in (3)–(4) above, the latter being only accented and the former contrastively stressed. Zeevat argues that this prosodic difference correlates with an interpretational difference, contrastively stressed *doch* being a corrective marker.<sup>5</sup> The unacceptability of (13B) in the relevant context thus indicates that *CSAK* cannot have an interpretation as a corrective marker. The second problem is illustrated by the contrast between (4) and (5) above, which suggests that *CSAK*, as opposed to *Duch* accented *toch*, does not get licensed in a sentence whose propositional content  $p$  is only *suggested* in the context according to definition (10), but does not follow by default reasoning from the common ground (that is, where *normally(p)* is not part of

---

<sup>5</sup> Zeevat (2003, 2006) makes a systematic difference between these two prosodic realizations of the *doch/toch* particle even by typographic means: he capitalizes only the occurrences of the particles that he considers contrastively stressed. In this paper, I am ignoring this distinction for the sake of being able to emphasize the prosodic parallel between accented *csak* and *doch/toch*, which I mark with capitals in the examples.

the common ground). Given these findings we will assume that Hungarian *CSAK* belongs to a subtype of adversative context markers that, when inserted into a sentence with propositional content *p*, can only mark that the following: there is a set of propositions in the common ground that constitute a reason for thinking that *p* is true, but that an analogous requirement does not hold for the negation of *p*.

Having illustrated the contribution of the discourse particle *CSAK* to the meaning of Hungarian sentences, we look at the interpretation of its homonym, the exclusive particle *csak*.

### 3. The meaning of the exclusive particle *csak*

Examples (14)–(17) illustrate four typical uses of the focus-sensitive exclusive particle *csak* ‘only’ in Hungarian. The syllables bearing the heaviest accent within the sentences (marking the information structural focus) are marked with capital letters.<sup>6,7</sup> As the English translations indicate, English *only* has analogous interpretations:

---

<sup>6</sup> In these examples, the constituents focused in an information structural sense are all identical to or included in the constituent in the syntactic focus position, referred to as [Spec,FP] in É. Kiss (2002).

<sup>7</sup> The exclusive particle is normally unaccented in these examples. However, in certain cases (where the focus is a non-complex expression, as in (14), for example), the accent of the focus can move over to *csak* for prosodic reasons (I. Kenesei, p.c.).

- (14) *Csak JÁnost hívták meg.*  
 only John:ACC invited:3pl VM  
 “Only John got invited.”
- (15) *Csak KÉT diákot hívtak meg.*  
 only two student:ACC invited:3pl VM  
 “Only two students got invited.”
- (16) *Csak a TITkárnyóvel tudtam beszélni.*  
 only the secretary:with could:1sg talk:INF  
 “I could only speak to the secretary.”
- (17) *Mari csak egy DIák volt.*  
 Mary only a student was  
 “John was only a student.”

(14) illustrates the simplest use of *csak*, on which it signals that no propositions generated by replacing the focus for a different element in the set of its alternatives (the set of contextually relevant people) are true. In addition, the presence of the particle in (14) conveys that the speaker has expected more alternative propositions of the latter kind to be true (that is, he expected that more people will get invited). (15) illustrates a case where *csak* excludes only those alternative propositions that are not entailed by the proposition denoted by the sentence. (That is, (15) does not exclude the truth of the proposition that there was one student who got invited.) In other words, the exclusive particle operates on an ordered set of propositions, that is, it has a scalar interpretation. The sentence also conveys that the speaker expected for alternative propositions ordered higher on the relevant scale to be true as well.<sup>8</sup> The interpretation of (16) that comes most readily to mind illustrates the following scalar use of *csak*: the sentence expresses that there is no proposition more rewarding (Bonomi and Casalegno 1993) that is true, given the aims of the discourse, than the one that the speaker talked to the secretary. (In a prototypical situation this means that he could not talk to the director, for example. Given that the alternative propositions are not ordered by entailment, the truth of (16) does not mean that all propositions less rewarding than the one expressed by the sentence are true.) This sentence also conveys that the speaker expected for alternative propositions ordered higher to be true. The scalar *csak* of (17) differs from the one in (16) in the following respect: assuming a prototypical situation where each person has

---

<sup>8</sup> Apparently non-scalar uses of *csak* like in (14) can, naturally, be viewed as special cases of scalar *csak* (cf. van Rooij 2002, Beaver 2004, for example).

only one job, *csak* seems to make a vacuous contribution to the truth conditions of (17). However, it cannot be considered superfluous even in such a context, since it also conveys, like all the examples above, that the speaker had expected that alternative propositions ordered higher would be true (e.g. like the one that Mari was a member of the staff).

The acceptability of sentences like (17), as well as the fact that the placement of constituents into the Hungarian syntactic focus position ([Spec, FP] in É. Kiss 2002) has also been claimed to result in an exclusive interpretation (cf. Kenesei 1989, Szabolcsi 1994, É. Kiss 1998, among others) have promoted approaches like that of Balogh (2005), which follows Zeevat's (2007) proposal for *only*, and argues that the contribution of *csak* to the meaning of Hungarian sentences is only pragmatic, and indicates that the proposition expressed by the sentence falls short of the speaker's expectations. This approach runs into the problem of not being able to account for the fact that the negated version of a *csak*-sentence like (14), illustrated in (18), and the negated version of its counterpart without *csak*, illustrated in (19), have different entailments: whereas the former entails that John was invited, the latter does not:

(18) *Nemcsak János*     *hívták*     *meg.*  
 not.only John:ACC invited:3pl VM  
 "Not only John got invited"

(19) *Nem János*     *hívták*     *meg.*  
 not John:ACC invited:3pl VM  
 "It was not John who got invited"

Szabolcsi's (1994) approach (based on Kenesei 1989, and Bonomi and Casalegno's 1993 theory for *only*) is able to account for the latter mismatch, and also for the apparent equivalence of the meaning of (14) and its variant without *csak* by suggesting a different division of the meaning of these two types of sentences into a presupposed and an asserted part. She proposes that *csak*-sentences presuppose that their *prejacent* (the proposition expressed by their variant without *csak*) is true. This suggestion, however, runs into the problem of predicting that *csak* is superfluous in the case of (17).

In view of the problems previous approaches have to face with, I believe that the contribution of *csak* to the interpretation of the Hungarian sentences illustrated above is best captured with the help of the proposal by Beaver and Clark (2008), who argue for an interpretation for exclusives that equally takes into account their truth-conditional

impact (excluding higher values on a scale), and their *mirative* function (the expression of the fact that a higher value was expected). Beaver and Clark's definition for the meaning of exclusives is repeated below, where *Current Question* refers to the question that the particular utterance addresses:

(20) *Meaning of exclusives*

The lexical meaning of exclusives is exhaustively described by:

*Discourse function:* To make a comment on the Current Question (CQ, [...]), a comment which weakens a salient natural expectation. To achieve this function, the prejacent must be weaker than the expected answer to the CQ on a salient scale.

*Presupposition:* The strongest true alternatives in the CQ are at least as strong as the prejacent.

*Descriptive Content:* The strongest true alternatives in the CQ are at most as strong as the prejacent. (Beaver and Clark 2008: 251)

This means that on Beaver and Clark's proposal to the meaning of exclusives, there is an ordering on the set of possible true answers to the Current Question, which includes the prejacent of the sentence containing the exclusive particle, from weak to strong.<sup>9</sup> According to the authors, the ordering is either based on entailment or some relevant pragmatic notion, e.g. newsworthiness, and it creates a structure on the set of true alternatives that can either be a pre-order or a partial order.

On this proposal, none of the occurrences of *csak* in (14)–(17) are predicted to be superfluous, since each of them introduces a presupposition, described in (20), which amounts to saying that among the alternative true answers that the speaker would have found appropriate to the Current Question beforehand, all are stronger or at least as strong as the prejacent. Given the descriptive content attributed to exclusives in (20), the proposal correctly predicts that in cases where the alternative propositions do not exclude each other, the truth of a *csak*-sentence entails the falsity of alternative answers stronger than the prejacent, but does not exclude the truth of weaker alternative answers.<sup>10</sup>

---

<sup>9</sup> In my CIL18 talk I made a suggestion for capturing the contribution of scalar *csak* to the presuppositions of Hungarian sentences that resembled Beaver and Clark's (2008) proposal very much, without having been aware of the latter.

<sup>10</sup> It appears to me that the contrast between the truth conditional meaning of Hungarian sentences with a

Having discussed the interpretation of exclusive *csak* in Hungarian, in the next section we will argue that assuming an interpretation of the type shown in (20) for exclusive *csak*, it is possible to put forth a reasonable explanation for how it acquired the discourse particle interpretation described in section 2 historically.

#### **4. From exclusive particle use to discourse particle use: historical development through semantic reanalysis**

In this section, I would like to show that assuming the interpretation proposed by Beaver and Clark (2008) for exclusives in (20), there is a natural way of accounting for the problem of how the adversative discourse particle use described in section 2 developed for *csak*, to which no real solution has been proposed in Hungarian historical linguistics so far.<sup>11,12</sup> The explanation will be based on the idea that the semantic change in the course of which the particle *csak* acquired its adversative interpretation was a consequence of semantic reanalysis, which took place in order to avoid *pragmatic overload*, an important cause in meaning change, according to Eckardt (2006).

Eckardt (2006) claims that semantic reanalysis takes place in order to avoid pragmatic overload when an expression is used in a particular type of construction where information necessary to compute the presuppositions/implicatures introduced by it is not readily available for the hearers, and therefore it requires too much pragmatic accommodation from them to understand the meaning of the construction. In such cases, assuming that they understand the intended overall meaning of the sentence, the hearers re-distribute the parts of meaning among the constituents in a way that frees the relevant

---

constituent in preverbal focus position and those containing the exclusive particle *csak* could be captured by modifying Beaver and Clark's (20) formula along the lines suggested by van Rooij (2002), according to whom, the exhaustive interpretation of free focus amounts to saying that no better true answer could be given, whereas an exhaustive particle conveys that there is no alternative true answer that is equally good. For lack of space, and due to the fact that in accounting for the meaning change resulting in the discourse particle *CSAK* we will rely primarily on the presuppositions of exclusive *csak*, we will not elaborate on this issue further here.

<sup>11</sup> Cf. Pólya (2008) for an overview of the various interpretations of *csak* that it acquired historically.

<sup>12</sup> It would be a topic for further research to find out whether the homonymy of an adversative discourse marker and an exclusive particle is attested in other languages as well, and whether theoretical explanations for this homonymy in other languages (if available) can be adopted for the Hungarian case.

constituents from the pragmatic overload.

The earliest appearance of *csak* as an exclusive particle is found in a codex (Jókai codex) written in the 14th–15th century. I found the earliest clear examples of the particle having the adversative discourse marker interpretation in texts dating from the middle of the 17th century.<sup>13,14</sup> In (21)–(23) below, three examples from the latter period containing a use of *csak* are shown that can only be associated with an adversative interpretation. (A clear indication of the adversative reading is that speakers of present-day Hungarian only find these sentences grammatical if the particle is pronounced with an accent.)

(21) ... *noha szivesenn igyekeztem, de bizony csak nem leheté*  
though with:pleasure strove:1sg but however CSAK not could  
“... although I strove with pleasure, it was still not possible to do”

(from a letter by Miklós Bethlen, 1672)

---

<sup>13</sup> Benkő (1993–1997) argues that the first occurrence of *csak* having the adversative interpretation (marked by the fact that it is translated into German as *doch*) dates back to the middle of the 16th century. There are, however, strong reasons to debate the accuracy of the author’s classification of the particular use of the particle as a synonym of *doch*, which cannot be discussed here for lack of space. Szabó T. (1978) cites an example he considers relevant from 1608.

<sup>14</sup> Due to the fact that only a very limited number of written texts are available electronically from before the middle of the 18th century in Hungarian, more exact estimates cannot be provided.

- (22) ... *egy darabig mind igyekezénk a szelet megcsalni*  
 one while:for continuously tried:1pl the wind:ACC cheat:INF  
*oldalfejt való ... mesterséges evezésekkel, ... de hiába, csak meg*  
 sideways being artificial rowing:PL:with but in:vain CSAK VM  
*kelle fordulni...*  
 must:PAST turn:INF  
 “... for a while we continuously tried to cheat the wind by rowing sideways  
 artificially, ... but in vain, we still had to turn round...”  
 (from a letter by Miklós Bethlen, 1672)

- (23) *Kedveseb jószágunk nincsen az életnél*  
 more:dear value:our be:NEG:3SG the life:than  
*Halálnak sarcoló pénzt ha fizethetnél*

*Az mig kedved tartya, csak addig élhetnél.*  
 that as:longliking:your holds CSAK that:until live:could:2sg  
 “We have nothing valuable than our lives, If you could pay ransom to death,  
 Would you save any of your dearest properties, To be able to live just long as  
 you wish?”<sup>15</sup>  
 (from the poem *Murány Venus conversing with Mars*, by István Gyöngyösi, 1664)

The only analysis in the literature about the relation between the exclusive and the adversative interpretations of *csak* is from Simonyi (1881). According to him, the adversative interpretation of the particle developed from another discourse particle use of non-accented *csak* (which appears to be more directly derivable from the exclusive interpretation than from the adversative one), to be paraphrased as ‘without interruption’.<sup>16</sup> One of the examples Simonyi considers relevant is shown below:

- (24) *Akármit ragyogjon a nap, de csak nem lát a vak*  
 no:matter:how shine:SUBJ the sun but CSAK not see:3sgthe blind

<sup>15</sup> Literal translation, by the author.

<sup>16</sup> The relevant discourse particle use of *csak* is illustrated by Simonyi’s (1881:193) following example:

- i) *csak beszélek, csak beszélek neki, de hiába*  
 only talk:1sg only talk:1sg him but in:vain.  
 “I keep talking to him, but in vain.”

“No matter how strongly the sun shines, the blind cannot see.”

(*Proverb*, cited by Simonyi 1881: 193)

The scarcity of the relevant data available prohibits one from deciding whether this explanation is on the right track. Nevertheless, I can see two potential problems with it. On the one hand, there seems to be no evidence for the fact that the use of non-accented *csak* on which it is to be paraphrased as ‘without interruption’ is earlier than the adversative use. (Neither Benkő (1993–1997) nor Szabó T. (1978) discusses the former interpretation.) On the other hand, Simonyi’s account would predict that immediately after the adversative interpretation for *csak* arises historically, constructions where *csak* associates with an activity or a state verb (phrase) should be more numerous than those where it associates with other types of verb phrases or is followed by a non-verb focus (as in (23), for example). The data I could get hold of do not support this prediction.

The alternative I would like to put forth is to say that the adversative interpretation of the *csak* particle came about as a result of semantic reanalysis. I claim that the change was initiated by constructions where the exclusive particle appeared to make a vacuous contribution to the descriptive content of the sentence, and where its contribution to the presuppositions gave rise to pragmatic overload. Let us first consider two examples of the construction type at hand. The first example is from the description of a religious dispute, and the second from the memoirs of a Hungarian aristocrat, citing the words of his second wife having the same illness as the one his first wife died from:

(25) ... *ha a lovak magokban mind sánták, ha öszve fogjákis*  
if the horses alone:PL all lame:PL if together harness:also  
*tsak sánták.*

CSAK lame:PL

“... if the individual horses are all lame, they are still lame if they are harnessed together.”

(from the *Sárospatak Dispute*, 1660)

(26) ... *csak úgy jár kegyelmed énvélem, mint az első asszonnyal.*

CSAK so go:3sg you I:with than the first wife:with

“... you fare the same way with me as with your first wife after all.”

(from the *Biography of Miklós Bethlen*, before 1710)

The examples in (25)–(26) (viewed in the context of the preceding sentences) have the following common features. First, the alternative answers to the Current Question in the sense of (20) (in which the foci of *csak* are replaced for their alternatives) exclude each other, therefore, *csak* does not make a contribution to the descriptive contents of the sentences (since more than one alternative answers could not be true simultaneously anyway). Second, the reason why the speakers of these examples use the *csak* particle is compatible with the discourse function of exclusive particles according to Beaver and Clark (2008), cited in (20), which is to make a comment on the Current Question “which weakens a salient natural expectation”. The natural expectation in the case of (25) is that the horses harnessed together are something better than lame, whereas the expectation in the case of (26) is that the husband will fare better with the second wife than with the first one, who died. Given, however that, as clear from the relevant contexts, the ordering on the set of alternative answers is based on the desirability of the states of affairs described by them, and the prejacent of both sentences describe states of affairs that are considered the least desirable, the presupposition that should be introduced by the exclusive use of *csak* in these examples according to (20) is that all relevant alternative answers describe states of affairs that are considered equally bad or better than the one described by the prejacent. This is what gives rise to the pragmatic overload, since the use of *csak* forces the interpreter to assume that there are alternative answers that are ordered below the prejacent with respect to the desirability of the states of affairs described by them, although it is not clear from the context what these alternative answers could be.

In both contexts, given that the foci of *csak* refer to minimal quantities, claiming that the state of affairs described by the prejacent is less desirable than expected is equivalent to saying that the former state of affairs is less desirable than any state of affairs compatible with the negation of the prejacent. Therefore, when interpreters are faced with the pragmatic overload, they can reorganize the meaning of sentences like (25)–(26) in a way that *csak* becomes responsible for conveying that it was a salient natural expectation that the negation of the prejacent would be true. (This is equivalent to saying that in a sentence *S* with a propositional content  $\phi$ , *csak* conveys that Zeevat’s condition *normally*( $\neg\phi$ ) holds, as discussed above.) This component of the meaning of

the sentence cannot, however, be considered a presupposition any more, since it is not cancellable, and the use of the particle is obligatory whenever the context has properties of a particular kind. The particle thus acquires the function of a context marker, characterized in section 2.2 above following Zeevat (2003, 2006).

It is assumed that the interpretation of *csak* as an adversative context marker spread afterwards to all three sentence types where it can appear now (declaratives, *yes-no* interrogatives and imperatives), including structures where *csak* cannot have an exclusive reading at all. Two relevant constructions of the latter type are illustrated in the examples below. In (27), (accented) *CSAK* is followed by a universal noun phrase, and in (28) by a negated noun phrase, neither of which can be interpreted as being the focus of an exclusive particle:

(27) *CSAK mindenki Jánost hívta meg.*

CSAK everybody John:ACC invited VM

“Everybody invited John after all.”

(28) *CSAK nem Jánost hívták meg.*

CSAK not John:ACC invited VM

“It wasn’t John who got invited after all.”

We have yet to account for the obligatory accenting of the *csak* particle on its interpretation as an adversative context marker. I assume that it is due to information structural constraints: given that both the prejacent and its negation count as given information in the context, the single new piece of information within a *CSAK*-sentence is carried by the discourse particle, which is then marked by accenting.<sup>17</sup>

## 5. Conclusions

In this paper, the interpretation of the Hungarian accented *CSAK* discourse particle was investigated. I was argued that the necessary and sufficient conditions for its appearance in discourses indicate that it has the function of an adversative context marker, as proposed by Zeevat (2000, 2003, 2006). It was shown that a plausible motivation for the meaning change in the course of which the exclusive particle *csak* acquired this discourse particle use can be given by assuming Beaver and Clark’s (2008)

---

<sup>17</sup> I thank Manfred Krifka for suggesting this explanation.

analysis for the interpretation of exclusive *csak*, and a process of semantic reconstruction due to pragmatic overload, a process of semantic change, described by Eckardt (2006).

# Focus Particle *Mo* and *Many/Few* Implicatures on Numerals in Japanese

Chidori Nakamura

Iwate University  
3-18-34 Ueda, Morioka 020-8550 Japan  
chidori@iwate-u.ac.jp

## Abstract

Japanese focus particle *mo* expresses scalar implicatures similar to English *even* and the implicatures have been analyzed in literature relating to ‘likelihood/expectation’ for the occurrences of propositions. This paper investigates the ‘numeral-CL-*mo*’ construction where *mo* follows a numeral and means either *many* or *few*; and clarifies the nature of ‘unlikeliness’ given by *mo* in terms of the probability (Fernando & Kamp 1996) and the set of alternatives (Rooth 1985) of quantities. It is shown (i) syntactic categories and scope of *mo* determine possible interpretations, (ii) conventional implicature of *mo*-phrase, together with the order of probabilities, provides *many/few* interpretations.

**Keywords:** scalar implicature, focus, *many*, monotonicity, probability.

## 1. Introduction

Japanese postpositions *mo*, *sura*, *sae*, *demo*, called focus particles, express scalar implicatures similar to *even* in English, and their implicatures have been analyzed in literature with regard to ‘likelihood’ or ‘expectation’ for the occurrences of propositions (Numata 1986 etc.). Among these focus particles, *mo* productively makes various conventional implicatures (Grice 1975, Karttunen & Peters 1979), when following or preceding a case marker. While the sentence without *mo* in (1) simply means ‘ten students came,’ the first *mo* in (2) expresses either *also* or *even* and the second *many* so as to implicate ‘others than students came’ and ‘ten is many’ respectively.

- (1) *Gakusei-ga juu-nin ki-ta.*  
student-NOM ten-CL come-PST  
‘Ten students came.’

- (2) *Gakusei-mo*                      *juu-nin-mo*                      *ki-ta.*  
 student-NOM.mo.also/even    ten-CL-mo.many    come-PST  
 ‘Ten students also came. / Even ten students came. (Ten is many.)’

This paper deals with the ‘numeral-classifier-*mo*’ constructions (‘*n-CL-mo*’, henceforth), where *mo* follows quantities and means either *many* or *few* according to environments; and clarifies how the *many/few* interpretations and the scale of likelihood/expectation are determined.

It is known that the interpretations of focused numbers are affected by the polarity of sentences, for they are interpreted as *many* in affirmatives such as in (3), but *few* in quantifier negations as in (4).

- (3) *Gakusei-ga*    *juu-nin-mo*                      *ki-ta.*  
 student-NOM    ten-CL-mo.many    come-PST  
 ‘Ten students came. (Ten is many.)’

- (4) *Gakusei-ga*    *juu-nin-mo*                      *ko-nakat-ta.*  
 student-NOM    ten-CL-mo.few    come-NEG-PST  
 ‘Less than ten students came. (Ten is few.)’

The polarity, however, does not explain the sentences such as below, where *mo* in conditional indicates *few* without negation.

- (5) *Gakusei-ga*    *hutari-mo*                      *kure-ba*                      *juubunda.*  
 student-NOM    two\_person-mo.few    come-COND    enough  
 ‘If only about two students come, it’s enough. (Two is moderate.)’

For the unified account of these, we consider syntactic categories and scope (Karttunen & Peters 1979) of the focus particle *mo*, together with monotonicity (Barwise & Cooper 1981 etc.) of quantities, in section 2.

Regarding the meaning or implicature of the ‘*n-CL-mo*’, the *many* and *few* interpretations, as well as *even*, have been explained in literature in connection with ‘likelihood’ or ‘expectation’ (Numata 1986 etc.): so to say, they are either ‘unlikely many’ or ‘unlikely few’ different from expectations. This unlikeliness, which has been considered to be the reason behind the *many/few* interpretations and can be seen in the examples above, serves our interest too if we want to give *mo* a single meaning rather

than the two *many* and *few*.

However, it is not clear how the unlikeliness determines the likely quantities, since any quantity can be ‘likely’ depending on the situation. If we say ‘*only ten came*,’ ‘more than ten’ is likely; but in ‘*as many as ten came*,’ it is ‘less than ten.’ That is, the uni-directionality of expected quantities is not given by the unlikeliness alone, and we seem to have no explanation why, for instance, the *n-CL-mo* in affirmative sentences as (3) indicates only smaller quantities as likely ones. The notion of likelihood should be elaborated to the extent the uni-directionality of likely numbers is uniquely determined. In section 3, we give a single meaning to various quantifier-focus *mo*-phrases, including one in conditional sentences which express speakers’ expectations as in (5), making use of the probability function (Fernando & Kamp 1996) and the set of alternatives (Rooth 1985) of quantities.

In addition, the correlation between the three meanings of *mo*, i.e., addition, scale, and *many/few*, such as seen in (2) is considered. There seems to be no necessity that the same morpheme, *mo*, is used for them, since in other languages they are expressed by elements different from each other; but it is still possible to see the common part of their interpretations, for explaining the cognation of the three *mo*.

## 2. Scope and monotonicity

In the ‘*n-CL-mo*’ construction, *mo* gives an interpretation of either *many* or *few* to the focused number as in the following examples. In each case, the number of coming or not-coming is the same, *ten*, i.e.,  $|A \cap B| \geq 10$ , or  $|A \cap B| < 10$ , where *A* stands for a NP (set of students), *B* a VP (set of coming individuals), and *n-CL-mo*, which is a determiner in Generalized Quantifier theory, specifies the relation between *A* and *B* (Barwise & Cooper 1981, Zwarts 1983). The interpretations of *n-CL* and *n-CL-mo* in affirmatives are regarded as ambiguous between ‘*n or more*’ and ‘*exactly n*’, if not specified.

When focus particle *mo* precedes case or other postpositions, this pre-case *mo*, a kind of particle/postposition within a NP which could be called ‘*fuku joshi*’ or ‘*juntai joshi*’ in Japanese, is invariably interpreted as *many* in both affirmative and negative sentences as shown in (6) and (7). The difference between affirmation in (6) and VP negation in (7) does not affect the interpretation of *mo*.

(6) *Gakusei juu-nin-mo-ga ki-ta.*

student ten-CL-*mo*.many-NOM come-PST  
'Ten students came. (Ten is many.)'

(7) *Gakusei juu-nin-mo-ga ko-nakat-ta.*  
student ten-CL-*mo*.many-NOM come-NEG-PST  
'Ten students were absent. (Ten is many.)'

By contrast, post-case *mo* or 'kakari joshi' in Japanese which follows case postpositions or adverbials, expresses *many* in affirmations but *few* in quantifier negations as seen in (3) and (4), repeated here.

(3) *Gakusei-ga juu-nin-mo ki-ta.*  
student-NOM ten-CL-*mo*.many come-PST  
'Ten students came. (Ten is many.)'

(4) *Gakusei-ga juu-nin-mo ko-nakat-ta.*  
student-NOM ten-CL-*mo*.few come-NEG-PST  
'Less than ten students came. (Ten is few.)'

This correspondence of syntactic categories and *many/few* interpretations can be stated as (8) below.

- (8) Categories and interpretations of *mo*.
- (i) pre-case *mo* in affirmation / negation: *many*
  - (ii) post-case *mo* in affirmation: *many*
  - (iii) post-case *mo* in negation: *few*

Since the pre-case *mo*'s *many* interpretation is fixed irrespective of environments, we may regard this *mo* as a kind of postfix in NPs and its meaning, *many*, can be stated in the lexicon. On the other hand, the post-case *mo*'s different interpretations seem to be explained in terms of polarity, for negation provides *few* interpretations; but it does not hold in conditionals we have seen in (5). Here the notion of monotonicity (Barwise & Cooper 1981 etc.), either increasing or decreasing, deserves consideration, as both negation and conditionals affect monotonicity.

If we see the monotonicity in scalar entailments, i.e., logical material implications, of focused numbers, the rules as (9) can be seen: if *n* is increasing in an environment,

*mo* gives it a *many* reading, but *few* if decreasing. Negation and conditionals are operators which reverse monotonic directions, thus provide environments for *few* interpretations.

(9) Monotonicity and interpretation of *n-CL-mo*.

- (i) increasing *n-CL*: *n* is *many*
- (ii) decreasing *n-CL*: *n* is *few*

Accordingly, *mo* indicates *many* in (3) ‘*Gakusei-ga juu-nin kita (Ten students came),*’ since it logically implies ‘*gakusei-ga kyuu-nin kita (nine students came)*’; but *few* in quantifier negation in (4) ‘*Gakusei-ga juu-nin ko-na-kat-ta (Less than ten students came)*’ which implies ‘*gakusei-ga jyuuichi-nin ko-nakat-ta (less than eleven students came)*.’ The same applies for pre-case *mo*, which provides *many* interpretations for both affirmation in (6) and VP negation in (7); since the negation in VP does not affect the monotonicity outside of it, and ‘*Ten students were absent*’ implies ‘*nine students were absent*.’ Thus, (9) explains both pre-case and post-case *mo*.

And if we consider the scope of focus particle *mo*, various interpretations are explained in terms of the scope ambiguity: focus particles must have the scope for a proposition in which the alternatives of a focused element are embedded (Karttunen & Peters 1979, Rooth 1985), and this scope determines the monotonicity.

Following Karttunen & Peters (1979), the focus is indicated by capital letters and the scope of focus by [ ] in the examples below. In (10) and (11) the different scope produces different interpretations. If the scope excludes conditional subordinator *ba* as in (10), the numeral must have increasing monotonicity and *many* interpretation; whereas if it includes the conditional, the numeral is decreasing and *few* as in (11).

(10) [*Gakusei-ga JUU-NIN-mo kure*]-*ba totemo ureshii*.  
 student-NOM ten-CL-*mo*.many come-COND very happy  
 ‘If as many as ten students come, I’m very happy. (Ten is many.)’

(11) [*Gakusei-ga JUU-NIN-mo kure-ba juubunda*].  
 student-NOM ten-CL-*mo*.few come-COND enough  
 ‘If only about ten students come, it’s enough. (Ten is few.)’

The scope ambiguity also explains different interpretations in quantifier negations below. The bigger scope which includes negation in (12a) creates the decreasing

monotonicity thus *few* interpretation, while the smaller one without negation in (12b) does not change the increasing monotonicity and provides *many*.

(12) a. [*Gakusei-wa JUU-NIN-mo atumara-nakat-ta*].  
 student-TOP ten-CL-*mo.few* gather-NEG-PST  
 ‘Less than ten students gathered. (Ten is few.)’

b. [*Gakusei-wa JUU-NIN-mo atsumara*]-*nakat-ta*<sup>1</sup>.  
 student-TOP ten-CL-*mo.many* gather-NEG-PST  
 ‘Less than ten students gathered. (Ten is many.)’

Likewise, when both reversing operators, i.e., negation and conditional, appear in a single sentence, either one of *many* and *few* is chosen according to the scope, as seen in (13) below.

(13) a. [*Gakusei-ga JUU-NIN-mo atsumara-nakere*]-*ba kono-kurasu-wa*  
 student-NOM ten-CL-*mo.few* gather-NEG-COND this-class-TOP  
*hirake-nai*.  
 open-NEG  
 ‘If as few as ten students don’t gather, we can’t offer the class. (Ten is few.)’

b. [*Gakusei-ga JUU-NIN-mo atsumara*]-*nakere-ba kono-kurasu-wa*  
 student-NOM ten-CL-*mo.many* gather-NEG-COND this-class-TOP  
*hirake-nai*.  
 open-NEG

[*Gakusei-ga JUU-NIN-mo atsumara-nakere-ba kono-kurasu-wa*  
 student-NOM ten-CL-*mo.many* gather-NEG-COND this-class-TOP  
*hirake-nai*].  
 open-NEG  
 ‘If as many as ten students don’t gather, we can’t offer the class. (Ten is many.)’

---

<sup>1</sup> The same scope assignment as in (12b) applies if *mo* is followed by the focus particle *wa*, as in ‘[*Gakusei-wa JUU-NIN-mo-wa atsumara*]-*nakat-ta*. (Ten students did not gather. ten: many).’

In (13b), two different scopes are possible for a single *many* interpretation, the smaller affirmative one and the bigger conditional one; since the conditional which follows negation reverses the decreasing monotonicity and creates the increasing one.

Thus, we can conclude here it is the scope of *mo* which determines the choice of *many* or *few* interpretations; and can sum up the interpretations in sentences as follows. Negation and conditionals which are reversing operators change monotonicity within the scope of *mo*, so that among the sentences we have seen, only negative or conditional sentences can be ambiguous between *many* and *few* according to the scope of *mo*. Affirmative sentences and VP negations should have only *many* interpretations, for they have no reversing operators affecting monotonicity of quantity. As well, pre-case *mo*, which cannot scope over quantifier negation, indicates invariably *many*.

Next, we turn to the unified account of *many* and *few* readings.

### 3. The meaning of *n-CL-mo*

#### 3. 1. *Unexpectedness, moderation, and the co-occurrence restriction*

As seen earlier in the Introduction, the *many/few* interpretations are considered to be related to ‘unlikeliness’ or ‘unexpectedness’ in the literature. In addition to this, Numata (1986) pointed out that *mo* in conditionals as in (5) is used for ‘softening’ or ‘moderating’ quantities.

- (5) *Gakusei-ga hutari-mo kure-ba juubunda.*  
 student-NOM two\_person-*mo.few* come-COND enough  
 ‘If only about two students come, it’s enough. (Two is moderate.)’

The number *two* above is *few*, for it can be modified by *seizei (few)*, but it is clearly ‘expected’ within the speaker’s estimation, so that the notion of ‘unlikeliness’ or ‘expectation’ without clear definition does not seem to explain these sentences.

Moreover, *n-CL-mo*, different from the quantifier *takusan (many)*, very often focuses on the number *two* if the speaker has expected numbers fewer than *two*, i.e., *one* or *zero*, as in (14); but it never co-occurs with the number *one* or ‘additive determiner (Zwarts 1996)<sup>2</sup>, which designates the least quantities, even if the speaker has expected

---

<sup>2</sup> A function *f* from Boolean algebra *B* to *B\** is said to be additive iff for each two

zero as in (15).

(14) *Gakusei-ga hutari-mo ki-ta.*  
student-NOM two\_person-mo.many come-PST  
'Two students came. (Two is many.)'

(15) *Gakusei-ga \*hitori-mo ki-ta.*  
student-NOM one\_person-mo come-PST  
'One student came. (One is many/few.)'

By contrast, *mo* occurs with the smallest number to compose a negative polarity item in quantifier negation as in (16), so that 'anti-additivity (Zwarts 1996)<sup>3</sup>' in the least quantity in negative environments does not obstruct *mo*.

(16) *Gakusei-ga hitori-mo ko-nakat-ta.*  
student-NOM one\_person-mo.few come-NEG-PST  
'Not a single student came. (One is few.)'

These co-occurrence restrictions on determiners should also be explained by the meaning of *n-CL-mo*. In the following 3.2, the notion of probability, *many*, and *few* are defined, and in 3.3 the unified interpretation of 'quantifier-*mo*' is shown.

### 3.2. 'Many' and probability

The correlation of the notions *many* and 'expectation' has been studied in literature (Barwise & Cooper 1981, Keenan & Stavi 1986, Partee 1988 etc.) for clarifying the meaning of quantifier/determiner *many* in English as in 'Many students came,' since unstated quantities which satisfy *many* are determined according to expectations in context. Regarding the two different readings or reasons of *many*, i.e., a cardinal one and a proportional one, Partee (1988) claims (17), where some number *n* in a weak cardinal reading and some fraction *k* (between 0 and 1) in a strong proportional

---

elements *X* and *Y* of the algebra *B*:  $f(X \cup Y) = f(X) \cup f(Y)$ . A determiner such as *one* in 'One student came', which is a function on NPs, is called an additive determiner.

<sup>3</sup> A function *f* from Boolean algebra *B* to *B\** is said to be anti-additive iff for each two elements *X* and *Y* of the algebra *B*:  $f(X \cup Y) = f(X) \cap f(Y)$ . A determiner such as *no* in 'No student came,' which is a function on NPs, is called an anti-additive determiner.

one are determined by fixed context, thus extensionally.

- (17) (i) cardinal reading:  $many(A, B)$  iff  $|A \cap B| > n$   
(ii) proportional reading:  $many(A, B)$  iff  $|A \cap B| > k \cdot |A|$

As opposed to this simple extensionality, Fernando & Kamp (1996) presents the intensionalized interpretations of *many*, considering how different expectations determine the values of  $n$  and  $k$  in a given context. They claim that ‘ $n$   $C$ ’s are many when  $|C|$  could well have been  $< n$ ,’ and show the interpretations of the determiner *many* as follows,

$$(18) \text{ Many } x(\phi, \psi) \text{ iff } \bigvee_{n \geq 1} ((\exists_{\geq n} x)(\phi \wedge \psi) \wedge n\text{-is-many}_x(\phi, \psi))$$

where  $\phi$  and  $\psi$  represents the set  $A$  and  $B$  above.  $(\exists_{\geq n} x)(\phi \wedge \psi)$  gives an existential claim ‘there are at least  $n$   $x$ ’s which are  $\phi$  and  $\psi$  in the actual world,’ and  $n\text{-is-many}_x(\phi, \psi)$  concerns expectation or probability of  $n$ .

The cardinal reading of *many* is given by substituting  $n\text{-IS-MANY}_x$  in (19) below for  $n\text{-is-many}_x$  above.

$$(19) n\text{-IS-MANY}_x(\chi) \text{ iff "it is probable that } (\exists_{< n} x)\chi\text{"}$$

$$\text{iff } p(\{w : |\chi|_{x,w} < n\}) > c.$$

$|\chi|_{x,w}$  is defined as  $|x : \chi \text{ in } w|$  and the probability function  $p$  on sets of worlds counts the number of possible worlds accessible in the model where the number of  $\chi$ - $x$ ’s is less than  $n$ . The values of  $p$  and  $c$  are fixed independently of  $\chi$ , and if a value of the probability function (between 0 and 1) is greater than  $c$ , it is probable; thus the notion of ‘probable’ is defined here within the possibility throughout accessible worlds.

The proportional reading on the other hand, is defined as

$$(20) n\text{-is-many}_x(\phi, \psi)$$

$$\text{iff "it is probable, given there are } |\phi|_x \text{ } \phi\text{-}x\text{'s, that } (\exists_{< n} x)(\phi \wedge \psi)\text{"}$$

$$\text{iff } p(\{w : |\phi \wedge \psi|_{x,w} < n\} \mid \{w : |\phi|_{x,w} = |\phi|_x\}) > c,$$

where the conditional probability  $p(X/Y)$  of  $X$  given  $Y$ , and  $c$  determine a probable number, which can be different from one in cardinal reading, according to the number of  $\phi$ - $x$ ’s.

These notions of probabilities can be used for the *n-CL-mo* constructions as the

resolution of the controversial ‘unlikelihood’ seen earlier. First of all, let us define the determiner  $n$ -CL and  $\neg n$ -CL in verbal/adjectival/nominal predicate sentences to fix the existential readings of  $n$ , as below.

$$(21) \ n\text{-CL}_x(\phi, \psi) \quad \text{iff} \quad (\exists_{\geq n} x)(\phi \wedge \psi) \\ \text{iff} \quad |\phi \wedge \psi|_x \geq n.$$

Since  $n$ -CL is a weak intersectional determiner, it can be regarded as a unary predicate applied to  $\phi \wedge \psi$ . And  $|\phi \wedge \psi|_x$ , where no world is specified, represents the cardinality of  $x$ 's which are  $\phi \wedge \psi$  in the actual world. If  $n$  is *five*, it means ‘there are at least five  $x$ 's which are  $\phi$  and  $\psi$ .’ The interpretation of  $n$ -CL is ambiguous between ‘exactly  $n$ ’ and ‘at least  $n$ ’ if not stated explicitly: the ‘exactly  $n$ ’ readings in those predicate sentences which are given by conversational implicatures are cancelable (Grice 1975, Gazdar 1979), so that the literal meaning of  $n$ -CL ought to be ‘ $n$  or more.’ This seems to be because the default interpretation of cardinal determiners in verbal/adjectival/nominal predicate sentences such as ‘*Gakusei-ga go-nin ki-ta (Five students came)*,’ assures us of monotonic reasoning, whereas cleft-like sentences such as ‘*Kita gakusei-wa go-nin dat-ta (It was five students who came)*,’ force ‘exactly  $n$ ’ readings. (21) does not represent interpretations in cleft sentences, where *mo* rarely appears.

The negation within the negative determiner  $\neg n$ -CL ranges over only the determiner, so that  $\neg(\exists_{\geq n} x)(\phi \wedge \psi)$ , and it is defined as a complementary determiner of  $n$ -CL as below.

$$(22) \ \neg n\text{-CL}_x(\phi, \psi) \quad \text{iff} \quad (\exists_{< n} x)(\phi \wedge \psi) \\ \text{iff} \quad (|\phi \wedge \psi|_x < n).$$

If  $n$  is *five*, it means ‘there are less than five  $x$ 's which are  $\phi$  and  $\psi$ .’

Then, the interpretations of  $n$ -CL-*mo* and  $\neg n$ -CL-*mo* with the cardinal interpretation of *many* are defined as follows.

$$(23) \ n\text{-CL-mo-MANY}_x(\phi, \psi) \quad \text{iff} \quad n\text{-CL}_x(\phi, \psi) \wedge n\text{-IS-MANY}_x(\phi \wedge \psi) \\ \text{iff} \quad (\exists_{\geq n} x)(\phi \wedge \psi) \wedge \text{"it is probable that } (\exists_{< n} x)(\phi \wedge \psi) \text{"} \\ \text{iff} \quad |\phi \wedge \psi|_x \geq n \wedge p(\{w: |\phi \wedge \psi|_{x,w} < n\}) > c.$$

$n$ -CL-*mo*, which ought to have a *many* interpretation, is regarded here as a new unary predicate  $n$ -CL-*mo*-*MANY*, and its interpretation is given as a conjunction of  $n$ -CL and Fernando & Kamp's  $n$ -*IS-MANY*. If  $n$  is *five*, it means ‘there are at least five  $x$ 's which are  $\phi$  and  $\psi$ , and it is probable that less than five  $x$ 's are  $\phi$  and  $\psi$ .’ In the same manner, negative determiner  $\neg n$ -CL-*mo*, which has a *few* interpretation, is defined as

$\neg n$ -CL-mo-FEW, a conjunction of  $\neg n$ -CL and a new predicate  $n$ -IS-FEW as below.

$$(24) \neg n\text{-CL-mo-FEW}_x(\phi, \psi) \text{ iff } \neg n\text{-CL}_x(\phi, \psi) \wedge n\text{-IS-FEW}_x(\phi \wedge \psi) \\ \text{iff } (\exists_{<n}x)(\phi \wedge \psi) \wedge \text{"it is probable that } (\exists_{\geq n}x)(\phi \wedge \psi) \text{"} \\ \text{iff } |\phi \wedge \psi|_x < n \wedge p(\{w: |\phi \wedge \psi|_{x,w} \geq n\}) > c.$$

If  $n$  is *five*, it means ‘there are less than five  $x$ ’s which are  $\phi$  and  $\psi$ , and it is probable that five or more  $x$ ’s are  $\phi$  and  $\psi$ .’

The proportional *many/few* readings are also gained if the unary predicate  $n$ -IS-MANY and  $n$ -IS-FEW above are substituted with proportional ones as follows.

$$(25) n\text{-CL-mo-many}_x(\phi, \psi) \\ \text{iff } n\text{-CL}_x(\phi, \psi) \wedge n\text{-is-many}_x(\phi \wedge \psi) \\ \text{iff } (\exists_{\geq n}x)(\phi \wedge \psi) \wedge \text{"it is probable, given there are } |\phi|_x \text{ } \phi\text{-}x\text{'s, that } (\exists_{<n}x)(\phi \wedge \psi) \text{"} \\ \text{iff } |\phi \wedge \psi|_x \geq n \wedge p(\{w: |\phi \wedge \psi|_{x,w} < n\} \mid \{w: |\phi|_{x,w} = |\phi|_x\}) > c.$$

If  $n$  is *five*, (25) means ‘there are at least five  $x$ ’s which are  $\phi$  and  $\psi$ , and it is probable that less than five  $x$ ’s are  $\phi$  and  $\psi$ , provided the number of  $\phi$ - $x$ ’s is the same as that in the actual world.’ And negative counterpart is given in the same manner as below.

$$(26) \neg n\text{-CL-mo-few}_x(\phi, \psi) \\ \text{iff } \neg n\text{-CL}_x(\phi, \psi) \wedge n\text{-is-few}_x(\phi \wedge \psi) \\ \text{iff } (\exists_{<n}x)(\phi \wedge \psi) \wedge \text{"it is probable, given there are } |\phi|_x \text{ } \phi\text{-}x\text{'s, that } (\exists_{\geq n}x)(\phi \wedge \psi) \text{"} \\ \text{iff } |\phi \wedge \psi|_x < n \wedge p(\{w: |\phi \wedge \psi|_{x,w} \geq n\} \mid \{w: |\phi|_{x,w} = |\phi|_x\}) > c.$$

Here we seem to have appropriate interpretations for each  $n$ -CL-mo and  $\neg n$ -CL-mo. However, above definitions do not give us the fundamental reason why *mo* expresses *many* in a positive determiner, but *few* in a negative one, since it is not explained how the direction of probable elements, i.e.,  $(\exists_{<n}x)(\phi \wedge \psi)$  in (23) and (25), or  $(\exists_{\geq n}x)(\phi \wedge \psi)$  in (24) and (26), is determined. We go on to this problem next.

### 3.3. Alternatives in quantity

Focus particles indicate the existence or non-existence of other elements than focused elements through conventional implicatures (Grice1975, Karttunen & Peters 1979). In order to capture this function of *mo*-phrases, the set of alternatives (Rooth 1985) and the focused subexpression (Fernando & Kamp1996) and replacement of alternatives are defined as follows.

A determiner  $Q$  in  $Qx(\varphi, \psi)$  is a relation between  $x$ -extensions  $\{x: \varphi\}$  and  $\{x: \psi\}$  of  $\varphi$  and  $\psi$ .  $Q_e^a$  is a determiner obtained by replacing  $e$  in  $Q$  by  $a$ , where  $e$  is a focused subexpression in  $Q$ ,  $A$  is a set of alternative quantities,  $a$  is an alternative in  $A$ , and  $a, e \in A$ .  $Q$  is made up of a quantity, weak cardinal or strong proportional, which co-occurs with *mo*;  $e$  is either a part or the whole of the  $Q$ ; and  $A$  consists of only quantities resembling  $e$  in ‘the most similar worlds modulo  $a/e$  (Fernando & Kamp 1996)<sup>4</sup>.’

Then, *mo*-phrases of quantity, which express probability and *many/few*, are interpreted as in (27)<sup>5</sup>.

(27)  $Q\text{-mo}_x(\varphi, \psi)$

iff " $Qx(\varphi, \psi)$ , and for some  $a$  other than  $e$  in  $Q$ , it is probable  $Q_e^a x(\varphi, \psi)$   
but not  $Qx(\varphi, \psi)$ "

iff  $Qx(\varphi, \psi) \wedge \exists a((a \neq e) \wedge p(\{w: Q_e^a x(\varphi, \psi)\}) > c > p(\{w: Qx(\varphi, \psi)\}))$ .

In the second conjunct,  $\exists a((a \neq e))$  assures the existence of an alternative, i.e., some other quantity than the focused one, and the following

$$p(\{w: Q_e^a x(\varphi, \psi)\}) > c > p(\{w: Qx(\varphi, \psi)\})$$

determines uni-directionality of alternatives, employing the probability function and  $c$  and the relation ‘ $>$  (is greater than)’ seen in section 3.2. Here, ‘it is probable’ is defined as ‘higher probability than  $c$ ’ as in Fernando & Kamp (1996), and another definition ‘it is not probable’ as ‘lower probability than  $c$ ’ is added.

Probabilities of propositions with quantities in  $A$  constitute a weak partial order (transitive, reflexive, antisymmetric), together with a relation ‘ $\geq$  (is greater than or equal to)’<sup>6</sup>. For instance, probability of ‘four or more students come’ should be the same

<sup>4</sup> The clarification of the notion of ‘resemble’ and ‘similar world’ are beyond the scope of this study; and we simply assume here ‘if  $Q\text{-mo}$  is made up of a number,  $A$  also consists of numbers or proportions whose cardinality is calculable within the same cardinality of  $\varphi$ ’ adopting the postulation in Fernando & Kamp (1996) ‘the switch  $a/e$  (regarding the alternation  $\chi_e^a$ ) could be viewed intensionally as moving to a most similar world modulo  $a/e$ .’

<sup>5</sup> For displaying the scope and focus of *mo* seen in section 2,  $Q\text{-mo}_x(\varphi, \psi)$  in (27) can be replaced by  $\text{mo}(Q_{F^x}(\varphi, \psi))$ , where *mo*’s scope is shown by  $( )$ , the focus by  $F$ . Thus,  $Q\text{-mo}_x(\varphi, \psi)$  iff  $\text{mo}(Q_{F^x}(\varphi, \psi))$ . We use here the former concise one for simplicity.

<sup>6</sup> The order can be a chain (a total weak partial order), if the substitution occurs only within positive integers.

or higher than that of ‘five or more students come’ in every model/context, as the latter materially implies the former in each world; their probabilities are the same only if there is no possible world in which ‘exactly five students come’ is satisfied. The actual interpretation of *Q-mo* is always obtained in accordance with this probability order, since *Q-mo* must choose *a* within the order. The strong partial order with  $>$  in (27) is identical to the conjunction of a weak partial order with  $\geq$  and an unequal relation  $\neq$ :

$$\begin{aligned} p(\{w: Q_e^a x(\varphi, \psi)\}) &> c > p(\{w: Qx(\varphi, \psi)\}) \\ &\equiv (p(\{w: Q_e^a x(\varphi, \psi)\}) \geq c \geq p(\{w: Qx(\varphi, \psi)\})) \wedge \\ &\quad (p(\{w: Q_e^a x(\varphi, \psi)\}) \neq c \neq p(\{w: Qx(\varphi, \psi)\})). \end{aligned}$$

Thus, the interpretation of *Q-mo* contains the weak partial order which is identical to the order of probabilities<sup>7</sup>. This is the reason why monotonicity between logical implications of numerals affects interpretations as seen in section 2, since logical implications determine the probability order. It is also explained why monotonic reasoning is crucial for this construction, since it creates logical implications.

In (27),  $(a \neq e)$  is actually not needed: since their probabilities are different, they cannot be the same. Thus, (27) can be replaced by (27)' below, which is identical to (27) but the redundant  $(a \neq e)$  is omitted.

(27)' *Q-mo*<sub>*x*</sub>( $\varphi, \psi$ )

iff " $Qx(\varphi, \psi)$ , and for some *a* other than *e* in *Q*, it is probable  $Q_e^a x(\varphi, \psi)$   
but not  $Qx(\varphi, \psi)$ "  
iff  $Qx(\varphi, \psi) \wedge \exists a (p(\{w: Q_e^a x(\varphi, \psi)\}) > c > p(\{w: Qx(\varphi, \psi)\}))$  .

To gain the interpretation that ‘alternative numbers are likely but the focused number is unlikely,’ which gives only probable alternatives, *c* is placed between probabilities of *e* and *a*. For if there is no *c*,

$$p(\{w: Q_e^a x(\varphi, \psi)\}) > p(\{w: Qx(\varphi, \psi)\})$$

simply indicates existence of other possible quantity in either direction of the order without ‘probable’ property. It can choose appropriate direction by the partial order between probabilities in quantities, e.g., probability of ‘four or more  $\varphi$ -*x*’s are  $\psi$ ’ is the same or higher than that of ‘five or more  $\varphi$ -*x*’s are  $\psi$ .’ But it cannot specify ‘likely’ quantities as alternatives, since any number greater than *one* has this property of *e* if *a* is

---

<sup>7</sup> To put it differently, alternatives of *Q-mo* constitute a preordered (transitive, reflexive) subset of  $\mathbb{A}$  by the relation ‘probability of the proposition containing ... is greater than or equal to that of ...,’ and *mo* chooses *a* whose proposition’s probability is higher than *c* and that of *e*.

possible in at least one world.

Likewise, if not the probability of the focused number  $e$ , then

$$p(\{w: Q_e^a x(\varphi, \psi)\}) > c$$

expresses only ‘alternative number is likely,’ and we cannot have the information ‘the focused number is unlikely.’ It allows

$$p(\{w: Qx(\varphi, \psi)\}) > p(\{w: Q_e^a x(\varphi, \psi)\}) > c,$$

where  $e$  cannot be a maximal element in the order created by  $mo$ , thus ‘uni-directional alternation from the focused number’ is lost.

We employ only the cardinal reading of *many* above, since it is enough for choosing appropriate alternatives. Though the quantity in  $Q$  can be proportional, such as *gojup-paasento* (fifty percent) or *sanbun-no-ichi* (one third),  $Q$ -*mo* can choose appropriate alternatives, since in any world, the probability of, for instance, *yonjup-paasento* (forty percent) is the same or higher than that of *gojup-paasento* (fifty percent). Admittedly, the proportional reading, given the number of  $\varphi$ - $x$ ’s, provides another reason why the focused number is unlikely in an extensional manner as seen in section 3.2. But this also does not seem to be necessary for  $Q$ -*mo*, since the extensionality of determiner is already given by  $Q$ , and the implicated alternatives by  $mo$  can be any quantities which satisfy  $Q$ -*mo* in the speaker’s mind. If we take  $c$  as intentional,  $c$  can be more flexible in  $Q$ -*mo* according to subjective expectations of the speaker, and we do not have to specify each reason extensionally.

The interpretation of  $Q$ -*mo* above can provide the uni-directionality in both positive and negative polar, regarding both  $n$ -CL-*mo* and  $\neg n$ -CL-*mo* defined in (21) and (22) in 3.2 as  $Q$ ’s. If, for instance,  $e$  is *five* and  $A$  consists of numbers, the following interpretations in (28) and (29) are given to them respectively.

$$(28) \text{ 5-CL-}mo_x(\varphi, \psi) \\ = (|\varphi \wedge \psi|_x \geq 5) \wedge \exists a(p(\{w: |\varphi \wedge \psi|_{x,w} \geq a\}) > c > p(\{w: |\varphi \wedge \psi|_{x,w} \geq 5\})).$$

Provided  $e$  is *five*, it chooses  $a$  from numbers *one* to *four* as a probable one in the possible worlds, making use of the transitive probability order in  $A$ . If the sentence is ‘*Gakusei-ga go-nin-mo* kita (As many as five students came),’ the interpretation amounts to ‘it was probable that fewer than five students came, but in fact five students, which was not probable, came.’ Thus, it has both the interpretations, *many* and *unlikeliness*. If *five* appears in the negative determiner  $\neg n$ -CL-*mo* as in

$$(29) \text{--}5\text{-CL-mo}_x(\varphi, \psi) \\ = (|\varphi \wedge \psi|_x < 5) \wedge \exists a(p(\{w: |\varphi \wedge \psi|_{x,w} < a\}) > c > p(\{w: |\varphi \wedge \psi|_{x,w} < 5\})),$$

the numbers more than *five* are chosen as probable ones. And the sentence ‘*Gakusei-wa go-nin-mo ko-nakat-ta. (Less than five students came)*’ indicates ‘it was probable more than five students came, but in fact, less than five, which was not probable, came.’

If we look here at the co-occurrence restrictions mentioned earlier, the reason behind additive restriction on *n-CL-mo* is obvious: if *e* is the least quantity in a context as *one person*, no *a*’s which satisfy *Q-mo* exist in  $\mathbb{A}$ ; i.e., due to the transitive probability order, no quantities can have higher probability than *one person*. Zero and negative integers are not in  $\mathbb{A}$ , as they are unable to construct a determiner for persons in verbal/nominal/adjectival predicate sentences. Therefore, *1-CL-mo* cannot appear in affirmative sentences such as ‘\**hitori-mo kita (one person came)*.’ On the other hand, *2-CL-mo* and  $\neg 1\text{-CL-mo}$  are possible, if the probable numbers are *one* and more than *one* respectively. For this reason, ‘*one-CL-mo*’ amounts to a NPI in Japanese.

We seem to reach the same interpretation of *many* as Fernando & Kamp’s “*n-is-many*” by way of slightly different semantics. The *many* interpretation in adverbial *many* is expressed by the likeliness of the complementary event, i.e., the proposition created by the negative determiner ‘ $<n$ ’, which amounts to the negation of ‘ $\geq n$ ’. And since ‘ $<n$ ’ and ‘ $\geq n$ ’ make complementary events and *c* is assumed to be big enough, there is no need to express the unlikeliness of ‘ $\geq n$ ’. On the other hand, the semantics of *Q-mo* provides the likeliness/unlikeliness only through substitution of alternatives, thus we cannot compare ‘ $\geq n$ ’ with ‘ $<n$ ’, but the transitive order of probabilities gives us the same interpretation.

This substitution mechanism can specify alternative quantities within other monotonic environments created by conditionals as in (30), where *mo* has the widest scope<sup>8</sup>.

$$(30) Q\text{-mo}_x(\varphi, \psi) \rightarrow \omega \\ \text{iff } "Q_x(\varphi, \psi) \rightarrow \omega, \text{ and for some } a \text{ other than } e \text{ in } Q, \text{ it is probable} \\ Q_e^a x(\varphi, \psi) \rightarrow \omega, \text{ but not } Q_x(\varphi, \psi) \rightarrow \omega" \\ \text{iff } (Q_x(\varphi, \psi) \rightarrow \omega) \wedge \\ \exists a(p(\{w: Q_e^a x(\varphi, \psi) \rightarrow \omega\}) > c > p(\{w: Q_x(\varphi, \psi) \rightarrow \omega\})).$$

Since *mo* ranges over conditionals, the likely quantities are determined within the whole

---

<sup>8</sup> As well as (27),  $Q\text{-mo}_x(\varphi, \psi) \rightarrow \omega$  means  $\text{mo}(Q_F x(\varphi, \psi) \rightarrow \omega)$ , where the scope and focus of *mo* are explicitly shown.

$(\varphi, \psi) \rightarrow \omega$ . If  $e$  is *five* and  $A$  consists of numbers, it means

$$(31) \text{ 5-CL-mo}_x(\varphi, \psi) \rightarrow \omega \\ = (|\varphi \wedge \psi|_x \geq 5 \rightarrow \omega) \wedge \\ \exists a(p(\{w: |\varphi \wedge \psi|_{x,w} \geq a \rightarrow \omega\}) > c > p(\{w: |\varphi \wedge \psi|_{x,w} \geq 5 \rightarrow \omega\}))$$

where the likely numbers should be more than *five*. If the sentence is ‘*Gakusei-ga go-nin-mo kure-ba juubunda* (If only about five students come, it’s enough),’ with the widest scope of *mo*, it amounts to ‘it is probable if more than five or six or seven... come, it’s enough; but in fact, if five come it’s enough, which is not probable in other situations.’ Thus, it indicates *five* as moderation, and the *five* which is *not probable* here can co-occur with the speaker’s estimation ‘five will come,’ if the person can imagine many other possible worlds which are different from the estimation, since *probable* is determined on the number of possible worlds.

Provided  $Q$  is 10-CL or  $\neg$ 10-CL, the *many/few* interpretations in sentences seen in section 2 are correctly given. Only the sentence (12b), where the scope of *mo* is smaller than quantifier negation, is hard to explain with the definitions of the negative determiner and  $Q$ -*mo* above, since *mo* cannot be negated by the wider scope negation. We must leave it to future study.

### 3.4. ‘Many/few’, ‘even’, and ‘also’

Lastly, we look briefly here at the correlation of the three meanings of *mo* seen in the Introduction, i.e., addition *also*, scalar *even*, and *many/few*. If we eliminate the meaning of determiner  $Q$  from the interpretation of  $Q$ -*mo* in (27) to see the conventional implicature of *mo*, it is “for some other  $a$  than  $e$  in  $Q$ , it is probable  $Q_e^a x(\varphi, \psi)$ , but not  $Qx(\varphi, \psi)$ ,” thus,

$$\exists a((a \neq e) \wedge p(\{w: Q_e^a x(\varphi, \psi)\}) > c > p(\{w: Qx(\varphi, \psi)\})).$$

It indicates ‘the existence of some other alternative that is probable than the focused one,’ and this interpretation is identifiable as the meaning of the NP-focus scalar *mo*, which means *even* following nouns/individuals, since it also designates some other alternatives as probable, as in ‘*John-mo kita* (Even John came).’<sup>9</sup> We can regard that these *mo* have the same conventional implicature which employs the weak/strong partial

---

<sup>9</sup> Regarding the meaning of *even*, Rooth(1985) employed a unary predicate unlikely’( $p$ ) on propositions, while Krifka (1991) adopted a probability relation  $\langle p$ , whose left proposition is less/least probable.

order of probabilities, or the preorder of alternatives, but only the domains of focused elements or alternatives are different from each other: if the domain is a set of individuals, it means *even*, if a set of quantities *many* or *few*. The complementary distribution also suggests they can be the same.

In addition, the interpretation above amounts to

$$\exists a((a \neq e) \wedge Q_e^a x(\varphi, \psi) \wedge p(\{w: Q_e^a x(\varphi, \psi)\}) > c > p(\{w: Q_x(\varphi, \psi)\})),$$

where ‘the existence of alternatives in the actual world’ is expressed by  $Q_e^a x(\varphi, \psi)$ . It is brought by the logical implications of quantified sentences, e.g., ‘four or more students come’ has higher probability than ‘five or more students come,’ and it is logically implied by ‘five or more students come.’ Thus, the interpretation of *Q-mo* includes an existential claim of alternatives, which is the same as the existential interpretation of addition *mo*, i.e., *also*, as in ‘*John-mo kita (John also came)*,’ though the domains are different. In the case of scalar NP-focus *mo*, the existence of probable alternatives is assured not in the actual world but in the possible worlds; since ‘John came’ does not logically imply ‘others came,’ and it is possible to say ‘*John-mo kita-noni hokani daremo ko-nakat-ta (Even John came, but no others came)*.’

This common interpretation, i.e., the existence of alternatives in either the actual world or possible worlds, can be one of the reasons why the same *mo* is used for both the existential reading and scalar ones; since it is natural to assume that the similarities between interpretations support the cognation of different meanings of the same morpheme.

#### 4. Conclusion

We can summarize the claims in this paper as follows.

- (i) Syntactic categories and the scope of *mo* determine *many/few* interpretations, by affecting monotonicity.
- (ii) The monotonicity of focused elements is crucial in interpretations, since it determines the probability order, by which *mo* chooses alternatives.

## Abstract

In this paper, I show that numerals do not constitute a semantic scale, and that numerals themselves do not have the meaning of 'at least', as (neo-)Griceans claim. There are two kinds of scalarity in interpreting numerals. One is the basic scalarity among numerals and the other that of being unlikely. The direction of the latter is determined contextually, based on a sentence itself and background knowledge, which, in turn, determines the interpretation of a numeral by taking the numeral mentioned as a (upper/lower) limit value. This leads to the meaning of 'at most/least'. This scalarity applies to domains of quantification. When there is no explicit quantification involved in a sentence, the default quantification is quantification over epistemic alternatives. The basic scalarity applies to each case in a domain of quantification requiring us to consider only the maximal numbers of elements in the domain.

**Keywords:** numerals, 'at least', 'at most', scalarity, likelihood, domain of quantification, quantification over epistemic alternatives.

## 1. Introduction

Grice's (1961) maxim of quantity consists of two sub-maxims like the following:<sup>1</sup>

- Make your contribution as informative as is required for the current purposes of the exchange.
- Do not make your contribution more informative than is required.

The maxim applies to utterances with scalar expressions, and yields implicatures. Neo-Griceans assumed that a numeral  $n$  has the semantic meaning of 'at least  $n$ ': the semantic meaning of (1a) is (1b). On the other hand, it comes to be interpreted as (1d) because

---

1 The original maxim of quantity mentions the factor of relevance to the context. Later this factor is more or less ignored and informativeness is more focused, and the maxim has got other names like the Q-principle (Horn 1984 and Levinson 1987) or the principle of volubility.

the speaker is supposed to follow the maxim of quantity: the speaker would mention a larger number if he or she could assert a stronger statement with the larger number. Therefore we get the implicature like (1c).

- (1) a. John has three children.
- b. John has at least three children.
- c. NOT(John has more than three children)
- d. John has *exactly three* children.

However, this view is easily refuted by the following observations.<sup>2</sup> Numerals are different from other scalar terms.

- (2) A: Are many of your friends linguists?  
    B: ?No, all of them are.  
    B': Yes, (in fact) all of them are.
- (3) A: Do you have three children?  
    B: No, four.  
    B': ?Yes, (in fact) four.

If all of your friends are linguists, it is also true that many of your friends are linguists. So after you deny that many of your friends are linguists, you cannot claim that all of your friends are. On the other hand, you can claim that you have four children after you deny that you have three children, as shown in (3B). On the other hand, after you assert that you have three children, it is awkward to claim that you have four children, as shown in (3B').<sup>3</sup> A more convincing example from Horn (1996, 316) is the following:

- (4) a. ??Neither of us liked the movie – she hated it and I absolutely loved it.
- b. Neither of us have three kids – she has two and I have four.

Here loving a movie entails liking it. If neither of us liked the movie, neither of us loved it. On the other hand, having four children does not entail having three, as (4b) shows. This would be surprising if *three children* meant 'at least three children'. This shows that numerals do not constitute a semantic scale.

A second argument against the semantic interpretation of a numeral *n* as 'at least *n*' is that a numeral *n* can have an 'at most *n*', 'at least *n*' or 'exactly *n*' interpretation, depending on the context. Sadock (1984, 143) and Carston (1998) gives some examples involving modality in which a numeral has an 'at least' or 'at most' interpretation.

---

2 Cf.. Horn (1992, 1996), Koenig (1991), Atlas (1992), etc.

3 You may think of a situation in which the discourse becomes appropriate, but in general, a numeral tends to be focused, which has the effect of excluding other alternatives. In this example, if the number *four* is also relevant in the context, the discourse is odd. See the discussion of (10-11).

- (5) a. That golfer is capable of a round of 100 (and maybe even 90/\*110).  
b. Women with two pre-schoolers are eligible for the welfare benefit.

In the first example, the number 100 is interpreted as 'at most 100', so the possibility of 90 is allowed. In the second example, the number *two* has an 'at least' interpretation since people with more pre-schoolers are more likely to get the welfare benefit. When necessity is involved, a numeral tends to have an 'at least' interpretation, as the following examples show.

- (6) a. In Britain you have to be 18 to drive a car.  
b. Mary needs three A's to get into Oxford.

Breheny (2008) shows that the interpretation of a numeral is completely dependent on background knowledge. Consider the following example.

- (7) No one who has three children is happy.

In this example, the quantifier introduces a downward-entailing context, but the numeral has three possible readings, depending on background knowledge. In a context in which more children means more stress, the numeral is likely to have an 'at least' interpretation. But if more children means more benefits, it gets an 'at most' interpretation. Having four children is taken to be the minimal requirement to get some benefits. We can also think of a context in which a specific number of children, namely three children, make their parents unhappy. In this context the numeral *three* is interpreted as 'exactly three'. Breheny (2008) discusses this example to show that monotonicity does not affect the interpretation of a numeral, and that the main factor of determining the interpretation of a numeral is background knowledge.

One thing to note in (7) is that the example involves quantification. When there is no quantification or modality involved, a numeral generally has an 'exactly' or, less likely, 'at least' interpretation.<sup>4</sup>

- (8) A: who has three children?  
B: John has three children.  
B': John has three children, in fact he has five.

In (8B), the numeral *three* seems to have an 'exactly' interpretation, if B does not add anything. In (8B'), however, it has an 'at least' interpretation. One interesting fact is that in neither case can we get an 'at most' interpretation.

Despite this generalization, there is an example discussed by Krifka (1999) in

---

4 Example (8) seems incompatible with (3), but here *five* is not relevant in the first place. This allows the reply in (8B').

which a numeral has an 'at most' interpretation even without any quantifier involved.

(9) In Guatemala, 3 % of the population owns 70 % of the land. (Krifka 1999)

In this example, the number 70 has an 'at least' interpretation, but *three* has an 'at most' interpretation. We have to be able to explain why numerals in general do not have an 'at most' interpretations when there is no quantification involved. In addition, we have to explain why the numeral *three* in (9) has an 'at most' interpretation.

## 2. Previous Analyses

The problems with the classical analysis of numerals have been discussed by many linguists, including Carson (1998), Breheny (2008), Van Kuppevelt (1996a, 1996b), Horn (1992, 1996), Koenig (1991), Atlas (1992), etc. Among these, Carston (1998) claims that the meaning of a numeral is *underspecified*, like the following.

[ X [THREE] ], where the value of X is pragmatically determined.

(cf. Recanati (1989))

We have seen that the interpretation of a numeral depends on the context in which it is used, but simply saying that X is given by the context is not an explanation. We have to explain how the interpretation is determined. This is what I am doing in this paper.

Van Kuppevelt (1996a, 1996b) shows that whether a cardinal (or other scalar term) is given an “at least” or an “exactly” interpretation depends on whether the term is in the topic or the comment part of the information structure of the utterance.

(10) How many children does John have?

- a. He has three children.
- b. \*He has three children, in fact five.

(11) Who has three children?

- a. John has three children.
- b. John has three children, in fact he has five.

In (10), *three* is in the comment and has the 'exactly' interpretation. This does not allow the possibility that John has more than three children. In (11), however, the numeral has an 'at least' interpretation in the topic position of the sentence, which allows the possibility that John has five children. With these examples, he tried to show that interpretation of numerals is affected by information structure, another contextual factor.

However, this explanation has some problems. First, it is not explained how an 'at most' interpretation is possible. It does not seem to depend on information structure.

Second, Krifka (1999) refutes their claim with the following example.

(12) A: How many children does Nigel have?

B: Nigel has fourteen<sub>F</sub> children, perhaps even fifteen<sub>F</sub>.

Here *fourteen* is focused, but it does not lead to an 'exactly' interpretation: it allows the possibility that Nigel has fifteen children. This shows that focus itself does not exclude other alternatives. Ultimately, it depends on the speaker's knowledge or certainty.

Geurts (2006) gives a semantic analysis of the semantics of numerals. He assumes that the basic meaning of a numeral  $n$  is that of a predicate that applies to sum individuals, following Krifka (1999). In this usage, a NP with a numeral basically has an 'exactly' interpretation. He tries to explain an 'at least' interpretation in the way of type-shifting, as in Partee (1986).

(13) a.  $\|n \text{ CN}\| = \lambda P \exists !x[\#(x) = n \ \& \ \| \text{CN}\|(x) \ \& \ P(x)]$

b.  $\lambda x[\#(x) = n \ \& \ \| \text{CN}\|(x)]$  (Quantifier Lowering)

c.  $\lambda P \exists x[\#(x) = n \ \& \ \| \text{CN}\|(x) \ \& \ P(x)]$  (Existential Closure)

(13a) is the meaning of a NP with a numeral when it is used as an argument. As the operator shows, the basic meaning of a NP with a numeral is an 'exactly' interpretation. From this, we get the meaning of a NP with a numeral as a predicate, as given in (13b), by applying Quantifier Lowering. Then we can get (13c) as the meaning of a NP as an argument again, by Existential Closure. (13c) is compatible with the situation in which  $x$  is more than  $n$ , a case of an 'at least' interpretation. By the derivations, Geurts tries to explain how an 'exactly' or 'at least' interpretation of a numeral occurs.

Geurts explained these meanings based on semantic type-shifting, but an 'at most' interpretation cannot be derived by semantic type-shifting. He claims that it is derived pragmatically. However, there is no evidence for accounting for 'at least' interpretations semantically and 'at most' interpretations pragmatically. As will be shown below, interpretations of numerals are determined contextually, and even predicative uses of NPs with numerals can have 'at least' interpretations.

(14) These are five pills, if not six.

In a predicate use, *five pills* normally has the meaning 'exactly five pills', but in this example it has an 'at least' interpretation. So the interpretation of a numeral in a predicative is also a pragmatic matter: the speaker's uncertainty.

In this paper, I am going to account for how a numeral is interpreted in a pragmatic approach. To support my analysis, I am going to make several claims, which

refute some previous analyses of numerals. First, I show that numerals do not constitute a semantic scale, and claim that the meaning of 'at least/most' is not part of the meaning of a numeral itself. There are two kinds of informativeness based on two kinds of scalarity: the basic scalarity among numerals and a contextual scalarity of likelihood. The basic scalarity requires the speaker or hearer to consider the maximal numbers of elements. The contextual scalarity comes in when some quantification is involved. It requires the speaker to provide a limit value in a set of the maximal numbers of elements in a context, and the limit number  $n$  is taken to be 'at least  $n$ ' or 'at most  $n$ ', when the scalarity is combined with lack of information, depending on the direction of scalarity. If no quantification is involved, quantification over epistemic alternatives is the default option. If no uncertainty is involved, a numeral has an 'exactly' interpretation.

### 3. Pragmatics in Using Numerals

#### 3.1 Evidence against semantic scalarity

First, numerals do not constitute a semantic scale. Suppose that John juggles with balls. And for some reasons, it is impossible to juggle with an odd number of balls.

(15) A: Anyone who can juggle with more than six balls can participate in the competition. Does John juggle with six balls?

B: Yes, he does. He can even juggle with ten balls.

In this example, *six* means '*at least* six', but B's answer does not entail that John can juggle with five or seven balls. Note that an 'at least' interpretation does not have anything to do with semantic scalarity.

Suppose one boy ate three apples, and two boys two apples each. (Krifka 1999)

(16) a. Three boys ate seven apples.

b. Two boys ate six apples.

In a given context, (16a) does not entail, or pragmatically imply, (16b). Accumulation is not a semantic process. When numerals constitute a scale, the set is determined in the context, not inherently in the language system. There are cases where numerals behave as if they constituted a semantic scale. This is related to the fact that the event of reading five books includes the subevent of reading four books. But this is still pragmatic because the inclusion relation is pragmatically restrained.

### 3.2. 'At least/most' not part of semantics

In some previous analyses, the meanings like 'at least/most' are part of the meanings of numerals. However, this is not the case. The same numeral can have different meanings depending on background knowledge. As I said, the interpretation of the numeral *three* in (7) depends on which context the sentence is uttered in. However, the number itself does not seem to have the meaning of 'at least' or 'at most'. One piece of evidence is that the three interpretations are always available, whether or not the relevant scales are semantic or pragmatic.

- (17) a. You must (at least) like studying maths if you want to do well in maths.  
b. You may (at most) watch her dance(, but you may not dance with her).  
c. No one who (at most) like studying maths do well in maths.  
d. No one who (at least) like studying maths fail in maths.

Here the expressions in parentheses indicate the possible interpretations of *like studying maths*. It is unlikely that *like studying maths* itself means 'at least/most like studying maths'. This shows that the meaning of 'at least' or 'at most' is not inherent part of the meanings of numerals.

In (7), it is clear that directions of contextual scalarity are determined by *background knowledge plus the whole sentence*, and that the relevant factor is also informativeness: the less likely the utterance, the more informative it is. If more children means more stress, the order of being less likely to hold is like the following:

Ordering of being less likely:  $1 > 2 > \mathbf{3} > \dots > n-1 > n$

This means that the smaller the number, the more informative the sentence becomes. When a number  $x$  is mentioned in the sentence, it means that the *lower* limit number  $x$  such that no one who has  $x$  children is happy is three, so it gets the meaning of 'at least'.

Now if we change the sentence as in (18), the direction of scalarity changes.

- (18) People who have three children are happy.

Since more children means more stress, the ordering of the sentence being less likely to be true is like the following:

Ordering of being less likely:  $n > n-1 > \dots > \mathbf{3} > 2 > 1$

In this context *three* is taken to be the *upper* limit number  $x$  such that people who have  $x$  children are happy. The numeral mentioned gets the meaning of 'at most three'.

Now we consider the two sentences with different background knowledge. Suppose that more children means more prosperity. Then the direction of scalarity

changes as below, and the numeral gets an 'at most' interpretation.

Ordering of being less likely:  $n > n-1 > \dots > \mathbf{3} > 2 > 1$

As to (18), the direction of scalarity is as follows:

Ordering of being less likely:  $1 > 2 > \mathbf{3} > \dots > n-1 > n$

And the numeral three is understood as meaning 'at least three'. This indicates that the direction of scalarity changes with background knowledge and the whole utterance, and that the numeral itself does not have the meaning of either 'at most' or 'at least'. Therefore the meanings like 'at least' and 'at most' must be associated with the whole sentence. So the meanings of the two sentences can be represented as follows:

AT\_LEAST/MOST[No one who has three children is happy]

AT\_MOST/LEAST[People who have three children are happy]

We can say a similar thing about sentences in which modality is involved. Suppose that people want to eat more apples. In this context, the numeral in the following sentence is interpreted as 'at most three'.

(19) You may have three apples.

If people want to eat more apples, you are less likely to give a permission of allowing people to have more apples. So the ordering of being less likely is the following:

(20) Ordering of being less likely:  $n > n-1 > \dots > \mathbf{3} > 2 > 1$

The larger the number, the stronger the permission becomes. So the number mentioned is taken to be the upper limit number  $x$  such that the speaker can allow the hearer to eat  $x$  apples. This can be expressed as follows:

AT\_MOST[You may have three apples]

The same thing happens to an obligation statement: (21a) is likely to mean (21b).

(21) a. You must have three apples.

b. AT\_MOST[You must have three apples]

Suppose that people want to solve fewer problems. Then it is less likely that permission or obligation statements are made with a smaller number. So the ordering of being less likely is like the following:

Ordering of being less likely:  $1 > 2 > \mathbf{3} > \dots > n-1 > n$

In this context, the statements in (22) are interpreted as those in (23).

(25) You may/must solve three problems.

(26) AT\_LEAST[You may/must solve three problems]

The discussion so far shows that a numeral does not have the meaning of 'at least' or 'at most'. It is not assumed that a numeral has an 'exactly' interpretation in the sense that statements with alternative numerals do not hold, either. A numeral mentioned is selected based on the basic scalarity among numerals, which will be discussed, with the exceptions where the maximal number based on the basic scalarity is irrelevant in the context, as in (11). A numeral has an 'at least' or 'at most' interpretation depending on how the context as whole is structured. This is discussed in the the following section.

#### 4. 'At least/most' Interpretations and Domains of Quantification

When the scalarity of being unlikely applies, the numeral itself does not have the meaning 'at least' or 'at most'. When a statement with a numeral is uttered, the context is structured into sub-contexts with respect to alternatives of the numeral. Each sub-context provides a domain of quantification. That is, the statement itself is associated with a certain domain of quantification, each of the alternatives introducing alternative potential domains of quantification. The alternative domains of quantification are ordered with respect to a scalarity like unlikelihood. If the context as a whole is structured directionally and the speaker is not quite sure about the other alternatives, the domain for the statement with the numeral mentioned is taken to be a limit case, and alternative propositions are implicated which are relevant to alternative domains of quantification and are more likely to hold, and other alternative propositions which are less likely to hold are excluded from the context. The basic assumption here is that a statement with a numeral itself has no implications about other numerals: that is, a numeral itself does not have an 'at least' or 'at most' interpretation.

I claim that an 'at least' or 'at most' interpretation is obtained when alternative statements with larger numbers or smaller numbers are more likely to hold. A numeral in a statement itself does not have such an interpretation. This idea can be clear when bare numerals are compared with numerals preceded by *at least* or *at most*. In general, when sentences with numerals have 'at least/most' interpretations, we get the same meanings by putting 'at least/most' before the numerals.

- (24) a. AT\_LEAST/MOST[No one who has three<sub>F</sub> children is happy]  
b. No one who has at least/most three children is happy.
- (25) a. AT\_LEAST[John must solve three problems]  
b. John must solve at least three problems.
- (26) a. AT\_MOST[John may eat three apples]

b. John may eat at most three apples.

Here (24-26a) have the same meaning as (24-26b), respectively. In the following two pairs, however, the second sentences do not seem appropriate.

(27) a. AT\_MOST[John must eat three apples]

b. ?John must eat at most three apples.

(28) a. AT\_LEAST[John may solve three problems]

b. ?John may solve at least three problems.

In the (a)-statements, *must* and *may* have narrower scope than AT\_MOST/LEAST, while in the (b)-statements, they have wide scope over *at most three apples* and *at least three*. AT\_LEAST/MOST can be attached to a sentence even when *at least/most* before a numeral cannot. Now we have to explain why the (b)-statements are not natural.

In (25a), *must* has narrower scope than AT\_LEAST. This means that there are other alternative domains in which the statement with a larger number is likely to hold. This is the situation in which if the domain is extended to include cases where John solves more than three problems, then it is true that John solves (at least) three problems in every possible world in the extended domain. This is a context we can utter (25b) appropriately.

In (27), the two statements have different interpretations. In (27a), *must* has narrower scope than AT\_MOST. This means that there are other potential domains of quantification in which it is likely that John must eat less than three apples. This means that the domain of quantification can be extended to include cases where John eats less than three apples. Then John eats three apples in some possible worlds and less than three apples in others in the extended domain. This context is not appropriate for uttering (27b). It is more appropriate for a statement like 'John may eat three apples'. (27b) is awkward because there is no context in which it can be uttered appropriately.

The intended meaning can be expressed with the following sentence instead.

(29) John must eat three apples at most.

Here the expression *at most* is equivalent to the operator AT\_MOST. The sentence means that the upper limit of the numbers of apples John must eat is three. This implicates that there are possibly other domains in which it is likely that John must eat fewer than three apples, which is understood as meaning that the upper limit of the numbers of apples John eats must be three.

A similar reasoning can apply to permission statements. (26a) means that *three* is the upper limit of the numbers of apples John may eat. There may be other domains of quantification in which John eats less than three apples. This is the situation in which if

the domain is extended to cover cases where John eats less than three apples, John eats three or fewer apples in some possible worlds in the extended domain. This is why we can say (26b) appropriately.

(28a), on the other hand, means that there are other possible domains in which it is likely that John may solve four or more problems. Then if the domain is extended, there are possible worlds in the extended domain in which John solves more than three problems, together with those in which John solves less than three. The situation is not appropriate for (28b) because *three* in this situation is not a limit value. (28b) is awkward because there is no context in which it is appropriately uttered.<sup>5</sup> For this reason, (28a) is, together with its scalar implicatures, understood as meaning that John may solve only three problems.

So far I have shown that obligation statements require numerals with 'at least' interpretations, and permission statements those with 'at most' interpretations, and in such cases, they have corresponding sentences with *at least/most* before numerals. With other interpretations, they do not have corresponding sentences with *at least/most* before numerals, because the latter cannot be uttered appropriately. AT\_LEAST/MOST is always possible because it only applies to a domain for the numeral mentioned.

## 5. Informativeness from the Basic Scalarity

There are two kinds of scalarity which apply to two different areas. I have discussed informativeness with respect to the scale of being less likely. In some sense, uttering a sentence which is less likely to be true is uttering a pragmatically stronger sentence. However, linguists have been more concerned with the more basic scalarity among numerals: the event of solving three problems includes that of solving two problems, unless the context excludes the possibility that the two numbers are relevant

---

5 One thing to explain is why (28a) does not allow John to solve less than three problems. The implicature is that it is not appropriate to say that John may solve less than three problems. This is understood as meaning that John is not allowed to solve less than three problems. This is contrasted with (27a), which implicates that it is not appropriate to say that John must eat more than three apples. It is understood as implicating that John must not eat more than three apples, not that John does not have to eat more than three apples. This is related to the observation that a scalar implicature is derived sometimes locally and sometimes globally. As for scalar implicatures, see Chierchia (2004), Sauerland (2004), Russell (2006), etc.

in the context. Informativeness from the basic scalarity requires us to consider only the maximal number of problems solved.

(30) a. John must solve three problems.

b.  $\Box \exists x[\#(x) \geq 3 \ \& \ \text{problems}(x) \ \& \ \text{solve}(j,x)]$

c. John must solve two problems.

d.  $\Box \exists x[\#(x) \geq 2 \ \& \ \text{problems}(x) \ \& \ \text{solve}(j,x)]$

The meaning of (30a) can be represented as (30b), but pragmatically it is supposed to mean that John must solve at least three problems. On the other hand, if there is an event of John solving three problems, it is also true that there is an event of John solving two problems. In the current context, however, we cannot say that John must solve two problems. We only consider the maximal numbers of problems John solves in every possible world. The numeral is taken to be the lower limit of the maximal numbers. That is, the scalarity from being less likely applies to domains of quantification, while the basic scalarity applies to each case in a domain of quantification, independently of the scalarity of unlikelihood.

This can apply to cases of quantification over individuals. Consider (7) again. When more children means more stress, the sentence means that no one who have at least three children are happy. In the domain of quantification, we have people who have three children. Having three children means having two children too, but we only consider the maximal numbers of children each person in the domain has. The number mentioned is taken to be the lower limit among the maximal numbers of children which people in the domain of quantification have, on the basis of the (un)likelihood scalarity.

The same distinction applies to cases where numerals have an 'at most' interpretation: the number mentioned is taken to be the upper limit, and it is the one in a set of maximal numbers.

(19) John may eat three apples.

$\Diamond \exists x[\#(x) \leq 3 \ \& \ \text{apples}(x) \ \& \ \text{eat}(j,x)]$

(31) John may eat two apples.

$\Diamond \exists x[\#(x) \leq 2 \ \& \ \text{apples}(x) \ \& \ \text{eat}(j,x)]$

(31) may follow from (19) pragmatically. Here again we only consider the maximal number of apples John eats in each possible world. 3 is the upper limit among them. The upper limit among the non-maximal numbers of apples people eat makes no sense at all. In (7), if the numeral has the interpretation of 'at most three', it must be the upper limit of the maximal numbers of children people have. We can say the same thing about (21a). The discussion so far indicates that the scalarity of being unlikely applies to domains of quantification, whereas the basic scalarity among numerals themselves applies to each

case in the quantification domain. And the latter works whether a numeral takes an 'at least' or 'at most' interpretation. This means that it does not determine the meaning of a numeral itself.

## 6. Statements with no Quantification Apparently Involved

So far I have claimed that numerals can be understood as meaning 'at least/most' or 'exactly' when there are domains of quantification involved. In the case, the basic scalarity among numerals is the only factor that works in the context. As I said, this scalarity does not determine the interpretation of a numeral. However, a sentence with no quantification involved can have 'at least' interpretations in general. Even 'at most' interpretations are possible in some exceptional cases, as in (9). This implies that even when no explicit quantification seems involved, there is some kind of quantification involved implicitly.

One such candidate is universal quantification over epistemic alternatives. As will be discussed below, the meaning 'at least/most' is related to lack of knowledge in some sense, and all statements inherently involve quantification over epistemic alternatives. Under the assumption of quantification over epistemic alternatives, a statement uttered in a context is taken to be what the speaker can assert *at least* in the current information state. Thus the default 'at least' interpretation arises from epistemic necessity, just as obligation statements require numerals to have 'at least' interpretations.

This is how the numeral in (32) gets an 'at least' interpretation.

(32) John ate three apples.

$n > n - 1 > \dots > \mathbf{3} > 2 > 1$

Here 3 is the upper limit. Even if the speaker can assert a weaker statement, the sentence does not mean that John ate at most three apples. Applying the epistemic necessity to the statement, we can get the following meaning.

AT\_LEAST[  [John ate three apples]]

With the universal quantifier, *three* has an 'at least' interpretation. We might coerce an 'at most' interpretation, but it would just mean that John ate only three apples.

We can apply the same reasoning to (9), and an 'at most' interpretation is derived. In (9), the relevant scale is the following:

*strongest*

<1,100>   <2, 100>   <3, 100>   <4, 100>   ...   <100, 100>

<1, 99>	<2, 99>	<3, 99>	<4, 99>	...	<100, 99>
...	...	...	...	...	
<1, 70>	<2, 70>	<3, 70>	<4, 70>	...	<100, 70>
<1, 69>	<2, 69>	<3, 69>	<4, 69>	...	<100, 69>

The actual statement includes the pair <3, 70>, where 3 is the lower limit and 70 is the upper limit, compared with other possible statements the speaker can assert. Then does the sentence mean that *at least* 3 % of the population owns *at most* 70 % of the land? In the correct meaning, the numbers have the opposite meaning. How is this explained? The answer is universal quantification over epistemic alternatives again.

[In Guatemala, 3 percent of the population owns 70 percent of the land]

With the universal quantifier , the pair of numbers is taken to be the lower limit and the statement must be taken to have the minimal strength.

AT\_LEAST[  [In Guatemala, 3 % of the population owns 70 % of the land]]

This opens the possibility that the statement can be strengthened further: that is, 3 can become smaller and 70 can become larger. So 3 has an 'at most' interpretation, while 70 has an 'at least' interpretation.

## 7. So-called 'Exactly' Interpretations

So-called “exactly” readings obtain when all the other alternative numbers are excluded. There are two such cases. One is cases where scalarity lies in the background but it is known that other alternatives are not appropriate to assert, and the other is cases where the context is structured in a way that no scalarity is involved. In (33) the numeral *only three* is understood as having two meanings.

(33) John ate only three apples.

(33) means that John ate no more than three apples, or that the number of apples John ate is only three, not two or four. The former is a scalar reading, which is more plausible, and the latter is, less likely, a non-scalar reading. Even in the former case, we do not say that the numeral has an 'at least/most' interpretation, because the speaker knows that John did not eat two or four apples. In neither case can we say that the numeral has different interpretations. This shows that so-called 'exactly' interpretations are obtained when the speaker knows that the other alternatives are excluded, regardless of whether

numerals constitute scalar terms or not.

## 8. Conclusions

In this paper I have shown that numerals do not have 'at least/most' interpretations. Such interpretations occur pragmatically when contexts provide such interpretations. Behind these interpretations lies directional likelihood with respect to numerals: the larger the numeral, the more or the less likely the whole sentence is to hold. In some sense, the less likely the statement, the more informative it is. However, there is another factor of informativeness: something like 'eating three apples includes eating two apples'. This always works in the basic cases which constitute a domain of quantification, regardless of whether the informativeness from likelihood applies in a set of domains of quantification or not. In cases where no explicit quantification is involved, we can assume that implicit universal quantification over epistemic alternatives is involved. This also leads to some limit interpretation of the numeral mentioned in a statement, the lower limit in general. Conclusively, an 'at least/most' interpretation arises when the numeral mentioned is taken to be a limit value.

# Partition Semantics and Pragmatics of Contrastive Topic

**Katsuhiko Yabushita**

Naruto University of Education  
Naruto, Tokushima 772-8502, Japan  
yabuchan@naruto-u.ac.jp

## Abstract

Two existing approaches to the semantics and the pragmatics of contrastive topic (CT) will be examined to be shown that neither of them is adequate enough because one cannot account for what the other can; moreover, there is a garden-variety class of CT sentences that is problematic to both of them. Against a backdrop of this, an alternative approach will be proposed couched in the (dynamic) partition semantics of questions and answers proposed by Groenendijk and Stokhof. The alternative approach will be demonstrated to be able to handle the class of CT sentences in question as well as capture the insights of both existing approaches, thus having the best of both worlds so to speak.

**Keywords:** contrastive topic (CT), semantics, pragmatics, partition semantics of questions and answers

## 1. Introduction

To the semantics and pragmatics of contrastive topic, there have been two approaches proposed in the literature: one is to take contrastive topic as an information-structural discourse regulating notion on a par with focus (Roberts 1996, Büring 1999, Kadmon 2001) and the other is to analyze a contrastive marker, phonetic or morphological as an focus-sensitive operator with its inherent semantic and pragmatic content (Lee 1999, 2006, Hara 2006, Oshima 2002). In the current work, we will review the two approaches and show that both of them have empirical problems; then, we will present an alternative analysis of contrastive topic couched in the so-called partition semantics of questions proposed by (Groenendijk & Stokhof 1984, Groenendijk 1999). It will be seen that the proposed analysis has the best of both worlds so to speak, being empirically more adequate than the existing analyses of either approach. A word is in order about the marking of Contrastive Topic. Crosslinguistically, there are more than one way of marking CT; by means of, e.g. a morpheme like *-wa* in Japanese and *-nun* in Korean and H\*LH% or L+H\*LH% tone (Pierrehumbert 1980) in English. In the following, a CT-marked constituent is marked with subscript CT or a CT-marker morpheme (*wa* in Japanese).

## 2. Two Existent Approaches to Contrastive Topic

### 2.1. CT as an information-structural discourse-regulating device

(Roberts 1996, Büring 1999, Kadmon 2001)

Consider the question-answer discourse in (1). It is intuitively clear that CT has much to do with the fact that the questions and the answer are congruent with each other as they occur in the order in which they do. The congruence can be described as follows: (1c) directly answers (1b), and (1b) is a sub-question of (1a), or to use Robert's terms, (1b) is part of "strategy of inquiry" aimed at answering (1a).

- (1) a. Who kissed whom?  
b. Well, who did Larry kiss?  
c. [Larry]<sub>CT</sub> kissed [Nina]<sub>F</sub>

Büring proposed that a contrastive topic induces a third type of semantic value besides ordinary and focus semantic values, called *topic* semantic value. He proposed that the topic semantic value of an expression is the set of alternatives of the focus semantic value in the sense of Rooth (1985, 1991). Then, the topic semantic value of a declarative sentence is a set of sets of propositions, i.e. a set of questions; the topic semantic value of (1c) is (2).

- (2) {‘Who did Larry kiss?’, ‘Who did Bill kiss?’, ‘Who did John kiss?’, ...}

Kadmon (2001) argued the focus and the topic semantic values for (1c) can account for the congruence in question; first, the focus semantic value of (1c) being equal to the ordinary value of (1b) is considered to be a formal semantic characterization of (1c) being a direct answer to (1b), and second, (1b) being an element of the topical semantic value of (1c), which is the set of the subquestions of (1a) accounts for the intuition that (1c) answers (1b) as part of "strategy of inquiry" aimed at answering (1a).

The above analysis of CT as an information-structural discourse-regulating device seems to be very successful as long as it is applied to sentences with one instance of CT and one instance of focus like (1c). However, in Japanese, there are simply garden-variety examples with more than one instance of CT and/or with no instance of fo-

cus like (3).<sup>1</sup> The apparent problem here is that the denotation type of topic semantic value, i.e. a set of questions cannot be assigned to such examples.

- (3) John wa Mary wa Bill ni wa shookai-shi-ta.  
           CT          CT          to    CT  introduction-do-Past  
       ‘John<sub>CT</sub> introduced Mary<sub>CT</sub> to Bill<sub>CT</sub>.’

## 2.2 CT as a focus-sensitive operator

### 2.2.1 Lee (1999, 2006) & Hara (2006)

The other approach takes CT to be a focus-sensitive operator on a par with particles like English *even*, *only*, and *also*, or their counterparts in the other languages. Lee (1999, 2006) and Hara (2006) proposed the following analysis of CT:

- (4) Semantics and Pragmatics of CT as a Focus-Sensitive Operator  
 a.  $CT(\langle \beta, \alpha \rangle)$  (semantic representation)  
 b.  $\beta(\alpha)$  (assertion)  
 c.  $\exists x[x \neq \alpha \wedge \neg[\beta(x)]]$ . (conventional implicature)

A word is in order about the notations in (4). First, in (4a), which is the semantic representation of a sentence with a CT,  $\langle \beta, \alpha \rangle$  is the structured meaning of the sentence with  $\beta$  and  $\alpha$  being the background and the focus parts, respectively. Second, in (4b), which is the assertion of the sentence,  $\beta(\alpha)$  is the result of function-applying  $\beta$  to  $\alpha$  or  $\alpha$  to  $\beta$  whichever is possible, being the ordinary semantic meaning of the sentence. The part of (4c) is supposed to capture the so-called “Reversed Polarity Implicature” (henceforth RPI) of CT; a sentence with a CT-marked constituent tends to imply a “contrasting” sentence with the constituent replaced with an alternative and of the opposite polarity. However, the matter of fact is that the alleged implicature can be absent as seen in (5), which should not be the case if it were really a conventional implicature.

- (5) John wa kita ga sonohokano hito ni-kanshite wa shira-nai.  
           CT  came but the other people about CT know-not  
       ‘[John]<sub>CT</sub> came, but as for the other people, I don’t know whether they came.’

---

<sup>1</sup>Noah Constant (p.c.) informed me that in English, he can think of examples that have two CT’s without a focus, but he hasn’t seen any examples with three CT’s.

### 2.2.2 Oshima (2002)

The above problem, in fact, can be got around by Oshima's (2002) variant in which the pragmatic feature of a CT sentence is not a conventional implicature, but the presupposition that there is some alternative to the CT-marked constituent such that it is not known that it has the property denoted by the background part, formalized as in (4c').

- (4) c'.  $\exists x[x \neq \alpha \wedge \neg[\beta(x)]]$  (presupposition), where  $\neg$  is a weak negation in three-valued logic.

However, it is doubtful that (4c') is a presupposition of a CT-sentence. Consider the following question-answer dialog:

- (6) Q: Dare-ga paatii-ni ki-mashi-ta ka.  
who-Nom party-to come-Polite-Past Q  
'Who came to the party?'

- A: Jon-wa ki-mashi-ta (kedo).  
John-CT come-Polite-Past (but)  
'John<sub>CT</sub> came.'

According to (4c'), at the time of the utterance of (6A), it would be presupposed that somebody other than John is not known to have come to the party or not. From which it follows that the questioner would be required to have the presupposition. However, the matter of fact is that simply, the utterance of (6A) is perfectly felicitous in contexts where she does not have the presupposition, or is rather more natural without the presupposition.

Independently of Oshima (2002), Hara & van Rooij's (2007) proposed a very similar analysis. They proposed that CT should have as its pragmatic component the following implicature, which is reformulated in our terms as in (4c'')

- (4) c''.  $\exists x[x \neq \alpha \wedge \neg K_{sp}[\beta(x)]]$  (implicature)

In (4c''),  $K_{sp}$  is an epistemic operator and ' $K_{sp}\phi$ ' is read as "the speaker knows that  $\phi$ ". (4c'') is different from (4c') only in that the absence of the relevant knowledge is required only of the speaker and the requirement is a conventional implicature, not a presupposition. However, it is as easy to find counterexamples for Hara & van Rooij's version as for Oshima (2002). Consider the following scenario. A test was administered to

a class of pupils, the teacher knows of all the pupils who passed the test or not, and the father of Mary, a pupil, who is rather nosy, asks the teacher who passed the test. To the question, the teacher can answer perfectly felicitously as in (7).

(7) Mary-wa goukakushimashi-ta ga,  
Mary-CT pass (the test)-Past but

(hokano seito nikanshite-wa iemase-n.)  
other pupils as-to-CT can-tell-not

‘Mary<sub>CT</sub> passed the test, (but I can’t tell as to the others if they passed it or not).’

In (7), the speaker, i.e. the teacher knows of all the students including Mary if they passed the test or not, but she can felicitously utter “Mary<sub>CT</sub> passed the test”, which is contradictory to Hara & van Rooij’s prediction. The use of CT in (7) is not so much characterized as ignorance on the part of the speaker as confidentiality, or secrecy.

The fact that the implicational/presuppositional features of CT sentences are very elusive, or hard to identify, I claim, suggests that they are not inherent attributes of the meaning of CT, but epiphenomena arising from some unique feature of CT in conjunction with their particular uses. Along the line of this view, I will propose a novel approach to CT in the following section. Before we move on to the new approach, let us review that CT sentences like (3) are problematic to the currently reviewed approach as well.

Let us summon (3) again.

(3) John wa Mary wa Bill ni wa shookai-shi-ta.  
CT CT to CT introduction-do-Past

‘John<sub>CT</sub> introduced Mary<sub>CT</sub> to Bill<sub>CT</sub>.’

In the current approach, which views CT as a focus-sensitive operator, (3) will necessarily be taken to have three instances of the operator, so the semantic representation will be alleged to be something as in (8).

(8) CT( $\langle\lambda x$ .CT( $\langle\lambda y$ .CT( $\langle\lambda z$ .INTRDUCED-TO(x, y, z), bill)), mary)), john))

Simply, it is by no means clear what (8) would mean in any of the analyses along with

the current approach, or more seriously what implicature or presupposition (8) would be associated with.

In the next section, we will propose an alternative approach to CT that can capture the insights of both of the existing approaches, yet will be free from the problems to them.

### **3. Alternative Approach: Partition Semantics and Pragmatics of Contrastive Topic**

#### *3.1. Partition Semantics and Pragmatics of Question and Answer: Groenendijk (1999), Groenendijk & Stokhof (1984)*

In this section, we will briefly review a semantic framework in which our current analysis of CT will be couched. It is a dynamic-semantic analysis of question and answer; specifically, one presented in Groenendijk (1999). The gist of the analysis is that not only indicative sentences but also interrogative sentences are interpreted as context change potentials (CCP). To accommodate interrogative sentences, contexts cannot be simply sets of possible worlds as in Stalnaker (1978); instead, they are now defined as equivalence relations on a set of possible worlds as follows:

(9) Definition (*Context*)

A context is an equivalence relation on a subset of the set of possible worlds.

To define the CCP of an interrogative sentence we first specify the *abstract*, or *predicate* meaning of the interrogative sentence.

(10) Definition (*Abstract, or Predicate Meaning of an Interrogative*)

The predicate meaning of an interrogative sentence is a lambda abstract binding the variables substituted for the WH-phrases in the interrogative sentence. (When there is no WH-phrase, i.e., the interrogative sentence is a YES-NO question, the predicate meaning is a proposition denoted by the corresponding declarative sentence.)

The predicate meanings of interrogative sentences will be illustrated with the following examples:

(11)

<u>Interrogative sentences</u>	<u>Predicate meanings</u>
a. ‘Who came to the party?’	$\lambda x.\text{came-to-the-party}'(x)$
b. ‘Who bought what?’	$\lambda y\lambda x.\text{bought}'(x, y)$
c. ‘Who ate what at which place?’	$\lambda z\lambda y\lambda x.\text{ate-at}'(x, y, z)$
d. ‘Did John come to the party?’	$\text{came-to-the-party}'(j)$

In general, when there are  $n$  WH-phrases in an interrogative sentence, the predicate meaning of the interrogative sentence is an  $n$ -place predicate; notably, when there is no WH-phrase, i.e., the interrogative sentence is a YES-NO question as in (11d), the predicate meaning is a 0-place predicate, i.e. a proposition. In terms of structured meaning approach to focus, the predicate meaning of an interrogative sentence coincides with the background part of the background-focus meaning.

Now that contexts and predicate meanings of interrogative sentences have been defined, we can proceed to define CCPs of interrogative sentences.

(12) Definition (Context Update by Interrogatives)

Suppose that  $\lambda\bar{x}\phi$  is the abstract meaning of an interrogative and  $C$  is a context. The update of  $C$  by the interrogative, denoted  $C + \lambda\bar{x}\phi$  is defined as follows:

$$C + \lambda\bar{x}\phi = \{\langle w, w' \rangle \in C : \llbracket \lambda\bar{x}\phi \rrbracket^w = \llbracket \lambda\bar{x}\phi \rrbracket^{w'}\}.$$

In words, given a context  $C$  and an interrogative sentence whose predicate meaning is  $\lambda\bar{x}\phi$ , updating  $C$  with the utterance of interrogative sentence turns  $C$  into an equivalence relation between possible worlds with respect to their extensions of  $\lambda\bar{x}\phi$ . In terms of partition,  $C$  will be partitioned into the cells of possible worlds such that every possible world in each cell has the same extension of  $\lambda\bar{x}\phi$  with one another.

Let us illustrate how the update works diagrammatically. Suppose that  $C$  is a context in which  $w_1$ ,  $w_2$ , and  $w_3$  are compatible with what has been known so far, i.e.,  $C = \{\langle v, u \rangle : v, u \in \{w_1, w_2, \text{ and } w_3\}\}$ , which is represented as in (13).

(13)

$$C = \left\{ \begin{array}{ccc} \langle w_1, w_1 \rangle & \langle w_2, w_1 \rangle & \langle w_3, w_1 \rangle \\ \langle w_1, w_2 \rangle & \langle w_2, w_2 \rangle & \langle w_3, w_2 \rangle \\ \langle w_1, w_3 \rangle & \langle w_2, w_3 \rangle & \langle w_3, w_3 \rangle \end{array} \right\}$$

Suppose, furthermore, that John came to the party in worlds  $w_1$  and  $w_2$  and he didn't in  $w_3$ . Then, the update of  $C$  with the utterance of 'Did John come to the party?', whose predicate meaning is **came-to-the-party'(j)** results in the following context,  $C'$ , which is diagrammed as in (14).

$$(14) \quad C + \text{came-to-the-party}'(j) = C' = \left\{ \begin{array}{ll} \langle w_1, w_1 \rangle & \langle w_2, w_1 \rangle \\ \langle w_1, w_2 \rangle & \langle w_2, w_2 \rangle \\ & \langle w_3, w_3 \rangle \end{array} \right\}$$

In the form of partition,  $C'$  is diagrammed as in (15).

$$(15) \quad C + \text{came-to-the-party}'(j) = C' = \begin{array}{|l} \hline \text{(the set of possible worlds where} \\ \text{John came to the party} \\ \hline \text{(the set of possible worlds where} \\ \text{John didn't come to the party} \\ \hline \end{array}$$

Having reviewed how a context is to be updated with an interrogative sentence, let us move on to the case of indicative sentence. The CCP of an indicative sentence is defined as in (16).

(16) Definition (Context Update by Indicatives)

Suppose that  $\psi$  is the meaning of an indicative sentence and  $C$  is a context. The update of  $C$  by the indicative sentence denoted  $C + \psi$  is defined as follows:

$$C + \psi = \{ \langle w, w' \rangle \in C : \llbracket \psi \rrbracket^w = \llbracket \psi \rrbracket^{w'} = 1 \}.$$

What the utterance of an indicative sentence does to a context is to eliminate from  $C$ , the ordered pairs of possible worlds such that the indicative sentence is false in one or both of the possible worlds. In terms of partition, it eliminates from a partition, the cells of possible worlds in which the indicative sentence is false.

Let us illustrate the update of a context with the utterance of an indicative sentence as defined in (16) going over some examples. Recall context  $C'$ , which has been updated with 'Did John come to the party?', i.e. (14), a set of ordered pairs of possible worlds, or equivalently, (15), a partition of a set of possible worlds. The update of  $C'$  with e.g. (17) '(Yes,) John came to the party' (**came-to-the-party'(j)**) will be illustrated as in

(18) and (19), where John came to the party in possible worlds  $w_1$  and  $w_2$ , but not in  $w_3$ .

(17) (Yes,) John came to the party:  $\text{came-to-the-party}'(j)$

(18)

$$C': \left\{ \begin{array}{cc} \langle w_1, w_1 \rangle & \langle w_2, w_1 \rangle \\ \langle w_1, w_2 \rangle & \langle w_2, w_2 \rangle \\ & \langle w_3, w_3 \rangle \end{array} \right\} + (17) = \left\{ \begin{array}{cc} \langle w_1, w_1 \rangle & \langle w_2, w_1 \rangle \\ \langle w_1, w_2 \rangle & \langle w_2, w_2 \rangle \end{array} \right\}$$

(19)

$$C': \begin{array}{|l} \hline \text{John came to the party} \\ \hline \text{John didn't come to the party} \\ \hline \end{array} + (17) = \begin{array}{|l} \hline \text{John came to the party} \\ \hline \end{array}$$

Next, let us go over the case of a WH-question. In the following, we will solely adopt the partition format for the ease of illustration. Suppose that  $C$  is to be updated with e.g. (11a), an interrogative sentence with one occurrence of WH-phrase, which will be reproduced here as (20), resulting in  $C''$  in (21). There, it is assumed that John and Mary are the only relevant people to consider whether they came to the party or not, and the block with  $\{a_1, a_2, \dots, a_n\}$  represents the cell for the set of possible worlds in which  $a_1, a_2, \dots, a_n$  and only  $a_1, a_2, \dots, a_n$  came to the party.

(20) 'Who came to the party?':  $\lambda x.\text{came-to-the-party}'(x)$

(21)

$$C'' = \begin{array}{|c|c|} \hline \{John, Mary\} & \{John\} \\ \hline \{Mary\} & \emptyset \\ \hline \end{array}$$

The results of updating  $C''$  with e.g. (22) and (23) will be as shown in (24)<sup>2</sup>.

(22) Meari to Jon ga ki-mashi-ta.

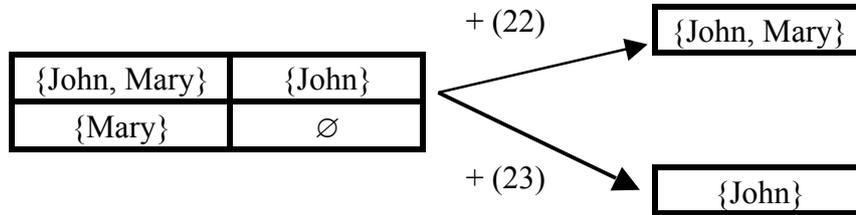

Mary and John Nom come-Polite-Past

'Mary and John came.'

<sup>2</sup>Here it is assumed that sentences (22) and (23) are interpreted exhaustively as they share the same focus structure with (20).

(23) Jon ga ki-mashi-ta.  
 John Nom come-Polite-Past  
 ‘John came.’

(24)

Following is the case of a WH-question with two WH-phrases:

(25) Dare ga nani o tabe-mashi-ta ka.  
 who Nom what Acc eat-Polite-Past Q  
 ‘Who ate what?’

Suppose that the domains of the eaters and the eatees relevant here are {John, Mary} and {hamburger, salad}, respectively. Then, the context resulting from updating C with (25) will be something as in (26) in terms of partition, where each cell represents the set of possible worlds in which for each ordered pair, the person of the first coordinate ate the foods of the second coordinate and no other eating events obtained.

(26)

$\langle j, \{h, s\} \rangle, \langle m, \{h, s\} \rangle$	$\langle j, \{h\} \rangle, \langle m, \{h, s\} \rangle$	$\langle j, \{s\} \rangle, \langle m, \{h, s\} \rangle$	$\langle j, \emptyset \rangle, \langle m, \{h, s\} \rangle$
$\langle j, \{h, s\} \rangle, \langle m, \{h\} \rangle$	$\langle j, \{h\} \rangle, \langle m, \{h\} \rangle$	$\langle j, \{s\} \rangle, \langle m, \{h\} \rangle$	$\langle j, \emptyset \rangle, \langle m, \{h\} \rangle$
$\langle j, \{h, s\} \rangle, \langle m, \{s\} \rangle$	$\langle j, \{h\} \rangle, \langle m, \{s\} \rangle$	$\langle j, \{s\} \rangle, \langle m, \{s\} \rangle$	$\langle j, \emptyset \rangle, \langle m, \{s\} \rangle$
$\langle j, \{h, s\} \rangle, \langle m, \emptyset \rangle$	$\langle j, \{h\} \rangle, \langle m, \emptyset \rangle$	$\langle j, \{s\} \rangle, \langle m, \emptyset \rangle$	$\langle j, \emptyset \rangle, \langle m, \emptyset \rangle$

### 3.2. Partition Semantics and Pragmatics of Contrastive Topic

Now that we have reviewed the partition semantics of questions and answers presented in Groenendijk (1999), I will propose to apply it for a novel analysis of contrastive topic. The thesis is intuitively as follows. The use of a sentence with contrastive topics “pre-supposes” a question under discussion (QUD), explicit or implicit; however, the sentence does not directly answer the QUD, but a “sub-question” derived from the QUD by

restricting the values of the WH phrases to the denotations of the contrastive topics. The implicational/presuppositional features observed surrounding CT are to be attributed to reasons why the speaker opts to answer the sub-question instead of the QUD.

Following is our analysis of the semantics and the pragmatics of CT. First is the semantic component:

(27) *Semantics of CT*

Suppose that

- (i)  $\gamma$  is a sentence with CT marked phrases,
  - (ii)  $?\text{-}\gamma$  is the interrogative sentence directly corresponding to  $\gamma$  in that only the focused phrases are replaced by the corresponding WH-phrases and if there are no focused phrase,  $?\text{-}\gamma$  is a polar interrogative sentence,
  - (iii) the sequence of the semantic representation of the CT-marked phrases and that for the variables for the WH-phrases are denoted  $\vec{t}$ , and  $\vec{x}$ , respectively,
  - (iv) the predicate meaning of  $?\text{-}\gamma$  is  $\lambda\vec{x}.R$ ,
  - (v)  $wh\text{-}\gamma$  is the interrogative sentence resulting from  $\gamma$  by replacing the CT marked phrases as well as the focused phrases if any with the corresponding WH-phrases,
- and,
- (vi) the sequence of the variables for the WH-phrases corresponding to the CT marked phrases is denoted  $\vec{y}$ .

Then,

- (vii) the predicate meanings of  $wh\text{-}\gamma$  is  $\lambda\vec{y}\lambda\vec{x}.R[\vec{t}/\vec{y}]$ , where  $R[\vec{t}/\vec{y}]$  is the result of replacing  $\vec{t}$  in  $R$  with  $\vec{y}$ .

Next is the pragmatic component:

(28) *Pragmatics of CT*

Sentence  $\gamma$  explicitly or implicitly assumes interrogative sentence  $wh\text{-}\gamma$  as QUD;

however, the answerer, or the utterer of  $\gamma$  opts to answer  $?-\gamma$  instead of *wh- $\gamma$*  for some reason.

Let us illustrate the current analysis by going over (1), which is reproduced here as (29).

- (29) a. Who kissed whom?
- b. Well, who did Larry kiss?
- c. [Larry]<sub>CT</sub> kissed [Nina]<sub>F</sub>

Let us recall the original observation about the congruity among the sentences in (29) made by Roberts (1996). That is, (29c) directly answers (29b), and (29b) is a “sub-question” of (29a), or to use Roberts’ terms, (29b) is part of “strategy of inquiry” aimed at answering (29a). And we have reviewed Kadmon’s account of the congruity with reference to CT in terms of Büring’s *topic meaning* and Rooth’s *focus meaning*. The account roughly went as follows. The focus meaning of (29c) and the ordinary meaning of (29b) are identical, which makes (29c) a congruent “direct” answer to (29b). The ordinary meaning of (29b) is an element of the topic meaning of (29c), whose generalized union is identical to the ordinary meaning of (29a). This warrants (29b) to be a sub-question of (29a).

The above account of CT as a discourse-regulator based on *focus* and *topic* meanings seems quite reasonable for what I call “canonical” examples of CT, i.e. sentences with exactly one instance of CT phrase and exactly one instance of focused phrase. However, as we have demonstrated with example (3), in Japanese, there are commonly sentences in which more than one instance of CT phrase and no apparent focused phrase occur. To those “non-canonical” examples of CT sentences, Roberts-Büring-Kadmon’s line of analysis cannot be extended.

Now let us go back to our current analysis and see how it can account for the workings of CT in relation to the congruity displayed in discourse (1). The CT sentence in question here, (29c) is  $\gamma$  in (27). Thereby, (29b) and (29a) correspond to  $?-\gamma$  and *wh- $\gamma$*  in (27), respectively. For the characterization that (27c) is a “direct” answer of (27b) and (27b) is a “sub-question” of (27a), there have already been relevant notions worked out in the theory which the current analysis is couched in, i.e. the semantic theory of questions and answers by Groenendijk & Stokhof (1984) and Groenendijk (1999). The relevant notions are *complete answer* and *partial answer*. Given a partition of the set of possible worlds induced by the predicate meaning of an interrogative sentence as in (12),

each block of the partition as a proposition represents a *complete* (and exhaustive) answer to the question, while the union of some but not all blocks is a *partial* answer, eliminating some blocks as not being the case. In terms of those semantic notions of answerhood, the following fact holds of  $?-\gamma$  and  $wh-\gamma$ :

(30) Every complete answer to  $?-\gamma$  is a partial answer to  $wh-\gamma$ .

It is reasonable to take *complete answer* to be a formal rendition of “direct answer” and to define that question  $Q_1$  is a “sub-question” of  $Q_2$  when every complete answer to  $Q_1$  is a partial answer to  $Q_2$ . From this and (30), it follows that  $\gamma$  (as interpreted exhaustively) is a direct answer to  $?-\gamma$  and  $?-\gamma$  is a sub-question of  $wh-\gamma$ ; in particular, (29c) is a direct answer to (29b) and (29b) is a sub-question of (29a). In this sense, the current semantic analysis of CT is as adequate as Roberts-Büring-Kadmon’s in characterizing the congruity among the sentences in (29). In fact, I contend that the current analysis is superior in that it is applicable to the “non-canonical” examples of CT sentences like (3) as well. Note that in the semantic rules of CT in (27), there is no restriction on the number of CT phrases (other than at least one) or of focused ones in a sentence. Thus, CT sentences with more than instance of CT and no apparent focused phrase like (3) will pose no problems to the current analysis, unlike to the Roberts-Büring-Kadmon’s. For example, (3) will be analyzed as  $\gamma$  with  $?-\gamma$  and  $wh-\gamma$  being ‘Did John introduce Mary to Bill?’ and ‘Who introduced who to whom?’, respectively.

We have shown that our current analysis of CT can capture Roberts’ original insights of CT as a discourse-regulator as adequately as Roberts-Büring-Kadmon’s; in fact, it is superior in that it can deal with the “non-canonical” examples as well as the “canonical” ones. Next, we will see how the current analysis fares with the other existent approach to CT, specifically, how it can account for the implicational/presuppositional features surrounding CT. In Section 2.2, we have reviewed the existing analyses along the line of the approach to CT that takes CT to be a focus-sensitive operator with some implicature or presupposition attached. For any of them, we have demonstrated that it is easy to find a counterexample to the alleged implicational/presuppositional contents, or that they are cancelable. Although, of course, the fact alone does not invalidate the approach per se, we also have pointed out that “non-canonical” examples of CT sentences will be problematic to the approach in question as well because it is by no means clear what their associated implicatures or presuppositions will be like.

In the current approach we take the position that there is no implicational or pre-

suppositional content that is hard-wired in the meaning of a CT sentence. Rather, we propose that what seems to be implicational or presuppositional features characteristic of CT be actually conversational implicatures arising from the use of a CT sentence instead of the corresponding non-CT version of the sentence. The clause relevant here is (28), *Pragmatics of CT*, which says that the use of a CT sentence indicates that instead of answering a QUD, the speaker opts to answer one of its sub-questions for some reason. Our contention is that what has been observed and claimed to be (conventional) implicatures and presuppositions of CT sentences is actually conversational implicatures due to particular reasons why the speaker chooses to answer a sub-question instead of the QUD itself. At this point, I don't know if there is any fixed number of reasons for the use of CT sentence or if there is, how many of them there are. We will not attempt to resolve this issue, for this is not directly relevant to the point of the paper. In the following we will put forward some, but enough reasons to cover what has been proposed to be the implicational/presuppositional features of CT in the literature.

For illustration, let us use the following CT sentence and interrogative sentences for  $\gamma$ , *wh*- $\gamma$ , and  $?$ - $\gamma$  in (27) as a case example.

- (31)  $\gamma$ : Jon-wa paatii-ni ki-mashi-ta.  
 John CT party-to come-Polite-Past  
 'John<sub>CT</sub> came to the party.'
- (32) *wh*- $\gamma$ : Dare-ga paatii-ni ki-mashi-taka ka  
 who-Nom party-to come-Polite-Past Q  
 'Who came to the party?';  $\lambda x$ .came-to-the-party'(x)
- (33)  $?$ - $\gamma$ : Jon-wa paatii-ni ki-mashi-taka ka  
 John-CT party-to come-Polite-Past Q  
 'Did John come to the party?'; came-to-the-party'(j)

According to the current theory, the utterance of (32) "presupposes" interrogative sentence (32), or the question denoted by it as QUD; however, instead of directly answering the question, the speaker answers interrogative sentence (33) for some reason. As in Section 3.1, suppose that the relevant domain of discourse is {John, Mary} and assume the diagrammatic conventions for partitions adopted there. Then, the partition representing the context updated with (32) is  $C''$  in (21), which is reproduced in (34).

(34)

$$C'' = \begin{array}{|c|c|} \hline \{John, Mary\} & \{John\} \\ \hline \{Mary\} & \emptyset \\ \hline \end{array}$$

On the other hand, the partition for the context updated with (33) is  $C'$  in (15), which is equivalently reproduced as in (35) to highlight its contrast with  $C''$ . In  $C'$ , the upper block and the lower one represent the set of possible worlds where John came to the party and that where John didn't, respectively and both of the blocks are non-committal about whether the other people, in this case, Mary came to the party or not.

(35)

$$C' = \begin{array}{|c|c|} \hline \{John, Mary\} & \{John\} \\ \hline \{Mary\} & \emptyset \\ \hline \end{array}$$

The question here is why the speaker opts to resolve the issue represented by  $C'$  instead of that by  $C''$ .

*Possible Reason 1: Lack of Information*

As to John, the speaker knows for sure that he came to the party, but for the other people, in this case, Mary, she doesn't know if they came to the party. So she restricts her assertion only to that John came, shying away from the issue as to whether the other people came to the party or not. This will nicely account for the continuation displayed in (36).

- (36) Jon-wa/#ga paatii-ni kita ga,  
John-CT/Nom party-to came but  
sonohokanohito nikanshitewa shira-nai.  
the-other-people about know-not  
'John<sub>CT</sub> came to the party, but I don't know about the other people.'

This feature of CT, i.e. that it can be used when the speaker doesn't have enough information to resolve the original question under consideration, is what Oshima's (2002) analysis and Hara & van Rooij's, (2007) took a special notice of and tried to capture. If the answerer uttered (37) instead of (31) in the state of information described above, she

would be taken by the hearer to imply that no other people came to the party due to the exhaustification mechanism (See van Rooij & Schulz 2006 for a formal formulation), which would violate the Maxim of Quality.

- (37) Jon-ga paatii-ni ki-mashi-ta.  
 John-Nom party-to come-Polite-Past  
 ‘John came to the party.’

*Possible Reason 2: Secrecy, or Confidentiality*

When the issue under discussion is who came to the party and furthermore, the answerer is willing to proffer only the information about John keeping secret, that about the other people. What she can do in terms of question and answer will be that instead of answering question ‘Who came to the party?’, she will answer a restricted version of the question in that ‘who’ is restricted to ‘John’, i.e., ‘Did John came to the party?’. This is exactly what the current theory specifies a CT sentence to be used for. The proposed use of CT in conjunction of secrecy is motivated by the natural continuation observed between the first and the second sentences in examples like (38).

- (38) Jon-wa/#ga paatii-ni kita ga,  
 John-CT/Nom party-to came but  
  
 sonohokanohito nikanshitewa ie-nai.  
 the-other-people about can-tell-not  
 ‘John<sub>CT</sub> came to the party, but I can’t tell about the other people.’

The counterexample presented above against Hara & van Rooij’s theory, i.e. (7) is just another example of the use of a CT sentence motivated by secrecy, or confidentiality.

*Possible Reason 3: Extension Specification by Positive and Negative Instances*

When the extension of a one-place predicate is asked by an interrogative sentence like (32), one way to specify the extension is to specify the positive instances of the extension and let the exhaustification (See again van Rooij & Schulz, 2006) imply that the rest of the domain is in the negative extension of the predicate. Another way is to specify both the positive and the negative instances of the extension (not necessarily exhaus-

tively) separately. Specifically, for the positive instances of the predicate, the answerer specifies that it is true that they are in the extension of the predicate, and for the negative instances, she specifies that it is not true that they are in the extension the predicate. This can be seen as an act of answering a WH-question by answering two Yes-No questions. To use (31) as an example, in our current analysis, (31) can be seen as the part of specifying the positive instances by answering the (implicit) question ‘Did John come to the party?’ in the two-part way of specifying the extension of the predicate under discussion. Then, (31) is expected to be followed by a sentence specifying some of the negative instances. For example, suppose that John, but not Mary came to the party. In terms of partition of  $C''$  in (39), the speaker could choose the shadowed block to be the case by uttering (37) plus exhaustification, ‘Only John came to the party’, or ‘John and nobody else came to the party’.

(39)

$$C'' = \begin{array}{|c|c|} \hline \{John, Mary\} & \{John\} \\ \hline \{Mary\} & \emptyset \\ \hline \end{array}$$

Alternatively, she can utter first (40a) and then (41a) to choose the shadowed blocks in (40b) and (41b), respectively to the same effect as designating the shadowed block in (39) to be the case directly.

(40) a. Jon-wa ki-ta.  
 John-CT come-Past  
 ‘John<sub>CT</sub> came.’

b.

$$C' = \begin{array}{|c|c|} \hline \{John, Mary\} & \{John\} \\ \hline \{Mary\} & \emptyset \\ \hline \end{array}$$

(41) a. Mearii-wa ko-naka-tta.  
 Mary-CT come-not-Past  
 ‘Mary<sub>CT</sub> didn’t come.’

b.

$$C'' = \begin{array}{|c|c|} \hline \{John, Mary\} & \{John\} \\ \hline \{Mary\} & \emptyset \\ \hline \end{array}$$

This use of CT sentences, i.e. that a CT sentence is used for specifying the positive instances being followed by a separate CT sentence for the negative instances or vice versa in identifying the extension of a predicate, is considered to be a feature of CT sentences that was discussed as Reversed Polarity Implicature (RPI) in section 2.2.1.

In the above, we have examined what the current theory of CT can say about the implicational/presuppositional features of CT that have been taken to be essential properties of CT in the approach that views CT as focus-sensitive operator. We have demonstrated those features can be seen as conversational implicatures arising as the addressee infers the reason why given a QUD, *wh*- $\gamma$ , by uttering a CT sentence,  $\gamma$ , the speaker opts to answer a sub-question, *?- $\gamma$*  instead of *wh*- $\gamma$ .

#### 4. Conclusions

We have reviewed two representative existent approaches to CT: one that views CT as an information-structural discourse-regulating device, specifically, it characterizes a CT sentence as an direct answer to a sub-question of a QUD, and the other takes a CT to be a focus-sensitive operator with conventional implicatures or presuppositions. The former approach, or strictly speaking, the particular analysis on the approach, we have demonstrated, is not general enough as a theory of CT because it cannot be extended to the so-called “non-canonical” examples of CT sentences, which has more than one instance of CT phrase and/or no focused phrase, and it does not address the implicational/presuppositional features of CT. As for the latter approach, the alleged implicatures and the presuppositions for CT proposed in the literature have all been shown to be easy to find counterexamples to or to be cancellable, which strongly suggests that those are not hard-wired in the pragmatics of CT. Furthermore, the non-canonical examples have turned out to be problematic to the approach as well in that it is not clear what their projected implicatures or presuppositions would be like.

We have proposed a new analysis of CT couched in the partition semantics of question and answer presented in Gronendijk & Stokhof (1984) and Gronendijk (1999) and demonstrated that the new analysis can capture the insights of both of the above

approaches and is yet free from the problems for them. That is, the new analysis can characterize a CT sentence as a direct answer to a sub-question of a QUD whether it is a ‘canonical’ or ‘non-canonical’ example and will analyze the implicational/presuppositional features of CT as conversational implicatures arising as the addressee infers the reason why the speaker opts to answer the sub-question instead of the QUD. In this sense, the current analysis can be said to have the best of both worlds of the existent approaches and more.

There are certainly many things about CT that have not been touched upon in this paper, among which is the fact that CTs can also occur in other types of sentences than declarative sentences at least in Japanese: interrogative, imperative, exhortative, and performative, as was pointed out by Tomioka (2007). The issue whether the current analysis can be extended to the occurrences of CT in non-declarative sentences is left for future research.

## Abstract

The division of labor between semantic and pragmatic aspects of the meaning of *almost* and other proximatives has been controversial since Sadock's (1981) proposal that *a almost  $\phi$ 'd* is true if *a* in fact  $\phi$ 'd: *Chris almost died* entails that Chris approached dying but only conversationally implicates that Chris didn't die. Given that *barely  $\phi$  = almost not  $\phi$* , *Dana barely survived* would likewise implicate, not entail, that Dana survived. While additional support has been marshaled for this "radical pragmatic" line, one persistent problem acknowledged by Sadock and not dispelled since is the non-cancelability of the *almost  $\phi \rightarrow$  not  $\phi$*  implication. New evidence for and against Sadock's approach and competing analyses is considered and a solution presented.

## 1. The proximal and the polar

Thirty years ago, the young leader of a fanatical cadre of radical pragmaticists circulated an underground manifesto calling for the overthrow of the bourgeois analysis of *almost*. In the published version of his manifesto, Sadock (1981: 257) posed the central question this way:

A sentence of the form *almost P*, in which *almost* is a verb phrase modifier, is used as if it meant, among other things, "not P." For example, someone who says *Sam almost died* would be taken as indicating that Sam didn't die...But what is the nature of the connection between the English word *almost* and the negative proposition?

The starting point for any analysis of *almost* is the recognition that my uttering (1) commits me in some sense to (1a) and (1b). But how?

- (1) It almost rained.  
a. It came close to raining.  
b. It did not rain.

Following the practice of Sevi 1998 and Horn 2002a, I shall refer to these aspects of the meaning of *almost* sentences as the proximal and polar components respectively. But are these implications created equal? Sadock offers three, or 3½, answers to his question, the traditional symmetricalist view in (2A), the moderate asymmetricalist view in (2B) (available in two flavors), and the radical asymmetricalist view in (2C):

- (2) A. (1b) is *entailed* by (1); (1) = (1a) & (1b) and is F if (1b) is false.  
B<sub>1</sub>. (1b) is (logically) *presupposed* by (1); (1) is neither T nor F if (1b) is false.

- B<sub>2</sub>. (1b) is *conventionally implicated* or pragmatically presupposed by (1); (1) is “strictly speaking true” but inappropriate if (1a) is true and (1b) known to be false.
- C. (1b) is *conversationally implicated* by (the utterance of) (1); (1) is T but misleading if (1a) is true and (1b) false. The inference from (1) to (1b) is a scalar implicature.

It is the radical pragmatic view in (2C) that Sadock endorsed: if you know (1b) is false, it’s misleading to assert (1), given the maxim of quantity. Hence, it is (*mirabile dictu*) true that 2+2 almost equals 4. I will argue here that in some respects Sadock’s approach is too radically pragmatic and in others not radically pragmatic enough.

## 2. Proximatives: what has (almost) been learned

I now turn to a review of some of what has been learned in the thirty years since Sadock’s manifesto—and what has been unlearned. We begin with a brief note on the problems surrounding the characterization of the proximal component. Typically it is viewed in terms of reference to possible worlds: *almost P* entails that P is ‘not far from being true’ (Ducrot 1973), that it is ‘true in a possible world not very different from the real world’ (Sadock 1981), or true in ‘a world which is almost not different from’ the actual world’ (Rapp & von Stechow 1999). But note the problem with circularity (is (1a) really distinct from (1)?) and consider the problems posed for any possible worlds account by sentences like *Planets travel in almost circular orbits* (Atlas 1984: 357) or *0.3333 almost equals 1/3* (Sevi 1998: 18)—or, most eloquently, by Sadock’s observation that *961 is almost a prime number*

might be adjudged true because the only blot on 961’s record as a prime number is the sad fact that it is the square of 31. If this one little fact were not true, then 961 would be a prime number. The imaginary world in which 961 is a prime number is not very different from the real world in the nontechnical sense that only one proposition has to changed to gain access to it, but of course it is *very* different from our world in the technical sense than it is an inconsistent world and lacks mathematics. (Sadock 1981: 259)

Two more bits of standard wisdom on *almost* that appear periodically in the literature are its role in arguments for lexical decomposition and intervention in polarity licensing. But while the varying scope possibilities for *almost* has been used to argue for decomposing causatives as in *I almost killed John* based on the availability of separate readings like ‘I almost did something that caused John to die’, ‘I did something that caused John to become almost dead’, etc. (Morgan 1969, McCawley 1973), Dowty (1979: §5.4) finds the evidence unconvincing and Rapp & von Stechow (1999) reject the corresponding scope argument for German *fast*. The common wisdom is that *almost* co-occurs with universals but not indefinites or existentials and thus serves as a reliable diagnostic for free choice as opposed to than NPI *any*. Such claims date back to Carlson 1981 and have been since entered received wisdom:

As pointed out by Horn (1972), free choice *any*, like other universal determiners, may be modified by adverbs like *almost* or *nearly*.

(Hoeksema 1983: 409)

We know that in general, FC-*any* can be modified by *almost* (just as other universal quantifiers can). Crucially, such modification...is rejected in downward entailing contexts like negation.

(Zepter 2003: 234)

More recently, Penka cites the purported impossibility of *\*I didn't see almost any student* (2006: (2b), (31), (35)) as evidence for an intervention constraint blocking NPI licensing across *almost* (cf. Horn 2000b: §III). Along the same lines, *almost* is periodically claimed to be a positive polarity item blocked from the scope of negation (e.g. Klein 1997: 87; Rapp & von Stechow 1999: 197; Horn 2000b: 87). But in fact, as noted in Horn (2005: 198-99), clauses with *doesn't {know/have} almost any, don't like almost any, NEG almost a single CN*, et al. are readily googlable:

- (3) In a story that didn't see almost any coverage here,...
- Global warming: we didn't see almost any snow in the winter
  - I didn't see almost any of the movies so I'm going by who I think is a good actor
  - I'm in the 5th week and i didn't see almost any results.
  - I don't pay almost a single cent for any of my art work
  - I do not know almost a single individual of talent who is not too busy...

*Almost* is often assumed, at least tacitly, to share its semantics (whatever they are) with its adverbial its adverbial “kin”; in particular the distribution of *almost* is taken to be essentially identical to that of *nearly*, *just about*, *damn near*, *virtually*, or *pretty much* (Sadock 1981, Morzycki 2001, Horn 2002a). But in fact, *nearly* is largely excluded from taking negative focused expressions (cf. van Dongen 1921 on *{Almost/#Nearly} nobody was there*); other differences between *almost n* and *nearly n* (for cardinal *n* focus) seem to involve speaker expectations (Sadock 2007).

Another standard assumption—e.g. by Morzycki 2007 and Atlas 2007, following (2A)-type symmetricalists, lexicographers, and butchers—is to equate *almost* with *not quite*. The *American Heritage Dictionary*, as endorsed by Atlas, glosses *almost* as ‘slightly short of, not quite, nearly’. The ‘nearly’ gloss doesn't quite work, but is ‘not quite’ at least nearly successful? As the marketing slogan for Boar's Head deli meats puts it, “Almost Boar's Head Isn't Boar's Head”—presumably, more exactly, it isn't *quite* Boar's Head even when it pretends to be. But as Sadock (1981: 263) pointed out, *almost but not quite* is not as redundant it would be if the two adverbials were synonymous; indeed, as Sadock also recognized, the *but* of contrast here indicates that *almost* and *not quite*, so far from mutual paraphrases, are at odds. This is reinforced by the frequently encountered tendency to repeat an *almost* to register the contrast with the *not quite*:

- (4) a. I almost felt sorry for Sonterra. Almost but not quite.  
(Linda Lael Miller (2003), *Don't Look Now*, p. 223)
- b. “You almost make it sound all right.”  
“Almost. Not quite.”  
(exchange on Law & Order, NBC-TV, about shading the truth)

- c. [Following a day of breathtaking adventures including an encounter with the Pope, Herr Doktor Professor Moritz-Maria von Igelfeld reflects that...]  
 the life of a diplomat, or even a schismatic if it came to it, could be almost as fulfilling as life as a professor of Romance philology. Almost, but not quite.  
 (Alexander McCall Smith (2004), *The Finer Points of Sausage-Dogs*)

Now we come to the interdefinability of *barely* with *almost not*, assumed in many treatises on proximatives (Ducrot 1973, Sadock 1981, Horn 2002a) but challenged in many others (Atlas 1997, Amaral 2007, Ziegeler 2008) on cross-linguistic grounds and the basis of the differential role played by expectation for the two proximatives. This issue aside, both adverbs have been assigned similar conjunctive (2A)-style expansions in the literature, as seen in (6), either or both of which are endorsed, *mutatis mutandis*, by Hitzeman (1992), Atlas (1997), Sevi (1998), and Rapp & von Stechow (1999). (For a tabular display of the various descriptive options advocated, cf. Horn 2002a: 60.)

- (6) a. *Lee almost passed*:  $\neg[\text{Lee passed}] \wedge \text{CLOSE-TO} [\text{Lee passed}]$   
 b. *Lee barely passed*:  $[\text{Lee passed}] \wedge \text{CLOSE-TO} \neg[\text{Lee passed}]$

### 3. Problems with (a)symmetry

The primary argument for a conjunctive analysis of the polar implication has always been its apparent non-cancelability. The contrast in (7) (= Sadock 1981: (23), (25))

- (7) a. ?Not only did Bill almost swim the English Channel, he did swim it.  
 b. Not only did Bill eat some of the cake, he ate all of it.

does render an implicature-based analysis problematic. On the other hand, the conjunctivist must cope with the troublesome fact that *barely VP* (despite its positive polar component) licenses negative polarity items, while *almost VP* (despite its negative polar component) does not:

- (8) a. She barely {budged/slept a wink/touched a drop/spoke to anyone}.  
 b. #She almost {budged/slept a wink/touched a drop/spoke to anyone}.

But notwithstanding its NPI-licensing ability, *barely* cannot be a downward entailing or non-veridical operator, given its polar entailment, i.e. the fact that *It barely rained* entails *It rained*. Note that cancellation is difficult, even with an epistemic rider:

- (9) a. #It barely rained and in fact (it's possible) it didn't.  
 b. #It almost rained and in fact (it's possible) it did.

The resolution of this conflict I have urged elsewhere (Horn 2002a, to appear) is to accept that while the polar component of the meaning of *barely VP* and *almost VP* is indeed entailed, it is not asserted—assertorically inert—predicting the quasi-negative behavior of the relevant clauses. Thus, the conjunctive analysis (2A) is correct...almost.

A particularly dramatic illustration of the contrast between asserted and non-asserted entailments comes from Sadock's contrast between *almost* and *not quite*, two approximatives that on the current view are equivalent at the level of what they entail

while differing as to what they assert. This is displayed in the table in (10), adapted from Schwenter (2002), who extends the distinction and analysis to Spanish.

(10) *almost* vs. *not quite*:

	Entailed	Asserted
Proximal Component <i>(almost)</i>	+	+
Polar Component <i>(almost)</i>	+	–
Proximal Component <i>(not quite)</i>	+	–
Polar Component <i>(not quite)</i>	+	+

Thus consider the difference between *It's too bad you almost died* (—now you'll need a long difficult recovery) and *It's too bad you didn't quite die* (—now I'll have to finish you off...). Given that what is relevant for negative polarity licensing is not downward entailment as such but downward *assertion* (with inert entailments disregarded), we predict the contrast in (11):

(11) I {never quite/\*almost} made it all the way through any of those papers.

The rhetorical negativity of *barely* and positivity of *almost*, as posited by Ducrot (1973) and supported by Sadock (1981) and Jayez (1989), is left unexplained by a pure (2A)-type symmetricalist analysis. Thus it's *good* news if my laptop is *almost* working and *bad* news if it's *barely* working, even though it's in the latter case that it actually functions. Similarly, compare:

- (12) a. The tank is almost half full—so {let's drive on/#we'd better stop for gas}.  
 b. The tank is barely half full—so {we'd better stop for gas/#let's drive on}.

although the tank in (12a) has less gas in it than the one in (12b).

Another asymmetry between polar and proximal components, as Ziegeler (2000) observes, is that the former cannot support causal explanation. Thus in (13), the kimchi could only have been an insufficient lure for me, not the ultimate deterrent.

(13) I almost moved to Korea because of the kimchi.

As for *barely*, its behavior as an NPI licenser derives from its downward assertive character: the polar entailment is transparent to polarity licensing. In fact, as the usenet posting in (14) shows, NPI licensing correlates with the invocation of a negative scale.

(14) The typical airline bathroom barely accommodates one person, much less two.

The rhetorical negativity of *barely* thus stands in opposition to its veridicality, whence the force of adversative *but* to mark this opposition while reversing the rhetorical direction of the utterance, as seen in (15a) (from a 2006 Luanne Rice novel *Sandcastles*) and in the “*barely but* sandwich” in (15b) (from “Grey’s Anatomy”, ABC TV, 5/08).

- (15) a. Sissela meowed from the bed above and Agnes barely heard. But *Brendan* did and after another kiss he pulled slightly away to look up.  
 b. He's alive. Barely, but...he's alive.

#### 4. Inverted readings and the permeable polar membrane

The polar component of *almost* and *barely* clauses is more peripheral to the primary force of the proximative, learned later than the proximal component (Amaral 2007) and more evanescent. In particular, the polar (negative) component is subject to flip-flopping in some contexts to yield “inverted” readings while the proximal component never is (Horn 2002a: 65, Schwenter 2002, Amaral & Schwenter 2007, Amaral 2007: 25; cf. also Ziegeler 2006: §4.7.1 and especially Amaral 2007 on the role of context).

Inverted readings were first recognized in the case of the Mandarin Chinese particle transliterated as *cha-yidiar* or *chadianr* and literally glossed as ‘miss-a-little’ (Li 1976, Biq 1989). While its ordinary interpretation is ‘almost’, when it scopes over a negative predicate it can be rendered as either ‘almost not’ (= ‘barely’) or as ‘almost’, with the negation essentially pleonastic, as in (16(ii)):

- (16) *Wo chadianr mei chi.* (i) ‘I almost didn’t eat’, ‘I barely ate’  
 I miss-a-little not eat (ii) ‘I almost ate’ [= *Wo chadianr chi le*]

The non-compositional pleonastic reading is the only one emerging in certain contexts:

- (17) *Wo chadianr mei zhuangdao qiang.* (i) #‘I almost didn’t bump into the wall’  
 I miss-a-little not bump-to wall (ii) ‘I almost bumped into the wall’

Similarly, in Spanish (Schwenter 2002, Pons Bordería & Schwenter 2005), negation under *por poco* ‘almost’ can—and in certain contexts must—be interpreted pleonastically, as in (19b(ii)), rather than compositionally, as in (19b(i)):

- (18) a. *Por poco sale.* ‘She almost left’  
 b. *Por poco no sale.* ‘She almost didn’t leave’  
 (19) a. *Por poco se mata.* ‘She was almost killed’  
 b. *Por poco no se mata.* (i) #‘She almost wasn’t killed’  
 (ii) ‘She was almost killed’

In general, *casi* ‘almost’ does not permit the inverted readings of *por poco*; Pons Bordería & Schwenter (2005) attribute this to diachronic differences in the history of the two approximatives and subtle pragmatic distinctions in expressiveness between them. In any case, Valencian Spanish contains a limited use of “inverted” *casi* explored by Schwenter (2002). Someone trying to squeeze out of her car after parking on a narrow street is forced to wait as many cars go past. When she’s finally able to escape, she sighs “¡*Casi salgo!*”—literally, ‘I almost get out’, but meaning ‘I barely/finally got out.’ Someone else, impatiently awaiting his friend at the auditorium door, sees her arrive a minute before the session starts and exclaims *¡Casi llegas!* ‘You just barely made it!’ (lit., ‘You almost arrive!’). In such cases, all restricted to simple present tense and utterance-initial occurrence, *casi p* clearly does not entail  $\sim p$ , since the truth

of *p* is obvious in the context, but is essentially equivalent to *apenas* ‘barely’. In other words, *casi p* here = canonical *casi + no (p)*, as in the standard Spanish expostulations *¡Casi no salgo!*; *¡Casi no llegas!*

Thus too, Swiss German *fasch* is normally equivalent to the standard *fast* ‘almost’, but also has an inverted ‘barely’ sense emerging in relevant contexts. And in English, a *near miss* can be either a goal barely missed or a disaster barely averted, i.e. nearly a non-miss, as in the case of air traffic collisions. Prescriptivists lambaste this latter, non-compositional interpretation, as in William Safire’s objection to “the overuse of *near*” in his 2 Jan. 2005 “On Language” column in the New York Times Magazine:

It became controversial with *near miss*, a nonsensical version of *near thing*; some of us patiently but uselessly pointed out that the writer meant “near hit.” *Near miss* has since entrenched itself as an idiom. (Idioms is idioms, and I could care less.)

Similarly, Bill Pidto referred on ESPN’s SportsCenter (24 Aug. 2001) to “Greg Norman, best known for his massive collapse in ‘96 and his other near misses.” But elsewhere, depending on the context, a near miss *is* nearly a miss:

[Headline:] Martin’s **near miss**

Great Britain curling skip Rhona Martin almost missed the [Salt Lake City] Winter Olympics because of a stomach problem...

(<http://news.bbc.co.uk/winterolympics2002/hi/english/curling>)

Finally we come to *the* permeable polar membrane represented by the distribution of the *un-noun* (Horn 2002b, 2005). These come in two flavors, the first of which is the Class A un-noun. A Class A unX is a non-member of the category X which, while lacking one or more criterial properties of category members, nevertheless shares salient functional attributes with them and effectively coerces a superset category of which both X and unX are members. The “sponsor” item for this class is the *un-cola*, introduced in a 1967 advertising campaign for the soft drink 7-Up; its intended interpretation posits a set (i.e. that of soft drinks) encompassing both colas and 7-Up, which is why *un-cola* wouldn’t have been as successful for promoting chocolate milk or beef jerky, which are by any definition not colas. Additional examples of Class A un-nouns appear in (20)

(20) The *Class A un-noun*: a Class A unX is *Almost* an X

*un-hit*

*Un-hit* of the week: Cardinals pitcher Garrett Stephenson came into last Saturday’s game with Atlanta 1 for 36 at the plate. Then he lined what looked like a single to right. But Brian Jordan charged, fielded it and threw him out at first.

(Baseball “Week in Review” column by Jayson Stark at espn.com, 11 Aug. 2000)

*unmartini*

Photo caption: *UNMARTINI* -- A Ginger Citrus Snap, with pomegranate seeds, at Tabla (*New York Times* 20 Jan. 1999, F1, “The Aperitif Moment: Sip or Flinch”)

*unpotato*

Photo caption: THE *UNPOTATO*: Jerusalem artichokes are roasted with thyme at Craft. (*NYT* 14 March 2001, F3)

*unpublications*

The main *unpublications* of H. P. Grice  
(Heading for column in bibliographic addendum to Grandy & Warner's 1986 festschrift for Grice, facing page listing 'The publications of H. P. Grice')

*unturkey* (and *unbird*)

The Great *UnTurkey*. Let One of Now & Zen's featherless friends be the centerpiece of Your Holiday table! This impressive creation is completely vegan and offers 5 solid pounds of boneless eating (enough for 8 hungry adults)! Made of delicately flavored tender seitan, dressed in a delectable "skin" made from yuba (beancurd skin), ...this innovative creation will delight vegetarians and non-vegetarians alike. This frozen "*unbird*" comes fully cooked, and needs only reheating to be enjoyed. (ad for Now & Zen, San Francisco, November 1999)

If a Class A un-X is almost (but not quite) an X, a Class B un-X is an X, but not a particularly good representative of its category. Note that whatever we think of the designated *un-place* New Jersey, it is most certainly a place, just as un-sheets are sheets.

(21) The *Class B un-noun*: a Class B unX is *Barely* an X

*uncollege*

Even though many Mids [= Midshipmen, i.e. U. S. Naval Academy undergraduates] refer to their school with bemused affection as "the *uncollege*", it remains one of the great bastions of "old college spirit" in its pristine form. (*Washington Post*, 22 Nov. 22, 1977, D1, "Navy Revives College Spirit For The Game")

*unbank*

Banking on the *Unbanks*: Tellerless Wonders Are Reinventing Small-Business Lending (Headline, *NYT* February 4, 1999)

*un-place* [referring to E.B. White's essay "Here is New York"]

And what he made just as clear was that any place else was just, well, any place else. Or perhaps an *un-place*. The closest of these is New Jersey. (Charles Strum, "Garden State? The Image is Closer to Crab Grass", *NYT Arts Section*, 27 Oct. 1996, p. 33)

*unsheets*

Now that the big names in bedding—Cannon, Fieldcrest and J. P. Stevens—are bringing out their own versions of *unsheets*, suggestible types can go see natural [unbleached, untreated cotton sheets] displayed...in department stores around town. (Liz Logan, "New Bed Linen," *NYT* 10 Oct. 1991, Home p. 1)

*unwoman*

label for infertile women, feminists, lesbians, nuns, etc. in Margaret Atwood's 1985 dystopian novel *The Handmaid's Tale* who are exiled to the colonies as slave labor

Summarizing, we can say that an *A*-class unX is not an X ( $\approx$  is almost/not quite an X), while a *B*-class unX is technically an X (but just barely an X). In some cases, however, it's hard to tell: is an *unbreakfast* (e.g. an eel and egg sushi roll consumed at 7:00 a.m.) a breakfast (because of its timing) if just barely, or almost a breakfast but not quite (given its structure)? What of the politician's sleazy illocution in "If I've offended anybody, I apologize?" or "I'm sorry if I hurt the feelings of anyone who can't take a joke"? Lakoff (2000: 31) employs *un-apologies*, "*apologies*" (with scare quotes), and *apologies* (without them) to refer interchangeably to this phenomenon. And, speaking of politics, what of those infamous disputed Floridian ballots? Americans of both blue and red stripe may have acknowledged that these were not ideal exemplars of their class, but the 2000 (un)election hinged on whether those dimpled, chad-hung *unvotes* were in fact votes or (as it turns out) not.

As we have seen, while proximatives entail and assert their proximal component, the polar component is more of a semi-permeable membrane. An early account of this variable permeability is given by P. Harder & C. Kock (1976), who insightfully invoke Ducrot's notion of argumentation theory for dealing with the negative orientation of *barely*, but—like the *almost = not quite* brigade—succumb to the temptation of dictionary-hugging. Of sentences like (22a) they write,

- (22) a. Roderick barely kissed Honoria.  
 b. Roderick kissed Honoria.

In terms of truth conditions, *barely* is strangely ambiguous. The *Shorter Oxford English Dictionary* lists as one of extant meanings "Only just; hence, not quite...". According to this description, *barely* entails, in [22a], either that Roderick kissed Honoria, or that he did not kiss her—we do not know which. The serious consequences of this confusion would be even more obvious, e.g., in a criminal case where Roderick was charged with rape, and where a witness made the statement *Roderick barely raped Honoria*. (Harder & Kock 1976: 28)

But any such ambiguity is far more plausible for *hardly* (cf. Amaral & Schwenter 2007) as in *Roderick hardly kissed Honoria*, than for *barely*. Harder & Kock find that it is "in any case clear that [22a] is always argumentatively stronger than [22b]", but this is untenable without a specification of what conclusion these statements are presented as arguments *for*. It appears that despite its promise, the Harder-Kock theory can hardly penetrate the polar membrane. We turn now to other perspectives on the slippery status of the polar component of proximatives.

## 5. The implicature line revisited

We now review one non-argument *for*, and offer one new argument against, the (2C)-type conversational line on the polar component.

### 5.1. The non-redundancy argument

A second fact that lends support to the idea that "not *P*" is a conversational implicature [of *almost P*] is that it can be reinforced—it can be made explicit without producing redundancy. Consider [22] as an answer to the question *Did Bill swim the English Channel?* (Sadock 1981: 263; cf. Sadock 1978: 293)

(22) Almost, but not quite.

But, as shown in Horn 1991 and contra Sadock 1978, informationally redundant propositions can be asserted as long as they introduce a rhetorical opposition (Anscombe & Ducrot 1983), typically signaled as above by *but*. Thus, we have (23a-d), where the *but* clause is semantically entailed/presupposed yet felicitously assertable:

- (23) a. I don't know why I love you, but I do.  
b. Obama barely won the nomination, but he did win.  
c. It's odd that dogs eat cheese, but (eat cheese) they do.  
d. I'm sorry I said it, but (say it) I did.

This doesn't show that *almost P-ing* is semantically distinct from *not quite P-ing*, but it does vitiate Sadock's non-redundancy argument for the implicature analysis.

## 5.2. The subset diagnostic

For a new argument for why the relation between *almost P* and *not P* can't be (just) conversational implicature, pace Sadock (1981) and Ziegeler (2000, 2006, 2008), consider the distribution of reduced assertions in a variety of cases. When dealing with clear instances of conversational implicature, we get the inclusive readings.

- (24) a. 20 students tried to solve the problem. [includes those who succeeded]  
b. 20 students solved most of the problems. [includes whoever solved them all]  
c. 20 students don't drink much. [includes any who don't drink at all]

Thus, if 5 students managed to solve the problem, they constitute 5 of the 20 who tried to solve it, if 5 students solved them all, the total is again 20, and if 5 are teetotalers, again we have just 20 in all. But now compare the case of proximatives, or the related example with *only* (see Horn 2002a, to appear b, and discussion below):

- (25) a. 20 students almost solved the problem. [excludes those who succeeded]  
b. 20 students barely passed the test. [excludes those who failed]  
c. 20 students solved only the last problem. [excludes any who solved none]

If (25a) is true and 5 students solved the problem, we have a total of (at least) 25 students—the 5 who succeeded and the 20 who almost did; (27b) and (27c) are parallel. This supports the view that conversational implicature does not suffice for the polar component of proximatives. What of conventional implicature (as on the (2B<sub>2</sub>)-style analysis of *almost/presque* in Jayez & Tovenà 2008)? While it is difficult to find testable examples, it is instructive that the 20-student set in (26a) includes the subset of masochistic students who deliberately seek out food they find painful to eat, and that in (26b) includes the subset who were given the answers ahead of time, suggesting that neither variety of implicature suffices to handle the polar implication.

- (26) a. 20 students find kimchi painfully spicy but attended CIL 18 anyway.  
b. 20 students managed to pass the test.

## 6. Scales vs. rank orders: the coercion effect

As we have seen, there is a palpable distinction between the behavior of the polar implication and that of classic scalar implicatures:

- (27) a. ?Not only did Bill almost swim the English Channel, he did swim it.  
 b. Not only did Bill eat some of the cake, he ate all of it.
- (28) A: It almost rained yesterday.      (29) A: It's likely it will rain tomorrow.  
 B: #Yes, in fact it did rain.              B: Yes, indeed it's certain it will.

This asymmetry is a problem for the claim that *almost P : P :: some : all*. But what if *almost P : P :: sick : dead*? We would be dealing then not with a true scale but a rank order (cf. Horn 2000a and references cited therein). See (30) for a notational differentiation and (31) for additional examples of rank orders:

- |                             |                           |
|-----------------------------|---------------------------|
| (30) <i>true scales:</i>    | <i>rank orders:</i>       |
| <scalding, hot, warm>       | «felony misdemeanor tort» |
| <certain, likely, possible> | «win place show»          |
| <loathe, hate, dislike>     | «dead sick»               |
- 
- |  |                            |
|--|----------------------------|
| (31) «general colonel lieutenant sergeant private» | «married engaged»          |
| «full professor associate prof. assistant prof.»   | «full house flush»         |
| «senior junior sophomore freshman»                 | «A B C D F»                |
| «a φ'd  a almost φ'd»                              | «a didn't φ  a barely φ'd» |

In a scale of the form <Y, X>, ...Y... unilaterally entails ...X...: if it's hot, it's warm; in a rank order <<Y, X>>, ...Y... unilaterally entails ...¬X...: if they're married, they're *not* engaged; if he's a colonel, he's *not* a lieutenant. Similarly, if she's a full professor, it's false that she's an assistant professor—although it's true that she's *at least* an assistant professor. Similarly, compare these exchanges between players in (non-wild card) poker, where having a full house outranks but precludes having a flush:

- (32) A: Do you have a flush?  
 B: {No/#Yes} (in fact) I have a full house.
- (33) A: Do you have at least a flush?  
 B: {Yes/#No} (in fact) I have a full house.

*Not only* (as opposed to *not just*) distinguishes between true scales (as in (27b) and rank orders, as in (34):

- (34) a. #Not only are we engaged, we're married.  
 b. This is not {just/#only} a one-night stand, it's true love.

As noted above, *S is at least P* differs crucially from *S is P* in its truth conditions and illocutionary potential. Thus consider the exchanges in (35) and (36):

- (35) a. Is your daughter a sophomore?  
 b. No/#Yes, (in fact) she's a junior.

- (36) a. Is your daughter at least a sophomore?  
 b. Yes/#No, (in fact) she's a junior.

The fact that *Amy is a sophomore* can be false when *Amy is least a sophomore* is true is consistent with the account of Geurts & Nouwen 2007, on which *A[my] is at least a sophomore* is assigned the logical form in (37)

$$(37) \quad \square [\text{sophomore (a)} \vee \text{junior (a)} \vee \text{senior (a)}] \wedge \diamond [\text{junior (a)} \vee \text{senior (a)}]$$

The effect of *at least* is to coerce a rank order into an acting (virtual) scale; (36a), unlike (35a), induces a disjunction between the item in question and “higher”/“better” alternative values = *Is your daughter a sophomore-or-more?*

This effect is the other side of the coin from the effect of focus in cases of “pragmatic intrusion”, the tendency for pragmatically derived “enriched” meanings within an embedded context to contribute compositionally to what is said (cf. Cohen 1971, Levinson 2000, Carston 2002, Recanati 2004). It is argued by Horn (2004, 2006, to appear a), King & Stanley (2005), and Geurts (in press) that in such cases as (38), originally from Levinson 2000,

- (38) a. Eating *some* of the cake is better than eating *all* of it.  
 b. Because the police recovered *some* of the missing gold, they will later recover it *all*.  
 c. Because the police recovered *some* of the missing gold, the thieves are expected to return later for the *rest*.

the double processing or retroactive accommodation is triggered by the role of focus on the scalar elements and by the minimal contrast. While *some* is normally compatible with *all* (to eat all of the cake is *a fortiori* to eat some of it), in the context of (38) the two are placed in opposition, and *some* is taken as amounting to *some but not all*. Focus alone is not enough to trigger reprocessing, as seen in (39):

- (39) a. #Because the police recovered *some* [i.e. only some] of the missing gold, the thieves are expected to return later.  
 b. #Because it's *warm* out [i.e. warm but not hot], you should still wear a shirt.  
 c. #Because you ate *some* of your gruel [i.e. and not all], you get no dessert.

In cases like (38), focusing a weak scalar item in a contrastive context can effectively coerce scales into rank orders, just as *at least* coerces rank orders into ordinary scale, whence the contrast between being at least almost finished (which is compatible with finishing) and being almost finished (which is not). Or is it?

## 6. On being almost dead vs. almost ready for dinner

“You thought something would change?”

“She almost died.”

“Almost dying changes nothing. Dying changes everything.”  
—exchange on “House”, ABC TV, 17 Dec. 2008

As we have seen, the paraphrase relation between *almost* with *not quite* assumed by some lexicographers and even some linguists and philosophers fails to account for the rhetorical difference between the two proximatives (see §3 above). On the account supported here, this difference is attributable to the fact that *almost* and *not quite* share their entailments but differ at the level of what they assert. Now consider the contrast between them in the context of (40):

- (40) A: So dinner is {(?)almost/#not quite} ready, right?  
B: Yes, in fact it *is* ready.

Accounting for the impossibility of *not quite* here is not the problem: to assert that dinner is not quite ready is to assert that it's not ready, whence the contradiction. But if the statement that dinner is almost ready *entails* (even though it does not *assert*) that it is, why is the positive response at least marginally possible (if not impeccable) in this case? Similarly, many speakers have no problem with the exchange in (41), while the apparently parallel cases in (42) and (43) seem far less acceptable.

- (41) A: Is your dissertation almost ready to file?  
B: (?)Yes, (in fact) {it *is* ready/it's *completely* ready}.
- (42) A: Is Fredo almost dead?  
B: #Yes, (in fact) he's *totally* dead.
- (43) A: Did you almost kill Sollozzo at the restaurant?  
B: #Yes, (in fact) I *did* kill him.

And, as we might expect, the cancellation facts yield a similar contrast:

- (44) A: (?)Dinner is almost ready, and in fact it *is* ready. (cf. (7a) above)  
B: #Fredo is almost dead, and in fact he *is* dead.

While there are several factors affecting the robustness of the polar implication and its cancelability, including the aspect of the predicate and the desirability of the outcome (cf. Ziegeler 2006, 2008, Amaral 2007), one consideration is that if dinner is almost ready in the actual world, it will be ready soon in all the inertia worlds determined in the context (cf. Dowty 1979: 148), while death is not similarly projectible from near-death as a default future. Furthermore, it must be acknowledged that at least in our culture, whether a dinner or a dissertation is ready or not is of considerably less import than the metabolic difference between being dead vs. not dead. Thus *almost P* is sometimes (virtually) compatible with *P* and sometimes incompatible with *P*, depending in part on the significance of the distinction (as the waggish Paul Grice might have put it) between *P*-ing and not *P*-ing.

## 6. A not so distant cousin: the pragmatic asymmetry of *only*

Disputes on the relative status of the two components of *only* clauses predate the related questions for the proximatives by a millennium or so. Since the 13<sup>th</sup> century, symmetricalists from Peter of Spain to Atlas (1993 et seq.), for whom (45a) essentially unpacks into the conjunction of (45b+c), have squared off against asymmetricalists (Geach, McCawley, Horn, et al.), for whom (45a) entails the negative (exclusive) component (45c) but at most presupposes or implicates the positive (prejacent) component (45b); cf. Horn 1996, Atlas 1996 for history and references.

- (45) a. Only love counts.  
b. Love counts.  
c. Nothing distinct from love counts.

Like the polar component of *barely/almost VP*, the prejacent of *only NP* is entailed, pace Ippolito (2006, 2008) and van Rooij & Schulz (2007):

- (46) a. #Only Sue passed the test, and (possibly) even she didn't.  
b. #Only the President can end the war—indeed, nobody can.

While semantically conjunctive and non-downward-entailing, however, *only XP* and *only n CN* phrases license NPIs (pace Atlas 1993 et seq., Giannakidou 2006), triggers subject-aux inversion, and produces scale reversal, very much like its proximate cousin *barely*:

- (47) a. \*(Only) Dana {would ever eat any of that stew/drank a drop/slept a wink}.  
b. \*(Only) in stories does a dropped glass betray agitation. [Graham Greene]  
c. \*(Only) a fool would even eat a bite of that jellyfish risotto.

The semantic and pragmatic parallel between cross-categorial *only* and VP-modifying *barely* is especially striking here. The scale reversal attested in (47c) and in (48) is a diagnostic of the rhetorically negative character of semantically non-monotonic particles.

- (48) *Patient's boyfriend*: "You can't do this. We lived together. We were going to have kids. You barely even know her."  
*Patient's mother*: "Apparently neither did you." ["House" episode, 9/07]

Even the *barely but* sandwich of (15b) has a partial analogue with *only*, as Galway Kinnell illustrates in his 1985 poem "Prayer" (formatting in original):

Whatever happens. Whatever  
*what is* is is what  
I want. Only that. But that.

Another parallel property shared by the polar component of proximatives and the prejacent of *only* is their predilection for taking wide scope with respect to complement-embedding emotives, i.e. the Karttunen & Peters (1979) diagnostics (but see Atlas 2002, 2007 for another view). What I just discovered in (49) is that Gore came close to winning, or Bush to losing, or that the tax cuts won't help the non-wealthy. The propositions that Gore lost, that Bush won, or that the wealthy benefit scope out of the discovery. Similarly, what's bemoaned in (50) is the near thing or the exclusion, not the polar or prejacent implication.

- (49) a. I just discovered that {Gore almost won/Bush barely won} the 2000 election.  
 b. I just discovered that the tax cuts will help only [<sub>F</sub>the wealthy].
- (50) a. It's too bad that {Hillary almost won/Barack barely won} the nomination.  
 b. It's too bad that the tax cuts will help only [<sub>F</sub>the wealthy].

On the assertoric inertia account (Horn 2002, to appear b), it's downward asserting, not downward entailing, environments that license NPIs—or at least *ever*, polarity *any*, and the minimizers. The Karttunen & Peters (1979) scopal diagnostics for presupposition or conventional implicature can be redefined as diagnosing material outside the scope of assertion. For Giannakidou (2006), on the other hand, *only* and emotive factives are “renegade” NPI licensers in languages like English. This conclusion is based partly on the fact that in such as Greek, NPIs are not licensed in these contexts (Giannakidou 1998, 2006):

- (51) *Monon i Theodora idhe {ti Roxani/\*kanenan}*.  
 only the Theodora saw-3SG the Roxanne/anybody  
 ‘Only Theodora saw {Roxanne/anybody}’ (Giannakidou 1998: 154)

In addition, Giannakidou stresses the fact that *only* clauses are veridical and the fact that they don't license all NPIs. But first, as we have seen with *barely*, veridicality is not a deal-breaker as long as the relevant entailment is assertorically inert (cf. also Horn to appear b), and second, licensing isn't a binary thing, as has been recognized at least since Horn 1970. Indeed, even those restrictive polarity items that Giannakidou sees as requiring overt negative licensers (the examples in (52) are reproduced from her (43)) do not always require them, as seen in (59):

- (52) a. \*Only Bill came either.  
 b. \*Only Bill is all that intelligent.  
 c. \*Only Bill arrived until Friday.
- (53) a. Few of *my* friends could make it here either.  
 b. If he's all that smart, why isn't he rich?  
 c. I'll be damned if I'll quit until I absolutely have to.

Do languages like Greek require downward entailment as opposed to downward assertion to rule out (52) and similar sentences? No—for two reasons. First, DENess isn't necessary for licensing in Greek. Disjunctive and *want*-contexts permit unstressed

*kanenas*, as Giannakidou (1998) has documented; cf. e.g. (54), courtesy of Jason Merchant (p.c.)

- (54) *I bike kanenas mesa i afisame ta fota anamena.*  
lit. ‘Either n-one came in or we left the lights on’

(Note the impossibility of the corresponding sentence in English: \**Either anyone came in or...*).

Second, DEness isn’t always sufficient. *At most n*, unlike *only n*, establishes a true downward entailing environment: if at most 5 students passed, then at most 5 students got A’s. (Notice that this is a question of actual DEness, not the Strawson DEness proposed for *only* in von Stechow 1999.) Yet the equivalent expression to *at most* fails to license even weak NPIs in Greek (Anastasia Giannakidou, p.c.):

- (55) \**To poli pende fitites ipan tipota.* ‘At most 5 students said anything’

Thus, we see that in Greek, *at most n* and *only n* are equivalently *non*-licensors, while in English they’re equivalently (medium-strength) licensors (cf. De Decker et al. 2005), so it can’t be DEness as such that’s relevant in either case.

On their conjunctive epistemic analysis of *at most n*, Geurts & Nouwen (2007) would unpack (56a) into a conjunction of (56b) and (56c).

- (56) a. At most 30 people have proved this theorem.  
b. It is (epistemically) possible that 30 people have proved this theorem  
c. for  $n > 30$ ,  $\neg$ [It is possible that  $n$  people have proved this theorem]

The obvious question arises under this analysis: Why is *at most n* an NPI licensor, given the conjunctive and hence apparently non-monotonic expansion in Geurts & Nouwen 2007? Notice that as seen in (57), the quasi-negative behavior of *at most n* nominals is shared by that of the upper-bounding proposition in (56c) but not by that of the positive epistemic proposition in (56b).

- (57) a. At most 30 people have *ever* proved this theorem.  
b. \*It is possible that 30 people have *ever* proved this theorem.  
c. It is not possible that more than 30 people have *ever* proved this theorem.

The key, as with the cases of *almost*, *barely*, and *only*, is to recognize that symmetry in the semantics may conceal a crucial asymmetry at the level of what is asserted. Because the entailment in (56b) is assertorically inert, *at most n* asserts only the negative proposition in (56c) and thus counts as effectively downward monotonic.

## 7. Concluding remarks

For Stalnaker (1979), an assertion is a proposal to change the context: a potentially controversial move to reduce the context set—the set of possible worlds constituting the “live options”—or equivalently a proposal to add the content of what is asserted to the common ground. I have proposed here, and in more detail in Horn (2002a), that the apparent tension between the evidence for the semantic symmetry of *almost* and *barely*

and the evidence for their rhetorical asymmetry can be resolved by distinguishing what is (simply) entailed from what is (not just entailed but) asserted. Material in the former category counts as inert, and as transparent with respect to a wide range of linguistic diagnostics, including the “subset” diagnostic introduced in §5.2 above.

In his important thesis on proximatives, Aldo Sevi (1998) defends a formally symmetric (2A)-style conjunctive analysis for the proximal and polar components: *almost p* entails (and asserts) *not p* and *barely* entails (and asserts) *p*. At the same time, he acknowledges, the polar assertion is “somehow ‘backgrounded’ or less ‘prominent’” than the proximal assertion (1998: 32). That is, “*almost* is ‘positive’ and *barely* is ‘negative’ in some sense” (1998: 34). But how, and in what sense? This is the question we have sought to address here, both for the proximatives and their exclusive cousin.

Like *barely*, *only NP* on the proposed account is neither downward entailing nor non-veridical. This would predict it shouldn’t license NPIs, and indeed it doesn’t in Greek, but in English its veridicality and non-monotonicity are overridden by downward assertion (in which assertorically inert components are disregarded), a property that is evidently irrelevant for Greek. Disjunctions, on the other hand, are not NPI triggers in English, where non-veridicality is insufficient for licensing NPIs. We thus obtain a parameterized account of polarity licensing to allow for cross-linguistic variation: (non-)veridicality must be invoked to account for the distribution of polarity items in some languages (Greek, Bengali), while downward assertion is relevant in others (English, Swedish).

Sentences based on *almost VP*, *barely VP*, *only NP*, *at most n CN*, and other quasi-conjunctive expressions entail both conjuncts of the relevant expansion but assert only one of those conjuncts (the other being *assertorically inert*). Recognizing this asymmetry at the pragmatic level enables us to capture asymmetries reflected (inter alia) by NPI licensing, scalar orientation, and discourse negativity while avoiding the contradictions incurred by a semantically asymmetric account. Like Atlas (2002: 12), I “remain as unconvinced as ever that downward entailment can explain the distributional data of NPI licensing”, but the fault, I have argued, lies not in the *downward* but in the *entailment*.

## Acknowledgments

Earlier versions of different subsets of this material were presented in Tel Aviv (June 1999), Chicago (Jan. 2000), Berlin (March 2001), Tokyo (May 2001), Reading (Sept. 2001), UMass (October 2001), Yale (April 2002), Chicago (April 2002), Pomona (April 2005), Potsdam (Dec. 2005), Swarthmore (April 2006), Anaheim (Jan. 2007), Leysin (March 2007), and Chicago (May 2007). I am grateful to commentators at those occasions and that of the scalar workshop at CIL 18 organized by Chungmin Lee, and I am indebted to Barbara Abbott, Patricia Amaral, Jay Atlas, Kent Bach, Ariel Cohen, Bart Geurts, Anastasia Giannakidou, Janet Hitzeman, Michael Israel, Jason Merchant, Scott Schwenter, Mandy Simons, and Debra Ziegeler for their thoughts and comments and in particular to Jerry Sadock for his inspiration. Of course, only I am responsible for any errors. For insightful recent treatments of the semantics, the scalar directedness and the cross-categorical nature of *almost*, *barely*, and their cross-linguistic analogues, see Penka 2006, Ziegeler 2006, 2008, Nouwen 2007, and Amaral 2007.

## Abstract

This paper reports adult and child knowledge of the generalized scalar implicature (GCI) of disjunction, the non-scalar 'Allover' GCI and the particularized No-contrast implicature. The contributions of scales, generalization and relational complexity to the developmental difficulty of phenomena at the semantic-pragmatic interface are discussed. Results show that children as old as 9-years do not demonstrate adultlike knowledge of the scalar GCI of disjunction or the No-contrast PCI, while the 'Allover' GCI is demonstrated at 5 years. We conclude that the quaternary-level relational complexity of the later developing implicature and the ternary-level complexity of the earlier developing implicature, as analyzed by Halford, Wilson and Phillips' (1998) Relational Complexity Metric can account for this developmental pattern, and not scales or generality.

**Keywords:** first language acquisition, semantic-pragmatic interface, implicatures, relational complexity.

## 1. Introduction

This paper reports results from experiments on adult and child knowledge of one type of scalar implicature (based on the *<and, or>* scale) and two types of non-scalar implicatures (the No-Contrast implicature based on the reference set *{but, and}* and the second on reference sets of attributes – the 'Allover' Implicature). The results show that even at the age of 9;6 Hebrew speaking children do not yet have adultlike knowledge of either the scalar or non-scalar implicatures of coordination. However, they do calculate the non-scalar 'Allover' Implicature from the age of 5 years. We argue that for children, it is the relational complexity of the semantic and pragmatic relations involved (as measured by the relational complexity metric suggested by Halford, Wilson and Phillips, 1998) that determines the age of calculation of a given implicature.

When investigating children's performance on conversational implicatures, we examine three issues which we consider to influence the developmental difficulty of each implicature. The first is the participation of a scale in the implicature: is there a difference in the difficulty of scalar and non-scalar implicatures? Cross-linguistically, the majority of investigations into child acquisition of implicatures have been into scalar implicatures with relatively late ages being reported (e.g. Papafragou and Musolino, 2003). Note however, that at least one non-scalar implicature has also been found to develop relatively late (e.g. Noveck and Chevaux, 2002).

The second issue is the generalized versus particularized nature of the implicature. Levinson (2000) expands the Gricean concept of Generalized Conversational Implicatures (GCIs), defining these inferences as the default interpretation of an utterance, as opposed to Particularized Conversational Implicatures (PCIs) which are dependent on specific contexts. In the current investigation we examine the relative difficulties of GCIs versus PCIs. Cross-linguistically, the majority of implicatures which have been investigated are GCIs. Note that there are difficulties which arise in investigating the development of PCIs due to their non-uniform appearance in adult communication (Paltiel-Gedalyovich, 2008).

The third and final issue bearing on the acquisition of implicatures is the complexity of processing the specific implicature phenomena. Differences in the age of acquisition of various implicatures may be independent of scalar involvement or of generalization and dependent on the complexity of the specific implicature as expressed by the relation which

it involves. Crosslinguistically, allusion has been made to processing difficulty of various implicatures resulting from the processing of reference sets (e.g. Reinhart, 1999), however, no detailed explanation has been provided for differences in the difficulty of various phenomena. We make use of Halford, et al's (1998) relational complexity metric to provide a detailed analysis of the complexity of each implicature investigated, and thus predict and account for differences in developmental ages. We argue that non-adultlike child behavior is not related to the involvement or non-involvement of a scale, nor to whether the implicature is particularized or generalized, but rather to the complexity of the specific implicatures

We view adult behavior as a crucial factor in interpreting child acquisition data. Adult behavior serves as the reference point for determining 'correct' (= adultlike) and 'incorrect' (= non-adultlike) responses. We therefore report and discuss adult as well as child data.

## 2.0 Scales versus non-scales

We take scalar implicatures to be those implicatures that are calculated based on Horn's entailment scales (Horn, 1976), while non-scalar implicatures include those calculated based on reference-sets or non-scales (e.g. Levinson, 2000). Entailment relationships existing between the members of the set determine whether the set is a scale or not. In scales, there is a unidirectional entailment relationship between the members of the reference set. In non-scales, there is either no entailment relationship or a bidirectional entailment relationship between set members. Thus, the scalar implicature calculated with the use of disjunction involves rejection of the truth of conjunction based on the scale *<and, or>*, where disjunction entails conjunction but not vice versa.

The non-scalar No-Contrast implicature calculated from the use of the non-contrastive *and* involves rejection of contrast based on the reference set *{but, and}*. This is a non-scale; although *but*, which includes contrastive meaning, is more informative than *and*, the truth of either of the members of the set entails the truth of the other.

The use of a bare attribute, say the color *blue*, gives rise to an implicature 'blue all over' (Harnish, 1991). This implicature is calculated by considering a set of unordered alternates *{blue, red, green, yellow...}*. The use of one member of the set in an utterance implicates that the other members of the set are false, i.e. uttering *blue* gives rise to the implicature that none of the other colors are true of the described object. So *red* will be false and therefore, *blue and red* will be false.

There is no specific developmental prediction which arises directly from the involvement of non-involvement of an entailment scale. Accounts which discuss the complexity of processing reference sets (e.g. Reinhart, 1999), do not distinguish between the difficulty in processing an ordered set of the type representing a scale versus processing a non-ordered set of the type representing a non-scalar reference set.

## 3.0 Generalized versus particularized implicatures

We adopt Levinson's (2000) version of the theory of Generalized Implicatures. According to this theory, GCIs are default interpretations arising with every utterance of a term which evokes the implicature. Cases in which the GCI is not apparent in the interpretation are considered to be the result of a cancellation of the GCI. (Note that some researchers, working for instance within the context of Relevance Theory, have challenged the default nature of implicatures which have hitherto been taken to be generalized, e.g. Bott and Noveck, 2004).

The implicature arising with the use of disjunction is considered to be a generalized conversational implicature or GCI (Levinson, 2000), while we take the No-contrast implicature to be a particularized conversational implicature (PCI), since the absence of contrast in *and* is context dependent and not part of the default interpretation. Uses of *and*

may give rise to many other implicatures, for example an implicature of sequence based on the maxim of manner giving the interpretation that the first conjunct precedes the second conjunction chronologically. This is shown in (1). *And* can also give rise to an implicature of causality as demonstrated in (2).

- (1) Implicature of sequence arising from conjunction  
'The boy put on a coat *and* went outside.'  
Implicature: he put on his coat before he went outside.
- (2) Implicature of causality arising from conjunction  
'The boy slipped and fell.'  
Implicature: slipping caused the fall

Levinson (2000) suggests that the 'Allover' implicature may also be a GCI and we adopt this view.

Here, too, there is no specific developmental prediction which arises from the theory of GCIs. There is no apparent reason to predict that a GCI will be harder or easier than a PCI. However, there are three points which should be considered. First, the variable nature of PCIs may provide children with less exposure to them and inconsistent evidence regarding when they arise. Second, determining adultlike performance in children for PCIs may prove difficult since the adults themselves will calculate these implicatures inconsistently and the target for child development will be therefore unclear. Finally, children's inconsistent calculation of GCIs may reflect their miscategorization of the implicatures as PCIs.

#### 4.0 Relational complexity of (some) implicature phenomena

The relational complexity of each of these implicatures may be determined using the relational complexity metric proposed by Halford, et al (1998). According to this metric the complexity of a given skill is determined by the number of elements which must be processed simultaneously. A developmental sequence indicating at which age each level of relational complexity is mastered is suggested and presented here in (3).

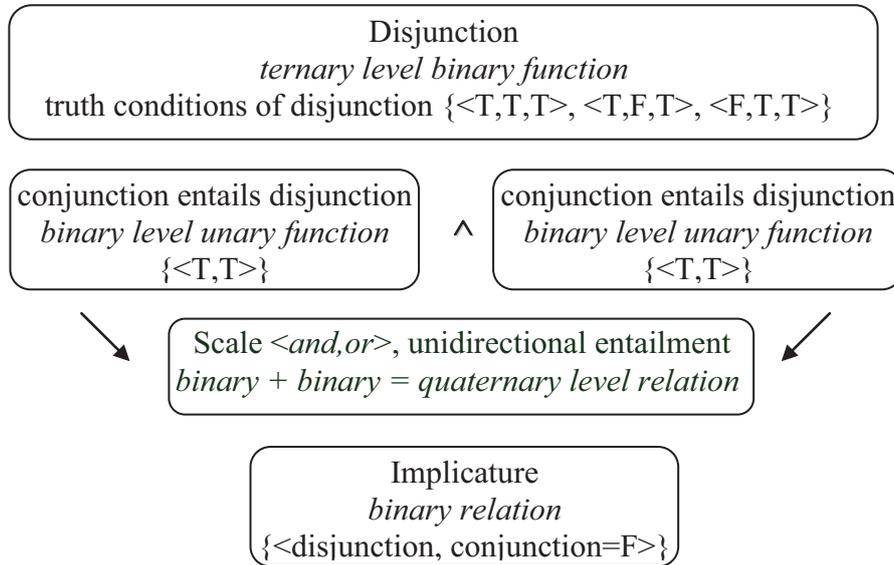

- (3) Ages of mastery of different levels of relational complexity

<i>Level of relational complexity</i>	<i>Age of mastery</i>
Unary	1 year
Binary	2 years
Ternary	5 years
Quaternary	11 years

##### 4.1. Relational complexity of the scalar implicature of disjunction

Within this framework, the scalar implicature based on the scale *<and, or>* is assigned quaternary level complexity, a level hypothesized by Halford, et al (1998) to be acquired only by age 11 years. The application of the relational complexity metric to this scalar implicature is illustrated in (4).

(4) Processing of scalar implicature based on *<and,or>*

If we apply the model given in (4) to the utterance *Bigbird is wearing a coat or a scarf* the result is as follows. The utterance itself is a *ternary* level binary function as interpretation involves application of the truth conditions of disjunction, the set of ordered sets {<T,T,T>, <T,F,T>, <F,T,T>} to the truth values of the conjuncts involved (*Bigbird is wearing a coat* and *Bigbird is wearing a scarf*).

The next step involves the scale *<and, or>*. We have unidirectional entailment which is the conjunction (a *ternary* level binary function based on the truth conditions of conjunction, the set of ordered sets {<T,T,T>}) of 'conjunction entails disjunction' and the negation of 'disjunction entails conjunction'. Entailment can be seen as *binary* level relation based on the ordered set <T,T> where the truth of one sentence (a disjunction) yields a guarantee of the truth of a second sentence (a conjunction). In order for the entailment relation to be unidirectional, the second condition must also hold, namely the negation of an entailment relationship such that conjunction entails disjunction. Negation is seen as a *binary* level unary function, as represented by the set of ordered sets {<T,F>, <F,T>}. Thus we have binary level negation having scope over *binary* level entailment.

The *ternary* level conjunction of the *ternary* level binary function of disjunction couples with the *ternary* level binary function of the unidirectional entailment yields a *quaternary* level relation.

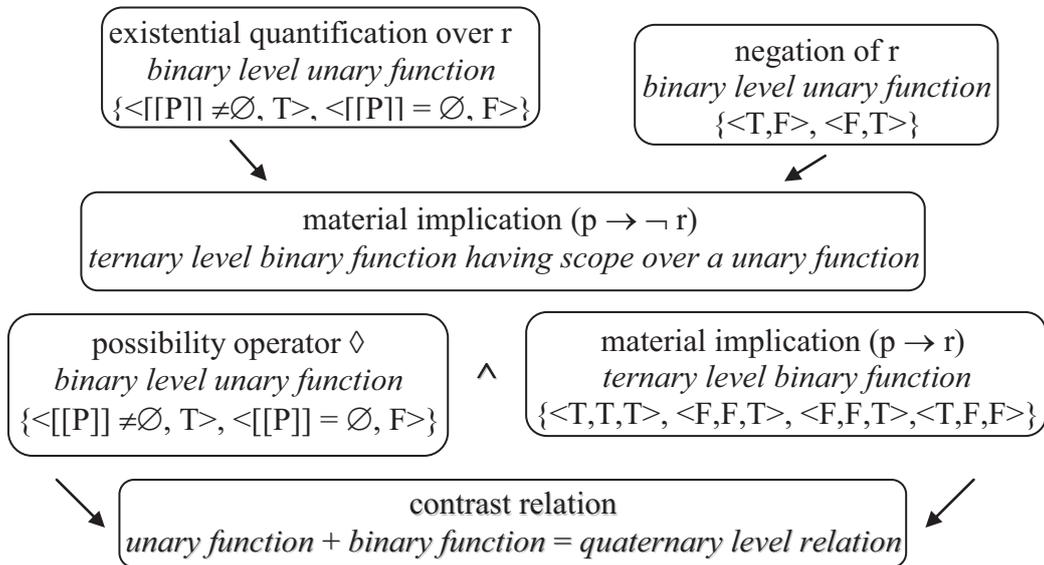

4.2. *The relational complexity of the NO-contrast implicature of and*

The relational complexity of the non-scalar No-contrast implicature based on {*but, and*} is quaternary because the relational complexity of the contrast relation of *but* is in itself quaternary. This application of the relational complexity metric is based on Winter and Rimón's (1994) analysis of *but*, shown in (5).

(5) Winter and Rimón's (1994:370) analysis of the contrast of *but*  
*presupposition of but: p implies not (r) and q implies r*

The application of the relational complexity metric to this analysis is given in (6).

(6) Processing of the contrast relation of *aval/but*

If we consider the utterance *The man hates cucumbers but eats a lot*, the analysis of the complexity of the utterance based on (6) would be as follows.

The utterance itself as conjunction is a *ternary* level binary function based on the set of ordered sets  $\{<T,T,T>, <T,F,F>, <F,T,F>, <F,F,F>\}$ , the truth conditions of conjunction.

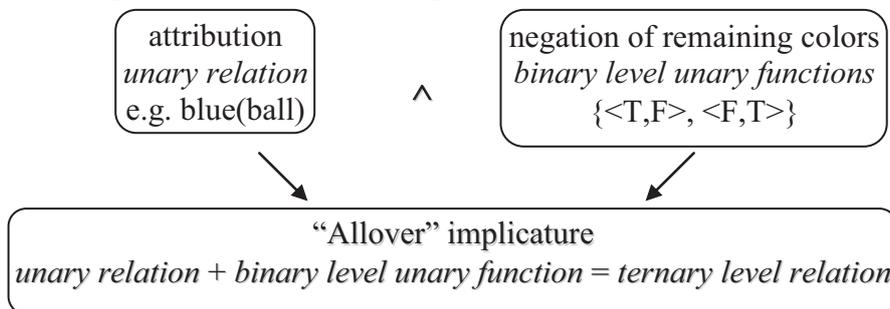

In addition, there is an expectation arising from the first conjunct, *The man hates cucumbers* of a material implication, specifically, 'if the man hates cucumbers then it is not the case that he eats a lot of cucumbers'. This material implication is a *ternary* level binary function, the set of ordered sets  $\{<T,T,T>, <T,F,F>, <F,T,T>, <F,F,T>\}$ .

The conjunction of the *ternary* level binary function, the conjunction and the *ternary* level binary function of the implication yields (at least) a *quaternary* level relation.

4.3 The relational complexity of the Allover implicature

Finally, the relational complexity of the Allover Implicature calculated with the use of attributes is ternary as shown in (7).

(7) Relational complexity of the Allover implicature

Following the analysis given (7) the relational complexity of the non-scalar implicature arising with the use of an attribute expression such as "the blue ball" will be as follows. The phrase itself involves attribution a unary relation (blue(x)). The remaining attributes in the set are negated. This involves multiple negation of the remaining colors, multiple binary

level unary functions based on the truth conditions of negation (the set of ordered sets  $\{ \langle T, F \rangle, \langle F, T \rangle \}$ ). These assertion of attribution of one attribute is conjoined in a ternary level binary function (based on the truth conditions of conjunction,  $\{ \langle T, T, T \rangle, \langle T, F, F \rangle, \langle F, T, F \rangle, \langle F, F, F \rangle \}$ ). Thus, the implicature is considered to have ternary level complexity. Ternary level relations are predicted to be acquired by 5 years (Halford, et al, 1998).

## 5.0 Experimental predictions

Returning to the three issues which arose in the introduction (above), we can formulate experimental predictions in each area.

First, consider the question of scale versus non-scale. As far as adult behavior is concerned, there are no discriminating predictions based on this issue. For the children, the presence/absence of a scale itself may not predict developmental difficulty. The processing of any kind of implicature scalar or non-scalar requires the comparison with some sort of reference set. There is no reason to suppose on face value that a scalar reference set requires greater processing ability than a non-scalar contrastive reference set. Note however, that a scale is analysed as quaternary (requiring the quaternary level conjunction of entailment and negation of entailment constituting unidirectional entailment). Since quaternary level processing is considered to be mastered only at 11 years, we can formulated the predictions in (8) regarding scales and non-scales.

- (8) Predictions for adult and child processing of scales and non-scales
- a) There will be no difference in the frequency of adults' calculation of the scalar implicature of disjunction (as evidenced by their rejection of disjuncts as descriptions of pictures where both disjuncts are true), and the frequency of adults' calculation of the non-scalar implicatures of No-contrast (as evidenced by their rejection of the use of neutral *and* in cases where there is no contrast between the conjuncts) or the Allover implicature (as evidenced by their preference for a wholly attributed object over a partially attributed object).
  - b) (i) Children's calculation of the quaternary level scalar implicature (as evidenced by their rejection of disjuncts as descriptions of pictures where both disjuncts are true) will not reach adultlike levels until the age of 11.  
 (ii) Children's calculation of the non-scalar implicatures cannot be predicted based solely on the absence of the scale, although in general all other things being equal this calculation should occur earlier than for scalar implicatures since the processing of a scale is quaternary.

Now consider the question of the generalized nature of implicatures. According to theory of GCI, GCIs are the default, typical interpretation of an expression in the absence of a special context, while PCIs arise only in specific contexts. The implicature associated with disjunction is considered to be a GCI, arising in all uses of disjunction and only canceled in particular contexts. As described above, we hypothesize that the Allover Implicature, like the scalar implicature of disjunction, is a GCI, while the No-Contrast Implicature of conjunction is a PCI. For adults there is a clear prediction that their performance on tasks requiring the calculation of a GCI will be very consistent, far more consistent than their performance on PCIs. These predictions are summarized in (9).

- (9) Predictions for adults:
- a) Adults will reject violations of the scalar GCI close to 100% of the time

- b) Adults will interpret use of a bare attribute as completely attributed, calculating the non-scalar Allover GCI close to 100% of the time
- c) Adults will show variability in rejection of violations of the No-Contrast PCI

For children, the consistency of the adult responses provides a very clear developmental target. Otherwise the generalized or particularized nature of an implicature should have no bearing on the developmental difficulty of the implicature. In the present case, the GCI of disjunction being quaternary will be predicted to develop only at 11 years while the Allover GCI will be predicted to develop by 5 years. The No-Contrast PCI of non-contrastive conjunction will also be predicted to develop only at 11 years, as this implicature is also quaternary. In short, we hypothesized that the acquisition of implicatures would be dependent on the relational complexity of the implicatures and be independent both of the nature of the reference set and whether the implicature is generalized or particularized, resulting in the predictions in (10).0

(10) Predictions for children:

- a) Children are not predicted to reject violations of the quaternary level scalar GCI before the age of 11 years
- b) Children are predicted to interpret use of bare attribute as completely attributed, calculating the ternary level non-scalar 'Allover' GCI from the age of 5
- c) Children will not reject violation of the quaternary level non-scalar No-Contrast PCI before the age of 11 years

The third and final issue we raised was the question of the relational complexity of the implicature phenomena involved. As is clear from the discussion to this point, we find this to be the crucial point in formulating developmental predictions for the implicatures. If we momentarily disregard the questions of scales and generalization we can derive the predictions given in (11).

(11) Predictions for children based on relational complexity alone

- a) Children are not predicted to reject violations of the quaternary level No-Contrast implicature consistently before the age of 11 years.
- b) Children are not predicted to reject violations of the quaternary level implicature associated with disjunction consistently before the age of 11 years.
- c) implicature before the age of 5 years.

We now turn to the experiments developed to test these predictions.

## 6.0 The experiments

### 6.1. Experiment 1 - Investigating the scalar implicature associated with disjunction

#### 6.1.1 Procedures

In order to test predictions knowledge of the GCI of disjunction and the No-contrast PCI, we carried out a variant of the Truth-Value-Judgment Task (Crain and Thornton, 1998). Children participated in individual sessions in their homes or kindergarten/school settings. Adults participated in individual sessions in their homes. A total of 141 typically developing monolingual Hebrew speaking children aged 2;7 to 9;6 and 17 monolingual Hebrew-speaking adults were asked to judge the acceptability of a puppet's descriptions of pictures prepared using the Creative Wonders Sesame Street ArtWorkshop (Henson Productions, Inc., 1995).

One condition tested calculation of the GCI based on the scale <and, o>.<sup>1</sup> There were 10 target items and 5 filler items. The target items were true descriptions of the stimulus pictures using *o* with both disjuncts true. The filler items were false disjunctions. In each case the experimenter described the picture to the participant and to the puppet and then asked the puppet to describe the picture. The participant was then asked to judge the appropriateness of the puppet's description. For descriptions judged to be unacceptable, the participant was asked to 'teach' the puppet the correct description. The items were mixed with two other conditions and organized in two different random presentation orders with approximately half of the participants presented with each presentation order. Sample target and filler items appear in (12) and (13) respectively.

(12) Target item eliciting calculation of the scalar GCI based on scale <and, or>:

Picture stimulus: Cookie Monster eating cookies and holding a balloon.

Experimenter description: *hine ugifletset. hu maxzik balon. hu oxel ugijot.*  
 Here Cookie-monster.he holds balloon. He eats cookies.  
 'Here's Cookie-monster. He's holding a balloon. He's eating cookies.'

Puppet's description: *ugifletset maxzik balon o oxel ugijot*  
 Cookie-monster holds balloon or eats cookies  
 'cookie monster is holding a balloon or eating cookies.'

(13) Filler item

Picture stimulus: Bigbird standing near a table which holds a drink and a sandwich.

Experimenter description: *hine tsiporet. hi lo shota mits, hi lo oxelet senvich.*  
 Here Bigbird.she no drinks juice she no eats sandwich  
 'Here's Bigbird. She's not drinking juice, she's not eating a sandwich.'

Puppet's description: *tsiporet shota mits o oxelet senvich.*  
 Bigbird drinks juice or eats sandwich  
 'Bigbird is drinking juice or eating a sandwich.'

### 6.1.2 Results and discussion

As predicted, adults consistently rejected true picture descriptions violating the scalar GCI associated with disjunction (97.1% of the time). This supports the prediction that as a GCI, this implicature will be consistently calculated by adults. The scalar nature of the implicature was not predicted to influence the consistency of the adults' responses and therefore will be discussed by comparison with performance on non-scalar implicatures below. In terms of complexity, the complexity of the implicature was analyzed as quaternary, within the predicted processing abilities of adults.

Even the oldest children failed to calculate the GCI with adult level consistency. Their rejection of the stimulus items ranged from 11% rejection for the 3 year olds, increasing gradually to 50.5% rejection for the 9 year olds. Even the oldest children's responses differed significantly from the adult responses ( $F(7,115)=13.07$ , MS error=11.623,  $p < 0.05$ ). The fact that the adults calculated this implicature as a GCI provides a clear target for child acquisition such that the children's inconsistent performance can be interpreted as immature language development. The source of the children's difficulty is predicted by the complexity of the specific implicature, analyzed as quaternary, and thus predicted to develop only at 11 years. The involvement of a scale in the implicature in itself did not lead to a prediction of non-adultlike behavior, and therefore in itself does not account for this result.

---

<sup>1</sup> This was part of a larger experiment into semantic and pragmatic knowledge of coordinators. Only the relevant conditions are reported here.

## 6.2. Experiment 2- Investigating the non-scalar implicature associated with non-contrastive conjunction

### 6.2.1 Procedures

A further condition of this same experiment testing calculation of the non-scalar, No-Contrast PCI based on the set {*but, and*}. This second condition deals with the non-scalar particularized implicature based on the non-scale of contrastive conjunction represented in Hebrew by *aval*, and what we may call neutral, conjunction, the Hebrew *ve*. Participants and materials were the same as for the previous condition, however, this time the target items involved the use of *ve* to coordinate two contrasting conjuncts while the filler items used *aval* to coordinate two contrasting conjuncts. Examples of target and filler items appear in (14) and (15) respectively.

(14) Target item the No-Contrast PCI based on reference set {*but, and*}:

Picture stimulus: Hungry dog walking away from bone

Experimenter's description:

*hine kelev. hu raev. hu ohev etsem. hu mashir et haetsem. muzar!*

here dog. he hungry. he likes bone. he leaves 'et' the-bone. strange.

'Here's a dog. He's hungry. He likes bones. He leaves the bone. Strange!'

Puppet's description: *hakelev raev ve mashir et haetsem*

The-dog hungry *and* leaves 'et' the-bone

'The dog is hungry *and* leaves the bone.'

(15) Filler item

Picture stimulus: Man eating a large pile of cucumbers.

Experimenter's description:

*hine ish. haish sone melafefonim. hu oxel harbe melafefonim. muzar!*

here man. The-man hates cucumbers. he eats many cucumbers. strange.

'Here's a man. The man hates cucumbers. He eats lots of cucumbers. Strange!'

Puppet's description: *haish sone melafefonim aval oxel harbe.*

The-man hates cucumbers *but* eats many.

'The man hates cucumbers but eats alot.'

### 6.2.2 Results and discussion

As predicted, adults rejected, the adults rejected the use of the less informative *ve/and* when the contrast allowed the use of the more informative *aval/but*, but only 50 % of the time, thus demonstrating that they calculate the implicature based on the non-scale PCI optionally. This does not indicate chance levels, but rather individual differences with individual participants consistently (> 80% of the time) calculating/failing to calculate the implicature. This is consistent with prediction that the No-contrast implicature is a PCI.

The majority of the children failed to demonstrate knowledge of the contrastive nature of *aval/but* in that they accepted the use of *aval/but* in non-contrastive coordinations. Thus, they showed no preference for the more informative *aval/but* in contexts where contrast was indicated (20% rejection of the less informative *ve/and*). The children's failure to calculate the non-scalar No-Contrast PCI we interpret as, a product of the difficulty of calculating the contrastive meaning of *aval/but* which is considered quaternary. In this case, the children do not see *aval/but* as more informative than *ve/and* and no implicature is calculated. Of those children who did demonstrate knowledge of the contrast of *aval/but*, only one (of 5) calculated the No-Contrast PCI. Conclusions about children's knowledge of particularized implicatures such as this are difficult to draw due to the inconsistency of adult calculation of these implicatures.

## 6.3. Investigating the 'Allover' implicature associated with some adjectives

### 6.3.1. Procedures

In order to test knowledge of the 'Allover' implicature associated with some adjectives, we carried out a pointing task with 38 typically developing monolingual Hebrew-speaking children aged 2;11-12;0 and 12 adults on their knowledge of non-scalar conversational implicatures in a pointing task. Participants heard target picture descriptions in two sets. The first set included 10 items using colors and the second set included 18 items using other attributes. The target items were equally divided between two experimental conditions: in the first the target picture was a completely attributed object compared with a partially attributed object and two other distracters, in the second the target picture was a partially attributed object compared with 3 distracters. Each set also included filler items where the items were different object of different colors/attributes were depicted. Children were pre-tested for knowledge of the colors and attributes before testing. Examples of experimental items for the 'allover' and 'partially' appear in (16) and (17) respectively, while a sample filler item appears in (18).

(16) Target item for Non-scalar 'Allover' GCI – 'allover' condition

Picture display of four balls: blue striped ball, all blue ball, all green ball, blue middle changing to green border

Stimulus: *tari li et hakadur hakaxol*  
show me 'et' the-ball the-blue  
'show me the blue ball.'

(17) Target item for partially condition

Picture display of four shirts: red shirt with yellow circle, green shirt with red circle, red shirt gradually changing to blue, green shirt with floral square on one shoulder

Stimulus: *tari li et haxultsa hapirxonit*  
show me 'et' the-shirt the-flowery  
'Show me the flowery shirt.'

(18) Filler item

Picture display of four objects: red ball, black giraffe, black parakeet, green hat

Stimulus: *tari li et ha-d iraffa ha-xamuda*  
show me 'et' the-giraffe the-cute  
'Show me the cute giraffe.'

### 6.3.2 Results and discussion

As predicted, adults calculated the 'Allover' GCI consistently for colors, selecting the completely attributed object picture 100 % of the time, and slightly less consistently for attributes, selecting the completely attributed object picture 99% of the time. The consistency of the Allover Implicature supports the existence of at least one type of default non-scalar implicature, much the same as that of default scalar implicatures (cf Levinson, 2000).

Children in the 5-6 year old age group exhibited adultlike preference for a completely attributed object 90% for attributes and 95% of the time for colors. The result for colors did not differ significantly from the adults' results ( $p > 0.05$ ), however, for the other attributes, this result was marginally significantly different from the adults ( $p = 0.57$ ) and adult consistency was only obtained by the 7-8 year old group ( $p > 0.05$ ). The later acquisition of the attribute adjectives is attributed to the later lexical acquisition of these types of adjectives (see e.g. Berman, 2004).

## 7.0 General discussion and conclusions

The first question we asked related to the scalar versus non-scalar nature of implicatures: Are scalar implicatures more difficult and therefore later acquired than non-scalar implicatures, simply because scales themselves are difficult to process? In the studies

reported here, for adults, the fact that an implicature includes a scale rather than a non-scale, or vice versa, does not appear to have an effect on the pattern of calculation of the implicature since one scalar and one non-scalar implicature were calculated consistently. In other words, even if scales are more difficult than non-scales, their difficulty is well within the abilities of adults.

As for children, is it the presence of a scale that makes an implicature difficult for children? In the studies reported here, one scalar (that of disjunction) and one non-scalar (the No-contrast) implicature were not mastered even by the oldest children participating in the study (the 9 year old group). There was also evidence from the non-scalar 'Allover' implicature that at least one type of non-scalar implicature is acquired relatively early. Taking these two points together we may conclude that the presence of a scale suggests a more difficult implicature, but the absence of a scale in itself does not guarantee that the implicature will be easy/early developing. For non-scalar implicatures the difficulty of the relations involved in the lexical/semantic content of the utterance appears to determine the difficulty and age of acquisition. The late development of the No-contrast implicature can be explained in terms of the late development of the underlying (semantic) contrastive meaning of the coordinator *aval*/but. The later age of calculation of the 'Allover' implicature for denominal and resultative adjectives. In terms of the implicature, there is no difference in the difficulty of calculation of the 'Allover' implicature for color adjectives and for denominal and resultative adjectives. The greater difficulty of calculating the implicature for these adjectives, results from the greater difficulty of the adjectives themselves. This is evidenced by the later comprehension and spontaneous use of these types of adjectives in Hebrew child language (e.g. Berman, 2004). For scalar implicatures, even given relatively simple lexical/semantic content, such as the semantic meaning of conjunction/disjunction, the implicature itself is complex.

The second question we asked regarded the acquisition of generalized versus particularized implicatures. This question was found to distinguish adult behavior. GCIs were calculated far more consistently than PCIs. There was primarily variation between individuals such that adult participants could be divided into two groups: those who consistently calculated the PCI and those who consistently failed to calculate the PCI. Yet, there was also some (20%) variation within individuals. This amount of variation although clearly not at chance levels differs from the approximately <5% variation found in the calculation of the GCIs.

The implications for the child data are not clear. We found that one GCI and one PCI were acquired relatively late with adultlike behavior not obtained even by the oldest participants, while one GCI was mastered at a relatively young age (5-6 years). At first glance this may appear to suggest that PCIs are mastered late while the mastery of GCIs is variable, dependent on some other factor. It is possible that PCIs are more difficult to acquire just because of their inconsistent nature. The input to children regarding the calculation of these implicatures will be inconsistent and even contradictory, and therefore more difficult to learn. Furthermore, regarding the inconsistent calculation of the GCI, it could be argued that the children know the implicature but are not aware that it is generalized and therefore calculate it only optionally. We find this explanation to be contradictory since it results in inconsistent particularized implicatures being both easier and harder at the same time. Thus, we consider that the generalized or particularized nature of an implicature is insufficient to predict its difficulty or age of acquisition.

Thus, viewing our data in terms of the first two questions yields equivocal results. We now turn to our third question. Is the determining factor in the acquisition of implicatures the complexity of the relations involved? Of the three implicatures studies, two were considered to have quaternary relational complexity, as determined by Halford, et al's (1998) Relational Complexity Metric. As predicted by their high complexity level, these implicatures were not demonstrated to be calculated by the oldest children participating in the studies, aged 9 years. Similarly, the implicature which was demonstrated by 5-6 year olds is analyzed as having ternary level complexity, a complexity level predicted to be mastered by 5 years. Thus, of the three possible factors we suggested as possible

explanations for the developmental pattern for three implicatures, the relational complexity of the implicature phenomena provides the best account for the children's data.

We cannot explain the late acquisition of the No-contrast PCI in terms of a specific difficulty with scales or with GCIs so we suggest that either the processing of the quaternary level relation is too difficult for these children (and note the difficult step in the process is the unilateral entailment). As far as the non-scalar PCI of contrastive conjunction, we saw individual differences within the adult group. For children, it appears that the problem here is not with non-scales being difficult, or of a PCI versus a GCI, but rather related to difficulty due to specific complexity of the contrastive meaning, before the stage of implicature calculation. This explanation is supported by the fact that for those children who did demonstrate knowledge of the contrastive meaning the results were very similar to the adults. Finally, the difficulty the children under the age of 5 showed appears to be related to the ternary complexity of the relation. Ternary level relations are predicted to be mastered by 5 years. Of course, here, too, it could be argued that they are not aware of the generalized nature of the implicature, but since the age matches the prediction based on the relational complexity metric, the processing difficulty explanation seems more likely.

In summary Hebrew speaking adults consistently calculate generalized implicatures, both scalar implicatures such as that of disjunction and non-scalar such as the 'allover' implicature. Furthermore, Hebrew speaking adults calculate far less consistently a particularized implicature. Lastly, the consistency of the adult responses does not appear to be related to the involvement of a scale in the implicature.

For children, the age at which they master calculation of implicatures appears to be a result of the relational complexity of the phenomenon and not related to the participation of a scale, or to the generalized or particularized nature of the implicature

Concluding, the results from these experiments exemplify the calculation of quantity implicatures using both entailment scales and non-scales; however, the consistency of calculation of the GCIs is much greater than the calculation of PCIs. Children's knowledge of these implicatures are argued to be adultlike dependent upon the complexity of the relations involved. The ages of acquisition found are consistent with the complexity of the skills being acquired as determined by Halford et al's (1998) relational complexity metric given above, 5 years for the ternary non-scalar GCI and 11 years for the quaternary scalar GCI and No-Contrast PCI.

But there are many questions which remain to be answered. Some of these relate to the limited number of implicatures investigated to date. Are there scalar implicatures which can be demonstrated in the preschool years? If so, this would challenge the analysis of the scale as contributing quaternary level complexity to scalar implicatures. What is the complexity of other implicatures? Particularly, we need more investigations of non-scalar implicatures. Regarding the generality of implicatures, which implicatures show cross-linguistic generalization and which do not, and why? And regarding the complexity of various implicatures, is the complexity of some implicatures so great as to account for adult inconsistency? At what age do children actually become adult-like in their calculation of the more complex implicatures? We need data from older children – and we are in the process of collecting these data for the implicatures investigated here.

# Negative Implicatum, Positive Implicatum

Mingya Liu

University of Tübingen  
Nauklerstr. 35, 72074 Tübingen, Germany  
*mingya.liu@uni-tuebingen.de*

## Abstract

Positive polarity items (PPIs) can co-occur with the anti-additive quantifier *no N* if intonation or enriched context makes it a contrastive negation or denial: the anti-licensing fails due to a positive implicatum (PI) that performs pragmatic licensing and it is to this PI that PPIs contribute their meaning. Similarly, the licensing of negative polarity items (NPIs) by *only* is due to the negative implicatum (NI) of the sentence and it is to this NI that NPIs such as *any*, *ever* and minimizers contribute their domain widening (Kadmon and Landman 1993) function. However, the PI related with *no N* is a conversational implicature, whereas the NI related with *only* is a conventional one and part of the sentence's truth conditions.

**Keywords:** explicature, implicature, focus operator, double-propositional, truth-conditional.

The study of polarity effects in natural language goes back at least as early as Bolinger (1960). There have been many fruitful results ever since, but none of them is perfect or exhaustive in its explanatory force. In this paper, we will compare two special cases in terms of polarity licensing, namely, one where the anti-additive quantifier *no N* fails to anti-license positive polarity items (PPIs) and the other where *only* licenses negative polarity items (NPIs). The central thesis is that polarity items can be pragmatically licensed, 'pragmatically' meaning beyond the logic of a single proposition, either by discourse or by the lexical pragmatics of the licensors.

In the first section, we will discuss to what extent the parallelism between NPIs and PPIs is (un-)justified. In the second section, we propose that if *no N* is used as contrastive negation or denial, a positive implicatum (PI) arises in discourse that renders the presence of PPIs possible. Our PI proposal is inspired by Linebarger's (1987) NI (negative implicatum) theory for NPI licensors such as *only*, where a purely semantic account or more accurately, a one-propositional semantics fails. The third section is all about *only*. We assume a double-propositional semantics for an *only* sentence and the two propositions contrast with each other in their logical properties, one being

downward-entailing (DE) and the other non-DE. This difference in polarity between the two propositions is the cause of all the complications that arise with *only* licensing NPIs. Fintel's (1999) Strawson-DEness does not account for this fact, but is a consequent of it. Our assumptions actually echo Atlas-Horn's two-entailment approach for *only*. However, we argue for a solution without turning to Horn's (2002) assertion/assertion inert distinction, namely, by admitting that NPIs such as *any, ever, lift a finger* update a sentence's truth conditions by domain widening (Kadmon and Landman 1993), but only of the DE proposition in the case of *only*. It follows that *only* and *no N* license NPIs and PPIs respectively, the former by its complex (discourse-oriented) lexical meaning and the latter by its collaboration with discourse into an un-anti-licensing context. A comparison between them and universal quantifiers is made in the fourth section. The last section offers concluding remarks. Throughout the paper, examples are in English or in German.

## 1. NPI-PPI (A)symmetry

NPIs are items that tend to only occur in negative contexts and PPIs are items that tend to only occur in positive contexts. For example, as (1) shows, the NPI *either* needs licensing by negation, as otherwise it would be unlicensed and the sentence would be ungrammatical; the PPI *too* is fine in an affirmative sentence, and would be anti-licensed by negation and the sentence would be at least odd. In all examples henceforth, boldfaced words are NPI licensors and underlined words are either NPIs or PPIs.

(1) a. *The King of France is \*(**not**) bald, either.*

b. *The King of France is (\***not**) bald, too.*

NPIs and PPIs also show oppositional behaviors towards Karttunen and Peters' (1979) contradiction negation or what Horn (1989) calls metalinguistic negation. In (2), negation is not used descriptively/truth-functionally, but metalinguistically to cancel the presupposition of the definite NP 'the King of France', namely, that there is a king of France, therefore, the NPI *either* is not licensed and the PPI *too* is not anti-licensed.

(2) a. *The King of France is **not** bald, \*either - (because) there is no king of France.*

b. *The King of France is **not** bald, too - (because) there is no king of France.*

Due to this symmetry, NPI-licensing contexts are often taken as potential anti-licensors of PPIs. However, extending the theories of NPIs to PPIs does not always succeed, because these two categories do differ in certain nontrivial aspects, two of which we will discuss here.

First, many works on NPIs attempt to generalize the key logical property of their licensing contexts that include not only negation but a variety of other semantic or pragmatic environments. The most influential proposal is made by Ladusaw (1980), who marks NPI licensing contexts as downward entailing (DE), which covers *not*, *n*-words (*nobody*, *nothing*, *never*), *few*, *hardly*, *without*, conditionals, etc. (3) contains a formal definition with an example: *few*, as a function  $\lambda u.few(u, call)$ , is downward entailing as law students is a subset of students and (3a) entails (3b).

- (3) *f* is downward entailing iff for all *x*, *y* such that  $(x \subseteq y) \rightarrow (f(y) \subseteq f(x))$
- a. ***Few students called.***  $\rightarrow$
  - b. ***Few law students called.***

However, the DEness seems to be just necessary but insufficient to anti-license PPIs. As Szabolcsi (2004) points out, it is not DEness but anti-additivity (AA) that PPIs detest. (4) provides a formal definition and an illustration with the AA operator *no one*. In the examples cited in (5), *few* and *at most n* are both DE quantifiers while *not* and *no one* are both AA: they show different co-occurring possibilities with the PPI *someone*.

- (4) *f* is anti-additive iff for all *x*, *y* such that  $f(x \cup y) = f(x) \cap f(y)$
- a. ***No one sang or danced.*** =
  - b. ***No one sang and no one danced.***
- (5) a. \**John didn't call someone.*  
 b. \****No one called someone.***  
 c. ***Few people called someone.***  
 d. ***At most five boys called someone.*** (Szabolcsi 2004: 414)

The second aspect where NPIs and PPIs differ is that sentences with unlicensed NPIs are ungrammatical and not repairable, as (6) shows, whereas sentences with anti-licensed PPIs are often only pragmatically odd such as (7a) and (8a) and therefore repairable by intonation or enriched context, as shown by (7b) and the dialogue in (8b).

- (6) a. \**John ever came.*  
 b. \**John is handsome at all.*
- (7) a. ?*John did **not** already come.*  
 b. *John did **not** already come. In fact, he is quite late.*
- (8) a. ?*John is **not** pretty handsome.*  
 b. A: *John is pretty handsome.*  
 B: *He is **not** pretty handsome. He is very handsome.*

The co-occurrence of some PPIs with AA contexts seems not to be ruled out categorically: PPIs do appear with contrastive negation or denial. It is exactly these cases that the next section focuses on.

## 2. No N, Positive Implicatum and PPIs,

The intuition that a purely semantic approach would not work for PPIs is based on the observation that as (9) and (10) show, although *kein N / no N* and *niemand / nobody* are both AA operators, they show different behaviors in terms of PPIs (anti-)licensing. In both (9) and (10), the second sentence sounds more natural than the first sentence.

(9) a. *Nobody would rather stay at home.*

b. *No girl would rather stay at home.*

(10) a. *Niemand bekräftigte die Notwendigkeit des Klimaschutzes.*

nobody asserted the necessity of the climate protection

‘Nobody asserted the necessity of climate protection.’

b. *Kein Politiker bekräftigte die Notwendigkeit des Klimaschutzes.*

no politician asserted the necessity of the climate protection

‘No politician asserted the necessity of climate protection.’

We propose that *kein N V* ‘no N V’ asserts  $[\neg\exists x(N(x) \wedge V(x))]$  and can induce a positive implicatum (PI)  $[\exists x(\neg N(x) \wedge V(x))]$  that derivatively licenses the PPI in the V position. The PI is a conversational implicature and thus cancelable. It obtains for example by intonation or through enriched context such as contrastive negation in (11).

(11) a. *No [girl] would rather stay at home. [Boys] do.*

b. *Kein [Politiker] bekräftigte die Notwendigkeit des Klimaschutzes,*

no politician asserted the necessity of the climate protection

*einige [Wissenschaftler] allerdings schon.*

some scientists though yet

‘No politician asserted the necessity of climate protection, but some scientists did.’

Szabolcsi (2004) keeps contrastive negation or denial out of her generalization about PPIs: “PPIs do not occur in the immediate scope of a clausemate anti-additive operator AA-Op, unless [AA-Op > PPI] itself is in an NPI-licensing context” (Szabolcsi 2004: 419). This at least covers the three cases in (12): the PPI adverb *durchaus* ‘absolutely’ is anti-licensed in (12a). It is shielded from anti-licensing in (12b), as it is embedded in the adjective phrase and therefore not in the affective domain of the anti-additive operator *niemand* ‘nobody’. This is what Szabolcsi means by clausemateness. We want to point out one step further that if we compute the logical form of (12b), it is clear that the PPI is scopally higher than the negative element. In the case of double negation such as (12c), they cancel each other out so that the PPI verb *bekräftigen* ‘assert’ still sounds fine in the sentence.

(12) I. Anti-licensing

a. \***Niemand** war mit dem Ergebnis durchaus zufrieden.

nobody was with the result absolutely happy

‘Nobody was absolutely happy with the result.’

II. Shielding:  $[\exists x(\dots \text{PPI}\dots) \rightarrow \exists y(y \text{ was happy at } x)]$

b. **Niemand** war mit dem durchaus brauchbaren Ergebnis zufrieden.

nobody was with the absolutely useful result happy

‘Nobody was happy with the absolutely useful result.’

III. Double negation

c. **Niemand** bekräftigte **nicht** die Notwendigkeit des Klimaschutzes.

nobody asserted not the necessity of the climate protection

‘Nobody did not assert the necessity of climate protection.’

Nevertheless, she mentions Horn’s (1989) analysis of denial as metalinguistic negation and Giannakidou’s suggestion that “denial counts extraclassical negation” (Szabolcsi 2004: 413). All in all, this leads to the conclusion that to account for cases such as (9)-(11), we need discourse logic involving either a preceding utterance (or a presupposed expectation) and the denial of it, or two utterances contrasting in polarity at the topic position. This means that although the PPI appears in a negative sentence, it should be interpreted in the logical form of a corresponding positive sentence. To put it informally, in (11b) the presence of the PPI verb *bekräftigen* ‘assert’ is justified as the event of asserting does exist although the agent is not any politician but some scientists. Similarly, in (11a) the predication *would rather stay at home* is attributed to *boys*.

We revise Szabolcsi’s generalization in (13). (13i) covers the case of double negation. (13ii) is about pragmatic licensing of PPIs, for example by denial or contrastive negation. (14a) and (14b) show that if a contrastive focus (CF) intonation is applied to the NP, both sentences sound better than before as the speaker either denies, for instance, a presupposed utterance or an expectation that ‘Students would rather speak Swabian’ or ‘Heidi Klum is absolutely pretty’, or else implicates that some people other than students would rather speak Swabian or someone other than Heidi Klum is absolutely pretty.

(13) A PPI does not occur in the immediate scope of a clausemate AA operator, unless:

- i. there is another negative operator available to cancel out the AA operator, or
- ii. there is a positive implicatum available to perform derivative licensing.

(14) a. **Kein**[**Student**]<sub>CF</sub> spricht lieber Schwäbisch.

No student speaks rather Swabian.

‘No student would rather speak Swabian.’

b. [Heidi Klum]<sub>CF</sub> ist **nicht** durchaus hübsch.

Heidi Klum is not absolutely pretty

‘Heidi Klum is not absolutely pretty.’

We will now move to the case of *only* licensing NPIs and show that the mechanism involved there is very similar to that with contrastive negation un-anti-licensing PPIs, namely, both involve two propositions that contrast with each other in polarity at the topic position.

### 3. *Only* and NPI Licensing

*Only* is among the most notorious cases for polarity licensing. In this section, we will discuss some available attempts and take our own standpoint, namely that an *only* sentence expresses two propositions, one (by the rest of the sentence, which we call the ‘explicature’ henceforth) being non-monotonic and the other (by a syntactically unpronounced element) is a negative conventional implicature. It is due to the second proposition that *only* is capable of licensing NPIs. However, this just holds when no extra negation intervenes of course.

#### 3.1. Strawson-DE and Veridicality

(15) a. **Only** John ate vegetables for breakfast.  $\neg$ -> **Only** John ate kale for breakfast.

b. **Only** John ever ate any kale for breakfast.

As (15) shows, *only* is not DE but does license NPIs. Fintel (1999) proposes that *only* is Strawson-DE as a remedy for the DE theory. “A function  $f$  of type  $\langle \sigma, \tau \rangle$  is Strawson-DE iff for all  $x, y$  of type  $\sigma$  such that  $x \Rightarrow y$  and  $f(x)$  is defined:  $f(y) \Rightarrow f(x)$ ” (Fintel 1999: 104). To put it informally, (16a) Strawson-entails (16c), as the entailment holds only when what is usually taken as the presupposition – what we call the explicature – of (16c), that is, (16b), also holds true.

(16) a. **Only** John ate vegetables for breakfast.

b. John ate kale for breakfast. (presupposition of the conclusion)

$\therefore$  c. **Only** John ate kale for breakfast.

However, despite the elegance of this proposal, it stays unclear whether *only* licenses NPIs due to its Strawson-DEness (which also leads to a further question whether DEness is the defining property for NPIs licensing).

It must be mentioned that Giannakidou (1998) proposes nonveridicality (Zwarts 1995) as the necessary NPI licensing condition because NPIs also occur in non-DE contexts such as questions, modals, and disjunctions. DEness is a subset of nonveridicality; in other words, in terms of negativity, the former is stronger than the latter. The entailment in (17a) does not hold since the proposition-embedding predicate *doubt* is a nonveridical operator: following Giannakidou's insights, the fact that it licenses the NPI *lift a finger* proves the relevance of nonveridicality to NPI licensing.

(17) *f* is nonveridical if  $f(x) \text{ -/→ } x$ .

a. I **doubt** that *John lifted a finger to help*. -/→ *John helped*.

Yet, this is irrelevant for the case of *only*, as it is not a nonveridical operator but rather a veridical one, at least regarding its explicature.

(18) a. **Only** *John ate any kale for breakfast*. → *John ate kale for breakfast*.

b. **Only** *John has ever been to the Nile*. → *John has been to the Nile*.

c. **Only** *John lifted a finger to help*. → *John helped*.

Therefore the explanation has to lie somewhere else.

### 3.2. Negative Implicatum

Linebarger (1987) claims that the focus operator *only* licenses NPIs through a conventional implicature that is 'negative':  $[\forall x(\neg G(x) \rightarrow \neg F(x))]$  and the NPI is contained in the F (topic) position. As she claims, this not only explains the fact that *only* licenses NPIs outside its focus but also that *only* licenses NPIs within its focus, that is, in the G position as well, as (19) illustrates.

(19) **Only** *those who have ever been to China know the complexity of the country*.

Our proposal is inspired by Linebarger's account but we propose a different NI for *only* as its lexical pragmatics. For simplicity, we assume that *Only a is F* and *Only Gs are F* have the same semantics and pragmatics, except that *only* induces a set of individuals as the set of the alternatives in the former, and a set of sets (properties) as the alternative set in the latter. We interpret the former as  $[F(a)]$  plus the implicature  $[\exists x(\neg(x=a) \wedge \neg F(x))]$  and the latter as  $[\exists x(G(x) \wedge F(x))]$  plus the implicature  $[\exists x(\neg G(x) \wedge \neg F(x))]$ . In other words, *only* has a two-component lexical meaning, differing in polarity, one we get explicitly and the other implicitly. But both are parts of truth conditions, as the implicature is conventionalized and not cancelable. Using Karttunen and Peters' (1979) labels, we present the entire meaning of an *only* sentence as  $\langle \phi^e, \phi^i \rangle$ :  $\phi^e$  is the explicature and  $\phi^i$  is the conventional implicature. We'll discuss the idea in more detail below.

### 3.2.1. *Only the Doppelgänger*

Combining the two components we worked out above, we get the entire meaning of the sentence *Only Gs are F* as in (20).

(20) Meaning of the (contrast) focus operator *only*:

$$[[\textit{Only Gs are F}]] = \langle [\exists x(G(x) \wedge F(x))], [\exists x(\neg G(x) \wedge \neg F(x))] \rangle$$

That is, as a contrastive focus operator, *only* expresses two propositions that contrast with each other at both the focus and the topic positions. The extensions of  $G$  and  $\neg G$  form together the entire target domain of foci; the contrast at the topic position  $F$  is one of polarity. We call *only* the Doppelgänger as the affirmative and the negative parts of its meaning always go hand in hand. *Only* is therefore only and always halfway negative. When negation intervenes in the first proposition such as *Only Gs are not F*, the other proposition turns positive at the topic position, that is  $\langle [\exists x(G(x) \wedge \neg F(x))], [\exists x(\neg G(x) \wedge F(x))] \rangle$ .

What follows are arguments for why we render both parts of meaning for *Only Gs are F* an existential closure instead of a universal one, as is often assumed in the literature.

3.2.1.1.  $\phi^e = \exists x(G(x) \wedge F(x)). \forall x(F(x) \rightarrow G(x))$ , as some linguists take as the logical equivalent of an *only* sentence, is too strong to be the explicature, or one of the two entailments or the “positive contribution” (van Rooij and Schulz 2007) of the sentence *Only Gs are F*, because the domain that *only* pins down in its focus is contextually dependent, and thus ambiguous. We exemplify with proper names at the focus position for simplicity.

(21) Scenario: I invited Peter, Markus, Tom and Tom’s wife and children and I say *a*.

a. ***Only Tom came.***

b. ***Only Tom came and nobody else.*** (Tom was the only person who came.)

c. ***Only Tom came. His wife and children did not.*** (Tom was the only person of his family who came.)

It can be argued that if (21a) is uttered to mean (21c), then Peter and Markus are simply outside the targeted domain and it is indeed the case. However, the crucial point is that this is not something that the hearer could get from hearing (21a), that is, the domain restriction is not lexically conventionalized and therefore we will not take a universal closure as part of the explicature, but rather an existential one. Therefore, the explicature of (21a) is  $\exists x(x=\text{tom} \wedge F(x))$  or  $F(\text{tom})$  instead of  $\forall x(F(x) \rightarrow x=\text{tom})$ , which presents rather the meaning of *Tom was the only person who came*, that is, (21b).

3.2.1.2.  $\phi^i = \exists x(\neg G(x) \wedge \neg F(x))$ . For similar considerations, we render the NI an existential closure because the universal closure in Linebarger's  $\forall x(\neg G(x) \rightarrow \neg F(x))$ , which is logically synonymous to  $[\forall x(F(x) \rightarrow G(x))]$  as  $a \rightarrow b \equiv \neg a \vee b \equiv b \vee \neg a \equiv \neg b \rightarrow \neg a$  (this makes the following arguments appear redundant), can be cancelled through contextual enrichment, whereas the existential one can not and conventional implicatures are not cancellable (Levinson: 1983).

(22) A: **Only** Ross came to the sandwich party yesterday.

B: Really? I heard Joey was there too.

A: Yeah, but Joey never misses a sandwich party anyway.

The domain of the contrastive foci, that is, the set of alternatives that *only* places in contrast with the rest of the sentence, is subjective. It is not always clear to the hearer whether the speaker means by (22A) that Ross was the only person in the universe who showed up at the party or the only person of a restricted domain. However, although the speaker can restrict the set from being universal/exhaustive, it should never be reduced to be empty. For this reason, it would be odd to say *Only Ross came to the sandwich party yesterday and all the others as well*, as we would have nothing there to contrast with Ross in polarity at the topic position.

To sum up, the truth conditions of the sentence *Only a is F* is  $\langle [\exists x(x=a \wedge F(x))], [\exists x(x \neq a \wedge \neg F(x))] \rangle$ , whereas  $\langle \forall x(F(x) \rightarrow x=a), \forall x(\neg F(x) \rightarrow x \neq a) \rangle$  is the truth conditions of the sentence *a is the only one who is F*.

3.2.1.3. *Extension of the Focus Domain*. The extension of G and  $\neg G$  is of existential/non-exhaustive nature, on which the speaker/hearer should agree, as this is the conventional meaning of *only*. The extension of G will be explicated, for example, it is Tom in (21a) or a set having at least Tom as its member but how about the set of  $\neg G$ ? What rules guide the speaker and the hearer concerning the use and the interpretation of *only*?

Despite the fact that *only* can be used even when we have for example just two individuals in the focus domain to compare with, it is often applied as an economic tool to save linguistic efforts and this is why in the first two scenarios of (24) it would be odd to use the b sentence instead of a. (23) is a rule that an ideal speaker should obey in communication.

(23) Productive Economy:

Maximize the contribution of the context and minimize linguistic efforts.

(24) I. Scenario: Tom didn't come. Mary didn't come. John came.

a. **Only** John came.

b. ?**Only** Tom and Mary didn't come.

II. Scenario: Tom came. Mary came. John didn't come.

a. **Only** John didn't come.

b. ?**Only** Tom and Mary came.

The interpretation of a linguistic utterance works differently though, in that the hearer is supposed to count mostly on the literal meaning of the utterance. That is, more generally, once linguistic efforts have been made (by the speaker), they should be maximally applied (by the hearer) for communicative purposes. Kennedy's rule of Interpretive Economy that he formulates in his recent paper on the vagueness of gradable adjectives seems to be able to support what we want to say here.

(25) Interpretive Economy:

Maximize the contribution of the conventional meanings of the elements of a sentence to the computation of its truth conditions. (Kennedy 2007: 36)

As (26) shows, the conventional meaning of an *only* sentence has two parts, in this case (26a) and (26b). The hearer always gets both of them for free, 'for free' meaning contextually independently and therefore both are part of the sentence's truth conditions.

(26) **Only** John didn't come.  $\Rightarrow$

a. John didn't come.

b. Someone other than John did come.

This certifies that *only* only guarantees the non-emptiness of the contrastive focus domain  $\neg G$  but exactly what goes into the domain is beyond the semantics and thus contextual.

### 3.2.2. *Even*

A natural question arises here, namely, since *only* can license NPIs by its negative conventional implicature, why cannot for example *even* do so as well? In (27) examples are cited from Karttunen and Peters (1979). From (27), we can infer a, b' and b'', the latter two being conventional implicatures.

(27) *Even* Bill likes Mary.

a. Bill likes Mary.

b'. Other people besides Bill like Mary.

b''. Of the people under consideration, Bill is the least likely to like Mary.

This shows that the conventional implicatures of an *even* sentence are more complicated than that of an *only* sentence, which has a clear-cut opposite polarity at the topic position to that of the contrasting explicatured proposition.

(28) a. *I am disappointed that even Bill likes Mary.*  $\rightarrow$

*I am disappointed that Bill likes Mary.*

b. *I am disappointed that only Bill likes Mary.* -/->

*I am disappointed that Bill likes Mary.*

The entailment in (28a) shows that (27b') and (27b'') are only implicated but not asserted. *Only*, however, is different. As (28b) shows, *Bill likes Mary* is not part of the states of affairs that the speaker is disappointed with but rather the part that counts as the conventional implicature. Does it mean that what we call the conventional implicature of *only* is the real assertion and that *Bill likes Mary* is what Horn calls the presupposition (Horn 1969) or what he calls more recently the inert assertion (Horn 2002)? Consider (29) before we talk more about Horn's idea in 3.3.

(29) a. *I got to know that even Bill likes Mary.* →

I got to know that Bill likes Mary.

b. *I got to know that only Bill likes Mary.* →

I got to know that Bill likes Mary.

### 3.3. Assertoric Inertia

For Horn among others, *only* is semantically conjunctive and non-DE. The two conjuncts, using his examples (Horn 2008), (30a) and (30b), are both entailments of (30), but only one, namely, in this case, (30b) is asserted while (30a) is "assertorically inert".

(30) **Only** love counts.

a. Love counts.

[Prejacent]

b. Nothing distinct from love counts.

[Exclusive]

The reason why *only* licenses NPIs, as he claims, is because "It's DOWNWARD ASSERTING, not DOWNWARD ENTAILING environments that license NPIs, or at least NPI *any/ever* and the minimizers" and *only* is downward asserting, as is the assertion (30b). That is to say, there is only a pragmatic asymmetry between the two entailments, namely one as asserted and the other as "assertorically inert". Manfred Krifka pointed out (during the discussion of Horn's invited talk at CIL18) that this pragmatic asymmetry can be considered in terms of information packaging. The basic idea is, in brief, that the negative contribution is prominent in the meaning of *only* and it is this part of meaning that licenses NPIs.

Therefore, our two-propositional semantics of *only* and Horn's double-entailment with differences in assertoric prominence, as we capture them, only differ in the pragmatic ordering of the two entailments indeed. What we call the explicature

corresponds to Horn’s “inert assertion” and our implicature is his assertion. Our motive for wanting to apply the distinction of explicature/implicature is that it captures the meaning of *only* by distinguishing what is said explicitly and implicitly, both as parts of an *only* sentence’s truth conditions, and thus both of its semantics. Below, we will suggest a solution without turning to Horn’s (2002) assertion/inert assertion distinction (our suggestion is not exactly against Horn’s idea, but we cannot decide yet how to relate the two or in what sense his or ours is more advantageous to the other), basically by admitting that NPIs that occur in an *only* sentence are licensed by the implicitly entailed negative proposition and it is to this proposition that these NPIs contribute truth-conditional meaning by what Kadmon and Landman (1993) call domain widening.

### 3.4. Polarity Items and Truth Conditions

The major trick of our proposal is to assume that polarity items contribute to the truth conditions of a sentence. NPIs such as *any*, *ever* and minimizers update the truth conditions of a sentence by domain widening (Kadmon and Landman 1993), by which they create a strengthening effect in the relevant utterance. With this assumption, (31a) is truth-conditionally not equivalent to (31b), as the presence of the NPI *any* widens the domain of what counts as breakfast. A glass of orange juice does not usually count as breakfast, but can possibly, and therefore (31c) is fine but (31d) is odd.

- (31) a. *George didn’t have breakfast today.*  
 b. *George didn’t have any breakfast today.*  
 c. *George didn’t have breakfast today, but drank a glass of orange juice.*  
 d. *?George didn’t have any breakfast today, but drank a glass of orange juice.*

Similarly, since the presence of NPIs such as *ever* widens the interval of reference time, the truth conditions of the sentence are changed, as (32) shows.

- (32) a. *Kim hasn’t had soup for breakfast, but only once in Korea ages ago.*  
 b. *Kim hasn’t ever had soup for breakfast, \*but only once in Korea ages ago.*

The truth-conditional contribution by polarity items such as *already/yet*, *either/too*, *still/anymore* is a different story, namely, both elements of each pair contribute by their lexical pragmatics one and the same conventional implicature (or presupposition) that we maintain should be part of the sentence’s truth-conditions.

- (33) a. *Peter is already here.* <p, q>  
 b. *Peter is **not** here yet.* <¬p, q>  
 p: Peter is here.  
 q: Peter is supposed to be here.

(34) a. *Peter is still here.* <p, q>

b. *Peter is **not** here anymore.* <¬p, q>

p: Peter is here.

q: Peter was here.

(35) a. *Peter is here, too.* <p, q>

b. *Peter is **not** here, either.* <¬p, r>

p: Peter is here.

q: Someone other than Peter is here.

r: Someone other than Peter is not here.

Each sentence expresses two propositions in its truth conditions. Take *already/yet* for example, (33a) and (33b) differ truth-conditionally in the polarity of the first proposition, but not in the second one. The same is with *still/anymore*. It is a bit more complicated with *too/either*, in that their conventional implicatures, (35q) and (35r) respectively, differ in polarity. The two propositions can be negated separately and thus there could be four possible results <p, q>, <¬p, q>, <p, ¬q> and <¬p, ¬q>. The third possibility obtains when negation is used metalinguistically to deny the conventional implicature. The last combination is unavailable, as negation cannot be used truth-functionally and metalinguistically at the same time, in other words, the two propositions must be negated separately if they are to. *Only* licenses NPIs of the *any-ever-lift a finger* type but not those of the *yet-either-anymore* type.

(36) a. **Only** *Kim had any soup for breakfast.*

b. **Only** *Kim has ever had soup for breakfast.*

c. **Only** *Kim lifted a finger to help with the cleaning up.*

d. \***Only** *Kim had breakfast yet.*

e. \***Only** *Kim had breakfast, either.*

f. \***Only** *Kim is crazy about kimchi anymore.*

As we have already argued above, the first type of NPIs all contribute to truth conditions of the sentence by domain widening. In the case of *only*, the truth-conditional update by these NPIs only occurs in the second, conventionally implicated, proposition.

(37) a. **Only** *Kim has had soup for breakfast.*

b. **Only** *Kim has ever had soup for breakfast.*

(37b) semantically expresses two things <Kim has had soup for breakfast; Someone other than Kim hasn't ever had soup for breakfast>. The first conjunct is not DE but the second is. Therefore, (37a) and (37b) actually entail (38a) and (38b) respectively.

(38) a. <Kim has had soup for breakfast;

Someone other than Kim hasn't had kimchi soup for breakfast.>

b. <Kim has had soup for breakfast;

Someone other than Kim hasn't ever had kimchi soup for breakfast.>

With these data and arguments, we want to show that the Strawson-DEness of *only* is the consequence of the fact that two propositions expressed by an *only* sentence logically differ from each other, namely one is non-DE and the other is DE. The mechanism involved there, namely to put the 'presupposition' (our explicature) of the conclusion sentence into the premises as in (16) is but to make the first proposition DE so that both turn downward entailing. However, it is not a necessary move as NPIs are not licensed by the first conjunct anyway. Therefore, the Strawson-DE of *only* is logically right but it is not an explanation.

Let's elaborate on the idea further:

(39) **Only** *Peter ate any vegetables.*

a. \*<Peter ate any vegetables; Someone other than Peter didn't eat vegetables.>

b. \*<Peter ate any vegetables; Someone other than Peter didn't eat any vegetables.>

c. ?<Peter ate vegetables; Someone other than Peter didn't eat vegetables.>

d. <Peter ate vegetables; Someone other than Peter didn't eat any vegetables.>

Only the NPI reading of *any* is relevant for the discussion here. (39a-b) are clearly wrong as the truth conditions of the sentence. (39c) is not quite wrong but it is rather the truth conditions of *Only Peter ate vegetables*. Similarly, as the dialogue that runs perfectly well shows: *After the party I was very disappointed that only Peter lifted a finger to help. In fact, he did most of the cleaning-up*, the domain widening by *lift a finger* does not target the proposition that Peter helped and in fact he could have been a big help. In other words, the NPI affects the negative proposition, namely *someone else didn't (or nobody else did) help, not even lifted a finger to help and I was very disappointed at this*.

The most likely reason why *yet*, *anymore*, *either* do not work the same way, as we speculate, is that they are different from NPIs *any*, *ever* and *lift a finger* in relation to negation. It is definitely not a question of their strength as PPIs, as *lift a finger* is a stronger NPI in English as *yet*, therefore, von der Wouden's (1997) classification fails to be explanatory here. Sentences such as *Anna is here yet/anymore/, either* are unavoidably ungrammatical as these NPIs require the modified propositions to be negative, in other words, these NPIs want grammatical licensing. The NPIs *any/ever/lifted a finger*, though, can be licensed pragmatically, for example in adversatives such as *It is amazing that Kim has ever had any soup for breakfast*, and these NPIs are used to turn a negative utterance stronger in the assertoric tone. In brief,

*yet/either/anymore* presuppose a negative proposition while *any/ever/lifted a finger* strengthen a negative proposition. Moreover, take the minimizer *lift a finger* for example, if Peter helped, it follows that he at least lifted a finger to help. In other words, from the sentence *Only Kim lifted a finger to help*, *Kim lifted a finger to help* is trivially true, although the sentence is usually not assertable except in its literal meaning. As for *any* and *ever*, we don't know whether the fact that they can appear in the explicature without contributing the domain widening function to the proposition has anything to do with their free choice reading. It is worth repeating that historically, *ever* did appear quite frequently in affirmative sentences as an intensifier. We will say no more than this, as sadly, the puzzle rises beyond the scope of the author's intelligence.

The DENess of the implicature gets lost if negation intervenes. The explicature turns DE but on the whole the DE still doesn't follow, so (40) does not entail that *Only Peter didn't eat any kale*. For the same reason as for (39c), (40c) is not really wrong but represents more accurately the truth conditions of *Only Peter didn't eat vegetables*.

(40) **Only Peter didn't eat any vegetables.**

- a. \*<Peter didn't eat vegetables; Someone other than Peter ate any vegetables.>
- b. \*<Peter didn't eat any vegetables; Someone other than Peter ate any vegetables.>
- c. ?<Peter didn't eat vegetables; Someone other than Peter ate vegetables.>
- d. <Peter didn't eat any vegetables; Someone other than Peter ate vegetables.>

(41), however, entails *Not only Peter didn't eat any kale*. It is DE on the whole as both propositions it expresses as in (41a) are DE *per se*. This means that the proper negation of a sentence such as *Only Peter ate vegetables* is *Not only Peter didn't eat vegetables*. Truth-conditionally speaking, (41) is synonymous to *Someone besides Peter didn't eat any vegetables, either*. Analogously, *Not only Peter ate vegetables* is truth-conditionally equivalent to *Someone besides Peter ate vegetables, too*. (42) is not a grammatical sentence, because neither proposition as in (42a) is able to accommodate the NPI *any*.

(41) **Not only Peter didn't eat any vegetables.**

- a. <Peter didn't eat any vegetables; Someone other than Peter didn't eat any vegetables.>

(42) \***Not only Peter ate any vegetables.**

- a. <Peter ate vegetables; Someone other than Peter ate vegetables.>
- b. \*<Peter ate vegetables; Somebody other than Peter ate any vegetables.>
- c. \*<Peter ate any vegetables; Somebody other than Peter ate vegetables.>
- d. \*<Peter ate any vegetables; Somebody other than Peter ate any vegetables.>

Still something has to be said about the contrast between (43a) and (43b).

(43) a. *I was disappointed that only Peter lifted a finger to help.* -/→

I was disappointed that Peter helped and somebody else didn't lift a finger to help.

d. *I got to know that only Peter lifted a finger to help.* →

I got to know that Peter helped and somebody else didn't lift a finger to help.

Horn's assertion/assertion inert seems more explanatory for cases such as (43a), where the negative assertoric tone with *only* (of the assertion) licenses NPIs. We are curious how it could also account for the difference between the two embedding predicates, one expressing a negative attitude as *be disappointed* and the other having a neutral tone as *got to know*. We haven't had any groundbreaking thoughts about this yet that could serve as an explanation.

#### 4. *Only, no and all*

*No N* works quite like the focus operator *only Ns*, except that *no N* expresses a negative proposition [ $\lambda P.\lambda x.\neg\exists x(N(x)\wedge P(x))$ ] and when used as contrastive negation, it can implicate a PI whereas *only* explicates a positive proposition and always implicates an NI, in case the rest of the sentence has no extra negation.

(44) *Shall we start the wedding?*

a. **Only** *the bride is here.*

b. **No** *bridegroom is here.*

To a question such as (44), both (44a) and (44b) can serve a felicitous answer, namely, the wedding cannot be started due to the absence of the bridegroom. However, we don't think that we can apply the same analysis for *no N* and *only Ns*. First, the answerer of (44a) has to know both that the bride is here and the bridegroom is not here but that of (44b) has to know that the bridegroom is not here, not necessarily knowing whether the bride is here or not. Therefore, the information conveyed by the two sentences (44a-b) is not the same.

This is to certify that the NI induced by *only* is a conventional implicature (context-independent) while the PI by *no N* is a conversational (context-dependent) one. The latter is cancelable while the former is not. Consider:

(45) *Shall we start the wedding?*

a. **Only** *the bride is here.* \**The bridegroom is here as well.*

b. **No** *bridegroom is here.* *The bride is not here, either.*

This is why both the positive/negative components of meaning for *only* should be of truth conditions, which is not the case with *no N*. However, as we already argued, the extension of the contrastive foci in the NI for *only* is contextually independent in the sense that it is of existential nature, that is, it should be a non-empty set but it is context-dependent in the sense that exactly what goes into the set is contextually variant.

Coming back to the contrast between *no N* and *nothing/nobody* that we discussed in the second section, the reason why *nothing* or *nobody* tends not to induce such a PI like *no N* is that the N node presupposes the existence of an N-set or a contrastive  $\neg$ N-set. This is an insight from Atlas (1996: 272): “*All Fs* seems to ‘presuppose’ that there are Fs, while the absolute individual quantifier NP *Everything* does not”, which he attributes to Strawson (1952). Therefore, *nothing/nobody* always serve an exhaustive answer concerning a certain domain of foci, while *no N* can but not necessarily. Observe (46):

(46) *Who came?*

- a. ***Nobody*** came. \**But some students came.*
- b. ***Nobody*** came. \****No*** professor, either.
- c. ***No*** professor came. *But some students came.*
- d. ***No*** professor came and ***nobody*** else, either.

Analogously, in a discourse, *All Fs are Gs* or *Every F is G* does not exclude  $[\exists x(\neg F(x) \wedge (\neg G(x) \vee G(x)))]$ , while the same thing will be redundant to follow *everything/everybody* due to their exhaustivity regarding the targeted domain of foci.

(47) *Who came?*

- a. ***Everybody*** came. \**Some professors came as well.*
- b. ***Everybody*** came. \**Some professors didn't come.*
- c. ***All*** students came. *Some professors came as well.*
- d. ***All*** students came. *Some professors didn't come.*

*All students came* can serve an exhaustive answer if the domain of foci only contains a set of students, or an inexhaustive one if the domain of foci contains more than a set of students. If (47) is meant to ask about both students and professors, simply saying *All students came* can implicate that *not all professors came*, and for this reason (47c-d) are both coherent. However, such an implicative potential is much weaker than with *only Ns* or *no N*, as the latter two have negativity in their meaning which is normally parasitic on their corresponding positive contrast, while a positive utterance with *all Ns* does not have to take a negative correlate.

By comparison, *only* derivatively licenses NPIs both outside and inside its focus while *all Ns* does so only in its restriction but not in its scope, because the latter, i.e. G, is not DE and not even such at the derivative level (undefined in its polarity). Compare

(48) with (19):

(48) \**All Students have ever read the book.*

Concerning the fact that both NPIs and PPIs are fine in the restriction of universal quantifiers, we believe that *all* in *all Ns*, also a quasi-focus operator, licenses NPIs not because of its DEness, but because the part it indicates as the focus (the relative clause) carries a negative implicatum.

(49) *All the students who had ever/already read the book attended the lecture.*

In fact, the relative clause in (49) with the PPI *already* sounds more like part of the background information; in comparison, the relative clause with the NPI *ever* is salient. With *ever*, we get a stronger NI that there are students who did not read the book (whether they attended the lecture or not), while with *already*, we get a stronger PI that there are students who read the book (earlier than expected). The relative clause with *already* can function as the non-restrictive appositive, but not that with the NPI *ever*, which has to be in the restrictor of universal quantifiers.

(50) a. *All my students, who had already read the book, attended the lecture.*

b. \**All my students, who had ever read the book, attended the lecture.*

To sum up, *all Ns* licenses both NPIs and PPIs, because it is not *all Ns* alone that contributes the NI, but the combination of *all Ns...NPI*, whereas the combination of *all Ns...PPI* does not necessarily do so. In other words, NPIs strengthen the existence of an NI while PPIs strengthen that of a PI. The same is true with *no N...PPI* vs. *no N...NPI*, but the other way around, namely, due to the presence of PPIs, the former strongly implicates a positive content, a preceding utterance or an expectation for instance.

(51) a. *No student has already read the book on phonology.*

b. *No student has ever read the book on phonology.*

More generally, licensing and anti-licensing are not just a matter of the licensors' logical properties and the licensees' sensitivity, but also an effect of the two combined with each other. As (51b) indicates, an utterance with the NPI adverb *ever* is more emphatic than one without: this strengthening effect obtains due to the combination of a domain widening NPI in the affective domain of a negative element. NPIs such as *yet*, *anymore*, *either* do not have the same function although they need licensing by negation as well.

## 5. Conclusion

To conclude, polarity items can be pragmatically licensed, 'pragmatically' meaning

that they can appear in one sentence but be licensed by another one with appropriate logical properties. NPIs are licensed both in and outside the focus of *only* due to its negative alter ego, or what we call the implicature (vs. the explicature) or Horn’s asserted entailment (vs. the assertorically inert entailment), which is negative both at the focus and the topic positions. PPIs in anti-licensing such as AA contexts can be rescued through a PI, but only when the AA contexts are appropriate, that is, when they have the pragmatic force like *no N* (often with the help of intonation/discourse contrast) to induce such a PI, which is strengthened again by PPIs themselves.

(52) The meaning of *only Ns*, *no N* and *all Ns*

	Explicature	Implicature
<i>Only Gs are F.</i>	$\exists x(G(x) \wedge F(x))$	Always implicates: $\exists x(\neg G(x) \wedge \neg F(x))$
<i>No G is F.</i>	$\neg \exists x(G(x) \wedge F(x))$	Strongly implicates: $\exists x(\neg G(x) \wedge F(x))$
<i>All Fs are G.</i>	$\forall x(F(x) \rightarrow G(x))$	Weakly implicates: $\exists x(\neg F(x) \wedge (\neg G(x) \vee G(x)))$

In the case of *only*, it is a conventional negative implicatum that performs the licensing of NPIs, whereas in the case of *no N*, it is a conversational positive implicatum that performs the licensing or more accurately, the rescuing of PPIs. In the case of *all Ns*, the occurrence of NPIs in its restriction renders the weak (negative) implicature more prominent, whereas that of PPIs does not. This argues for a bi-directional view on polarity effects (at least for NPIs such as *any*, *ever*, *lift a finger*), that is, there is a pragmatic effect, e.g. the strengthening of a conversational (in the case of universal quantifiers *all Ns*) or a conventional (in the case of *only*) negative implicature by NPIs. As most research on polarity items focuses on sentence-level licensing, we want to call for future research at the discourse-level, especially regarding how the presence of polarity items in discourse affect communicative reasoning.

## Acknowledgements

I am grateful especially to Frank Richter for his invaluable comments and also to Regine Eckardt, Sam Featherston, Doris Penka, Janina Radó, Manfred Sailer, Jan-Philipp Soehn for helpful discussions. I thank Laurence Horn for his comments to my presentation at the workshop *Contrastiveness in Information Structure and/or Scalar Implicatures* organized by Chungmin Lee and Ferenc Kiefer at CIL18. Many thanks also to Lucas Ogden for proofreading this paper. All remaining errors and shortcomings are of course my own responsibility. This research is funded by the *Landesstiftung*

Baden-Württemberg.

# Topic, Focus, and Exhaustive Interpretation

Robert van Rooij\*  
Universiteit van Amsterdam, ILLC  
Nieuwe Doelenstraat 15, Amsterdam  
R.A.M.vanRooij@uva.nl

## Abstract

In this paper I will defend the claim that both focus and topic should be interpreted exhaustively, but that topic gives rise to an additional inference as well. To defend the first claim, a notion of ‘dynamic exhaustification’ is crucial. It is shown that on the basis of the second claim, an alternative explanation can be given for Büring’s (1997) scope data.

**Keywords:** Topic, focus exhaustive interpretation

## 1 Introduction

Consider the following sentence with a typical topic-focus, or hat-contour:

- (1) [John]<sub>T</sub> ate [broccoli]<sub>F</sub>.

In this paper I argue that the (strong) pragmatic interpretation of this sentence is as follows:

- (a) Focus should be interpreted exhaustively: John ate only broccoli.

---

\*The ideas in sections 1-4 and 6 of this paper were presented during the 2007-Contrastiveness and Scalar Implicatures workshop of CIL 18 in Seoul. The ideas and even the writing of sections 2-5 date back to 2004. It is built on ideas developed together with Katrin Schulz. The ideas presented in section 6 were developed in cooperation with Yurie Hara to improve on some ideas of Hara (2004) and discussed in a joint draft that was never published. I would like to thank both Katrin Schulz and Yurie Hara for their ‘intellectual’ contribution to this paper.

- (b) Topic must be interpreted exhaustively: Only John ate (only) broccoli.
- (c) The speaker takes it to be possible (or even knows, if he is competent) that at least one alternative of the form ‘ $x$  ate  $y$ ’ not entailed by (1) is true. From (a) it follows that this alternative cannot be ‘John ate  $y$ ’, with  $y$  different from broccoli; from (b) it follows that this alternative cannot be ‘ $x$  ate broccoli’, with  $x$  different from John. Thus, the alternative must be something like ‘Mary ate the beans’.

In section 2 of this paper I will propose how to interpret focus exhaustively. In section 3, I will defend claim (a), despite the existence of sentences like ‘[Some boys]<sub>T</sub> ate [broccoli]<sub>F</sub>’, by making use of *dynamic exhaustivity*: exhaustive interpretation is sensitive to the denotation of discourse referents. In section 4 I will defend (b) mainly on empirical grounds. But I also suggest that claim (b) already makes sense for conceptual reasons. Section 5 deals with topic accent and the economic encoding of information. Section 6 discusses claim (c), and it will be shown that in terms of it we can account for all the scope-inversion data in Büring (1997), without giving rise to some of the problems of the latter analysis. Section 7 concludes this paper.

## 2 Bare focus, Circumscription, and Exhaustivity

Consider the following sentence:

- (2) John introduced [Bill]<sub>F</sub> to Sue.

In this sentence the item *Bill* is focussed. In what types of contexts can we appropriately use a sentence like (2) with this focal accent, and what is its effect? The central intuition implemented by most theories of focus (e.g. Jackendoff 1972, Rooth 1984) is that (2) can only be used appropriately in a context in which the question expressed by *Who was introduced by John to Sue?* was at issue and in which (2) was not yet common ground. Many theorists (e.g. Rooth 1992, Krifka, 1995) have proposed that focal stress gives, in addition, rise to Gricean Quantity implicatures. In case of example (2) to the implicature that for none of the other individuals under discussion it is true (as far as the speaker knows) that John introduced this other individual to Sue.

There are two popular theories of focus-dependent interpretation on the market that can account for these intuitions: Rooth’s (1984, 1992) alternative semantics, and the structured meaning approach of Jacobs (1984), von Stechow (1990) and Krifka (1995).<sup>1</sup> To start with the latter, assume that a sentence is represented as a Background-Focus pair  $\langle B, F \rangle$ , and that the item in focus gives rise to a set of alternatives  $Alt(F)$ . The background  $B$  indicates that a question of the form *Who has property B?* is at issue. Then we can describe Krifka’s analysis in terms of Jacob’s assertion operator as follows:<sup>2</sup>

- (3)  $\llbracket \mathbf{Assert}(\langle B, F, Alt(F) \rangle) \rrbracket = \llbracket B(F) \rrbracket$  iff  $B(F)$  is assertable and for all  $F' \in A(F)$  such that  $B(F') \neq B(F)$ , the speaker has reasons not to assert  $B(F')$ .

Krifka explicitly states that there might be various reasons for not asserting alternative propositions  $B(F')$ : it might be that  $B(F')$  is weaker (entailed by)  $B(F)$ , or that the speaker may know that  $B(F')$  is false or lacks sufficient evidence for it. In particular, it might be that  $B(F')$  is stronger than (entails)  $B(F)$ , and that the speaker knows that this stronger proposition is false. In the latter case, Krifka notices that the assertion operator can account for many scalar implicatures. This is such an important special case of the assertion operator that he defines it as a special operator called ‘Scal.Assert’:

- (4)  $\llbracket \mathbf{Scal.Assert}_1(\langle B, F, Alt(F) \rangle) \rrbracket = \{w \in \llbracket B(F) \rrbracket \mid \neg \exists F' \in Alt(F) : w \in \llbracket B(F') \rrbracket \wedge B(F') \models B(F)\}$

According to this interpretation rule, any world that verifies the sentence is excluded for which there is an alternative  $F'$  in  $Alt(F)$  such that replacing  $F$  in the sentence by  $F'$  gives rise to a statement that is true in this world and more informative than the actual assertion given. Obviously, for this analysis to have any effect for a sentence like (2), Krifka has to assume that denotations of conjunctive noun phrases like “Bill and Mary” can be alternatives to (the denotation of) “Bill”, and that the background predicate  $B$

<sup>1</sup>Only later we will discuss another theory that is perhaps not so popular.

<sup>2</sup>This rule slightly differs from the one given explicitly by Krifka in that we assume that  $Alt(F)$  is closed under conjunction (group-forming), instead of Krifka’s assumption that  $F'$  can be any subset of  $Alt(F)$ . This doesn’t seem to make any difference, though.

is *distributive* in nature. But if we do so, we can conclude from (2) that John didn't introduce  $d$  and Mary to Sue, for any  $d \neq$  Bill, which, in combination with the semantic interpretation of (2), gives rise to the intuitively correct prediction that John introduced only Bill to Sue.

Another nice feature of interpretation rule (4) is that it predicts correctly for an example such as (5):

(5) John introduced [Bill and Mary]<sub>F</sub> to Sue.

In particular, it doesn't rule out the truth of (2) just because there are alternatives to "Bill", namely "Mary" and "Bill and Mary", for which the sentence is true as well.

Krifka's analysis is stated in terms of a Background-Focus structure. A very same rule can be stated, of course, in terms of Rooth's (1984, 1992) alternative semantics as well.<sup>3</sup>

(6)  $\llbracket \text{Scal.Assert}_2(\phi) \rrbracket = \{w \in \llbracket \phi \rrbracket \mid \neg \exists \psi \in \text{Alt}(\phi) \mid w \in \llbracket \psi \rrbracket \wedge (\llbracket \psi \rrbracket \subset \llbracket \phi \rrbracket)\}$

The only difference between (4) and (6) is that for the latter we don't assume that the operator 'Scal.Assert' has immediate access to its focussed and backgrounded parts. Instead, it is assumed that we can give a recursive definition of the set  $\text{Alt}(\phi)$ . As far as the analysis of examples like (2) is concerned, it doesn't matter whether we take (4) or (6), as long as also for the latter case we limit ourselves to distributive predicates, and assume that  $\text{Alt}(\phi)$  is closed under conjunction.

Unfortunately, even if we limit ourselves to distributive predicates, the pragmatic interpretation rules (4) and (6) have some serious flaws. They give rise to wrong predictions if the item in focus is of a disjunctive or existential form. Both interpretation rules have the effect that (7-a) and (7-b) denote the impossible proposition.

(7) a. John introduced [Bill or Mary]<sub>F</sub> to Sue.  
 b. John introduced [one person]<sub>F</sub> to Sue.

---

<sup>3</sup>In this rule, and later, we could replace  $\text{Alt}(\phi)$  by a contextually given subset of  $\text{Alt}(\phi)$  as suggested by Rooth (1992), Roberts (1996), and others. We will leave these changes to the reader.

The reason is that one can infer from neither the semantic meaning of (7-a) nor that of (7-b) that any of the standard alternatives is true. Therefore (4) predicts that all these alternatives are false, resulting in the impossible proposition. Assuming that in these cases the alternatives involve generalized quantifiers obviously doesn't help: the original alternatives remain alternatives when we make this shift, and the problems remain as well.

It is easy to see that changing (4) and (6) to interpretation rule (8) doesn't really help.

$$(8) \quad \llbracket \mathbf{Scl.Assrt}_3(\phi) \rrbracket = \{w \in \llbracket \phi \rrbracket \mid \forall \psi \in \mathit{Alt}(\phi) : w \in \llbracket \psi \rrbracket \rightarrow (\llbracket \phi \rrbracket \subseteq \llbracket \psi \rrbracket)\}.$$

Also this interpretation rule gives rise to the false prediction that (7-a) and (7-b) denote the impossible proposition: neither the alternative that John introduced Bill to Sue nor the alternative that John introduced Mary to Sue is entailed by (7-a) and both are thus predicted to be false.

We have seen that it is wrong to assume that disjunctive sentences rule out worlds where the *stronger* propositions obtained by the disjuncts themselves are false, and assuming that now (suddenly) these disjuncts are not alternative propositions anymore also doesn't seem to be natural. According to us, Gricean reasoning should just rule out worlds where more of the relevant alternative propositions are true than demanded to verify the sentence. This intuition is directly expressed in the following interpretation rule. For reasons to become obvious soon, we will call this interpretation rule one of *exhaustive interpretation*.

$$(9) \quad \llbracket \mathit{Exh}(\phi) \rrbracket = \{w \in \llbracket \phi \rrbracket \mid \neg \exists v \in \llbracket \phi \rrbracket : \{\psi \in \mathit{Alt}(\phi) \mid v \in \llbracket \psi \rrbracket\} \\ \subset \{\psi \in \mathit{Alt}(\phi) \mid w \in \llbracket \psi \rrbracket\}\}$$

Notice that (9) doesn't give rise to any of the (potential) problems discussed above for sentences (5), (7-a), and (7-b). It is predicted that the sentences can be true in worlds in which John introduced Bill to Sue, because such worlds are among the ones that verify the embedded clauses that make only a minimal number of elements of  $\mathit{Alt}(\phi)$  true. For (5) they are predicted to be the only ones, while (7-a) and (7-b) allow other worlds as well. But (9) predicts that (7-a) and (7-b) are only true in worlds in which John introduced only one person to Sue.

Obviously, if we define the following (partial) ordering relation between worlds, ' $<_{\mathit{Alt}(\phi)}$ ' in terms of the sets of alternative sentences that are true in

those worlds,  $v <_{Alt(\phi)} w$  if and only if  $\{\psi \in Alt(\phi) : v \models \psi\} \subset \{\psi \in Alt(\phi) : w \models \psi\}$ , we can define (9) equivalently as  $\llbracket Exh(\phi) \rrbracket = \{w \in \llbracket \phi \rrbracket \mid \neg \exists v \in \llbracket \phi \rrbracket : v <_{Alt(\phi)} w\}$ . Suppose now that  $\phi$  is of the form ‘ $P(\alpha_F)$ ’ and that we define  $Alt(\phi)$  in terms of predicate  $P$  as follows:  $Alt(\phi) =_{def} \{P(\mathbf{d}) \mid d \in D\}$ , with  $\mathbf{d}$  a name for  $d$ . In that case (9) comes down to interpretation rule (10):

$$(10) \quad \llbracket Exh(\phi, P) \rrbracket = \{w \in \llbracket \phi \rrbracket \mid \neg \exists v \in \llbracket \phi \rrbracket : P(v) \subset P(w)\}$$

In van Rooij & Schulz (2004) and Schulz & van Rooij (2006) it is explained that if we would additionally assume a *ceteris paribus* condition for considering alternative worlds, (10) actually comes down to Groenendijk & Stokhof’s (1984) principle of exhaustive interpretation, or to McCarthy’s (1980) rule of predicate circumscription.

Interpretation rules (9) and (10) make strong predictions. For (2) for instance, it predicts that John introduced no-one else to Sue than Bill. A complaint often heard against interpretation rules like (4), (6), and also (10) has it that all we can conclude by standard Gricean reasoning is that the speaker *only knows* of Bill that he was introduced by John to Sue, leaving it open that he doesn’t know that anyone else was so introduced as well.<sup>4</sup> The Gricean interpretation of  $\phi$  that the speaker only knows  $\phi$  can be formalized by the following interpretation rule  $\llbracket \mathbf{Grice}(\phi) \rrbracket = \{w \in \llbracket \square\phi \rrbracket \mid \forall \psi \in Alt(\phi) : w \in \llbracket \square\psi \rrbracket \rightarrow (\llbracket \phi \rrbracket \subseteq \llbracket \psi \rrbracket)\}$ , with ‘ $\square\phi$ ’ meaning that the speaker knows that  $\phi$ . The strengthening from *not know* to *know that not* is then mostly contributed to the extra assumption that the speaker knows who John introduced to Sue. We fully agree with this intuition, and in Spector (2003), van Rooij & Schulz (2004), and Schulz & van Rooij (2006) it is even shown how exhaustive interpretation rules (9) and (10) can be inferred and thus motivated by this type of Gricean reasoning.

### 3 Exhaustive interpretation and discourse referents

It is standardly assumed that the focal phrase of a sentence is marked phonologically by falling intonation. But phrases can also receive a rising intonation

---

<sup>4</sup>This complaint goes back at least to Soames (1982) and has been taken up by recent defenders of the Gricean picture such as van Rooij & Schulz (2004), Sauerland (2004), and Spector (2003).

and the use of this intonation also seems to have interpretational effects. The denotation of the phrase with rising intonation was called the ‘independent focus’ by Jackendoff (1972), but is more often referred to as the (sentence, or contrastive) *topic* of the sentence, as in the work of Büring (1997, 2003), Roberts (1989), Kadmon (2001) and others. In this section we will say that such phrases have topical accent and limit ourselves to example sentences with a *hat*-contour, or a bridging accent, i.e., examples with both topical and focal accentuated phrases. Before we discuss how to interpret phrases with topical accents, however, it will prove instructive first to discuss a problem observed by Eckhardt (1995) for the analysis of focus hitherto assumed.

Consider a sentence like (11)

(11) [Half]<sub>T</sub> of the children wore [green]<sub>F</sub> shorts.

Intuitively, this sentence is true if half of the children wore green shorts, and the other half red shirts. Unfortunately, as noted by Eckhardt, this does not come out if we interpret the focal expression exhaustively by using a strong notion of exhaustivity. For if we would do so in the straightforward way, we would predict that for all alternative colors C to ‘green’, the sentence ‘Half of the children wore shorts with color C’ has to be false, which we don’t want.

We have noticed in the previous section that interpreting focal accent in a strongly exhaustive way does not always correspond with the facts, and that in general we should interpret focus in a weaker way, saying that of the alternative sentences the speaker does not know that they are true. Perhaps the problem disappears when we assume this weaker notion of exhaustivity. Indeed, in that case we would rightly predict that (11) can still be used truthfully in the situation sketched above. Unfortunately, however, this can not be the whole solution to the problem. To see this, notice that a speaker might naturally answer a question like ‘What kind of shirts did the children wear?’ with (11) immediately followed by (12):

(12) and the [other half]<sub>T</sub> of the children wore [red]<sub>F</sub> shorts.

And now we don’t want to conclude after (11) that the answerer does not know that (12) is true. Thus, even if we assume that focus should be interpreted in a weakly exhaustive way we would end up with a wrong prediction.

From Eckhardt’s discussion it might seem that the problem discussed above is due to the very particular quantificational expression ‘half’. In fact, however, the problem is of a very general nature. Consider sentences like

(13-b) and (13-c) as answers to question (13-a).

- (13) a. What did the boys eat?  
b. [Some boys]<sub>T</sub> ate [broccoli]<sub>F</sub>.  
c. [One boy]<sub>T</sub> ate [broccoli]<sub>F</sub>.

If we would interpret ‘broccoli’ in a strong exhaustive way, and ‘some’ or ‘one’ as ‘at least some/one’, it would mean for (13-c) that for all alternatives  $x$  distinct to broccoli, the sentence (*at least*) *one boy ate x* has to be false. But this gives the wrong result that from (13-b) we can conclude that *none* of the boys ate anything else than broccoli (replacing ‘one’ in (13-c) by ‘some’ gives the same result). Again, weakening exhaustive interpretation by interpreting it as ‘minimal knowledge’ doesn’t really help: it would falsely predict that one cannot continue answer (13-c) by something like ‘and two boys ate the beans’.

In the discussion above we completely ignored the fact that in the sentences that gave rise to the problems the ‘quantified’ expression received a topical accent. Taking this into account, one obvious solution to the problem seems to be that (at least) in topic-focus constructions, the expression with focal accent should not receive an exhaustive interpretation. But notice that this would be a pity! Among others, we would have to give up the general rule that the item with focal accent should always be interpreted exhaustively.

In contrast to the above suggestion, in this paper we would like to argue that focus should *always* be interpreted in an (at least weakly) exhaustive way, and that the above observations indicate that topical expressions should be interpreted somewhat differently than standardly assumed.

To discuss the standard theories of topical accent, let us take a look at the following dialogue.

- (14) a. Who ate what? What did Larry eat?  
b. [Larry]<sub>T</sub> ate [broccoli]<sub>F</sub>.

Just as it is standardly assumed that by our use of focal, or falling, accent we indicate something about the context in which the sentence is used (i.e., what is the question under discussion) and about how the sentence should be interpreted (i.e., exhaustive with respect to the focal accent), something similar is standardly taken to be the case for our use of rising, or topical accent. First of all, also our use of topical accent is taken to indicate that a set of alternatives is relevant, and that some kind of (general) question

is under discussion. Second, it is generally agreed that the topical accent indicates that the sentence that contains the topical phrase does not by itself completely resolve the relevant question for all alternatives under discussion. We share those intuitions, but we do not think that the ways these intuitions are accounted for are fully appropriate.

The perhaps best-known theory of topical accent is due to Büring (1997, 2003). Büring builds his theory of topic on top of Rooth's theory of focus. Just as Rooth (1984) assumed that any sentence  $\phi$  has a focus-semantic value,  $\llbracket\phi\rrbracket^F$ , the value that we denoted so-far by  $Alt(\phi)$ , Büring assumes that all sentences also have a *topic-semantic value*,  $\llbracket\phi\rrbracket^T$ . Consider sentence (14-b). We know already that its focus semantic value,  $Alt((14-b))$ , is the following set of propositions:  $\{\lambda w\llbracket\text{Larry ate } f \text{ in } w\rrbracket : f \in F\}$ , where  $F$  is the set of relevant kinds of food. Hamblin's (1973) identifies this set of propositions as the meaning of the question '*What did Larry eat?*'. Büring (1997) proposes that the topic-semantic value of (14-b) is the following set of Hamblin-questions:

- (15) a.  $\llbracket(14-b)\rrbracket^F = \{\llbracket\text{Ate}(\text{larry}, f)\rrbracket : f \in F\} \approx \text{What did Larry eat?}$   
 b.  $\llbracket(14-b)\rrbracket^T = \{\llbracket\text{Ate}(d, f)\rrbracket : f \in F\} : d \in D\}$   
 $\approx$  For each individual of set  $D$ , what did that individual eat?

To account for the first intuition discussed above, Büring proposes that (14-b) can be used appropriately only if both questions (15-a) and (15-b) are under discussion. Obviously, this immediately explains the felicity of the sequence (14-a)-(14-b): the second question of (14-a) is identical to (15-a), while if one wants to know the complete answer to the first question of (14-a), one has to address all questions in (15-b). To account for the second intuition that all relevant issues are not fully resolved by a sentence like (14-b), Büring demands that the interpretation of (14-b) leaves open some issues addressed in (15-b). And this comes out appropriately as well in case  $D$  contains other elements than 'Larry': whether we interpret the focus in (14-b) exhaustively or not, the sentence only *partially* addresses (15-b) and leaves open the possibility that Bill, for instance, ate something else than broccoli.

Although Büring notices that topical accent many times gives rise to a partitive reading, he does not suggest that as a consequence we should interpret phrases with topical accent in a non-standard way. But, as we saw above, if we interpret the phrases with topical accent in (11), (13-b)

and (13-c) in a standard quantificational way, the analysis makes the wrong predictions for these examples once we interpret focus exhaustively. As for (11), Eckhardt herself provided us already with the right intuition: what gives rise to the problem is the assumption that the noun phrase ‘half of the children’ should be interpreted *quantificationally*, and this not only in the sentence (11) itself, but also in all the focal-alternatives that are supposed to be excluded by exhaustive interpretation. Instead, she suggests, we should look at the actual set of children that constitute this half, and assume that by exhaustification it is excluded that any of the other children also were green shorts.

One natural way to account for this intuition is to assume that the speaker had a particular group of children in mind when she used (11), and referred to this group by her use of the topical noun phrase ‘half of the children’. In this paper we don’t want to be committed to such a referential analysis of certain noun phrases, and we want to show that using any form of dynamic semantics will already help us to solve this problem.

Instead of looking at Eckhardt’s original example, we will consider the examples (13-b) and (13-c). What we want to account for is the intuition that the (contrastive) topical accent on ‘Some/One boy(s)’ in (13-b) is used to indicate that more than some boys (one boy) are (is) under discussion, with the result that (13-b) and (13-c) can at most be *partial* answers to question (13-a). Following the suggestion of Eckhardt, we propose that in (13-c), for instance, we have to exhaustify the focal expression not with respect to the quantifier ‘one boy’, but with respect to the *denotation* of the discourse referent introduced by ‘one boy’.<sup>5</sup> Thus, if this denotation is *S*, the alternatives that are excluded by exhaustive interpretation are all of the form ‘*S* ate *f*’, where *f* is some kind of food different from broccoli. The easiest way to state exhaustive interpretation when discourse referents are crucial, we feel, is by using exhaustification rule (10) or its weakly epistemic variant. In that case we can represent (13-c) simply as something like (16).<sup>6</sup>

---

<sup>5</sup>The suggestion that for the interpretation of topical accent, we need to make use of discourse referents is not new. Vallduví & Zacharski (1994), for instance, claim that “[...] the internal structure of information states which is, in fact, crucially exploited by the different information-packaging strategies used by speakers in pursuing communicative efficiency is at least a system of file cards connected by pointers.”

<sup>6</sup>In this explicit representation, ‘*Exh*’ is used as an operator that can be used freely in the representation of the sentence. This way of representing things here is only for convenience, however. In Schulz & van Rooij (2006) a *dynamic exhaustivity operator* is

$$(16) \quad \exists X[Boy(X) \wedge Exh(card(X) = 1 \wedge Ate(X, Broccoli), \lambda y.[Ate(X, y)])]$$

Sentence (13-c) is now predicted to mean that one boy ate broccoli, and, depending on whether the speaker is taken to be competent on the subject matter of discourse, either that this one boy is known to have eaten nothing else, or that the speaker doesn't know that this one boy ate anything else. As a consequence, the idea to interpret topical quantificational expressions with respect to denotations of discourse referents allows us to interpret (as a default) focus exhaustively also in hat-contours without the undesired consequence: it is still possible that non-members of the denotation of the discourse referent  $X$  ate something else than broccoli, i.e. beans.

Combining the ideas that focal phrases be interpreted exhaustively and topical phrases referentially has an extra appealing consequence. Representing (17-a) by (17-b):

$$(17) \quad \begin{array}{l} \text{a.} \quad \text{and [three boys]}_T \text{ ate [pizza]}_F \\ \text{b.} \quad \exists Z[Boys(Z) \wedge Exh(card(Z) = 3 \wedge Ate(Z, Pizza), \lambda y.[Ate(Z, y)])] \end{array}$$

we correctly predict that if the speaker indicates that he is knowledgeable about the subject matter of the discourse and that the answer is complete after sequence (13-c)-(17-a), that 4 boys were under discussion. Thus, we predict that the topical phrases have *disjoint* denotations, as is natural in partitive constructions. The reason is that if all members of  $X$  have only property  $P$  (among the relevant ones) and all members of  $Y$  only property  $Q$  and  $P \neq Q$ , it follows that  $X$  and  $Y$  have mutually disjoint denotations. Notice that this doesn't follow solely from our proposal to interpret the topical phrases in (13-c) and (17-a) 'referentially', as the interpretation of a discourse referent, we needed the extra assumption that the focal phrases be interpreted exhaustively as well.

---

defined that takes scope over the whole sentence (and in particular over the existential quantifier), but is interpreted just as (16) should intuitively be interpreted. Thus, our proposal is still completely compatible with a Gricean *global* analysis of implicatures.

## 4 Exhaustive interpretation of topics

Eckardt (2003), however, shows that topical phrases do not always have mutually disjoint denotations. Consider the following sequence:

- (18) a. At different days of my measles, an increasing numbers of red spots appeared on my face:  
b. [One spot]<sub>T</sub> had appeared by [Monday]<sub>F</sub>,  
c. [two spots]<sub>T</sub> by [Tuesday]<sub>F</sub>,  
d. and [three spots]<sub>T</sub> had appeared by [Wednesday]<sub>F</sub>.

Now we don't conclude that we are talking about 6 different spots. The reason is, intuitively, that in contrast to (13-c) and (16) the only thing that is crucial for the interpretation of the numerical expressions here is the *quantity* of spots involved, not their identity. In accordance with many others making use of dynamic semantics, we suggest that phrases like *one N* can have both a '*referential*' reading – where discourse referents are introduced immediately –, and a '*quantificational*', one, where discourse referents are introduced only after the interpretation of the whole sentence. An exhaustive reading of the focal expressions in (18-b) now doesn't have the effect that the specific spot introduced had appeared only by Monday, but rather just that only on Monday one spot had appeared. This has the result that the topical expressions in (18-b) and (18-c) need not denote mutually disjoint sets of spots anymore.

But the resulting proposal that at least some numeral expressions with topical accent receive a quantificational interpretation gives rise to some wrong predictions. First, and worst, we are back to our original problem: on a quantificational reading of *one spot* (and the assumption that focus should be interpreted exhaustively) we falsely predict from (18-b) that on all other days than Monday no spot appeared. Second, the analysis doesn't predict the inappropriateness of a sequence like (13-c) followed by (19):

- (19) and [three boys]<sub>T</sub> ate [broccoli]<sub>F</sub>.

Intuitively, sequence (13-c)-(19) is out because the speaker could have coded the expressed information more economically by just saying that *all* boys ate broccoli. But the proposal under discussion has to stipulate an extra constraint to account for this. Similarly, we don't account for the intuition that (18-b) implicates that on Monday *only* one spot appeared.

To account for these problems we propose/suggest that in sentences with a hat-, or bridge-contour, not only the item with focal accent, but also the one with topical accent should (by default) be interpreted exhaustively (with respect to the relevant domain).

There are at least two reasons why a uniform analysis of focal and topical accent is at least *prima facie* desirable. First, it would be unnatural to propose quite different meaning contributions to a supposed phonetic distinction that can hardly, if at all, be observed experimentally.

How much ‘meaning’ do you have to attach to specific accent types, if it turns out that it is hard to make a phonetic distinction among them?

Experiments have shown that every speaker realizes a sentence in a different fashion. However, hearers *are* able to determine whether a phrase is accented or not [...]. Our working hypothesis, then, is that it does not matter *what* accent is used by a speaker, but *that* he uses an accent. (Krahmer and Swerts, 2007)

A second reason for why a uniform analysis of focal and topical accent is desirable is given by Féry (1992, p. 60): “As a matter of fact, it is nearly always possible to replace a hat pattern by a sequence of two falling accents”. But she mentions two restrictions, however, for when this replacement is appropriate. First, the replacement is in order only if the two accents have approximately the same prominence. Second, the hat pattern is necessary and cannot be replaced by a sequence of two falling accents in case of explicit contrast and gapping. To illustrate the case of contrast, Féry (1992) claims that (20-a) is acceptable, but (20-b) is not:

- (20) a. John is often sick, [Mary]<sub>T</sub> [never]<sub>F</sub>.  
b. \*John is often sick, [Mary]<sub>F</sub> [never]<sub>F</sub>’.

For a simple sentence with a hat-contour like (14-b) our proposal that not only the item with focal accent, but also the one with topical accent should (by default) be interpreted exhaustively means that in case the speaker is taken to be competent about the subject matter of discourse, it is interpreted not only as saying that Larry ate only broccoli, but also that only Larry ate (only) broccoli. When the topical phrase is of a more complex nature, like in (13-c), with a denotational reading of ‘one boy’, the proposed analysis predicts that (the speaker knows) only (of) the boy introduced (that he)

ate only broccoli, while (18-b), with a quantified reading, implicates that on Monday (as far as the speaker knows) only one spot appeared. Note that we also make the intuitive correct prediction for

- (21) a. A: Did your wife kiss other men?  
b. B: [My wife]<sub>T</sub> [didn't]<sub>F</sub> kiss other men.

Just as Büring (1997) we predict that the reply (21-b) gets the reading that the speaker knows only of his own wife that she didn't kiss other men, suggesting that he is not so sure of A's wife.

In general we predict that not only topical phrases that are interpreted referentially, but also the ones we interpret quantificationally gives rise to *contrastive* readings. The prediction that topical phrases involve a contrast is behind almost any analysis of topical accent. According to Bolinger (1986),

[...] contrast involves cases where one or more individual items are singled out from a larger (but limited) set as being true regarding some relationship whereas others in the same set are untrue.

There are some doubts, however, whether not only focal, but also topical accent really has this strong contrastive effect. We have seen already that we predict such a contrastive reading only in case we take the speaker to be competent about the subject matter. But even then this seems to be a too strong prediction. First, it seems possible that one can answer question (22-a) appropriately by a sequence like (22-b)-(22-d):

- (22) a. Who ate what?  
b. Let's see.... [Larry]<sub>T</sub> ate [broccoli]<sub>F</sub>.  
c. [John]<sub>T</sub> ate [broccoli]<sub>F</sub>.  
d. And [Bill]<sub>T</sub> had [the beans]<sub>F</sub>.

We agree, but are also convinced that this can be done appropriately only in case the speaker has to check for herself with respect to each individual (Larry, John, and Bill) what he ate, and does so just before she uttered (22-b), (22-c), and (22-d) respectively. Thus, we think that the answerer cannot have uttered (22-b) appropriately when she already had the plan, or strategy, to continue the answer with (22-c) and (22-d). But in that case the sequence is not a counterexample to our assumption that both focal and topical expressions should be interpreted exhaustively also in topic-focus sentences: if we interpret both exhaustively with weak epistemic force, we

receive the correct prediction (or so we feel) that at the moment the speaker utters (22-b), she does not know yet whether someone else (i.e. John) also ate (only) broccoli.

A second, though very similar, kind of example that seems problematic for our assumption that topical accent involves a strong form of contrast that follows from our proposal that also topical phrases be interpreted exhaustively are sequences like (23-a)-(23-b).

- (23) a. Where can I find find the cutery?  
 b. The [forks]<sub>T</sub> are in [the cupboard]<sub>F</sub>, and the [knives]<sub>T</sub> and [spoons]<sub>T</sub> too.

At first it seems that these examples cannot be ‘explained away’ in a similar way as we dealt with (22-a)-(22-d): the topical phrases are now mentioned in the same sentence. Still, we feel that there is something special about (23-b): if one wants to give an answer like this, one is *required* to use an additive focus particle like *too* in the second conjunct (cf. recent work of Henk Zeevat). Indeed, it seems that an answer like (23-b) without the focus particle is fully inappropriate. We would like to suggest here that this is because by the use of such an additive focus particle in the second conjunct, the speaker suggests that the hearer is not allowed to interpret the first conjunct exhaustively, i.e., that he should *cancel* the implicature induced by exhaustive interpretation.

Although we propose that both topical and focal expressions should be interpreted exhaustively, this doesn’t mean that we predict that it is irrelevant how a phrase is accentuated, as long as it is accentuated. If we would claim that, we would end up with the wrong prediction that there is no difference in meaning between sentences with bridging accent and sentences with double focal accent. We propose, however, that the function of using the second topical accent, instead of a second focal accent, is that the sentence should receive an exhaustive reading with respect to *two predicates* (or two sets of alternative sentences), and not with respect to *one relation*, which would (or at least could) be the result if the sentence contains a double focal accent.<sup>7</sup> To illustrate, for a double focal example such as [Larry]<sub>F</sub> ate [pizza]<sub>F</sub>, we only minimize the sentence *one* time, with respect to relation *ate*, and conclude that (as far as the speaker knows) only one eating event took place and that the answer was complete; for bridging accent with a topical accent

---

<sup>7</sup>This seems compatible with Féry’s first constraint on when we can replace a hat-pattern with two times focus accent.

on ‘Larry’, however, we minimize with respect to focus *and* topic. In the latter case we end up with the interpretation that only Larry ate only pizza, and it is left open whether Bill, for instance, ate broccoli. The double focus sentence is interpreted as (24-a), the topic-focus sentence as (36):

- (24) a.  $Exh(\text{John ate Pizza}, \lambda xy[Ate(x, y)])$   
 b.  $Exh(Exh(\text{John ate Pizza}, \lambda y[Ate(j, y)]), \lambda x[Exh(Ate(x, p), \lambda y[Ate(x, y)]))]$

Notice that as a consequence we predict that in contrast to a sentence with a double focal contour, a sentence with bridging contour is allowed if the speaker only *partially* answers the question under discussion. In section 6 we will discuss whether giving a partial answer should be associated with topical accent.

## 5 Strategic economic encoding

According to the above analysis, topical and focal items are both interpreted exhaustively, but we exhaustify the topical expression ‘later’ than the focal one.<sup>8</sup> What is the reason for this difference? We believe that it reflects the strategy of how to *economically encode* the to be transmitted information.

Roberts (1996), Kadmon (2001), and Büring (2003) correctly propose that a topical accent indicates that a set of questions is under discussion and that a *strategy* is at stake. However, we feel that they underestimate the role of the answerer. It is the *answerer* who has to decide how to economically encode the complete information she has to convey such that the hearer can still process it. In this section we want to propose that the information structure of the sentence, or its topic-focus structure, reflects the strategy of the speaker to economically encode the information to be transmitted.

Consider multiple *wh*-question (25).

- (25) Who ate what?

Let us adopt a partitional analysis of questions. If we now assume that

---

<sup>8</sup>This doesn’t mean that as a result the topical expressions should always have wide scope. If so, it would give rise to the prediction that  $[Alle]_T \text{ Politiker sind } [nicht]_F \text{ korrupt}$ . receives the small-scope reading of negation, which is wrong as made clear by Büring’s (1997). We will come back to this example in the next section.

only John and Mary and only broccoli and pizza are under discussion, it follows that the semantic meaning of (25) is identical to the intersection of the semantic meanings of (26-a) and (26-b), and also to the intersection of the semantic meanings of (27-a) and (27-b).

- (26) a. What did John ate?  
 b. What did Mary ate?
- (27) a. Who ate broccoli?  
 b. Who ate pizza?

More concretely, if we denote the partition that represents the meaning of interrogative sentence  $S$  by  $\llbracket S \rrbracket$ , and if we define  $Q \sqcap Q' = \{q \cap q' : q \in Q \ \& \ q' \in Q' \ \& \ q \cap q' \neq \emptyset\}$  for two partitions  $Q$  and  $Q'$ , we see that  $\llbracket (25) \rrbracket = \llbracket (26-a) \rrbracket \sqcap \llbracket (26-b) \rrbracket = \llbracket (27-a) \rrbracket \sqcap \llbracket (27-b) \rrbracket$ . Now suppose that John ate only broccoli, and Mary only pizza. We believe that (25) can in these circumstances equally well be answered by the sequence (28-a)-(28-b) as by the sequence (29-a)-(29-b) with the respective topic-focus patterns:

- (28) a.  $[\text{John}]_T$  ate  $[\text{broccoli}]_F$ ,  
 b. and  $[\text{Mary}]_T$  ate  $[\text{pizza}]_F$ .
- (29) a.  $[\text{broccoli}]_T$  was eaten by  $[\text{John}]_F$ ,  
 b. and  $[\text{pizza}]_T$  was eaten by  $[\text{Mary}]_F$ .

Roberts (1996) proposes that a sentence like (28-a) presupposes both (30-a) and (30-b), while Kadmon (2001) and Büring (2003) argue that it rather presupposes both (30-a) and (30-c)

- (30) a. What did John eat?  
 b. For each individual, what did that individual eat?  
 c. Who ate what?

Notice that although (30-b) and (30-c) differ in that whereas the former denotes a set of questions, the latter denotes only one questions, on a partitional analysis of questions the two are closely related: as we have seen above,  $\llbracket (30-c) \rrbracket$  is just the intersection of the set of questions denoted by (30-b), i.e.  $\llbracket (26-a) \rrbracket \sqcap \llbracket (26-b) \rrbracket$ .

Similarly, a sentence like (29-a) presupposes both (31-a) and (31-b) according to Roberts (1996), while it presupposes both (31-a) and (30-c) according to Kadmon (2001) and Büring (2003):

- (31) a. Who ate broccoli?  
 b. For each kind of food, who ate it?

Obviously, also here it holds that if these questions have a partition semantics, and if we take the intersection of the whole set of questions, then both (30-b) and (31-b) will correspond with the question (30-c).

Now suppose that John and Mary are still the only relevant individuals, but they not only had a main dish, but also a desert, either an ice cream or a cake. Then, we think, the only natural way to answer (25) is to ‘go by individuals’:

- (32) a. [John]<sub>T</sub> ate [broccoli and an icecream]<sub>F</sub>,  
 b. and [Mary]<sub>T</sub> had [a pizza and a cake]<sub>F</sub>.

One might think that this is just because ‘going by individuals’ is more natural than ‘going by food’. This doesn’t seem to be the crucial factor, however, because we observe the same effect with a question of the form *Who kissed whom?* where only individuals are involved. How this latter question is typically answered also typically depends on how many kissers versus kissed ones there are. A more natural reason why in the above case we answer question (25) by ‘going by individuals’ is because of the form of the question: ‘who’ was mentioned before ‘what’ in (25). What has to be explained now, though, is why the questioner didn’t ask (33).

- (33) What was eaten by whom?

We believe that (33) should be asked instead of (25) if there were more people than kinds of food, because in that case the answer can most economically be given by first mentioning the food, as in answers like:

- (34) a. [broccoli]<sub>T</sub> was eaten by [John, Paul and Mary]<sub>F</sub>,  
 b. and [pizza]<sub>T</sub> was eaten by [Bill, Sue, and Peter]<sub>F</sub>.

Our suggestion is related to a proposal made recently by Komagata (2003). Komagata proposes that the information structure of a sentence is a means to *balance* the information load carried by the theme (topic) and the rheme (focus) of an utterance. It is natural to measure the information load of a question as the average information load of its answers. Using information theory and a natural balancing principle, he shows that the ordering of an expected theme followed by a surprising rheme is more desirable than the

ordering of a surprising theme followed by a expected rheme.<sup>9</sup> We will not make use of information theory in this paper to make Komagata’s suggestion more precise. But already our informal description explains why the natural way to answer (25) is to ‘go by individuals’ if John and Mary are the only relevant individuals, but they not only had a main dish, but also a desert, either an ice cream or a cake. If, however, there are more people than kinds of food, Komagata’s balancing principle explains why the answer to (25) should ‘go by food’.

## 6 Topical implicatures

We have not yet discussed Büring’s (1997) demand that the use of topical accent implicates the existence of an open question. As is well-known, it is in terms of this extra constraint that he explains a number of interesting scope data as observed, among others, by Féry (1992). Let us inspect the best-known example, (35), which in principle could have 2 readings, (35-a) and (35-b):

- (35) [Alle]<sub>T</sub> Politiker sind [nicht]<sub>F</sub> korrupt.  
 all politicians are not corrupt.  
 a. It is not the case that all politicians are corrupt. ( $\neg\forall$ )  
 b. No politician is corrupt. ( $\forall\neg$ )

The empirical observation is that only the first reading is observed. It is worthwhile to see that we cannot yet explain this observation. A natural explanation would be that only one of the readings is compatible with the exhaustive inferences we have proposed above. It is easy to see how the implicatures of the  $\neg\forall$  reading are computed: exhaustive interpretation due to ‘[nicht]<sub>F</sub>’ doesn’t give rise to any additional inference (because the alternative ‘ $\forall x[P(x) \rightarrow C(x)]$ ’ is already entailed to be false), but exhaustive interpretation due to ‘[Alle]<sub>T</sub>’ leads to the implicature that (the speaker thinks it is possible that) at least some politicians are corrupt (the alternative ‘ $\neg\exists x[P(x) \wedge C(x)]$ ’ is not (known to be) true). This implicature is consistent with the assertion, meaning that there is nothing to prevent (35)

---

<sup>9</sup>However, if the theme is totally predictable (i.e., has zero entropy), the ordering does not affect the information balance. Examples like *Q: Who knows the secret? A: Peter<sub>F</sub> knows it*, which are problematic for more naive ‘old things first’-hypotheses, can now be accounted for.

to receive the  $\neg\forall$  reading. On first thought it seems that for the  $\forall\neg$  reading, on the other hand, a problem will occur, because now one of the exhaustivity inferences will be in conflict with what is asserted. The exhaustive interpretation due to  $[\text{Alle}]_T$  leads now to the implicature that it is not the case that (the speaker knows that) there is a politician who is not corrupt ( $\neg\Box\exists x[P(x) \wedge \neg C(x)]$ , or equivalently  $\Diamond\forall x[P(x) \rightarrow C(x)]$ ), which is incompatible with what is asserted (on the  $\forall\neg$ -reading). On second thought, however, this is not really the case: the alternative  $\exists x[P(x) \wedge \neg C(x)]$  is already entailed by (and thus weaker than) what is asserted (if it is presupposed that there are politicians), so this sentence is *not* implicated to be (possibly) false. So, nothing is implicated that is inconsistent with the  $\forall\neg$  reading, and we cannot yet explain the observation that this reading does not exist.

Just as Büring (1997), we propose to explain these empirical observations by an extra implicature triggered by the topical accent. However, we won't adopt Büring's proposal, because that gave rise to the so-called 'last-answer problem'. Instead, like Wagner (2007), we make a *weaker* proposal, namely that a contrastive topic used in hat-contour comes with the following felicity condition.

(36) Topic Felicity Condition:

There exists at least one alternative that is derived from substituting topic and focus values for other salient objects that is (i) not entailed by the assertion, and (ii) compatible with what the speaker knows.

In case the speaker is taken to be knowledgeable, condition (ii) is strengthened from  $\Diamond\psi$  to  $\Box\psi$ . Notice that condition (36) gives rise to the pragmatic inference, or implicature, that some non-entailed alternative has to be (possibly) true, and in terms of this implicature we propose to account for Büring's (1997) scope data. To see the working of condition (36), consider the example I started out with:

- (37) a. Who of John and Mary ate broccoli and pizza?  
 b.  $[\text{John}]_T$  ate  $[\text{broccoli}]_F$  and  $[\text{Mary}]_T$  ate  $[\text{pizza}]_F$

The first conjunct of (37-b) gives rise to the focus-exhaustive inference that John didn't eat pizza, and the topical-exhaustive inference that Mary didn't eat broccoli.<sup>10</sup> On the strong version of our new felicity condition of topic

<sup>10</sup>The most obvious way to formally our extra topical inference of  $\phi = "[\text{John}]_T$  ate  $[\text{broccoli}]_F$ " is as follows:  $\exists\psi \in \{Ate(x, y) : x \in T \ \& \ y \in F \ \& \ \phi \not\models Ate(x, y)\} : \Diamond\psi$ ,

marking, it must be the case that one of the following alternatives must be true:  $\{\text{Ate}(j,p), \text{Ate}(m,b), \text{Ate}(m,p)\}$ . Because the first two are ruled out by the focus- and topic-exhaustive inferences, it immediately follows that the last one has to be true: Mary ate pizza.

But if this is the inference, why is it still appropriate to assert the second conjunct of (37-b)? The reason is that exhaustive interpretation is based on (i) standard *Gricean interpretation*, and (ii) the assumption that the speaker is (maximally) *competent*. In general, the competence assumption cannot be assumed, and all that is left is the Gricean interpretation. According to the Gricean interpretation, the first conjunct of (37-b) gives rise to the focus-based inference that it is not known that John ate pizza, and to the topic-based inference that it is not known that Mary ate broccoli. The felicity condition is weaker as well: at least one of the following alternatives is not ruled out:  $\{\text{Ate}(j,p), \text{Ate}(m,b), \text{Ate}(m,p)\}$ . Notice that in this case all three of them are still possible, which means that the second conjunct from (37-b) cannot yet be derived from the first conjunct and its (weak) pragmatic implicatures. Only in case it is assumed that the speaker is competent – i.e. knows the extension of the question-predicates of ‘what did John eat’ and ‘who ate broccoli’ –, we can derive from the first conjunct of (37-b) given as answer to question (37-a) that Mary ate pizza, and thus that the second conjunct is superfluous.

As already indicated above, Büring’s (1997) original proposal of how to interpret topical accent gives rise to the *last answer problem*. If it is assumed that after the interpretation of a clause with a topical accent there still must be an open question, it is predicted that after the second conjunct of (37-b) is asserted, it should be an open question what John ate, or an open question whether Mary ate broccoli. Intuitively, however, this is not the case: after the second conjunct of (37-b) is interpreted we know exactly who ate what. Despite the fact that our proposal is very close to Büring’s (1997) analysis, it

---

with  $T$  and  $F$  the set of topical and focal alternatives to John and broccoli, respectively. However, there are reasons to prefer the following formulation of basically the same idea:  $\exists\psi \in \{\text{Ate}(x,y) : x \in (T - \{j\}) \ \& \ y \in (F - \{b\}) \ \& \ \phi \neq \text{Ate}(x,y)\} : \Diamond\psi$ . The main reason for preferring this alternative is that in this way we can easily explain why a sentence like “John did [not] <sub>$T$</sub>  eat [five] <sub>$F$</sub>  apples” seems to implicate that John ate at least one apple (without it being required that he ate exactly four apples). The reason is that the predicted topical inference is now that the speaker thinks it is possible that John ate at least one apple, which after strengthening gives the desired result.

is easy to see that this ‘last answer problem’ does not arise on our analysis.<sup>11</sup> The reason is that we predict only that (at least) *one* possibility statement must be true, which is weaker than Buring’s requirement that an issue is unresolved, meaning that (at least) *two* possibility statements must be true. In our case, the topical condition predicts that the second conjunct of (37-b) can be felicitously uttered only if one of the following propositions must be (possibly) true: {Ate(j,b), Ate(j,p), Ate(m,b)}. But this condition is obviously satisfied, because it is explicitly asserted by the first conjunct of (37-b) that the proposition expressed by the first element of this set is true.

Let us now return to the scope-data, and in particular to (35). We have seen already before that none of the exhaustivity implicatures can rule out one of the two possible readings of this sentence. However, the new topical implicature *can* do so. The new topical implicature for both readings of the sentence will now be that (the speaker thinks it is possible that) at least some politicians are corrupt ( $\diamond\exists x[P(x) \wedge C(x)]$ ). This implicature is compatible with the  $\neg\forall$  reading of the sentence, but *incompatible* with its  $\forall\neg$  reading. For this reason, or so we propose, example (35) doesn’t have the latter reading.

Our approach can also account for further German data discussed by Buring (1997). (38), for instance, is predicted to be infelicitous since it fails to have any extra topical-implicature in any scope ordering. Thus, condition (i) of rule (36) is not met.

- (38) \* $[Alle]_T$  Politiker sind  $[immer]_F$  betrunken.  
all politicians are always drunk

Both orderings (all>always and always>all) are semantically equivalent. The assertion in either ordering entails all the alternatives. Hence, (38) cannot be uttered with the topic-focus contour.

The following example, (39), is claimed to have only the surface (No>always) reading.

- (39)  $[Kein]_T$  Politiker ist  $[immer]_F$  betrunken.  
no politician is always drunk

---

<sup>11</sup>Of course, the problem doesn’t show up in Buring’s (2003) newer analysis either. But the explanation in this latter paper is rather different from the one adopted in Buring (1997), while the one we proposed is very similar in spirit to this earlier proposal, it is just weaker.

In the non-surface reading (always>no) the extra topical inference that (the speaker thinks it is possible that)  $\exists t \exists x [P(x) \wedge B(x, t)]$  is incompatible with what is asserted ( $\forall t [\neg \exists x [P(x) \wedge B(x, t)]]$ ), and thus is ruled out. On the other hand, the surface reading (No>always) is available, because this time the extra topical inference is compatible with and not entailed by what is asserted. Intuitively, (39) uttered with a topic-focus contour indeed induces an interpretation that some politicians are sometimes drunk. The predicted implicature is attested.

By similar reasoning, one can show that we predict in accordance with Büring (1997) that (40) and (41) are ambiguous between their two scopal readings: the proposed extra topical implicature that (the speaker thinks it is possible that) some politicians are sometimes drunk is not entailed but still compatible with what is asserted on both of their readings.

(40) [Kein]<sub>T</sub> Politiker ist [nie]<sub>F</sub> betrunken.  
no politician is never drunk

(41) [Alle]<sub>T</sub> Politiker sind [selten]<sub>F</sub> betrunken  
all politicians are rarely drunk

What this shows is that our analysis can predict the scope data discussed in Büring (1997).

## 7 Conclusion

In this paper we proposed that a sentence like (1), [John]<sub>T</sub> ate [broccoli]<sub>F</sub>, should pragmatically be interpreted as follows:

- (a) Focus should be interpreted exhaustively: John ate only broccoli.
- (b) Topic must be interpreted exhaustively: Only John ate (only) broccoli.
- (c) The speaker takes it to be possible (or even knows, if he is competent) that at least one alternative of the form ‘ $x$  ate  $y$ ’ not entailed by (1) is true. From (a) it follows that this alternative cannot be ‘John ate  $y$ ’, with  $y$  different from broccoli; from (b) it follows that this alternative cannot be ‘ $x$  ate broccoli’, with  $x$  different from John. Thus, the alternative must be something like ‘Mary ate the beans’.

In section 2 we argued in favor of an exhaustivity rule that differs somewhat from some better-known standard alternatives. In sections 3 and 4 we considered some problems for this rule, and argued that exhaustive interpretation should be sensitive to discourse referents and that also topics should be interpreted exhaustively. This holds for topical expressions in general, whether they have a ‘referential’ or a ‘quantificational’ reading. Our unified interpretation of topical and focal expressions does not predict that the accents are interchangeable: in section 5 we argued that the different kinds of accents reflect the way the speaker economically encodes the information she wants to communicate, while in section 6 we proposed that topical accent gives rise to an extra implicature on top of the one due to exhaustive interpretation. It is shown that this extra topical implicature is weaker than a similar implicature proposed by Büring (1997), but still can account for relevant scope data.

## Abstract

Contrastive Topics (CTs) in Japanese mimic foci more than topics in many ways. Their prosodic properties are essentially the same as the pattern found with foci, and information structurally, they can correspond to new information. Based on my previous analysis of CTs, in which CTs always involve contrasted speech acts, I will iron out some wrinkles I left behind earlier; in particular, how a focus and a CT are distinguished when they appear simultaneously in one sentence. I argue that a focus is subjected both to the exhaustifying operation at the level of proposition and to the set-generating operation at the level of speech act whereas a CT must be spared from being subjected to the exhaustification below speech act. The differentiation is achieved via the ‘selective binding’ approach to association with focus proposed by Wold (1996).

**Keywords:** topic, focus, contrast, scalar implicature, speech act, selective binding

## 1. Contrastive Topics and Contrasted Speech Acts

Contrastive Topics (CTs, henceforth) are a multi-faceted phenomenon that cannot be analyzed comprehensively in a small project like the current paper. I would like to begin, therefore, by defining what the scope of the paper is and where the limitations lie. First of all, I will focus almost exclusively on CTs in Japanese; contrasted expressions that come with the particle *wa*. CTs in Korean are, to a large extent, comparable but not totally identical to the Japanese counterpart. While I certainly do not intend to proclaim that my account should be unconditionally extended to Korean, I hope that it will provide some guideline for the Korean cases. Cross-linguistic variations beyond Japanese and Korean must wait for another occasion. I have expressed my general view on

CTs as contrasted speech acts in Tomioka (to appear), and the main topic of this paper is one of the unresolved issues in that paper, namely the interactions between foci and contrastive topics. My working hypothesis is that a CT is actually nothing but an instance of focus. The primary difference between a CT and a garden-variety (free) focus is the levels at which their focus values (sets of alternatives) are ‘used up’. Hence, I call my analysis a scope theory of CT. This paper examines a variety of consequences of this thesis.

My proposal for Japanese CTs can be summarized as follows. The focal accent on a CT generates a non-singleton focus value in the sense of the traditional Alternative Semantics for Focus (cf. Rooth 1985, 1992, Kratzer 1991 among others). These focus alternatives of a CT are preserved until the computation goes beyond the speech act level, which, following Krifka (2001, 2002), I assume to be explicitly represented in syntax. The preservation of the focus values is the primary function of the topic marker *wa*. The presence of alternative speech acts encourages the hearer to speculate why the speaker didn’t carry out any speech acts among the alternatives other than the very act that she engaged in. The pragmatic effect of uncertainty, non-finality, and/or incompleteness is the result of the hearer’s speculation on alternative speech acts.

The analysis is based on a variety of empirical facts of Japanese CTs, some much discussed in the past and others new. They are in many ways epitomized by an example like (1).

- (1) Trying to give an advice on where to visit in Japan, one might say;

*KYOOto-ni-wa/KYOOto-ni-WA iki-nasai*  
 Kyoto-to-TOP/Kyoto-to-TOP go-imperative  
 ‘(At least) go to KYOto.’

First, as the parenthesized *at least* in the English translation suggests, (1) elicits scalar implicature or a pragmatic effect close to it. CTs are often connected to such pragmatic weakening (cf. Jackendoff 1972, Carlson 1983, Büring 1997, Lee 1999, Hara 2006 among others), and Japanese CTs are no exceptions. Second, Japanese CTs do not receive special prosody distinct from focus. It is hard, therefore, to motivate a theory of CTs that makes crucial use of two distinct accents (e.g. Büring 1997, 2003, Kadmon 2001). Furthermore, a CT can be the sole focal element in a sentence. In other words, a CT in

Japanese can but need not be accompanied by another focal expression. In (1), for instance, the predicate *iki-nasai* ‘go-imperative’ does not get focal accent; on the contrary, its pitch is dramatically reduced as a result of the ‘post-focal reduction’ process (cf. Ishihara 2003 among others), which lowers the pitch range of the material that linearly follows a focused item. These facts do not sit well with an analysis that treats a CT as a thematic topic that is contrastive (e.g. Valduvi and Vilkuna 1998). Another obvious point in the example (1) is its sentence form: It is an imperative sentence, and Japanese CTs indeed appear in sentences of various speech acts; assertions, interrogatives, imperatives, exhortatives (*let’s do X*), volitionals (*I shall do X*), and performatives. While the pragmatic weakening of a CT is often associated with the knowledge state of the speaker, the use of a CT can be independent of it. For instance, the speaker may utter a sentence with CT out of politeness, intentionally leaving out the information that is known to the speaker but is judged inappropriate or impolite by the speaker. This is a challenge to a knowledge-based account, most notably Hara (2006) and Hara and van Rooij (2007). The speaker’s knowledge is not necessarily relevant to CTs in non-assertion sentences, such as the imperative example in (1), and the theory cannot easily be extended to those cases of CTs where politeness is the main motivation for their uses. Finally, one cannot miss the morphology; the same particle is used for a CT and a so-called thematic topic (a TT).

In my analysis, a CT is treated as an instance of focus, and no special semantic function, apart from generating alternatives, is associated with it. It is not a topic in the sense of the Topic-Focus articulation, and there is nothing that prevents a CT from corresponding to new information. There is also no reason to suppose that CTs are limited to assertion sentences, and with alternative speech acts, one is invited to speculate all sorts of reasons for the alternative acts being left out. Although the speaker’s knowledge being partial may often be the most salient in our reasoning, some contexts encourage us to seek out reasons other than the speaker’s knowledge. Finally, the role of the particle is argued to be the guarantor of the preservation of the focus value of a CT until the speech act level. This is where a CT and a TT converge. If there is any linguistic expression that can take scope beyond the speech act level, the most likely candidate is a TT. In one branch of theories of sentence topics, first advocated by Jacob (1984) and later elaborated by Krifka (2001), Endriss (to appear) and Endriss and Hinterwimmer. (to appear), a topic selection is regarded

as a speech act of its own. A sentence topic, therefore, lies outside of the scope of the speech act operated on the main sentence. This ‘outside of a speech act operator’ is the common denominator for a CT and a TT.

The bottom line of the idea is that a CT is just an instance of focus whose focus value (a non-singleton set of alternatives) happens to be ‘resolved’ or ‘used up’ at the level higher than a proto-typical focus. In the following section, we will see how the possible interpretations of a CT are restricted by the presence of the focus option. More concretely, the two focalizing strategies compete, and due to the stronger meaning associated with focus, the focus option is preferred to the CT option. It is also vital for a theory like mine to have a proper way to distinguish two focal expressions, and Section 3 will be devoted to this issue. I will examine a sentence that contains both a CT and a focus and demonstrate that focus sensitive operators are selective binders. Adopting Wold’s (1996) analysis of nested foci, I suggest that a focus is bound twice; once by the exhaustive operator that generates a strong meaning and second time by the set-generating operator at the speech act level. A CT, on the other hand, gets caught only by the higher operator over speech acts.

## 2. Focus vs. Contrastive Topic

### 2.1. Focus Wins

The necessity of considering focus in determining possible interpretations of CTs is exemplified by an example like (2), where a measure expression is marked for a CT.

- (2) How many people will come to the party?

*ZYUU-Nin-wa/ZYUU-nin-WA kuru-desyoo.*

TEN-CL-top/Ten-CL-TOP come-evid

‘(At least) Ten people will come, (as far as I can tell).’

This sentence elicits a set of alternative assertion acts of the form ‘assertion that X-many people will come,’ and the hearer is invited to think about possible reasons for the speaker’s not making any other than ‘the assertion that 10 people will come.’ The reason for 9 and under is obvious: Asserting 9 (or less)

people will come when you know that at least 10 people will come would not be considered cooperative since you are asserting a proposition that is weaker and hence less informative. The story is different for over 10. One could speculate that the reason for the speaker's not asserting 11 (or more) people will come is because she knows that such a proposition is false. If we allow this kind of reasoning, then, we would arrive at the conclusion that the speaker meant that exactly 10 people will come. This is not right. (2) never receives the 'exactly 10' interpretation.<sup>1</sup> I argued that we can keep out the strong reading for a measure phrase CT by letting the focus strategy compete with the CT marking. In exactly the same situation as in (2), one could have said (3).

(3) How many people will come to the party?

*ZYUU-Nin kuru-desyoo*  
 TEN-CL come-evid  
 'Ten people will come.'

In this example, the measure expression is without the particle and is interpreted as the focus of the sentence. As is typically the case of a focused numeral, it carries the 'exactly N' implicature. Since this strategy is always available for the

---

<sup>1</sup> Chung-min Lee (pc) pointed out to me that this is not entirely true. I speculate that he may have in mind a case like (i).

(i) I have ten cousins, and...

ROKU-NIn-wa nihon-ni sunde-imasu-ga (nokori-no) YO-NIn-wa  
 SIX-people-Top Japan-in live-prog-but rest-gen FOUR-people-top  
 kaigai-ni imasu  
 abroad-in be

'(Of my ten cousins), SIX of them live in Japan, and the remaining FOUR live abroad.'

It is certainly true that there is no scalar meaning associated with the CT numerals in (i), in which the two (proportional) numbers are overtly contrasted with each other. When a CT numeral is used as an answer to a *how many/much* question, however, it necessarily induces the 'at least' implicature.

speaker, the hearer must take it as a part of his/her reasoning for a CT. Specifically, the hearer must find a reason why CT is chosen over focus, which would lead to a stronger implicature. Therefore, the hearer does not assume that the speaker knows/believes that it is false that 11 or more people will come. This in effect keeps the ‘exactly 10’ interpretation out from the hearer’s speculation and leads to the ‘at least 10’ interpretation.

## 2.2. *Focus Wins: More Case Studies*

As supporting evidence for the competition between focus and CT, I presented in Tomioka (to appear) the case of the infelicitous CT-marking of a universal quantifier in an affirmative sentence. This fact was noted by Hara (2006), who provided an account based on a scalar presupposition specifically tailored for a CT. I have shown that, by letting the CT strategy compete with focus, we can explain the phenomenon without any special presuppositions. In this section, I would like to add two more facts that are easily explained if we assume that focus and CT compete.

If the pragmatic weakening of a CT is due to the existence of a focus strategy as an alternative option, then we would predict that no weakening takes place when the focus strategy is independently blocked. This prediction is borne out. Consider (4).

- (4) Did both Erika and Ken pass?

*ERika-wa/ERika-WA ukat-ta*  
Erika-CT/Erika-CT pass-past  
“[Erika]<sub>CT</sub> passed.”

While it is still possible to speculate that the speaker doesn’t know the outcome for Ken, the strong meaning is not blocked. In other words, we can entertain the possibility that the speaker implied that Ken didn’t pass. The reason for the survival of the strong meaning is the unavailability of focus. In the context of (4), (5) is not an appropriate answer.

(5) Did both Erika and Ken pass?

#*ERika-ga ukat-ta*  
Erika-nom pass-past  
“[Erika]<sub>F</sub> passed.”

Therefore, no competition arises, and the strong meaning survives.<sup>2</sup>

The second piece of evidence comes from CT-marking of disjunctive NPs. Imagine the following discourse.

(6) Who passed?

[*ERika-ka KEn*]-*ga ukat-ta*  
Erika-or Ken-nom pass-past  
“[Erika or Ken]<sub>F</sub> passed.”

The answer is doubly exhaustive. As a complete answer to the question to *who passed?*, it carries the implicature that no one other than Erika or Ken passed. At the same time, the disjunction *ka* ‘or’ brings out the typical scalar implicature that not both of them passed. If the disappearance of a stronger, exhaustive meaning with a CT is tied to its competition with focus, then, it would be predicted that the CT counterpart of (6) eliminates the focus-related strong meaning but preserves the ‘not-both’ meaning. This is precisely what happens in (7).

(7) Who passed?

[*ERika-ka KEn*]-*wa/WA ukat-ta*  
Erika-or Ken-CT pass-past  
“[Erika or Ken]<sub>CT</sub> passed.” can mean “One of them passed, but I am not sure if people other than Erika or Ken passed.”

---

<sup>2</sup> It is important to note that the option of using *-dake* ‘only’ does not come into play. We are in a situation very similar to the implicature associated with a numeral. In order to obtain the ‘exactly N’ reading for a numeral, we cannot consider the expression *exactly N* as an option.

So far so good. The range of possible interpretations of a CT is influenced by the availability of the focus strategy. Since focus is more informative, whenever the two strategies are compared, the focus wins over the CT if the speaker knows enough or feels confident to use it. But how do we ensure that focus is stronger? Do we not also evoke a similar sense of alternative speech acts when we use focus, instead of CT? If so, where does the difference between the two strategies lie? These are the questions that I will address in the following section.

### 3. Grammar of (Anti-)Exhaustivity

#### 3.1. Exhaustive Operator in Syntax

How does the exhaustive meaning of focus come about? One idea is found in Krifka (1995), who proposes that so-called ‘free’ focus is actually an instance of association with focus; the operator it associates with is Assertion Operator. I follow the idea that focus is always associated with some operator, but the relevant operator is not a Speech Act operator but one that specifically derives exhaustivity. Fox (2006), for instance, advocates the view that the exhaustivity associated with disjunction and other scalar items is derived via the exhaustivity operator (Exh).<sup>3</sup>

$$(8) \text{ Exh } (A_{\langle \text{st}, \triangleright \rangle})(p_{\text{st}})(w) = p(w) \ \& \ \forall q \in \text{NW}(p, A): \neg q(w) \quad (= \text{Fox 2006, (15)})$$

Notes:  $A_{\langle \text{st}, \triangleright \rangle}$  = a set of (scalar) alternatives

$\text{NW}(p, A)$  = a set of alternatives that are not weaker than  $p$

Although Fox does not specifically discuss the exhaustivity associated with contrastive focus, its potential to be extended to contrastive focus is quite obvious.<sup>4</sup> So, focus gets caught by the Exh operator while a CT is spared from it and the alternatives generated by it move up to the speech act level. How could this distinction be made?

---

<sup>3</sup> (8) is not the final version that Fox endorses, but it is simpler and serves out purpose perfectly well.

<sup>4</sup> Fox himself is quite receptive to this possibility (Fox 2006, footnote 13).

### 3.2. Focus Index and Selective Binding

The issue becomes crucial when a CT is accompanied by a focus. While a CT can be the sole focalized element in a sentence, it can appear with an additional focus.

(9) Who ate what?

*ERika-wa MAME-o tabe-ta (kedo)*  
 Erika-top beans-acc eat-past (but)  
 ‘Erika ate beans (but ...)’

This sentence receives the interpretation very similar to the English A-/B-accents (cf. Jackendoff 1972, Büring 2003) and the German Rise-Fall contour Büring 1997, Krifka 1998). From the meaning specified in (8), it is obvious that the Exh operator sits at the level of proposition (or more generally, at the level of sentence radical). Since a CT is structurally lower than this operator, it becomes crucial to prevent the focus value of the CT from being accidentally caught by the Exh operator. LF movement of a CT over the Exh operator seems like a reasonable option. However, I have expressed skepticism about this option in Tomioka (to appear), and as it will become clear later, the movement turns out to be quite problematic. If one opts for a different solution, then, the best candidate is Kratzer’s (1991) idea of focus indices. Furthermore, we postulate that focus-sensitive operators, such as the Exh operator, are indexed so that, for any given focus-sensitive operator, only the co-indexed focus expressions are computed. Specifically, I adopt the system of ‘selective binding’ of focus indices that Wold (1996) developed. First, I assume the following LF for (10).

(10)[Op<sub>1</sub> [<sub>Speech Act P</sub> Assert [<sub>IP</sub> Exh<sub>2</sub> [<sub>IP</sub> [ERika-wa]<sub>1</sub> [MAME-o]<sub>2</sub> tabeta ]]]]

The first operator Op<sub>1</sub> is a simple alternative generating operator without any quantificational meaning whereas Exh<sub>2</sub> is an index-sensitive version of our previous Exh. Their meanings are represented as below.

(11)a.  $\llbracket \text{Exh}_i \alpha \rrbracket^g = \lambda w. \llbracket \alpha \rrbracket^g(w)=1 \ \& \ \forall p \in \text{NW}(p, \{\llbracket \alpha \rrbracket^g \cup \langle i, x \rangle : x \in D\tau\})$

$$[p(w)=0]$$

$$b. \llbracket \text{Op}_i \alpha \rrbracket^g = \{ \llbracket \alpha \rrbracket^g \cup \{ \langle i, x \rangle \} : x \in D\tau \}$$

Another important ingredient in Wold's analysis is the Novelty Condition on focus indices:

(12) For a focus-sensitive operator  $\Omega$   $\llbracket \Omega_i \alpha \rrbracket^g$  is defined only if  $i \notin \text{Dom}(g)$

In other words, beyond the constituent that contains  $\Omega$  and its sister,  $g(1)$  is not defined. With (11) and (12), the semantic values of (10) are computed as follows.

- (13)a.  $\llbracket \llbracket \text{IP Exh}_2 \llbracket \text{IP [ERika-wa]}_1 \llbracket \text{MAME-o} \rrbracket_2 \text{ tabeta} \rrbracket \rrbracket \rrbracket^g = \lambda w. \text{ Erika ate beans in } w \text{ and for all } p \in \text{NW}(p, \{ \lambda w. \exists x. P(x) \text{ and Erika ate } x \text{ in } w : P \in D_{\langle e, t \rangle} \}), p(w)=0. \text{ The proposition that Erika ate beans (and nothing else).}$
- b.  $\llbracket \llbracket \text{Op}_1 \llbracket \text{Speech Act P Assert} \llbracket \text{IP Exh}_2 \llbracket \text{IP [ERika-wa]}_1 \llbracket \text{MAME-o} \rrbracket_2 \text{ tabeta} \rrbracket \rrbracket \rrbracket \rrbracket \rrbracket^g = \{ \text{assertion that } x \text{ ate beans (and nothing else)} : x \in D_e \}$

This is obviously not right. (13b) is a set of assertions of the form 'assert that  $x$  ate beans (and nothing else)', which would lead to the uncertainty/incompleteness implicature that the speaker may not know whether the other people did the exclusive eating of beans. What we need is the implicature that the speaker may be unsure what the other people ate.

### 3.2. Double Indexing of Focus

To amend the selective binding analysis, let us go backward and try to understand what kind of alternative speech acts are needed. Instead of (13b), we should have (14).

(14)  $\{ \text{assertion that there is } x \text{ such that } P(x) \text{ and } y \text{ ate } x : x \in D_e, P \in D_{\langle e, t \rangle} \}$

We can get (14) by letting the alternative generating Op at the speech act level bind both the CT and the focus. Since the focus needs to be bound by the Exh operator at the IP level, we assign two indices to the focus.

(15) [Op<sub>1,2</sub> [Speech Act P Assert [IP Exh<sub>3</sub> [IP ERika-wa<sub>1</sub> [[MAME-o]<sub>2</sub>]<sub>3</sub> tabeta ]]]]

This may look a little exotic, but a case like this is not unknown. Krifka (1991) points out that one focused expression can be bound by two distinct focus-sensitive operators.

- (16)a. I once only drank [WIne]<sub>F</sub> .  
 b. I also once only drank [[WATer]<sub>F</sub>]<sub>F</sub>

(16b) means that, in addition to the exclusive drinking of wine at some point, I also had an experience of exclusive drinking of water at another occasion. Wold (1996) revisits this example and proposes the double-indexing on *water*.

(17) I also<sub>1</sub> once only<sub>2</sub> drank [[WATer]<sub>1</sub>]<sub>2</sub>

At the point where the smaller VP *only<sub>2</sub> drank [[WATer]<sub>1</sub>]<sub>2</sub>* is interpreted, the index 1 is not in the domain of *g*, so we ignore it. The indexed *only<sub>2</sub>* introduces the index 2 to the domain of *g*, and the object *[[WATer]<sub>1</sub>]<sub>2</sub>* is now replaced with a variable. This variable is the basis of generating the alternative VP meanings over which *only<sub>2</sub>* quantifies. When we proceed beyond the VP level, the index on the *only<sub>2</sub>* (i.e., the index 2) is no longer in the domain of *g*, according to the Novelty Condition specified in (12). When the larger VP *also<sub>1</sub> once only<sub>2</sub> drank [[WATer]<sub>1</sub>]<sub>2</sub>* is interpreted, the index 1 is added to the domain for *g*, *[[WATer]<sub>1</sub>]<sub>2</sub>* turns into a variable that is to be bound by *also<sub>1</sub>*.

With the double-indexing and the novelty condition on focus indices, we now have the following computations for (15).

- (18)a.  $\llbracket [IP\ Exh_3\ [IP\ [ERika-wa]_1\ [MAME-o]_2]_3\ tabeta\ ] \rrbracket^g = \lambda w. \text{Erika ate beans in } w \text{ and for all } p \in NW(p, \{ \llbracket [IP\ [ERika-wa]_1\ [MAME-o]_2]_3\ tabeta\ ] \rrbracket^g \cup \langle 3, P \rangle : P \in D_{\langle e, t \rangle} \}) , p(w)=0.$   
 $= \lambda w. \text{Erika ate beans in } w \text{ and for all } p \in NW(p, \{ \lambda w. \exists x. P(x) \text{ and Erika ate } x \text{ in } w : P \in D_{\langle e, t \rangle} \}) , p(w)=0. \quad [= (13a)]$
- b.  $\llbracket [Op_{1,2}\ [Speech\ Act\ P\ Assert\ [IP\ Exh_3\ [IP\ [ERika-wa]_1\ [MAME-o]_2]_3\ tabeta]]] \rrbracket^g$   
 $= \{ \llbracket [Assert\ [IP\ Exh_3\ [IP\ [ERika-wa]_1\ [MAME-o]_2]_3\ tabeta\ ] \rrbracket^g \cup \langle 1, x \rangle \cup \langle 2, P \rangle : x \in D_e, P \in D_{\langle e, t \rangle} \}$

= {assertion that there is x such that P(x) and y ate x:  $x \in D_e, P \in D_{\langle e, t \rangle}$ } [= (14)]

(18b) correctly generates the kind of alternative speech acts that would lead to the implicature that the speaker may be unsure what people other than Erika ate.

### 3.4. Consequences and Implications

The conclusion we reached above is that a focus is bound twice whereas a CT is always spared from being bound by the Exh operator at the level of proposition. Double indexing on focus seems independently needed, and there are no reasons to suppose that the same strategy should not be exploited in the focus/CT co-occurrence case. The proposal nonetheless raises several questions. (19) is a non-exhaustive list of issues and questions that arise in connection with the current analysis.

- (19) a. What does the operator at the speech act level do? Is it possible to consider it as a kind of Exh operator that applies to speech acts?
- b. While we must assume that the Exh operator at the IP level is a selective binder, the operator at the speech act level can be unselective.
- c. When a focus and a CT co-occur, a focus is bound by the speech act level operator, as well as by the Exh. What about a focus without a CT? Does it also get bound twice?

(19a) is a distinct possibility. It has been pointed out in the literature (e.g., Krifka 2008, citing John Searle's work on speech acts) that 'negation' of a speech act is typically weak. The effect can be seen by the negation of a performative sentence; *I do not promise to leave* is weaker than *I promise not to leave* while *I do not want to leave* and *I want not to leave* are often interchangeable. If the operator at the speech act level is an Exh, and we use 'speech act negation' as a part of its meaning, the result is the implicature that the speaker engaged in the ordinary value speech act but did not engage in any other (stronger) speech acts among the alternatives. The current version, on the other hand, simply generates a set of alternative speech acts, and the existence of such a set itself is supposed to guide the hearer to the inference that the Exh would have licensed. Unfortunately, I cannot think of any empirical facts that favor one approach over the other.

(19b) and (19c) are intimately interconnected. It seems certainly possible to regard the focus operator at the speech act level to be unselective in the sense that it binds all

focus variables in its scope. If that is the case, the operator is not something specifically made available for interpreting CTs. Then, it is natural to suppose that the same operator is present even when a sentence contains a focus but not a CT. This in turn means that focalization, either as a focus or a CT, always lead to the generation of alternative speech acts. With focus, however, the Exh operator also binds the focus, and the structure always involves double indexing.

(20) [Op<sub>1</sub> [Speech Act P [IP Exh [IP ... [[focus]<sub>1</sub>]<sub>2</sub> ... ]]]]

The strong meaning that results from the Exh severely limits the range of speculation on the hearer's part, however. Unlike cases with CTs, we are not allowed to entertain different reasons for not engaging the alternative speech acts. With assertion acts, practically the only reasoning possible is that the speaker knows/believes that the alternative propositions are false.

### 3. Closing Remarks and Remaining Issues

Extending my previous analysis of CTs, I have examined how foci and CTs interact. The availability of using focus carves out possible interpretations of the CT counterpart as a consequence of the competition between the two strategies. I have also proposed a way to differentiate two focal expressions by adopting Wold's idea of selective binding and double indexing of focus.

In Tomioka (to appear), I left behind many issues as my homework. The focus/CT interaction and the mechanism of differentiating the two strategies was one of them, and I hope that I made a small progress here. The (non-exhaustive) list of remaining issues are crosslinguistic variations (including micro-variations between Japanese and Korean), CTs in complex sentences, such as conjunctions and embedding under attitude verbs, and a variety of syntactic positioning effects (cf. Vermeulen 2008). Although I believe that satisfactory accounts for these issues within the current proposal are possible, I will have to leave them for other occasions in the future.

Acknowledgement: This paper has been presented in various occasions other than at CIL 18; at University of British Columbia, Nanzan University, and University of Delaware. I received valuable comments, suggestions, criticisms and encouragement. The following individuals deserve special mention for their particularly useful input;

Seth Cable, Beata Gyuris, Yurie Hara, Katalin E. Kiss, Kyle Johnson, Yoshihisa Kitagawa, Manfred Krifka, Chung-min Lee, and Reiko Vermeulen. Needless to say, I alone should be held responsible for any errors and shortcomings in the paper. This research received financial support from International Travel Award from the University of Delaware and National Science Foundation Grant #BCS-0650385 and the International Travel Award from the University of Delaware awarded to the author.

# Scalar Implicatures, Presuppositions, and Discourse Particles: Colloquial Russian *–to*, *že*, and *ved'* in Combination<sup>i</sup>

Svetlana McCoy-Rusanova

Rutgers University, USA

Russian Program, 195 College Avenue, New Brunswick, NJ 08903, USA

## Abstract

This paper tackles the problem of interaction between multiple discourse particles in the same utterance. It examines how presuppositions and/or implicatures contributed by individual particles are combined to account for connotations which arise in utterances containing multiple particles. The subject of study is two-way combinations of set-evoking colloquial Russian particles *–to*, *že*, and *ved'*. The data are drawn from constructed minimal discourses. The study integrates the theories of information structure (Vallduví 1992), scalar implicatures (Hirschberg 1985/1991), and discourse organization (Büring 2000). The current approach to decomposing the meaning of particles by examining them in combination sheds new light on the context-independent interpretations of the particles and makes another step towards understanding their complex roles in discourse.

**Keywords:** discourse particles, colloquial Russian, scalar implicature, presupposition.

## 1. Introduction

There has recently been a growing interest in formalizing the meaning of *discourse* (alternatively, *modal*, or *pragmatic*) *particles* in various languages, especially in German, Dutch, and Russian. (For cross-linguistic studies see, for example, volumes edited by van der Wouden et al. 2002, and Fischer 2006; for German and Dutch particles see Zeevat 2000, 2002, Karagjosova 2001a/b, Eckardt 2006, etc.; for the colloquial Russian particles see Bitextin 1994, Parrott 1997, Feldman 2001, McCoy 2001, Hagstrom and McCoy 2003, Post 2005, etc.) However, the problem of interaction between multiple particles in the same utterance has not yet been adequately addressed (for a notable exception see Parrott 1997).

The subject of this paper is three colloquial Russian particles *–to*, *že*, and *ved'* and the goal is to examine how presuppositions and/or implicatures contributed by

individual particles are combined to account for connotations which arise in utterances containing multiple particles. The study integrates the theories of information structure (Vallduví 1992) and discourse organization (Roberts 1996, Büring 2000).

For the purpose of comparing the contributions of each particle first in isolation and then in combinations, let us hold the discourse setting as constant. Speakers A and B are discussing a particular book, for example, some bestseller that everybody else in the group has read, except for A and B. Speaker A recommends that B read this book, while B utters (1) – a sentence containing either a single particle *–to*, *že*, or *ved'* or a combination of these particles:

- (1) Situation: A recommends that B read a particular book. B replies:  
Ty *–to/že/ved'* eë ne čital!  
You *Particle(s)* it NEG read  
'You haven't read it!' [+ *additional meaning(s) contributed by the particle(s)*]

All of the resulting sentences share the same assertion (i.e., *the hearer has not read the book*). However, each of them is unique in the set of implicatures and/or presuppositions that arise due to the particular particle(s) being used.<sup>1</sup>

The paper is structured as follows: Section 2 summarizes context-independent meanings of each of the three particles. Section 3 discusses possible combinations of *–to*, *že*, and *ved'* and examines how their invariant meanings are preserved and combined with each other. Finally, Section 4 comments on the nature of the additional meaning contributed by the particles.

---

<sup>1</sup> The decision to draw data from a constructed discourse rather than natural language corpora is motivated by the need to isolate and compare the contribution of each particle without accounting for multiple variables that are necessarily present in recordings of natural speech. (For a study based on data drawn from colloquial Russian corpora, see McCoy 2001.)

Furthermore, the presence of negation in the tested sentence should not affect conclusions on the contributions of each particle. The constructed discourse situation could be reversed: A and B could be talking about a bestseller that nobody in the group except A has read; and B would be soliciting A's advice by uttering a sentence which asserts *You have read it* and contains the particle(s). However, I am finding this situation slightly more unnatural than in (1) above, especially with particles *že* and/or *ved'* which add the tone of contradiction to the utterance. This issue is worth discussing in more detail in the future.

## 2. Background on the Colloquial Russian Particles *-to*, *že*, and *ved'*

This section draws primarily on the insights developed in McCoy 2001 and Hagstrom and McCoy 2003, where the particles *-to*, *že*, and *ved'* are analyzed as set-evoking (or set-generating or “kontrastive,” after Vallduví & Vilkuna 1998) lexemes (for other approaches, in addition to references in McCoy 2001, see Marshall 2002, Bolden 2005). The use of such a particle by the speaker makes the hearer generate a set of alternatives, essentially in the same way as Focus alternatives (in the sense of Rooth 1985) are generated in English by the use of certain intonation contours. The particles, however, differ with respect to the types of sets that are being evoked, which we turn to next.

### 2.1. The particle *-to*

The particle *-to*, as in (2), cliticizes to a contrastive theme/topic (or “kontrastive” link, after Vallduví 1992 and Vallduví & Vilkuna 1998), shown in (3), and marks **a set of sets of propositions** (same as **a set of questions**), shown in alternative ways in (4-5).

(2) Ty-*to* eë ne čital!

You *-to* it NEG read.

‘As for you [*compared to the other people*], you haven’t read it [*although you may have done something else with it, such as browsed through it/bought it/etc.*].’

(3) [+K/Link You] (*-to*) [+K/Rtheme haven’t read] it

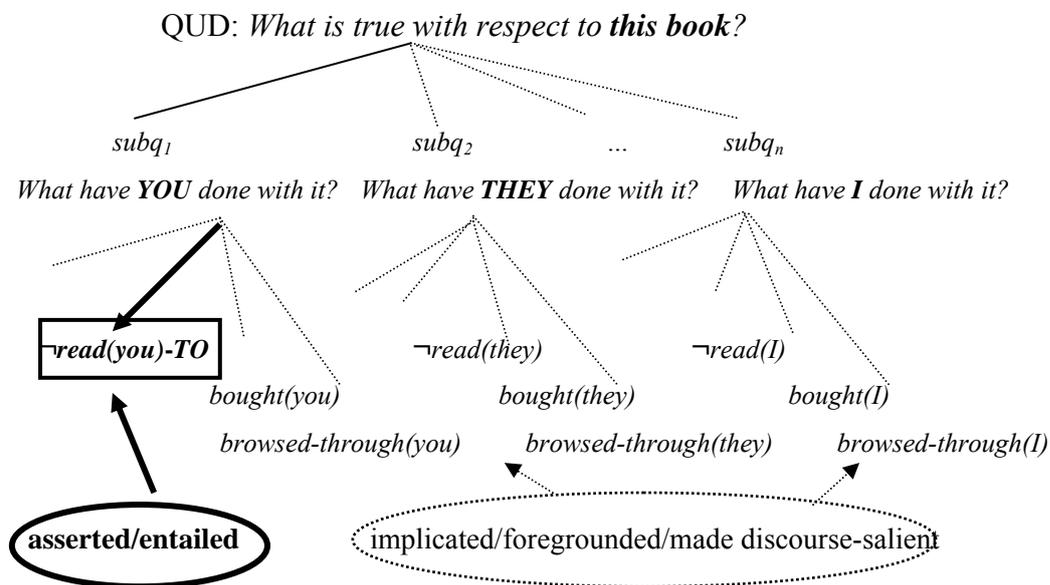

(4) M(*-to*) = { { **You haven’t read it**; You’ve browsed through it; You’ve bought it; }  
 { They haven’t read it; They’ve browsed through it; They’ve bought it }  
 { I haven’t read it; I’ve browsed through it; I’ve bought it; ... } }

(5) M(*-to*) = { { What have **you** done with it? }  
 { What have **they** done with it? }  
 { What have **I** done with it? }; ... }

Sentences with *-to* generate scalar implicatures in the same way as sentences with contrastive topics do (see, for example, Lee 2006). Essentially, *-to* creates two points of contrast: *you* vs. *they/I/etc.* and the property of *not having read the book* vs. other

context relevant properties, such as *browsing through it* or *buying it*.<sup>2</sup> The latter set forms a pragmatic, contextually relevant, scale:  $\langle \textit{read the book}, \textit{browse through the book}, \textit{buy the book} \rangle$  (following Hirschberg 1985/1991). While it is asserted that the truth value of the proposition *read-it(you)* is false, the truth values of the other propositions are not determined. However, the discourse could naturally proceed in that direction or truth values of some propositions could already be part of common ground. This is graphically represented in (6), which utilizes the Question Under Discussion (QUD) discourse model (Roberts 1996, Büring 2000):

(6) D-tree for an utterance with *-to*, (2):

<sup>2</sup> The position of *-to* in the sentence is determined by which element plays the role of a contrastive topic/theme/link: if, for example, *-to* were cliticized to *eē* 'it/this book,' the generated set of questions (or the set of sets of propositions) would be organized around the contrast on *this book* vs. *that book* or *this book* vs. *this article* vs. *this dissertation* and the respective properties of each of these entities (the property of *not having been read by you* vs. other relevant properties).

## 2.2. The particle *že*

The particle *že*, as in (7-8), is the sentential *že* (in the sense of Parrott 1997, as opposed to the phrasal *že*): even though it can appear in different positions, the resulting sentences have the same meaning.

- (7) Ty *že* eë ne čital!  
'But you HAVEN'T read it!  
[even though you believe and/or act as if the opposite is true]'

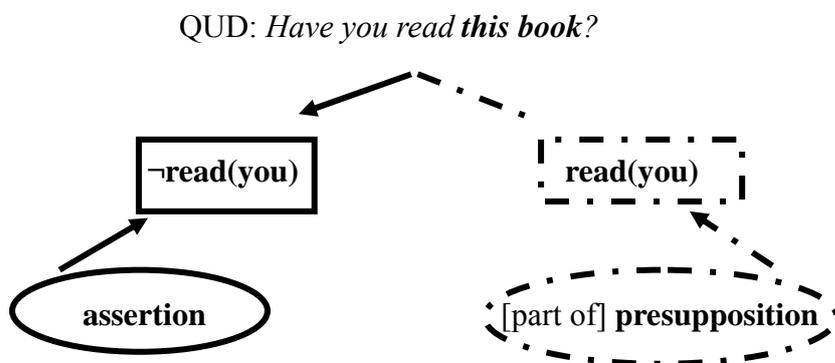

- (8) Ty (*že*) eë (*že*) ne čital (*že*)!

This particle has been analyzed as a so-called *verum focus marker*: it creates contrast on the polarity of the proposition. Thus, in (7-8) the proposition *the hearer has not read the book*, uttered by the speaker, is contrasted with the contextually relevant proposition *the hearer has read the book*, which may be attributed (possibly erroneously) by the speaker to be true of the hearer on the basis of the hearer's behavior and/or presuppositions or implicatures of the hearer's previous utterances. To elaborate on the discourse situation in (1) when A recommends that B read a particular book: what may have made B utter (7) is B's knowledge that A has just bought this book and, therefore, has not had any time to read it. While the fact of A's buying the book is true, B's conjecture that A has not read the book may or may not be true (a couple of possible scenarios: A had previously read a library copy of the book and decided to buy a copy to own; or A already owns a copy and has read it and is buying another one for a gift to somebody else, etc.). The natural way for the discourse to proceed is in the direction of finding out which of the two mutually exclusive propositions is true: either *the hearer has read the book*, or *the hearer has not read the book*.

To summarize, the set evoked by *že* in (7) consists of two propositions, only one of which can be true, as shown in (9). Proposition *p* marked with *že* asserts *p* and presupposes that the hearer believes, or acts like,  $\neg p$  (cf. Hagstrom and McCoy 2003). The discourse tree for (7) is shown in (10).

- (9) M(*že*) = {**You haven't read it;** *You've read it*}

(10) D-tree for the utterance with *že*, (7):

### 2.3. The particle *ved'*

Researchers agree that while *že* is perceived as a verbal attack on the addressee, *ved'* (11-12) is less argumentative and more of a polite reminder or advice to the addressee (see references in McCoy 2001).

(11) Ty *ved'* eë ne čital!

‘You haven’t read it, you know! [*I’m reminding/advising you to do so*]

(12) (*ved'*) Ty (*ved'*) eë (*ved'*) ne čital (*ved'*)!

The discourse situation in (1) can be elaborated in the following way to make for the felicitous use of the particle *ved'*: A recommends B to read some bestseller; B knows that A hasn’t read it yet but takes A’s recommendation as echoing or endorsing the opinion of others (if it is a bestseller, it should be good).

The particle *ved'* evokes the same set of mutually exclusive propositions as *že* does (see 9-10). However, *ved'* lacks the presupposition that the hearer believes or acts as if  $\neg p$  is true. Instead, by using *ved'* the speaker indicates that s/he is aware that the hearer knows  $p$  but is not thinking about it at the moment (cf. Parrott 1997, McCoy 2001).

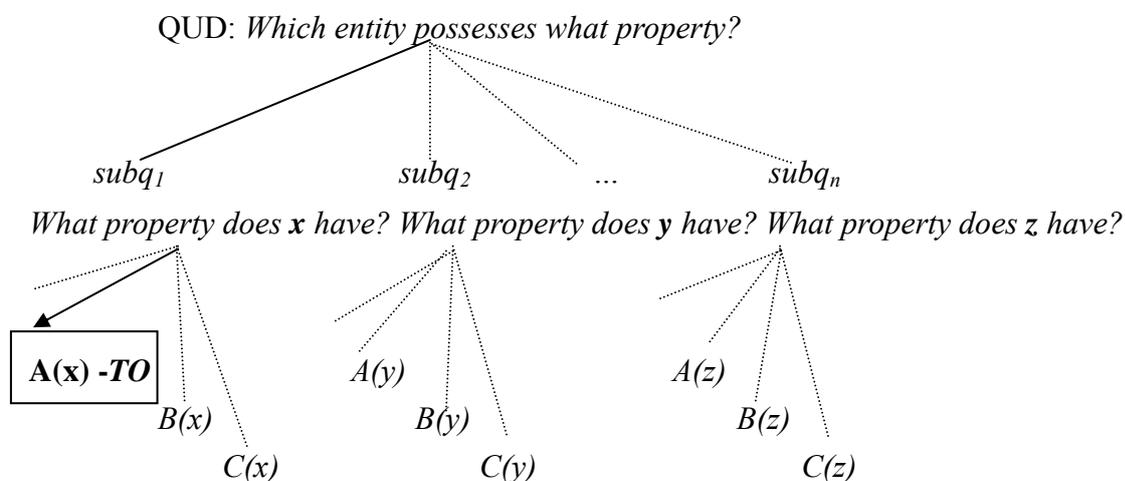

2.4. Summary on the particles *-to*, *že*, and *ved'*

The particle *-to* generates a set of sets of propositions, or alternatively, a set of questions, shown in (13-15), in which the proposition marked by the particle *-to* is asserted, while the other propositions are implicated, foregrounded, or made discourse-salient:

$$(13) M(-to) = \{ \{ \mathbf{A(x)}, B(x), C(x), \dots \}; \\ \{ A(y), B(y), C(y), \dots \}; \\ \{ A(z), B(z), C(z), \dots \}; \dots \}$$

$$(14) M(-to) = \{ \text{What is true of } x?; \\ \text{What is true of } y?; \\ \text{What is true of } z?; \dots \}$$

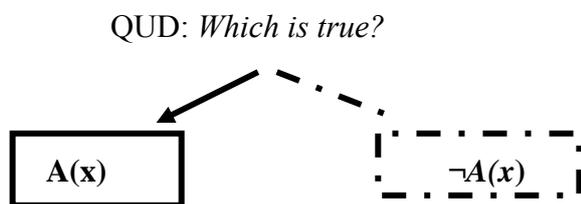

(15) D-tree for utterances with *-to*:

The particles *že* and *ved'* generate a set of mutually exclusive propositions, only one of which could be true, shown in (16-17). The proposition marked by *že* or *ved'* is asserted by the speaker, the other proposition is attributed by the speaker to be a part of the addressee's knowledge or belief set:

$$(16) M(\textit{že/ved}') = \{ \mathbf{A(x)}; \neg A(x) \}$$

(17) D-tree for utterances with *že* or *ved'*:

Now let us proceed to examine whether these context-invariant meanings of the particles are preserved in utterances containing combinations of these particles.

### 3. Particles in Combination

If two particles are used in the same clause, one of them assumes “scope” on a term, while the other one takes “scope” over the proposition.

#### 3.1. A combination of *-to* + *že*

In this combination, as in (18), the particle *-to* is cliticized to the term which functions as a contrastive topic/theme/link, while *že* takes a wider, sentential, scope:

- (18) Ty-*to* (*že*) eě (*že*) ne čital (*že*)!  
 ‘As compared to the others, you HAVEN’T READ it!’  
 [*Other activities you may have done with it do not count; what is relevant is that you haven’t read it - but the others may have!*]

The result of adding the *že*-type of contrast to the set of sets of propositions evoked by *-to* is the following: in the ‘you’-subset, the asserted proposition *You haven’t read the book* is contrasted with the proposition *You have read the book*, which is a part of the *že* presupposition [*you believe or act as if you have read the book*]. This, however, has a consequence for certain propositions in the remaining subsets within the *-to* implicature set, namely those that share the property of *having read the book*: *read-it(they)* and *read-it(I)*, which become foregrounded. This accounts for the connotations of utterances with *-to* + *že*: the most salient contrasts in (18) are between  $\neg$ *read-it(you)* and *read-it(they)*:

- (19) M(-to+že)= { **You've read it; You haven't read it;** You've bought it;}  
 {*They've read it;* They haven't read it; They've bought it}  
 {*I've read it;* I haven't read it; I've bought it;...} }

### 3.2. A combination of *-to* + *ved'*

Similarly to the *-to* + *že* combination, the particle *-to* here cliticizes to the contrastive topic/theme/link and *ved'* takes a sentential scope, as in (20). The resulting *-to* + *ved'* set in (21) is identical to the *-to* + *že* set in (19).

- (20) (*ved'*) Ty-*to* (*ved'*) eě (*ved'*) ne čital (*ved'*)!  
 'As compared to the other people involved, you haven't READ it, you know!'  
 [*My advice is that you should!*]

- (21) M(-to+ved')= { **You've read it; You haven't read it;** You've bought it;}  
 {*They've read it;* They haven't read it; They've bought it}  
 {*I've read it;* I haven't read it; I've bought it;...} }

A legitimate question arises: if there is no difference in the set membership, then what accounts for the difference in connotations between (18) and (20)? One possible explanation is the different presuppositions the two particles carry.

Another way to explain the phenomenon is to examine it from a completely different perspective (which is beyond the scope of this paper), i.e., the cognitive statuses of referents marked by the two particles and, specifically, the speaker's assessment of the hearer's state of knowledge and the set of matters of current concern (in the sense of Yokoyama 1986; for a detailed treatment of these two particles see Parrott 1997). Thus, in (18), *že* marks the proposition *You haven't read this book* as the one that should have been activated/present in addressee's set of matters of current concern (thus, the tone of aggressiveness, impatience, contradiction, confrontation, etc.). A possible continuation of the discourse for (18) is:

- (22) Ty-*to že* eě ne čital! Počemu *že* ty s nimi sporiš'?  
 'But as for you, you HAVEN'T READ it yet. Why on earth are you arguing with them?'

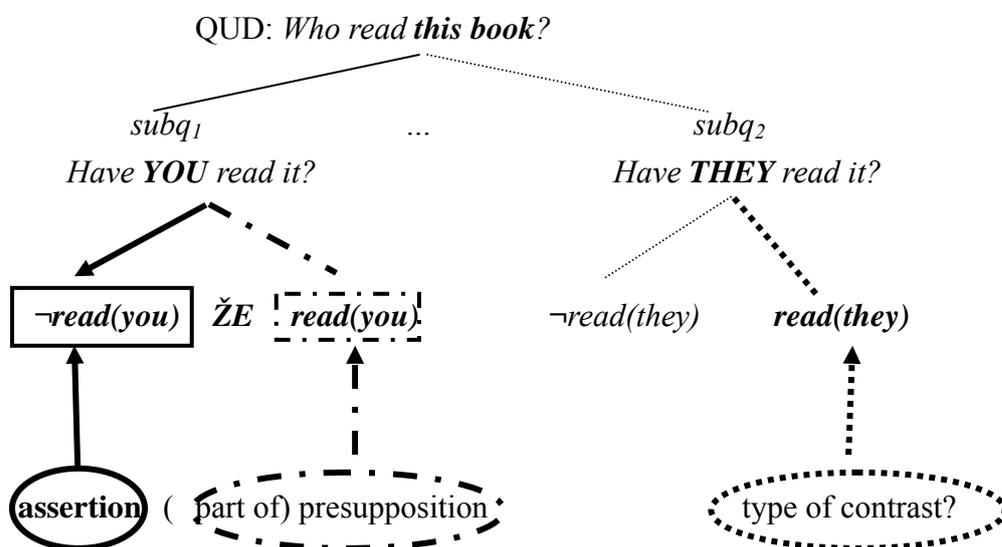

*že* + *že*, shown in (27), consists of two pairs of propositions with opposite polarity values inside each pair – *You have (not) read it* and *They have (not) read it* – and the two pairs of propositions differ in one term: *you* vs. *they*. Notice that this *že* + *ved’/že* set and its corresponding Discourse tree (28) differ in important ways from the *-to* + *že/ved’* set in (19/21) and its D-tree in (24):

(25) (*ved’*) Ty *že* (*ved’*) eĕ (*ved’*) ne čital (*ved’*)!  
 ‘As opposed to the other party involved, you haven’t read it, you know!  
 [*while they have!*]

(26) Ty *že* (*že*) eĕ (*že*) ne čital (*že*)!  
 ‘As opposed to the other party involved, you HAVEN’T read it!  
 [*but they have!*]

(27) M(*že* + *ved’/že*) = { { **You haven’t read it**; *You’ve read it* }  
 { They haven’t read it; *They’ve read it* } }

(28) D-tree for an utterance with *že* and *že/ved’*:

besides its occurrence in emotional speech and the flavor of being somewhat substandard. She also calls attention to the existence of the marginal colloquial form *žež* (which is common in Belorussian).

#### 4. Conclusion

This paper has examined three colloquial Russian particles *-to*, *že*, and *ved'* and has demonstrated that the context-invariant meaning of individual particles is preserved in sentences containing particle combinations.<sup>4</sup> With respect to sets evoked by combined particles, the result is not a simple intersection or union of sets, due to the fact that one of the particles assumes a narrow scope on a kontrastive/focused term, while the other takes a wide, sentential, scope. The sets evoked by the particles individually are:

- *-to*: a set of sets of propositions;
- *že/ved'*: a set of two propositions contrasting in polarity (with different presuppositions/implicatures).

The sets evoked by the combination of particles are the following:

- *-to + že/ved'*: a set of sets of propositions, which includes two mutually exclusive propositions;
- *že + ved' / že + že*: a set containing two pairs of mutually exclusive propositions.

However, some issues have not yet received adequate treatment and have to be left for future research. The present treatment of the relationships among the propositions within the evoked sets is still on a rather intuitive level and would benefit from further formalization. The difference between the particles *že* and *ved'* needs to be examined in greater detail with respect to the evoked sets.

It would also be illuminating to sort out layers of connotations and determine their exact nature; i.e., whether these added meanings are actually presuppositions (see Hagstrom and McCoy 2002 for the discussion of *že*), or conversational implicatures (Grice 1975), or conventional implicatures (Potts 2005), or some combination of the above. Thus, the idea of utilizing the notion of scalar implicature (Hirschberg 1991) with respect to the connotations that arise with the use of the particle *-to* sounds promising.

---

<sup>4</sup> A combination of all three particles is not only possible but rather frequent in colloquial speech. The membership set evoked by *-to + že + ved'* should be similar, if not identical, to the sets in (19/21) and its discourse tree should be the same as in (24). However, the limits of this paper do not allow me to go into further detail here.

This data would also benefit from being examined from another angle, i.e., with respect to the notion of contrast that is currently being developed (Molnar 2001, de Hoop and de Swart 2004, etc.). Contrastiveness within closed sets (*že, ved'*) vs. that operating in open sets (*-to*) and the properties that result from the intersections of these sets (the particle combinations) lend themselves well to the discussion on the nature of contrast.

Finally, the findings would benefit from being tested on native speakers and/or confirmed by natural language corpus research.

## Abstract

This paper aims to characterize weakly negative adversative predicates (AP) with reference to nonveridicality and expletive negation (EN). Some may be weaker licensers of NPIs which even evade nonveridicality. Emotive predicates are not nonveridical (Lee (1999)) but they license weak NPIs, whereas some nonveridical desiderative predicates have a partial licensibility of NPIs. Following Kadman and Landman (1993) and Lee (1999), we argue that those emotive predicates are the weakest licensers of NPIs, yielding a ‘settle for less’ interpretation or more broadly a ‘concessive type of begging’ in the speaker’s attitude. We can subdivide APs according to their negative force: they are classified into two categories by the possibility of triggering EN in the complements (Van der Wouden 1994). We claim that APs which can trigger EN in some languages are relatively weak in negative force and that they bear the feature [+nonveridical], although they vary in negative force. We show that some APs triggering EN are not strong enough to be anti-additive and instead are just DE or nonveridical at most. We also extract the predicates of apprehension *e.g. fear/afraid* and the predicates of dubitation *e.g. doubt (whether)* in Korean and in Japanese because they clearly show that the EN marker *anh(K)/nai(J)* can be triggered in the complement only if they have a non-factive interrogative complementizer such as *-(u)lkka* or *-ci(K)/-ka(J)* ‘whether,’ which we assume is a lexical realization of the feature [+nonveridical] in the matrix predicate. In contrast, when they lack the feature, they act as factive-like predicates, taking the quasi-factive complementizer *-kes* ‘that,’ showing neither DE nor nonveridicality.

**Keywords:** nonveridicality, emotive factive predicate, adversative predicate, expletive negation, predicate of apprehension, predicate of dubitation

---

<sup>1</sup> An earlier version was presented at the CIL18 Workshop on Contrastiveness in Information Structure and/or Scalar Implicatures. We thank the participants including Larry Horn and Manfred Krifka for their questions, comments and discussion. Still an earlier version was presented at PACLIC21 in 2007.

## 1. Introduction

This paper starts from two questions concerning nonveridicality and adversative predicates (APs henceforth) such as the following:

- (1) How can we handle emotive factive predicates (EFP) *e.g. lucky* which license NPIs and some nonveridical predicates *e.g. hope*, which partially license NPIs?
- (2) Can APs be treated as one category though there are intuitive differences of negative force among them?

The introduction of nonveridicality (Zwarts 1995, Ladusaw 1996, Giannakidou 1997, Lee 1999) has been a helpful guideline making up for the deficiency of Downward Entailment (henceforth DE), yet it still has unsolved puzzles as mentioned in (1). In addition, no clear attempt was made about the differences between APs such as *dislike*, *hate* and those such as *hinder*, *fear* as a licenser of NPIs until Van der Wouden (1994) first pointed it out in connection with expletive negation (henceforth EN).

This paper is organized as follows: Section 2 starts with a quick review of previous researches on NPI licensing contexts. Section 3 shows counter-examples to nonveridicality and treats them as the weakest licensers related to pragmatic licensing. Section 4 deals with two types of APs and their meaning templates correlated with EN in the complements. We also show that APs which can trigger EN are not strong enough to be anti-additive, instead they are DE. Section 5 will exclusively treat predicates of apprehension and of dubitation which are nonveridical but sometimes fail to be even nonveridical and act as factive predicates.

## 2. Previous Researches on Licensing Contexts of NPIs

Since Ladusaw (1979) proposed ‘downward entailing’ (or ‘monotone decreasing’) as a function of NPI licensing, more accurate properties (Zwarts 1993, Van der Wouden 1994, Nam 1998 for Korean) were proposed, creating a hierarchy of negative expressions. The following are three negative functions which largely show three types of NPIs in negative force: Weak, strong and the strongest. Weak NPIs are licensed by downward entailing, strong NPIs by anti-additive and the strongest NPIs by anti-morphic function.

(3) Three negative functions (examples are from Lee 1999)

- (a) A functor  $f$  is downward entailing iff for any  $a_1, a_2 \in A$ , if  $a_1 \leq a_2$ , then  $f(a_2) \leq f(a_1)$ . *e.g. at most (weak).*
- (b) A functor  $f$  is anti-additive iff  $f(X \vee Y) = f(X) \wedge f(Y)$ . *e.g. no, before, every (strong).*
- (c) A functor  $f$  is anti-morphic iff  $f$  is anti-additive and additionally  $f(X \wedge Y) = f(X) \vee f(Y)$ . *e.g. not (the strongest).*

The stronger functions form proper subsets of the weaker functions. Thus, anti-morphic function is a proper subset of anti-additive function and anti-additive function is a proper subset of downward entailing function. However, DE is not perfect enough to predict the distribution of NPIs since there are many non-DE contexts where NPIs are licensed (Zwarts 1995, Giannakidou 1997, 2002). Moreover the behaviors of NPIs do not exactly correspond to the negative functions in natural languages (Lee 1999). For instance, there are hardly any NPIs cross-linguistically that are exclusively licensed by the strongest functor, a sentential negation (Lee 1999). In order to account for non-DE contexts, Zwarts (1995) adopts a weaker function, which is ‘nonveridicality’, and Giannakidou (2002, 2007) developed it with Greek subjunctive mood. Zwarts' (1995) definition about nonveridicality, as simplified, is as follows:

(4) Nonveridicality

Let  $O$  be a monadic sentential operator.  $O$  is said to be veridical just in case  $Op \Rightarrow p$  is logically valid. If  $O$  is not veridical, then  $O$  is nonveridical. A nonveridical operator is called averidical iff  $Op \Rightarrow \sim p$  is logically valid.

Zwarts claims that NPIs are sensitive to nonveridical contexts. As shown above, overt negation *not* is averidical and belongs to nonveridicality at the same time. We also take the view that nonveridicality is an extension of DE (Giannakidou 2002). Thus DE forms a proper subset of nonveridicality. In this respect, nonveridicality appears to cover all the licensing contexts of NPIs. However, there are two problems, i.e., over-generation: there are nonveridical predicates such as *dream* that do not license NPIs, and under-generation: some predicates such as emotive factive predicates even evade nonveridicality. In addition, some nonveridical predicates partially license NPIs. These will be treated in the next section.

### 3. Unsolved Puzzles with Nonveridicality

#### 3.1. Emotive Factive Predicates

Emotive factive predicates (EFP) in Korean such as *tahayng-i-ta* 'lucky', *nollap-ta* 'surprising' and *hwuhoyha-ta* 'regret', license the weak NPI form *amwu-i-ra-to* 'any', as Lee (1999) observed.

- (5) *amwu phyo -i -ra-to kuhay-ss-uni tahayng -i- ta.*  
any ticket -be-DEC-even get-PAST-since luck -be -DEC  
“(I) am lucky that (I) got any tickets (at all).”

Kadmon and Landman (1993, henceforth K&L) explain the licensibility of NPIs in EFPs with a ‘settle for less’ interpretation. *Any* is licensed just in case a ‘surrogate wish’ is satisfied. That is, though the speaker's ‘real wish’ is not satisfied, he is willing to settle for less and be glad about the ‘surrogate wish’.

Lee (1999) is sympathetic with ‘settle for less’ by K&L and argues that EFPs can license NPIs when they yield a ‘concession type of begging’ interpretation. According to him, the phenomenon of negative polarity and free choice is one and the same phenomenon based on the *wh*-indefinites plus concessive indicator cross-linguistically (Lee 1997). The concession in NPIs and FCIs can be interpreted variably depending on different contexts. The categories of strong NPIs and FCIs belong to the concession type of ‘betting’ and the category of weak existential NPIs belongs to the concession type of ‘begging.’ Although the English NPI *any* does not show the strong - weak distinction on surface, *any* in EFP complements is a weak existential NPI type and most typologically distinct languages from English have the weak form manifested on surface. To yield the concession type of begging, the speaker's real motivation behind the phenomenon should be considered. Example (5) implicates that the speaker did not expect to get *any* ticket and (s)he feels lucky in a concession to this expectation though (s)he couldn't get the very ticket or preferable tickets (s)he wanted. This argument can be supported by Giannakidou (2002) as she proposes a ‘pragmatic licensing’ for a solution of the EFPs, rather than a purely semantic account.<sup>2</sup> Although the semantic/pragmatic boundary is

---

<sup>2</sup> Giannakidou (2006) uses the term ‘indirect licensing’ as a secondary condition to nonveridicality, arguing that *any* can be in the scope of veridical expression if this expression generates a nonveridical inference. She distinguishes her notion of ‘indirect licensing’ from that of Linebarger's in that her notion makes appeal to the global context of sentence, which contains the assertion (entailments and presuppositions) and implicatures (conventional as well as conversational) while Linebarger just allows a

controversial, this kind of licensibility of weak NPIs is not universally witnessed, when cross-linguistically examined. *Content* ‘content’ in French, for instance, does not license NPIs (Lee 1999).

(6) \**Je suis content d'avoir obtenue quelque ticket que ce soit.*

I am content to have got any ticket that it be (sub.)

“I am happy to get any ticket.”

From the examples above, we argue that EFPs should be considered as the weakest licensers of NPIs because (i) the negative implicature behind the speaker’s motivation and concessive interpretation for this implicature should be considered, which belong to the pragmatic domain, and (ii) licensibility of weak NPIs in EFPs shows cross-linguistic variation.

Another interesting point on EFPs is that factive presupposition in this predicate is weaker than assertive force, as Moeschler & Reboul (1994) argue.

(7) *C'est vrai que Max est linguiste.*

“It is true that Max is (ind.) a linguist.”

(8) *Il est surprenant que Max soit linguiste.*

“It is surprising that Max is (sub.) a linguist.” (Moeschler & Reboul 1994)

For Moeschler & Reboul (1994:251-2), the proposition ‘Max is a linguist’ in (7) must be true in order for the whole sentence to be true. But this is not required for (8). ‘Max is a linguist’ might be false and the entire sentence will be considered as true, only if ‘the fact that Max is a linguist is surprising’ is true. The use of ‘subjunctive mood’<sup>3</sup> with EFPs in French also supports our argument that the complements of EFPs are weaker in assertiveness; they can be associated with a negative implicature more easily. As Lee (1999) already mentions, these subtleties must be taken care of to account for all different sorts of NPIs.

On the other hand, the distinction between ‘emotive adversative predicates’ e.g. *sad*, *surprising* and ‘emotive non-adversative affective predicates’ e.g. *lucky*, *glad* should be made, because it seems that *sad*, *surprising*, *ashamed* are a little more permissive with *any* than *lucky*, *glad* (e.g. *He was glad to take some money*, Klima

---

negative conversational implicature.

<sup>3</sup> Traditionally indicative represents the act or state as an objective fact while subjunctive expresses subjective actions such as will/wanting, emotion, doubt, possibility, necessity, judgment, comparatives.

1964). Still another group is positive: *sure, smart, anxious, in favor of*, not licensing NPIs.

(9) I am surprised/sorry/ashamed that he ever said anything.

(10) a. I'm glad/\*sure that I ever met him.

b. I'm glad/\*sure I said anything. (K&L 1993)

Concerning this problem, Linebarger (1987, cited by K&L 1993) maintains that sentences with APs have a negative implicature. Let's take examples ((11)-(13), modified from K&L):

(11) I am sad that he had to feel any survivor's guilt about living while others died.

(11') I want for him not to have to feel any survivor's guilt.

(12) *ku-ka amwu chinkwu i -ra -to iss-ta -ni nollap-ta.*  
he-NOM any friend -be-DEC-even have-DEC-since surprising-DEC

"It's surprising that he has any friend."

(13) *C'est surprenant que quoi que ce soit résiste à une réinstallation de Mac OS X.*

"It is surprising that anything is resistant to reinstall Mac OS X."

Sentence (11) is said to implicate sentence (11'). However, (11') does not seem to be a mere conversational implicature, because emotive affective predicates can also be affected by speaker's conversational implicature. K&L argue that there is a special connection between (11) and (11') and this connection is an entailment determined by lexical semantics. However, if emotive APs have a negative entailment in its lexicon, why do they always take weak NPIs as shown in the Korean and French examples of (12), (13), while some other APs take strong NPIs? This observation leads us to conclude that a negative proposition inferred by an emotive AP may not be a negative entailment in its lexicon, but rather, something weaker, and we tentatively suggest that the connection between (11) and (11') be a conventional implicature. Emotive APs will be treated as weak NPI-licensing APs along with the predicates of apprehension and of dubitation which will be presented in section 5.

### 3.2. Nonveridical Predicates

The second problem about nonveridicality: nonveridical fiction predicates such as *dream, imagine* do not license NPIs, whereas nonveridical desiderative predicate *hope*

in English licenses NPIs for a very limited population of native speakers. Observe:

- (14) a. %I hope there is *any* food left. (Lee 1999, from Giannakidou 1999 via Horn, p.c. and S. Strauss, p.c.)<sup>4</sup>  
b. In Korean, a weak NPI *amwu umsik-i-ra-to* ‘any food’ is fully licensed in the same context as (14a) with the verb *para-ta* ‘hope.’

Example (14) shows that *hope* or its Korean equivalent can license a weak NPI only if the speaker's negative implicature is evoked in the context. As for (14), it is acceptable only if we imagine that the speaker expects or is worried that there is no food left in some possible world. The verb *hope* as well as other desiderative verbs such as *want*, *desire* is a nonveridical and intensional verb which can be affected by speakers' pragmatic attitudes at the time of utterance. If the speaker believes that the argument proposition of these verbs has the possibility of realization the verbs do not license NPIs. If the speaker tends to believe the impossibility of realization of the argument proposition and yields a concessive type of ‘begging,’ then they do license NPIs. Thus, we treat *hope* as the weakest type of NPI licenser along with emotive (non-adversative) factive predicates. In the mean time, *dream*, *imagine* are fiction verbs, so their argument proposition is always realizable in the speaker's specific world. For this reason, they do not license NPIs.

The counter-examples presented above show that nonveridicality is neither a necessary nor a sufficient condition of licensing NPIs. Nevertheless, the notion of nonveridicality is useful to figure out weak licensers of NPIs among APs to be dealt with shortly.

#### 4. Two types of Adversative predicates

##### 4.1. Adversative Predicates and Expletive Negation

In this section, we deal with the adversative predicates (APs), which have been treated without any clear distinction in their negative force. To define ‘adversative predicate’ is not easy and only few studies have been made of this. Espinal (1991, cited by Van der Wurff 1999) describes APs as “certain lexical items which trigger [...] some

---

<sup>4</sup> In French, a volitional verb *souhaiter* does not license the weak type of NPI *quoi que ce soit*.  
(1) \**Je souhaite qu'il y ait quoi que ce soit de laissé.*  
“I hope that there is anything left.”

sort of negative import”. Hoeksema and Klein (1995), using the term ‘negative predicates’, explain that the truthfulness of their complements may be called into doubt and existential entailment may be canceled. The definitions are vague and raise a question why APs show differences both in licensing EN and types of NPIs in the complements. Van der Wouden (1994) characterizes APs as correlated with EN. We, deriving ideas from his observation, will draw a distinction between strong and weak APs by their licensibility of strong and weak types of NPIs in section 4.2.

The contexts where EN appears show cross-linguistic diversity. EN shows up in the embedded clause of some APs and also in two more environments: comparatives of inequality and certain conjunctions related with time. The following are the contexts where the EN marker *ne* appears in French, which is one of the languages having diverse contexts triggering EN.

(15) The contexts where the EN marker *ne* appears in French

- a. Adversative Predicates or Expressions: *avoir peur* ‘to be afraid’, *craindre* ‘to fear’, *douter* ‘to doubt’, *empêcher* ‘to prevent’, *nier* ‘to deny’, *de peur que* ‘for fear that’, *de crainte que* ‘for fear that’.
- b. Comparatives of inequality: *autre* ‘other’, *meilleur* ‘better’, *mieux* ‘best’, *moins* ‘less’, *pire* ‘worse’, *plus* ‘more’, *plutôt que* ‘rather than’.
- c. Conjunctions: *à moins que* ‘unless’, *avant que* ‘before’, *sans que* ‘without’.

Let’s take a look at the example of (15a).

(16) *Je crains qu’il ne dise quoi que ce soit qui offenserait les banques.*

I fear that he EN say(sub.) anything which offend(cond.) the bank

“I fear that he **ne** might say anything which would offend the banks.”

The issue of whether *ne* in Modern French is or is not inherently negative does not come to a firm conclusion (Rowlett 1998). In this paper, we suggest that French *ne* is not inherently negative but it expresses a most widely nonveridical context, namely, not a thoroughly veridical context. French *ne* negates verbs with other reinforcing adverbs such as *pas*, *point*, *plus*, *jamais* etc, but *ne* alone cannot mark negation except with very restricted expressions.<sup>5</sup> Besides, *ne* is often dropped in spoken French and

---

<sup>5</sup> Pseudomodal verbs such as *savoir* ‘to know’, *oser* ‘to dare’, *pouvoir* ‘to be able’ and some frozen expressions in French can be fully negated with pre-verbal *ne* alone. For these cases he assumes that there is non-overt operator (OP[+NEG]) in SpecNegP (Rowlett 1998).

*pas* alone negates a sentence. Also *ne* has an expletive use. The EN *ne* is called a ‘non-negative *ne*’ because it is usually regarded semantically redundant and does not affect the sentence meaning, being optionally used. However, when the EN *ne* is triggered by APs, the speaker’s attitude of undesirability toward an uncertain phenomenon is expressed, whereas the sentence without EN shows the speaker’s neutral attitude. In example (16), the speaker expresses his or her attitude that uncertain event in the complement is undesirable, by triggering EN.

Within the Guillaumian framework (Martin 1987), EN *ne* is interpreted as a sign of possibility as a movement going from the positive to the negative. That is, EN *ne* catches the negative movement in the speaker’s psychology. In this sense, the contexts which trigger EN have an uncertain or a weakly negative meaning.

We can notice in (16) that the verb *craindre* ‘fear’ licenses both EN *ne* and weak NPI *quoi que ce soit* with the subjunctive. However, the three contexts above in (15) allowing EN in French should not be collapsed into one category, as Van der Wurff (1999) claims, since there are other languages having EN only in some more limited contexts. (15b, c) and some of (15a) are regular DE contexts licensing strong or weak NPIs depending on different languages. Moreover, the contexts in (15a, c) can trigger EN *ne* in the complements with the subjunctive but the subjunctive is not required in (15b). Therefore, the contexts triggering EN intersect with the subjunctive in French. In this respect, this paper focuses exclusively on those limited APs in (15a) rather than all contexts licensing EN as in French.

#### 4.2. Analyzing Expletive Negation under Adversative Predicates

Van der Wouden’s (1994) attempt to correlate adversative predicates (AP) with EN provides a formal fingerpost over most linguists’ intuitive presumptions. He regiments APs into two categories by lexical meaning templates. The template of the APs triggering EN is given as ‘V THAT NOT X’ while that of the other APs is ‘NOT V THAT X’ (Van der Wurff 1999). From the templates, we can see that EN is involved in the indirect (and often weak) negation of the embedded proposition. Examples (17) and (18) are the analyses of meanings of *fear* and *hinder* which trigger EN in languages that have it (Van der Wouden 1994).

(17) HINDER X = CAUSE X NOT TO BECOME THE CASE

(18) FEAR X = BELIEVE THAT X WILL BE THE CASE AND HOPE THAT X  
WILL NOT BE THE CASE

Progovac (1992) points out that APs can license NPIs only in their complement position.<sup>6</sup> She suggests that NPIs can be licensed by a polarity operator in the complementizer position of a clause governed by APs whose function is to make the truth value of the clause indeterminate.

Espinal (1991, 1992 cited by Van der Wurff 1999) focuses on EN and proposes that the specifier position of NegP will be filled not by a negative element but by a truth value operator that is not negative. NegP has a head that is negative, yet the negative meaning of the NegP is absorbed by the matrix predicate so NegP remains expletive.

Concerning French *ne*, Rowlett (1998:34-5) assumes that *ne* is licensed in two ways; it is licensed by (indirect) selection or it can be licensed by spec-head agreement. The EN *ne* is licensed by the first way. According to him, the availability of EN *ne* is determined by the immediately superior predicate. Thus EN *ne* is accompanied by neither overt operator such as *pas* nor non-overt operator<sup>7</sup>. That is, when EN *ne* is triggered, there is no operator bearing the feature [+NEG] to transmit it to Neg° where *ne* is located, unlike in Espinal.

From their arguments, we can notice that a polarity or truth value operator is not negative, and an operator bearing [+NEG] does not exist when EN *ne* appears at Neg° in French. The reason we are alluding to this is that they are affected by the feature [+nonveridical] in the matrix predicate. In the case of APs which can trigger EN such as *deny*, *prevent/hinder*, *fear*, *doubt* in French, they presuppose the non-factivity of the complements. According to the definition of nonveridicality in (4), if Op--/-->p, O is nonveridical. In this respect, we suggest that APs triggering EN bear the feature [+nonveridical], although there is a hierarchy in negative force among them.

Hoeksema and Klein (1995) show that strong NPIs *ook maar-indefinites* ‘any-indefinites at all’ in Dutch can be licensed only in the complements of APs and explain this by mapping types of NPIs and types of APs with Partee’s type shifting. But they just treat monotone-decreasingness of APs and do not mention relative degree of their negative force. Choi & Lee (1998) show that APs such as *samka-ta* ‘refrain from’ and *kecelha-ta* ‘refuse’ are anti-additive and license a strong NPI *te-isang* ‘anymore’ in Korean<sup>8</sup>.

---

<sup>6</sup> Hoeksema and Klein (1995) give a list of English negative predicates which trigger NPIs with four different argument types.

<sup>7</sup> Please refer to footnote 4.

<sup>8</sup> Choi & Lee (1998) argue that APs which license *te-isang* are **anti-additive**. For example, *hate* in Korean licenses *te-isang* and is anti-additive. Sentences (2) and (3) show mutual entailment relation.

(2) Mary hates raising dogs or cats. ↔ (3) Mary hates raising dogs and Mary hates raising cats.

In this paper, we will treat APs which trigger EN. We have already mentioned that EN expresses the speaker's attitude of undesirability toward an uncertain phenomenon with APs. This also corresponds to our argument that APs triggering EN bear the feature [+nonveridical], namely, the truth value of the clause is not determinate. We assume that they are relatively weak in negative force.

As shown in the examples of (19) and (20), *puinha-ta* 'deny', *panghayha-ta* 'hinder,' which trigger EN in some languages (but not in Korean) do not license a strong type of NPI *te-isang* 'anymore' in Korean.

- (19) \**John-un te-isang ku-lul manna-l-kes ul puinhay -ss -ta.*  
 J -TOP anymore him-ACC meet FUT-COMP deny -PST-DEC  
 "John denied that he would meet him anymore." (OK in English)
- (20) ?\* *ku-nun nay-ka te-isang ppang-ul mek -ki lul panghayha-n-ta.*  
 He-TOP I-NOM anymore bread-ACC eat -COMP hinder-PRES-DEC  
 \* "He hinders me from eating the bread anymore."

However, the other APs such as *phokiha-ta* 'give up', *eryep-ta* 'difficult', *silheha-ta* 'dislike' license *te-isang* in the complements (See Choi & Lee 1998 for further examples).

- (21) *Kiho-nun te-isang ku-ekey mal-ul kel -ki ka erye -wess -ta.*  
 K -TOP anymore him-to word-ACC talk-COMP difficult-PST -DEC  
 "It was difficult for Kiho to talk to him anymore."

Moreover, *puinha-ta* 'deny' can license only the weak type of NPI *amwu-N-i-ra-to* 'any N' but not the strong type *amwu-N-to* 'any N'<sup>9</sup> whereas *eryep-ta* 'difficult'<sup>10</sup> can license both of them.

- (22) *Joe -nun amwu-phyo\*(-i-ra)-to sa-ss-ta -nun kes ul puinhay-ss-ta.*  
 J -TOP any ticket-be-DEC-even buy-PST-DEC-Comp deny-PST-DEC  
 "Joe denied that she bought any ticket."
- (23) *John-un amwu(-i-ra)-to manna-ki eryep-ta.*  
 J -TOP anyone meet -Comp difficult-DEC.

<sup>9</sup> Existential weak type NPIs are also licensed in verbs such as *panghayha-ta* 'hinder' in (20).

<sup>10</sup> The strongest type of NPI *amwu-to* 'anyone' or *amwu-N-to* 'any N' are licensed in the verbs such as *phokiha-ta* 'give up' and *silheha-ta* 'dislike' as well. These predicates do not trigger EN in any language. However *amwu-to* shows more restricted distribution than *te-isang*.

“It is difficult for John to meet anyone.”

The difference between (22) and (23) is the availability of EN in the complements. *Puinha-ta* ‘deny’ in (22) triggers EN (in some languages) and cannot license a strong type of NPI *te-isang*, not to mention the strongest type of *amwu N-to*. By contrast, *eryep-ta* ‘difficult’ in (23) does not trigger EN and license even the strongest type of NPI in Korean. We have shown that the contexts which license *te-isang* are anti-additive. Therefore, APs in (19)-(20) are not strong enough to be anti-additive. Instead, they are DE as shown in (24)-(25).

(24) |pizza| ≤ |food|

a. Jane prevented me from buying food.

-->b. Jane prevented me from buying pizza.

(25) a. John denied that I ate food.

--> b. John denied that I ate pizza.

Sentence (24a) and sentence (25a) respectively entail (24b) and (25b), therefore they can license *any* as DE, e.g. *Jane prevented me from buying any food*. We summarize the classification of APs according to their negative force in Table 1.

Table 1. Two Types of Adversative Predicates

EN; Strong/Weak NPI	Meaning Template	Negative Force	Examples
EN not triggered Strong NPI	Not V that X	Anti-additivity	<i>silheha-ta</i> ‘dislike’ <i>eryep-ta</i> ‘difficult’ <i>phokiha-ta</i> ‘give up’
EN triggered Weak NPI	V that Not X	DE	<i>puinha-ta</i> ‘deny’ <i>panghayha-ta</i> ‘prevent/hinder’

We should point out that all APs triggering EN are not as weak as to be nonveridical in negative force, though they bear the feature [+nonveridical]. However, they show relatively weak negativity comparing to the other APs. As example (22) shows, only a weak NPI is licensed in this DE context. If the postulated negative were directly associated with the complement S, a strong NPI must be licensed in it because of the locality condition on strong NPIs, which is not the case.

In fact, EN shows considerable variation not only cross-linguistically but also lexically. In the next section, we will show weaker APs such as *fear* or *doubt* with data

in Korean and Japanese because they are good examples triggering EN with a non-factive interrogative complementizer which requires the feature [+nonveridical].

5. *Predicates expressing apprehension or dubitation: a weaker type*

We have shown that APs such as *prevent/hinder* and *deny*, which trigger EN in some languages are relatively weak in negative force, falling under DE, but not anti-additive. Among the APs, an apprehensive predicate is the most widely exemplified context as an AP triggering EN in many languages. *Fear* in Yiddish also triggers EN as in (26).

- (26) *di tsvey hob-n moyre ge-ha-t es zol im nit shat-n zum gezunt.*  
 the two have-3PL fear have-PTCP it shall he.DAT EN harm-INF to.DEF.ART health  
 “Both of them were afraid that it would harm his health.” (Bjoern Hansen, Ms)

Also, predicates expressing apprehension and dubitation can trigger EN in Korean and Japanese as well.<sup>11</sup> (K stands for Korean and J for Japanese.)

- (27) a. *ney -ga kamki-ey keli ci -nun anh ass-ul kka kekceonha-go iss-ta.*(K)  
 you-NOM cold-ACC catch -TOP (do) -EN -Comp fear -PROG-DEC  
 (a, b) “(I) fear that you might catch cold.” ((28b) is from Kinoshita 1998)
- (28) a. *ku-ka param-i-ra-to phiwu-ci -nun anh ass -ul kka uysimha-ko iss-ta.*  
 He-NOM cheat -be-DEC-even do -TOP EN PST -Comp doubt-PROG-DEC  
 “(I) doubt that he cheated on me.” (K)
- b. *watashi-wa kare ga usotsuki de-wa nai -ka to utagatte-i-masu.*  
 I -TOP he NOM liar DEC-TOP EN Comp doubt-PROG  
 “I doubt that he is a liar.” (J)

We observe that these two predicates can take two different types of complementizer in Korean and Japanese which are *-(u)lkka* or *-ci(K)/-ka* (J) ‘whether’ as in (27-28) and

<sup>11</sup> An EN marker is also shown with the DE conjunction *before* and its equivalents, which license NPIs and in particular a strong NPI in Korean (example (4d) is from Kinoshita 1998). Observe:

(4) a. *?etuwe cici -anh ki cen-ey tora-wa-ra..* (K)  
 b. *kuraku nara -nai mae-ni kaette-kuru no-desuyo.* (J)  
 dark become -EN before return -IMP.  
 “Please come back before it gets dark.”

-kes(K) /-koto or-no(J) ‘that’ as in (29-30).

- (29) a. *na-nun nay-ka tanci salm-ey hengmi-lul ilh-ess ta -nun kes-i twuryep-ta.*  
I-TOP I-NOM simply life-in interest-ACC lose-PST-DEC-Comp afraid-DEC.  
“I am afraid that I simply have lost all interest in living.” (K)
- b. *boku mo hito-o kizutsukeru -no ga kowaii.*  
I also person-ACC hurt -Comp afraid  
“I am also afraid of hurting a person’s feeling.” (J)
- (30) a. *na-nun John-i mihonnam-i-ra nun kes-i uysimsurep-ta.*  
I-TOP J-NOM bachelor-be-DEC Comp doubt -DEC  
“I doubt that John is a bachelor.” (K)
- b. *watashi-ga tamatama sono sennin ni atta -to iu -koto o utagau hito -ga iru.*  
I -NOM by chance that hermit meet-Quat. say -Comp doubt person-NOM exist  
“There is a person who doubts my saying that I met that hermit by chance.” (J)

However, the predicate of apprehension and dubitation can trigger the EN marker in complements, only when it takes *-(u)lkka* or *-ci(K)/-ka* (J) ‘whether’ as a complementizer in Korean and Japanese.

- (31) a. *na-nun etten silswu -i -ra -to ha -ci anh -ass -ul kka twuryep-ta.*  
I-TOP any mistake-be-DEC-even do- EN -PST -Comp afraid-DEC.  
b. *na-nun etten silswu -i -ra -to ha -ss -ul kka twuryep-ta.*  
(Lit.) a&b “(I) am afraid that I might have made any mistake.” (K)
- (32) a. *kare -ga shiken-ni ochiru- no de -wa nai -ka to shimpaishi-tei-ru.*  
He -NOM exam DAT fail Comp -TOP EN Comp worry-PROG-DEC  
b. ?? *kare-ga shiken-ni ochiru-ka shimpaishi-tei-ru.*<sup>12</sup>  
(Lit.) a&b “(I) am worried that he might fail the exam.” (J)

The meanings of (31a-b) and (32a-b) remain the same regardless of the existence of the EN marker. The expletive *anh* in (31a) often falsely invites a negative interpretation. If *anh* is used negatively here, the speaker is worried about not having made any mistake, which is absurd. A weak NPI is impossible.<sup>13</sup> Interestingly, the EN marker *-anh* can be triggered by the psychological verb *sip-ta* ‘seem’ in Korean, when

<sup>12</sup> In Japanese, when apprehensive verb is constructed with a negative expression such as *fail*, the usage of EN seems to be a frozen expression.

<sup>13</sup> If EN+interrogative complementizer ‘*-anh -ulkka*’ is followed by the auxiliary *po-a* ‘guess’, it receives negative interpretation.

it takes the non-factive interrogative complementizer *-(u)lkka* or *-na* as well. In that case, the verb *sip-ta*, as a typical nonveridical verb, can also license weak existential NPI.

- (33) *ku ai -ka amwu kes\*(-i-ra) -to mek -ci anh-ass -ulkka sip-ta.*  
 the boy-NOM any thing –be-DEC-even eat -EN -PST COMP seem-DEC.  
 “It seems (to me) that the boy ate something or other.”

On the other hand, the APs such as *panghayha-ta* ‘prevent’ and *puinha-ta* ‘deny’ in Korean cannot take *-(u)lkka* or *-ci(K)*.<sup>14</sup> They don’t trigger EN in Korean or Japanese. In this respect, data in Korean and Japanese clearly show that the predicates triggering EN always take non-factive interrogative complementizer. We claim that this complementizer is the lexical realization of the feature [+nonveridical] in the matrix predicate. A yes/no or verum (truth) question seeks either affirmation or denial, and a negative question in its long form (‘Isn’t it the case ---?’) or particularly a tag-question form (‘---, isn’t it?’ ‘---, didn’t it?’) tends to be the speaker’s strongly positively-biased agreement-seeking statement/question. In Korean, as in ‘*pi-ka w-ass-ci-anh-a!*?’ (It rained, didn’t it!), the post-tense contracted long-form negation is an affirmation-securing rhetorical marker. That’s why in Korean, in Japanese as well, the long-form negation in the interrogative complementizer became an EN marker.

In contrast, the negative marker *-an* is always used in a short-form negation and marks negation even with non-factive interrogative complementizer *-(u)lkka* or *-ci* ‘whether’.

- (34) *pi -ka an o -l kka kekchengtoyn -ta.*  
 rain-NOM NEG marker come -Comp fear -DEC  
 “I am afraid that it is not going to rain.”

Example (35) can get only one negative interpretation from the pre-verbal negative marker *an*, but not from EN *anh*, which is reflected in the English translation.

- (35) *pi -ka an o -ci anh -ulkka kekchengtoyn -ta.*  
 rain-NOM NEG marker come EN -Comp fear -DEC  
 “I am afraid that it is not going to rain.”

<sup>14</sup> The Japanese counterparts *hininsu-ru* ‘deny’ and *samatage-ru* ‘prevent’ cannot take the interrogative complementizer *-ka*, either.

In the mean time, the negative marker *anh* gains a negative power and changes the meaning of the whole sentence with the non-interrogative complementizer *-kes* ‘that’.

- (36) *pi -ka o -ci anh -l kes-i kekchengtoyn -ta*  
 rain-NOM come - NEG marker -Comp fear -DEC  
 “I am worried that it’s not going to rain.”

Lastly, we should mention that the EN licensibility crucially originates from the predicates of apprehension or dubitation with the interrogative complementizer. *Ahn* in (37) is interpreted as negation maker but not as EN when used in matrix interrogation.

- (37) *nayil pi -ka o -ci anh-ulkka?*  
 Tomorrow rain -NOM come -Comp NEG -Q  
 “Isn’t it going to rain, tomorrow?”

Then, what are the differences between the sentences with *-(u)lkka* or *-ci(K)/-ka* (J) ‘whether’ as in (27-28) and *-kes(K)/-koto or-no*(J) ‘that’ as in (29-30)? We will explain this with Korean examples. Hoeksema and Klein (1995) treat *fear* and *doubt* as DE. They show that *doubt* licenses NPI *any* in non-interrogative complements but do not deal with *doubt if/whether*. It also licenses an NPI, e.g. ‘She **doubted if** she would learn *anything* new from Bill. They only treat *fear/afraid* with extensional NP or gerundive complements.

However, in Korean when the predicates expressing fear and doubt take *-(u)lkka* or *-ci* ‘whether’ as a complementizer, they tend to be nonveridical but not monotone decreasing. In (38), we interpret the meaning of *-kka twuryep-ta* (‘Lit.) afraid whether’ as ‘afraid that something will/might happen’ since the English ‘afraid/fear’ cannot take ‘whether’ as a complementizer<sup>15</sup>.

- (38) |pizza| ≤ |food|  
 a. *Jane un nay-ka umsik-ul mek -ess -ulkka twuryeweha-n-ta. -/->*  
 Jane-TOP I-NOM food-ACC eat-PST -Comp afraid -PRES-DEC  
 “Jane is afraid that I might eat **food**.”

<sup>15</sup> In Korean, *-ulkka* is decomposed into *-ul*, the futurity/conjecture modal, and *-kka*, the interrogative component. In English, the idea of near future possibility of complement clause of ‘fear’ can be expressed by *will* or the modal verb ‘may’ or ‘might’. They are basically the same but ‘might’ is more appropriate for the less likely possibility.

b. *Jane un nay-ka sangha-n umsik-ul mek -ess -ulkka twuryeweha-n-ta.*

“Jane is afraid that I might eat **contaminated food.**”

(39) |Hyundai| ≤ |car|

a. *Jane un nay-ka cha-lul sa-ss -unu ci uysimha-go iss-ta. ? -/->*

Jane-TOP I-NOM car-ACC buy-PST -Comp doubt-PRES-DEC

“Jane doubts whether I bought a car”

b. *Jane un nay-ka Hyundai-lul sa-ss -unu ci uysimha-go iss -ta.*

Jane doubts whether I bought a Hyundai.

The Complementizers *-ulkka* in (38) and *-ci* in (39), both meaning ‘whether,’ as *wh*-complementizers, express the non-factivity of the complement. We have claimed that non-factive complementizer *-(ul)kka* or *-ci* ‘whether’ is a lexical realization of the feature [+nonveridical] in the matrix predicate. For this reason, we tentatively conclude that *twuryep-ta* ‘fear’ and *uysimha-ta* ‘doubt’ in Korean express nonveridical contexts with *-(ul)kka* or *-ci*, failing to be DE. For example, in (38), if Jane is afraid that I might eat food, Jane is afraid of the possibility of my eating food, wishing that I had eaten no food. What Jane is concerned about is exclusively the occurrence of my eating food regardless of the kind. In this respect, (38a) does **not necessarily** entail (38b). If Jane is afraid that I might eat food, it is possible that Jane is afraid that I might eat clean food or bad food, and so on. Thus, apprehension predicates are not DE in a strict sense.

The entailment inference with *-ci uysimha-ta* ‘doubt whether’ in (39a-b) is more or less controversial among Korean speakers. We maintain our claim that the Korean verb *uysimha-ta* ‘doubt’ bears the feature [+nonveridical] and can be realized with the non-factive complementizer. However, it seems to be true that *uyshimha-ta* ‘doubt’ provides the speaker’s psychological negative attitude more directly than *twuryep-ta* ‘fear’ as their meaning templates shows in (43-44). We will leave further investigation of this question for the future.

Concerning apprehensive predicates, we assume that it bears a [conjecture] modal operator in itself. The speaker conjectures that the object event of fear may happen readily or might have happened already in his or her mind when using apprehensive predicates. Since this [conjecture] operator is always associated with the complement proposition, apprehensive predicates always yield a nonveridical interpretation in any language. Notice that *conjecture* is nonveridical, regardless of the tense of proposition P, since it is possible to conjecture a past event.

(40) CONJECTURE P -/-> P

This conjecture operator licenses the non-factive complementizer *-(ul)kka* or *-ci* in Korean and modal auxiliary verbs like *will* and *might* in English. If the apprehensive predicate takes an extensional noun complement which presupposes the existence of the object, as in ‘I am afraid of that dog’, *-(ul)kka* or *-ci* is not licensed.

On the other hand, when the predicates *twuryep-ta* ‘fear’ and *uysimha-ta* ‘doubt’ take *-kes* ‘that’ as a complementizer in Korean, they are not nonveridical and act as emotive factive APs such as *nollap-ta* ‘surprised’/*sulphu-ta* ‘sad’, failing to be DE, either.<sup>16</sup> *-Kes* can be both a clausal complementizer ‘that’ and a general entity nominal ‘the thing’, and is used mainly with factive predicates in Korean. Although there are some verbs which do not presuppose the factivity with *-kes* (e.g. *tut-ta* ‘hear’), *twuryep-ta* ‘fear’ and *uysimha-ta* ‘doubt’ become factive with this *-kes* complementizer. Generally, the *-kes* complement tends to be externalized with emotive and psychological predicate and the existence of the state of affairs of the complement is presupposed.

In Korean, weak existential NPIs appear more naturally and freely with the *-(ul)kka* ‘whether’ complementizer than *-kes* ‘that’. In English, *afraid* shows a stricter distinction. *Afraid* can license (weak) NPIs only when it is combined with an NP and gerundive complements, as Hoeksema & Klein pointed out. The FCI reading, as in (41b), is possible because of the [conjecture] modal operator hidden in the apprehensive predicate. Observe:

- (41) a. \*I am **afraid that anyone** showed up. (Robert Fouser, Jeff Holliday p.c.)<sup>17</sup>  
 b. I am **afraid that anything might** happen.<sup>18</sup>
- (42) a. John, however, is bored with her and **afraid of forming any** permanent ties.  
 b. I should say the government led by congress prime minister, is **afraid to take any** decision.

*Afraid of* and *afraid to*, only in limited kinds of complements, as in (42a, b), license weak existential NPIs, but as shown above, *afraid that* in English does not license NPI

---

<sup>16</sup> The same inference is given by Giannakidou (2006) and similarly by K&L.

(5) a. Larry {regrets/is surprised} that John bought a car. [Honda ≤ car]  
 b. Larry {regrets/is surprised} that John bought a Honda.

In Strawson DE, (5a) entails (5b), providing a presupposition that ‘John bought a Honda’. However this presupposition is given merely by the context independently of the sentence (5a). The presupposition we can infer from (5a) is only that John bought a car. Thus (5a) does not logically entail (5b). Consequently, *regret/surprised* are not DE.

<sup>17</sup> FCI reading is OK.

<sup>18</sup> The weak existential NPI meaning is possible with *-kes* ‘that’ in Korean, unlike in English

*any*. This supports our argument that apprehensive predicates are nonveridical but not DE. In case of *uysimha-ta* ‘doubt’, the licensibility of weak NPI with *-kes* ‘that’ seems to be more permissive both in Korean and English as in (43).

- (43) a. *na-nun amwu-i-ra-to w-ass-ta -nun kes i -uysimsureyp-ta.*  
 I-TOP anyone come-PAST-DEC-Comp -doubtful -DEC.  
 b. I doubt that anyone came.

Interestingly, the meaning templates of these verbs have close relations with ‘believe’.

- (44) fear that = believe X and want not X  
 (45) doubt that = believe not X

As Giannakidou (1997:111) mentioned, epistemic attitudes such as *believe* express relations between individuals and propositions are veridical and its complement proposition is true in an individual’s model world. If we really doubt that something is true, we believe that it is not true because we do not have evidence for its truth. That is, ‘doubt that’ presupposes the falsity of its complement in the *individual’s* world and shows his psychological state of mind whereas ‘doubt whether’ expresses uncertainty, making the complement non-factive. Likewise, ‘fear that’ with *-kes* presupposes the fact of its complement in the individual’s world, while it expresses the individual’s wonder whether something might happen and fear of possibility with a non-factive complementizer *-(u)lkka* or *-ci* ‘whether’ in Korean. Compare these predicates with the following emotive factive APs.

- (46) sorry that = know X and want not X  
 (47) surprised that = know X and expect not X

There are differences between *believe* and *know*. The epistemic *know* is veridical both in the individual’s world and the real world, whereas *believe* is veridical in an individual’s world but not necessarily in the real world (Giannakidou 1997).<sup>19</sup> This splitting argument may explain why apprehensive and dubious predicates can be interpreted as both veridical and nonveridical. From the data we have shown above, we discriminate weaker APs from weak APs in Table 2.

<sup>19</sup> For Montague and Zwarts, *believe* should be nonveridical since believe p  $\not\rightarrow$  p.

Table 2. Types of Adversative Predicates by Negative Force

EN; Strong/Weak NPI	Meaning Template	Negative Force	Examples
EN not triggered Strong NPI	Not V that X	Anti-additive	<i>silheha-ta</i> ‘dislike’ <i>leryep-ta</i> ‘difficult’ <i>phokiha-ta</i> ‘give up’
EN triggered; (Not in Korean) Weak NPI	V that Not X	DE	<i>puinha-ta</i> ‘deny’ <i>panghayha-ta</i> ‘prevent’
EN triggered; Weaker NPI	V X & V’ that Not X /V that Not X (V=believe)	Nonveridical With-(u)lkka/-ci ‘whether’	<i>twuryep-ta</i> ‘fear’/ <i>uysimha-ta</i> ‘doubt’
EN not triggered (in Korean)	V X & V’ that Not X (V= know)	Veridical With <i>kes</i> ‘that’	<i>uysimha-ta</i> ‘doubt’ <sup>20</sup> , <i>twuryep-ta</i> ‘fear’ <i>nollap-ta</i> ‘surprised’ <i>sulphu-ta</i> ‘sad’

## 6. Conclusion

In this paper, we characterized different types of adversative predicates by their negative force in relation to nonveridicality and EN.

We also touched on emotive factive and desiderative predicates which are presented as counter-examples to nonveridicality. The emotive non-adversative affective predicates such as *lucky* and some desiderative predicates such as *hope* can be affective by speakers’ pragmatic attitudes at the time of utterance. We claimed that the speaker can generate a negative conversational implicature and because of a ‘settle for less’ or ‘begging’ concession weak existential NPI is licensed. Moreover, their licensibility is not witnessed cross-linguistically, so we classify them as the weakest licensers of NPIs.

As for APs, we showed that some APs such as *deny* or *prevent/hinder*, which can trigger EN in some languages, are weakly negative. They are DE but not strong enough to be anti-additive while the other APs are anti-additive. In addition, we extracted the predicates of apprehension and of dubitation, since they show different characteristics, failing to be DE in its strict sense. We reached the solution with data in Korean and Japanese. The predicates expressing fear or doubt are the only APs triggering EN in Korean and Japanese and these predicates can take two types of complementizers.

<sup>20</sup> The meaning of *doubt* here is *question the truth of*.

When they take the non-factive *wh*-complementizer *-(u)lkka* or *-ci(K)/-ka(J)* ‘whether’, they do not assert/presuppose the existence of state of affairs of the complements, thus they are nonveridical and trigger EN. When they take *-kes(K)/-koto* or *-no(J)* ‘that’, they act as emotive factive adversative predicate. In this sense, we argue that the predicates of apprehension and dubitation are unique and weaker APs. Data from Korean and Japanese clearly show that the predicates triggering EN always take a non-factive complementizer, which requires the feature [+nonveridical] in the matrix predicate.

## Abstract

This paper justifies three aspects of *wh*-constructions in (northern) Saisiyat: (a) it is a *wh*-in-situ language, (b) under the Lexical Merger Parameter hypothesis (Tsai 1994, 1999), it resorts to a mixed parameter setting, evidence coming from the formation of indefinite *wh* construals which is established either at the morphological domain through (partial) reduplication, or the clausal domain via unselective binding by a group of clausal operators, and (c) like Chinese, Saisiyat also displays the *how-why* alternation phenomenon, but there exist certain variations due to its own morphological nature.

**Keywords:** Saisiyat, Lexical Merger Parameter, *wh*-construction, indefinite *wh* construal.

## 1. Introduction

The purpose of this paper is to investigate syntactic patterns of *wh*-interrogatives and *wh*-indefinites in northern Saisiyat, one of the Austronesian languages spoken in Hsinchu, Taiwan.<sup>1</sup> The current population of Saisiyat is estimated to be around five thousand, but only a small number of them are fluent speakers. Due to historical and territorial factors, some older Saisiyat people are also speakers of Atayal (another Austronesian language), Mandarin Chinese, Japanese, or Taiwanese Southern Min.

The first point addressed in this study is the syntactic distribution of *wh*-phrases in *wh*-questions. It has been suggested by the literature that *wh*-words (in *wh*-questions) among western Austronesian languages appear in at least three patterns: clefting, *wh*-in-situ, and adjunct fronting (Guilfoyle, Hung & Travis 1992, Kroeger 1993, Huang et al. 1999, Potsdom 2006, inter alia). What I will show is that on the contrary, Saisiyat appears to be completely *wh*-in-situ, diverging from the general patterns above. Second, the indefinite *wh* construals (henceforth IWCs) in Saisiyat are found to be formed on

two grounds: morphological reduplication and long-distance licensing, based on the previous discussion that *wh*-words behave as syntactic variables in Saisiyat. Finally, I show that the so-called “*how-why* alternation” phenomenon (Tsai 2008) is also attested in this language, manifested particularly by the instrumental *wh*-adverbial *how*, which exhibits strict mapping at the syntax-semantics interface.

## 2. Saisiyat as a *wh*-in-situ language

According to the data collected from my own fieldwork, there are at least 18 *wh*-words found in northern Saisiyat, many of which contain ‘*ino*’ (see Table 1):

Table 1: *Wh*-words in northern Saisiyat

I. Adverbial Interrogatives		‘inay’ino’	‘from where’
		‘ila’ino’	‘to where’
<i>Wh</i> -word	Gloss	II. Nominal Interrogatives	
nak’ino’	‘how’		
‘inoan’	‘when (irrealis)’	<i>Wh</i> -word	Gloss
ka’inoan	‘when (realis)’	hiae’	‘who’
powa’	‘why (no tense)’	kano’	‘what’
‘ampowa’	‘why (irrealis)’	hayno’	‘which’
mampowa’	‘why (realis)’	piza’	‘how many’
nompowa’	‘for what (purpose)’	koza’	‘how much’
haw’ino’	‘where (far)’	Say’ino’	‘person from where’
ray’ino’	‘where (near)’	‘inak’ino’an	‘what kind’

As is mentioned, Saisiyat *wh*-elements stay in-situ in *wh*-questions, be they arguments or adverbial. Various examples are listed in (1)-(6):<sup>2</sup>

- (1) Argumental *wh*: *kano* ‘what’  
‘oebay Sebet<en> noka **kano**  
Oebay hit<PV> GEN **what**  
‘What was hit by Oebay?’
- (2) Argumental *wh*: *hi:ae* ‘who’  
‘oebay S<om>bet hi **hiae**

Oebay hit<AV> ACC **who**  
 ‘Who did Oebay hit?’

- (3) Argumental *wh*: *hayno* ‘which’

niSo ‘am ka **hayno**  
 GEN.2S want Acc **which**  
 ‘Which one do you want?’

- (4) Adverbial *wh*: *nak’ino* ‘how’

‘oebay **nak’ino** rima’ kilapa:  
 Oebay **how** go Kilapa:  
 ‘How did Oebay go to Kilapa:?’

- (5) Adverbial *wh*: *inoan* ‘when (irrealis)’

ka kawaS **inoan** ‘am kayzaeh  
 NOM sky **when.IRR** will good  
 ‘When will the weather be good?’

- (6) Adverbial *wh*: *nompowa* ‘for what (purpose)’

So’o rim’an **nompowa** rima’ kilapa:  
 NOM.2S tomorrow **for.what** go Kilapa:  
 ‘For what do you go to Kilapa: tomorrow?’

Quite obviously, (6)-(11) suggest that all Saisiyat *wh*-words stay in-situ. This does not change when they are inside an embedded clause (7) or a complex NP (8)-(9):

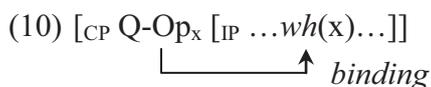

- (7) So’o komoSa’ waliSan **hayno** kayzaeh si’ael<en>  
 NOM.2S think boar **which** good eat<PV>  
 ‘Which boar do you think is delicious?’

- (8) yao hinoa’ s<om>i’ael ka -[<sub>NP</sub> t<in>alek ni **hiae**’ tatimaeh ]  
 NOM.1SG like <AV>eat ACC <PERF>cook GEN **who** vegetable  
 ‘What is x, x a person, such that you like to eat the vegetables cooked by x?’

- (9) So’o Sarara’ -[<sub>NP</sub> **inak’ino’an** nineme kayba’en ]  
 NOM.2SG like **what.kind** dye clothes

‘What is x, x a kind of dye, such that you like the clothes made with x?’

In this regard, *wh*-words (including both arguments and adverbials) in this language can be treated as polarity items, i.e. (syntactic) variables, which need to be bound by certain proper operators/licensers (see Cheng 1994 for a similar claim for Chinese). In interrogative sentences, such a licensor is the covert Q-operator (as the complementizer) which bears the [+WH] feature. The licensing of the *wh*-variable by the Q-Operator is thus accomplished at the clausal level, as it is in other *wh*-in-situ languages. The relation is schematized in (10):

### 3. Indefinite *wh* construals in Saisiyat

Tsai (1994, 1999) advocates a formal typological theory in terms of the Lexical Merger Parameter to account for a “parametrized” *wh*-dependency relation across languages. In this framework, the syntactic domains in which a proper licensor binds its variable can be divided into three levels: clausal, phrasal, and morphological. English, for instance, is argued to have the operator-variable pair at the morphological level, since the indefinite construals of *wh*-elements are spelled out by compound words like *some-how* or *what-ever*, where “*some-*” and “*-ever*” play the operator role. A relatively highly analytic language like Chinese, on the other hand, resorts to long-distance (i.e. clausal) licensing in forming IWCs. In such languages, *wh*-words can be interpreted with indefinite readings in-situ, as long as some proper clausal licensor is present.

In this section, I will show that concerning the IWCs, Saisiyat simultaneously practices these two approaches, namely the English-type strategy, where morphological reduplication plays an important role, and the Chinese-type strategy, where long-distance binding by sentential operators constitutes the licensing of indefinite *wh*’s.

#### 3.1 Morphologically licensed IWCs/quantifier formation

Morphological reduplication is a productive phenomenon in Saisiyat, contributing to various syntactic/semantic functions (Yeh 2000). As the examples below will indicate, this morphological-level operation in Saisiyat can turn interrogative *wh*-words into indefinite ones, which in a sense resembles English *what-ever* or *some-what* forms, only

differing in whether they are reduplication or not:

- '*ila'ino*' 'to where' → '*ila'ino'ino*' 'to anywhere'  
 (11) 'oebay rima' 'ila'ino~ino' ma' kayzaeh  
 Oebay go to.anywhere also good  
 'It is okay for Oebay to go anywhere.'

- kano*' 'what' → *kanokano*' 'anything/whatever'  
 (12) hizae' mae'y:aeh kano~kano' si'ael<en>  
 that person anything eat<PV>  
 'He is a person who eats anything.'

- piza*' 'how many' → *pizpiza*' 'few'  
 (13) hini' piz~piza' raromaeh  
 here few bamboo  
 'There are few bamboos here.'

- ray'ino*' '(at) where' → *ray'ino'ino*' '(at) anywhere'  
 (14) ray'ino'~ino' ma' '<in>aSkan<an>' ila  
 at.anywhere also <PERF>put<LV> ASP  
 '(It) has been placed anywhere.'

As these examples show, interrogative meanings of *wh*-words are replaced by indefinite readings, more specifically universal quantificational readings. What they imply is that the reduplicated part should be treated as the realization of morphological operators, which license the indefinite readings of the *wh* forms. Such hypothesis can be illustrated in (15a), which is largely in parallel with the structures of *wh-ever* or *some-wh* forms in English proposed in Tsai (1999:45-46), shown in (15b):

- (15a) Saisiyat morphological IWCs (15b) English morphological IWCs

In (15a), *kano*' is the manifestation of a variable, and its (partial) reduplication form,

RED<sub>x</sub> (*kano* in this case), functions as the operator/licenser for the indefinite reading, the binding occurring at the D<sup>0</sup> (morphological) domain. Thus, RED<sub>x</sub> corresponds to the existential operator *-some<sub>x</sub>*, and by the same token *kano*'(x) is the counterpart of *ind.*(x) such as *-at* or *-ere* in English. The only difference between Saisiyat and English, then, is the way their systems of lexicon take to overtly realize the operators: Saisiyat uses reduplication, presumably due to its own syntactic nature, whereas English has certain “specialized” elements (*some-/ever*) for them.

In addition, as Tsai (1994) has noticed, such morphological operator-variable pairs are not created solely for *wh*-words. In English, *al-* can also be regarded as some kind of prefix responsible for the quantificational forces of adverbs like *also*, *almost*, and *already*. This is in fact a natural consequence, if we treat it as another case of (15a) and (15b), i.e. quantifiers in English-type languages should also comply with the same morphological mechanism, at least in this case. This speculation gains support from (13), where the quantity adjective *pizpiza*' originates from the quantity *wh*-word *piza*'. We summarize the discussion in this section in Table 2:

Table 2: Morphological-level IWCs in Saisiyat (FCI = Free Choice Item)

Simple <i>Wh</i> -form	(Partial) Reduplication	Ind. Reading	Status
<i>kano</i> 'what'	<i>kanokano</i> 'anything'	Universal	FCI
<i>'ila'ino</i> 'to where'	<i>'ila'ino'ino</i> 'to anywhere'	Universal	FCI
<i>ray'ino</i> 'at where'	<i>ray'ino'ino</i> 'at anywhere'	Universal	FCI
<i>piza</i> 'how many'	<i>pizpiza</i> 'few'		Quantifier

Note further that since there is no overt licenser for *kanokano*', *'ila'ino'ino*' and *ray'ino'ino*', it is more reasonable to treat them as free choice items (which can occur in affirmative sentences) in opposite to polarity items.

In next section, we will see that Saisiyat also implements the licensing of IWCs at the sentential domain, a feature of Chinese-type languages.

### 3.2 Long-distance licensing of indefinite *wh* construals

To gain a better view, let us take a look at the IWCs in Chinese first. It is widely acknowledged that *wh*-phrases in Chinese can be analyzed as existential polarity items which are licensed in yes-no questions, conditionals, *dou*-quantifications, negations or possibility-indicating expressions (Huang 1982, Li 1992, Cheng 1994, Tsai 1994, Cheng and Huang 1996, Lin 1996, 1998). One well known construction evidencing this feature

in Chinese is the “bare-conditionals” (Cheng and Huang 1996), illustrated in (16a) and its logical representation (16b):

- (16) a. shei xian lai, shei xian chi  
 who first come who first eat  
 ‘If X comes first, X eats first.’  
 b.  $\forall_x [x \text{ is a person} \ \& \ x \text{ comes first}] (x \text{ eats first})$

What (16) shows is that both the *wh*-phrases in the antecedent (restriction) clause and consequence (nuclear scope) clause are treated as variables bound by the covert universal necessity operator ( $\forall$ ).

Such variable-like characteristic of *wh*-words is testified in Saisiyat as well. The following sentences (17)-(21) are instances of long-distance binding, where *wh*-phrases receive indefinite readings from their c-commanding operators:

*Universal conditional-concessive clauses*

- (17) a. ‘ana **kano**’ kita’<en> niSo ma’ panabaeh-ani yakin  
 no.matter **what** see<PF> GEN.2SG also tell-EMP ACC.1SG  
 ‘Tell me whatever you see.’  
 b. ‘oebay ‘ana rima’ **‘ila’ino** ma’ kayzaeh  
 Oebay no.matter go **to.where** also good  
 ‘It is fine for Oebay to go anywhere.’

*Conditionals*

- (18) a. So’o So Sarara’ **hayno**’ kapinao:’, payakai’ yakin  
 NOM.2SG if like **which** lady tell ACC.1SG  
 ‘If you like any lady, tell me.’  
 b. So **hiae**’ ‘okay s<om>i’ael ka pazay, payakai’ yakin  
 if **who** NEG <AV>eat ACC rice tell ACC.1SG  
 ‘If there is anyone who doesn’t eat rice, tell me.’

*Causal sentences*

- (19) a. sia s<om>i’ael **kano**’, ma’isa:’ ‘ayaeh  
 NOM.3SG <AV>eat **what** so ill  
 ‘He has (probably) eaten something, so (he) is ill now.’  
 b. korkoring **nak’ino**’, ma’isa:’ h<om>angih ila  
 child **how** so <AV>laugh ASP

‘Something has happened to the child, so (s/he) is crying.’

*Universal donkey sentences (bare conditionals)*

- (20) a. **hiae'** 'ima t<om><in>epeS **hiae'** Sebet<en> ma'an  
**who** Rel <AV><PERF>spit **who** hit<PV> GEN.1SG  
 'I will hit whoever spits.' (Lit.: 'Who spits, I hit who.')
- b. So'o **nak'ino'** <m>ayakay, yao ma' **nak'ino'** <m>atawaw  
 NOM.2SG **how** <AV>say NOM.1SG also **how** <AV>do  
 'I will do whatever you say.' (Lit.: 'How you say, how I do.')

*Negation*

- (21) a. 'okik ra:m **hiae'** <m>wai:' rini' kano' ketesnenan  
 NEG know **who** <AV>come here so door  
 h<in>awaeh  
 <PERF>open  
 '(I) don't know if someone came here, so that the door is opened.'
- b. hini' 'okik **piza'** raromaeh  
 here NEG **how.many** bamboo  
 'There are not many bamboos here.'

In (17), the morpheme *'ana* behaves pretty much like *no matter* in English or *wulun* in Mandarin, occupying a high syntactic position in essence. Although *'ana* seems to be attached to the *wh*-word in (17b), it can be separated from the *wh*-word by the verb 'go' as in (17b), hence a clausal-level operator. The conditional marker *So* in (18) plays the same role in licensing the IWCs. Things are a little bit different in (19), where there is a consequence marker *ma'isa:*' in the consequence clause, which apparently does not c-command the *wh*-words. Expecting the answer by further research, one tentative account at hand is to call for an LF-movement of the consequence clause. After the movement, *ma'isa:*' c-commands and thus properly licenses the *wh*-phrases. An alternative is to regard (19) as involving a covert modal that implements the IWCs. Either way, the *wh*-variables are bound by sentential operators, a typical feature in Chinese-type languages. Furthermore, it is existential readings that are assigned to the *wh*-words. Bare conditionals (20) resemble (16) in permitting the necessity operator ( $\nabla$ ) to bind multiple *wh*-phrases. Finally, negation also serves to be the licenser as well in (21), where *wh*-phrases are interpreted as existential.

On empirical ground, Saisiyat IWCs undoubtedly can take place in the clausal domain. That is, clausal operators can license indefinite *wh*-words in this language. I

summarize the above discussion below (see Table 3):

Table 3: Clausal-level IWCs in Saisiyat

Licensing Environment	Indefinite- <i>wh</i> Licensor	Ind. Reading
Universal conditional-concessive clauses	' <i>ana</i> 'no matter'	Universal
Conditionals	<i>So</i> 'if'	Universal
Causal sentences	<i>ma'isa:</i> 'so'	Existential
Bare conditionals	$\forall$ (necessity operator)	Universal
Negation	' <i>okik</i> 'not'	Existential

All the indefinite readings of *wh*-words above are licensed by clausal operators including conditional operator, necessity operator, or negation operator. Since these licensors constitute pairs with *wh*-variables neither at a morphological scale nor at a phrasal scale, we conclude that Saisiyat is featured as a Chinese-type language, allowing long-distance licensed *wh*-indefinites.

#### 4. *How-why* alternations in Saisiyat

Tsai (2008) observes that cross-linguistically, two *wh*-adverbials can “alternate” with each other at the syntax-semantics interface. Specifically, the comitative-oriented *how* is taken as a  $\nu$ P-modifier, which denotes the instrumental/manner reading. It can also occupy a higher position, scoping over a whole proposition and receives the causal interpretation, functioning as another *wh*-adverbial *why*. Such distinction is revealed in English by *how* and *how come*, as (22) shows:

- (22) a. How did John handle this matter? [instrumental/manner]  
 b. How come John arrived so late? [causal]  
 (Tsai 2008:84)

The syntax-semantics mapping is more transparent if we consider Chinese. With highly analytic nature, *how* in Chinese has the instrumental/manner reading at a  $\nu$ P-peripheral position, but has the causal reading at the CP-periphery, with certain syntactic operators as the “watersheds”:

- (23) a. tamen    **zenme(\*-yang)**    hui/keyi    chuli    zhe-jian shi?  
 they        **how(-manner)**    will/can    handle    this-Cl matter

- ‘How come they will handle this matter?’
- b. tamen hui/keyi **zenme(-yang)** chuli zhe-jian shi?  
 they will/can **how(-manner)** handle this-C1 matter  
 ‘By what means will/can they handle this matter?’  
 (Tsai 2008:95)

When *zenme(-yang)* follows the modals *hui/keyi* ‘will/can’, only the instrumental or manner interpretation is available, and the nominal-like element *-yang* is optional. But if it precedes the modals, only the causal reading is possible, *-yang* prohibited. In what follows, we will see that the *how* in Saisiyat has a very close pattern to this one.

#### 4.1 Three positions & interpretations of how

The interpretations of *how* in Saisiyat are subject to its syntactic positions: when preceding negation or occurring in a sentence without agentivity, we have a causal *how*, which has the similar meaning as *why*, as in (24); after a modal, only the instrumental or manner meaning is conceivable as in (25); and lastly, in the lowest position (after the verb) the *how* is assumed to be an argument (i.e. complement) of the verb, inquiring the result/resultative state of the subject’s hunting in (26):

(24) Pre-negation/non-agentive *how*:

- a. ‘oebay **nak’ino’** ‘okay rima’ kilapa: [causal]  
 Oebay **how** NEG go Kilapa:  
 ‘How come Oebay did not go to Kilapa:?’
- b. hini’ pongaeh **nak’ino’** ila minpongaeh ila [causal]  
 this flower **how** ASP bloom ASP  
 ‘How come this flower has come to bloom?’

(25) Post-modal *how*:

- rim’an So’o ‘am **nak’ino’** rima’ kilapa: [instrumental]  
 tomorrow NOM.2S will **how** go Kilapa:  
 ‘How will you go to Kilapa: tomorrow?’

(26) Post-verbal *how*:

- niSo ‘oemalep **nak’ino’** ila [resultative]  
 GEN.2SG hunt **how** ASP

Table 4: The family of *why* in Saisiyat

The <i>why</i> 's	Prefix	Interpretation
<i>powa</i> '	∅	why (not related to tense)
' <i>ampowa</i> '	' <i>am</i> 'will'	why (inquiring the cause of an event which has not happened yet)
<i>mampowa</i> '	<i>mam</i> (progressive marker)	why (inquiring the cause of an event which has already happened before)
<i>nompowa</i> '	<i>nom</i> 'for'	for what (purposive, not related to tense)

The semantic distinctions of the *why* family are subtle, since not all of my informants could distinguish the differences from one another. One informant told me that '*ampowa*' was the most frequently used word when expressing the meaning of *why*, all others of much lower frequency. This is likely to be a result of lexical competition, where one form of *why* ('*ampowa*') won out, others falling out of use.

Unlike *how*, it is not clear whether these complex *why*'s in Saisiyat also respect the same syntactic configuration. As (29) shows, the free distribution of the *why*'s does not display semantic distinctions, i.e. they have a freer word order without semantic differences, according to my major informant:

- (29) a. So'o rim'an '**ampowa**' rima' kilapa: [sentence-internal]  
**why.IRR**
- b. rim'an So'o rima kilapa: '**ampowa**' [sentence-final]  
**why.IRR**
- c. '**ampowa**' So'o rim'an rima kilapa: [sentence-initial]  
**why.IRR**
- d. So'o rim'an r ima' kilapa: **nompowa**' [sentence-final]  
**for.what**
- e. So'o rim'an **nompowa**' rima' kilapa: [sentence-internal]  
**for.what**
- f. So'o rim'an **mampowa**' rima' kilapa: [sentence-internal]  
**why.REA**
- g. So'o rim'an rima' kilapa: **mampowa**' [sentence-final]  
**why.REA**

If this is true, we then arrive at an asymmetry between *how* and *why*: *how* has a nearly

one-to-one corresponding relation between syntax and semantics, but *why* does not. Although details require further fieldwork and study, a first approximation toward this asymmetry is that the syntactic configuration is reduced to the morphology of *why*, since its variants can be teased apart by overt morphological elements. *How*, on the other hand, lacks the ability to “fuse” with other morphemes, and as a consequence it must reflect various interpretations by way of syntactic leveling. This is reminiscent of the loss of case markers in some Indo-European languages that resulted in the fossilization of word order, and it would be interesting to see if such phenomenon is also visible in other Austronesian languages.

## 5. Concluding remarks

Through preceding discussions we have seen that as a *wh*-in-situ language, northern Saisiyat happily embraces two approaches to build up its *wh*-dependencies: one is morphological reduplication, the other long-distance licensing/binding. By means of investigating IWCs, we see that morphological reduplication in Saisiyat patterns with *wh-ever* or *some-wh* forms in English which can be analyzed as operator-variable pairs. On the other hand, long-distance licensing is also possible for indefinite *wh*'s, which links sentential operators with *wh*-variables at a clausal scale. Finally, I have also discussed the “*how-why* alternation” in Saisiyat, which in a way resembles that of Chinese (cf. Tsai 2008), but at the same time diverging from Chinese in another, i.e. the *how* in Saisiyat behaves pretty much as the *how* in Chinese, while the *why*'s in these two languages differ from each other.

One may wonder how the two-way strategy (Chinese- and English-type) in Saisiyat is motivated. As Tsai (1997) has recognized, language evolution and language contact may both result in the change of parameter settings of Universal Grammar. It is therefore not unreasonable to say that the Chinese-type parameter in Saisiyat possibly results from the influence from Mandarin Chinese and/or Hakka, which are typical *wh*-in-situ languages spoken in its nearby territory. In another word, the mixed setting of Lexical Merger Parameter in this case supposedly turns out to be a reflection of language contact which triggered the Chinese-type parameter in Saisiyat. The English-type parameter, realized by the morphological mechanism, should be closer to the more original appearance of this language, under the current speculation.

Within the formal syntactic framework, this study not only contributes to the formal theory of linguistic typology, but also sorting out the language-internal structures

and functions of the *wh*-interrogatives and *wh*-indefinites. Future research on Saisiyat is expected to expand the scope and widen the view in this paper.

## Notes

<sup>1</sup> I would like to express my gratitude to the following Saisiyat speakers, without whom this study would be impossible: Kalaeh Taro, Okaya Atow Hayawan, Tahes Oebay, Yomin A Taro, Lalawaw Bay, and especially 'O Yong A Tahes. Thanks also go to Hsiu-Chuan Liao, Paula Rogers, Wei-Tien Dylan Tsai, Atsuko Utsumi and Ting-Chi Wei for their helpful comments and suggestions. All errors and misinterpretations are my own responsibility. The research in this paper is partially supported by the National Science Council of Taiwan (NSC 96B3057RA), for which I am also grateful.

<sup>2</sup> Abbreviations in the glossary are listed as follows: NOM: nominative case, ACC: accusative case, GEN: genitive case, LV: locative voice, AV: agent voice, PV: patient voice, IV: instrumental voice, PERF: perfect, IRR: irrealis tense, REA: realis tense, 1S: first person singular, 2S: second person singular, 3s: third person singular, ASP: Aspect, EMP: emphatic marker, and NEG: negation.

## Abstract

It is the main goal of language documentation to create a representative corpus of texts of an individual language, which are processed in a way that they are easily accessible to non-speakers and non-specialists of the respective language. "Representative" in this context means that a selection of texts is included in the corpus covering the uses of language in the speech community. The hope which is silently implied is that such a text corpus would be representative also with respect to the language system. This, however, cannot be guaranteed. Often, the descriptive linguist has to broaden the range of linguistic data he/she has at hand from the corpus by various types of elicitation techniques applying his/her knowledge on linguistic notions and their typological variation and elaborating on categories, paradigms and constructions already found in the target language. The main conclusion to be drawn from the study of deictic motion verbs in Hocak is that there is no such thing as a pure principled documentation of an individual language, but that language documentation and language description go hand in hand to some degree. Good language documentation needs reference to descriptive linguistics.

**Keywords:** deictic motion verbs, language documentation, language description, Hocak (Siouan)

## 1. The Problem

Language documentation has been established as an autonomous linguistic activity independent from a super-ordinate purpose of language description. The ways to collect data in language documentation existed, of course, before. Descriptive linguists recorded texts, transcribed texts, glossed texts, and translated texts and even collected social and cultural knowledge for a better understanding of certain speech acts and parts of discourse all the time. However, the final purpose for these data collections was always to serve as a data base for grammatical or lexical description. Since the emergence of language documentation as a independent task, the collection of linguistic data was no longer subordinate to these descriptive ends, i.e. a good language documentation is no longer automatically good for the needs of language description, because the data are collected for another purpose, namely to be representative of the language in use. This is meant by the tension between language documentation and descriptive linguistics in the title of this paper. The problem will be further elaborated in §1.1, in §2 and §3, the problem will be illustrated with regard to the description of the system of deictic motion verbs in Hocak (a Siouan Language, still spoken in Wisconsin,

USA). We will finish with some conclusions and suggestions in §4 for a practical solution of this dilemma.

### 1.1. *What is language documentation: methods and goals*

Documentation of a language is an activity (and, derivatively, its result) that gathers, processes and exhibits a sample of data of the language that is representative of its linguistic structure and gives a fair impression of how and for what purposes the language is used. Its aim is to represent the language for those who do not have access to the language itself. (Lehmann 2001:88)

The natural manifestations of language are in texts in the broad sense. Language documentation consists of a representative corpus of texts (again in the broad sense). *Representative* in this context means that the sample of texts included in the corpus are examples of the variety of ways, functions, and purposes the language is used for in the speech community. Variation in the usage of a language can be found along the parameters which replicate the basic communicative functions of language (cf. Jakobson 1960; Lehmann 2001:94):

- a) Speech act participants: who speaks to whom
- b) Context of speech act: situation of speech
- c) Purpose: illocution, ritual, etc.
- d) Topic
- e) Medium: written, oral

The texts of a corpus of language documentation are linguistically processed in a way that they are accessible to non-speakers of the language. This includes:

- a) audio and video recordings (raw data),
- b) transcriptions (i.e. written representation),
- c) interlinear one-to-one morphemic glossing of the texts,
- d) free translation,
- e) notes which provide the background knowledge for the semantic, pragmatic and cultural interpretation of the utterances.

Since the mid-90ies, language documentation has been established in the literature as a purpose-independent and autonomous linguistic activity no longer subordinated to the interests of descriptive linguistics. The principle independence of language documentation from the specific scientific interests of descriptive linguistics or of any other sub-discipline of linguistics such as sociolinguistics, anthropological linguistics, psycholinguistics, etc. was in particular stressed by Himmelmann (1998:167), but also claimed in Lehmann (2001). The only *raison d'être* for language documentation is the broad and principled representation of the usages of a language and its accessibility to it for non-speakers of the language. But, and this was also stressed repeatedly too in the literature, a good language documentation should be useful for different disciplines (anthropology, sociology, etc.) and linguistic sub-disciplines

(discourse analysis, language acquisition, phonetics, ethics, language rights, field methods, corpus linguistics, educational linguistics, etc.).

## 1.2. *What is language description: the methods and goals*

Description of a language is an activity (and, derivatively, its result) that formulates, in the most general way possible, the patterns underlying the linguistic data. Its aim is to enable the user of the description to compare this language to other languages. (Lehmann 2001:88)

The description of a language consists of the identification of the linguistic units of a language, their meanings, and the rules of combination associated with them. The lexicon and the grammar are the basic components of a language description. These components may also serve other purposes than typological or comparative ones; for instance educational purposes as the basis for language teaching materials etc.

The parameters according to which variation in language usage can be determined are either extra-linguistic or semantic or pragmatic in nature. These parameters do not concern the structure of the language. There is one problem with the definition of documentation of a language given above: it is not clear in advance what the "linguistic structure" of the language is, in particular if we have to do with a previously undocumented language for which no grammatical description exists. However, with regard to descriptive linguistics, the hope is implicitly or explicitly maintained that a representative text corpus of language documentation would be representative also with respect to the language system. This, however, cannot be guaranteed (see also Lehmann 2001:92).

In well known languages which are already described linguistically in some depth, there may be ways to vary the functional dimensions in a way that presumably all systematic variation will be represented in the corpus. Yet, in languages which are poorly described or not described at all – and this is the usual case with small scale endangered languages - the documentary linguist cannot know in advance what structural variation the language has. It might be objected that a principled and exhaustive language documentation would cover all kinds of systemic variation; this, however, is an ideal situation beyond the capacities of human linguists. It is also doubtful whether this would be even in principle a possibility given the infinite character of language and language use.

And in addition: If it is a serious requirement of language documentation that it should serve the scientific interests of various sub-disciplines of linguistics, it is clear that the consequence would be that a language documentation cannot fit any of these purposes perfectly.

The consequence is that the descriptive linguist has to broaden the range of linguistic data he/she found represented in the text corpus by various types of elicitation techniques applying his/her knowledge on linguistic notions and their typological variation and elaborating on categories, paradigms and constructions already found in the target language.

Our conclusion so far is: A language documentation does not suffice for a future description of the grammatical and lexical structure of the language both in a theoretical

and in a practical perspective. If the purpose of a language documentation is to serve as empirical basis for a language description, language documentation has to be supplemented by the methods of language description with regard to language data. This conclusion is probably not controversial among documentary linguists, but often not taken seriously in the design of language documentation.

This tension between language documentation and language description will be exemplified in the remainder of this paper with regard to the set of deictic motion verbs in Hocak and their linguistic description.

## 2. COME and GO verbs in Hocak: what the text corpus reveals

Siouan languages all have a more or less complex system of deictic motion verbs (henceforth DMV). The first mention of DMV in Hocak can be found in Lipkind (1945:44); cf. Table 1.

**Table 1. Hocak DMVs as described by Lipkind (1945:44)**

phase \ motion	come	go	come back	go back
begin, start	<i>huu</i>	<i>ree</i>	<i>guu</i>	<i>keré</i>
arrive, end	<i>jii</i>	<i>hii</i>	<i>kirí</i>	<i>gii</i>
be on the way	<i>huhé</i>	<i>rahé</i>	<i>guhé</i>	<i>karahé</i>

Unfortunately no further explanation of the semantic categories encoded in the paradigm was given by Lipkind. We will see later that the English gloss **back** in Table 1 does not really provide a good semantic description of the semantic opposition encoded here.

Most of the verbs in Table 1 occur also in the corpus of texts collected by the members of the DoBeS project "Documentation of the Hocak language"<sup>1</sup>. The text corpus of this study consists of 41 texts. A variety of different text-types/ text genres is represented: personal narratives, ritual texts, speeches and prayers, descriptions, instructive texts, short humorous conversations, and one song. Most of the texts included in this corpus were recorded by the Do-Hocak team, some of the older ritual texts, however, were adapted from Paul Radin's field notes and publications (cf. Radin 1915, 1923, 1949, 1950). Unfortunately, everyday-like spontaneous conversations are underrepresented in this corpus; and we believe this holds for most of the DoBeS documentation projects. All texts have been translated or re-translated (old translations

<sup>1</sup> See the website of the documentation project at the University of Erfurt: [http://www.uni-erfurt.de/sprachwissenschaft/Vgl\\_SW/Hocank/index\\_frames.html](http://www.uni-erfurt.de/sprachwissenschaft/Vgl_SW/Hocank/index_frames.html)

are sometimes rather free) by our main and most reliable consultants. Table 2 summarizes the occurrences of the different DMVs in the Hocak text corpus. Given are the textual frequencies of the verbs ranked accordingly in the table and the various translations for the individual forms provided by the speakers of Hocak.

**Table 2. DMVs: their frequency and English translations in the corpus**

	DMVs	n=	English translations
1.	<i>hii</i>	117	'arrive', 'get there', 'arrive going'
2.	<i>ree</i>	71	'go', 'become', 'start going'
3.	<i>jii</i>	66	'get there', 'arrive coming', 'arrive'
4.	<i>kirí</i>	61	'return', 'arrive returning'
5.	<i>keré</i>	47	'go back', 'leave', 'depart'
6.	<i>gii</i>	34	'arrive returning',
7.	<i>guu</i>	24	'approach', leave returning',
8.	<i>huu</i>	10	'start coming'
9.	<i>rahé</i>	5	'be on the way going', 'become'
10.	<i>huhé</i>	3	'be on the way coming here'
11.	<i>karahé</i>	2	'going back', 'be on the way going back',
12.	<i>guhé</i>	1	'be on the way returning', 'coming back'

The paradigm of Hocak DMVs is quite complex compared to the quite simple English dichotomic paradigm with only two members, namely *come* and *go*. The Hocak DMVs are most commonly translated as "come" and "go" or "arrive" and "return" by the speakers. These translations, however, do not let the researcher comprehend the full meaning of the DMVs. In most cases, the speakers do not consider it necessary to give the extra information that the DMVs contain. They tend to keep their translations short, so that it is almost impossible to grasp the DMVs' full meaning when translations with periphrastic character are not given

The problem for the descriptive linguist is: on the basis of the English translations given in the text corpus of Hocak, it is extremely difficult if not impossible to identify and reconstruct the systematic character of the verbs listed in Table 2. The lexical glosses there are taken either from the translations of the speakers, or they are taken from Lipkind's grammar (1945), which, fortunately, already recognized the paradigmatic nature of the DMVs in Hocak. To be more specific, the problems are the following:

- 1) the glosses often do not represent the deictic nature of the verbs, e.g. in 1. *hii* = 'arrive', 4. *kirí* = 'return', 5. *keré* = 'leave', 'depart', 7. *guu* = 'approach'.
- 2) the aktionsarten category is not systematically represented in the English translations except for the progressive/ continuative verbs 'be on the way DMV', compare e.g. 2. *ree* = 'go', vs. 'start going', 4. *kirí* = 'return' vs. 'arrive returning', and so on.
- 3) the notion of base/ home lexicalized in the DMVs is either ignored or rendered in English by the adverbial 'back', which does not really correspond to it, compare for instance 5. *keré* = 'leave' vs. 'depart' vs. 'go back'.

The source of this translation problem is that the English verbs of COMING and GOING do not show the same semantic complexity as the DMVs in Hocak. If they are used as glosses for the translation, they conceal the semantic structure behind the Hocak

forms. In order to give a correct English translation for these verbs, long winded paraphrases would be necessary. This problem is almost unavoidable since English is the language used in the fieldwork with Hocak speakers.

The descriptive linguist cannot recognize the systematic character of the Hocak DMVs from the individual occurrences of DMVs in our texts. The descriptive linguist needs translations, which reflect the semantic complexity of these verbs. And the descriptive linguist even cannot decide on the basis of these data which of the forms in question are real deictic motion verb and which ones are just motion verbs.

The second major problem is that minimal pairs do not occur in the texts of the corpus. Minimal pairs allow the identification of the semantic structure. Therefore, additional data have to be elicited in a controlled fashion, in order to confirm or reject any hypothesis about the deictic nature of individual forms.

A third problem may lie in the selection of text genres and text types included in the Hocak corpus. In order to explore the semantics and functioning of deictic forms in a language, it is necessary to have various face-to-face conversations in the text corpus of the language documentation. Such text types are notorious difficult to evoke or to elicit from speakers, since they are considered highly unnatural. Our guess is that there is a significant asymmetry in the number and size of texts containing face to face conversations in all text corpora created by the DoBeS projects. This is not only a problem of the Documentation of the Hocak language. The result is that deictic forms in their prototypical usages are generally underrepresented in the language documentation. But, even if language documentation contains a number of real spontaneous conversations which have to do with traveling and movement etc. it is doubtful whether this will suffice for a language description. a) It is doubtful, whether all forms of the paradigm are used at least once in these conversations, and b) it is doubtful whether these occurrences are well enough glossed and translated to arrive at the generalizations the descriptive linguist searches for.

### **3. The system of deictic motion verbs in Hocak**

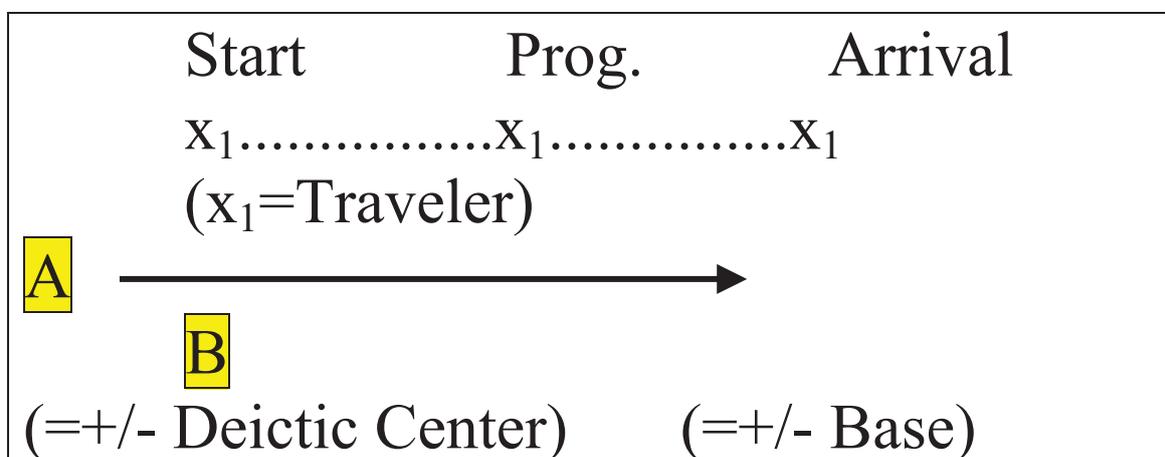

#### *3.1. The lexical paradigm: distinctive semantic features*

The twelve Hocak deictic motion verbs are comparable to and are often translated simply as *come* and *go* in English, but they have a much more complex inherent semantics. The first distinction is between motion toward or not toward the deictic center; the second distinction encoded is between motion toward a base/home versus not toward base/home; and the third distinction is between the aktionsarten start, departure, on the way/ in progress, and arrival. The semantic features are summarized in Table 3.

Table 3. Distinctive semantic features of DMVs in Hocak<sup>2</sup>

		phase of motion		
		start, depart	be on the way	arrive
-motion toward DC [GO]	-motion towards Base	<i>ree</i>	<i>rahé</i>	<i>hii</i>
	+motion towards Base	<i>keré</i>	<i>karahé</i>	<i>gii</i>
+motion toward DC [COME]	-motion towards Base	<i>huu</i>	<i>huhé</i>	<i>jii</i>
	+motion towards Base	<i>guu</i>	<i>guhé</i>	<i>kiri</i>

Table 4. The semantic structure of DMVs in Hocak

The semantic components and notions lexicalized in the DMVs are schematically represented in Table 4. Firstly, the defining notion of deictic motion verbs is the inheritance of a deictic center. The Deictic Center DC is usually the speaker, but may shift to other persons in particular in narrative texts with only third person participants. Secondly, the Traveler. The traveler is the individual whose movement is designated by the DMV. The traveler is the subject/actor of the DMVs. Thirdly, the Home/Base. The location to which the traveler belongs, or with which he/she is associated with habitually is the home/base of the traveler. This may be the home or the work place or may be of a less permanent character such as the gathering place. The Home/ Base can also be a place the Traveler just left before returning to it. In this case, the Home/ Base need not be the residential place of the traveler. Fourthly, the phase of the motion. Each deictic motion event is distinguished according to its aktionsart: start, or departure, in progress or on the way, and finally the arrival. Fifthly, the Apogee (Cumberland 2005:289). There is an additional notion which does not appear in the schema in Table 4, namely the apogee, which means the turning point in a journey. As

<sup>2</sup> Our account of the DMVs in Hocak owes much to the investigation of the cognate forms in Assiniboine by Linda Cumberland (2005:Chapter 8) in her PhD dissertation from Indiana University.

soon a journey is conceptualized as returning to the home base the verbs with the feature specification [+motion to home base] have to be used even, if there are other stops/goals which are arrived at in between.

The inherent semantics of the DMVs explains in part the different frequencies of their respective occurrence in the corpus (and the different abilities to combine with other verbs in complex verbal predicates); cf. the frequencies in Table 2.

a) All the morphologically complex progressive forms (<"start+he") are rare; they are formed on the basis of the inchoative forms. Morphologically the progressive forms are more complex than the [+start/inchoative] forms, i.e. they are the marked forms.

b) The two most frequent DMVs are unmarked with regard to [-DC, -B].

c) The three most frequent forms are unmarked with regard to [-B].

a), b) and c) comply very well with the prediction of markedness theory: the semantically less complex form is also more frequent and formally less marked. However, an interpretation of the figures in terms of the markedness theory has to be cautious - it is not really clear how the asymmetry with regard to the text types [narrative texts vs. face to face conversation] affects the frequency of occurrence.

d) RESULTATIVE/Arrival forms are used significantly more often than start/inchoative forms which shows that the endpoint of a movement, the result is more salient semantically than the initial point or the path.

### 3.2. *Additional data: psycholinguistic elicitation techniques*

In order to collect additional data that would show how the DMVs in Hocak are actually used, two video sessions using a psycholinguistic elicitation technique were recorded. Both sessions were recorded with the same native speaker of Hocak (Waac Hanažiga<sup>3</sup>). Each time the same simple map-like setting and the same four characters in the form of little plastic manikins were used as stimuli.

The characters used were:

- **Waac Hanažiga** (the native speaker participating in the session),
- **Kunu** (his imaginary son),
- **Hinu** (his imaginary daughter),
- **Teega** (his imaginary uncle).

Each one of these characters had their own home, which was marked down as on a map. Other positions on the map were places to which people go on a habitual basis:

- the store,
- the office,
- the school,

and one place, to which people do not go regularly (any more):

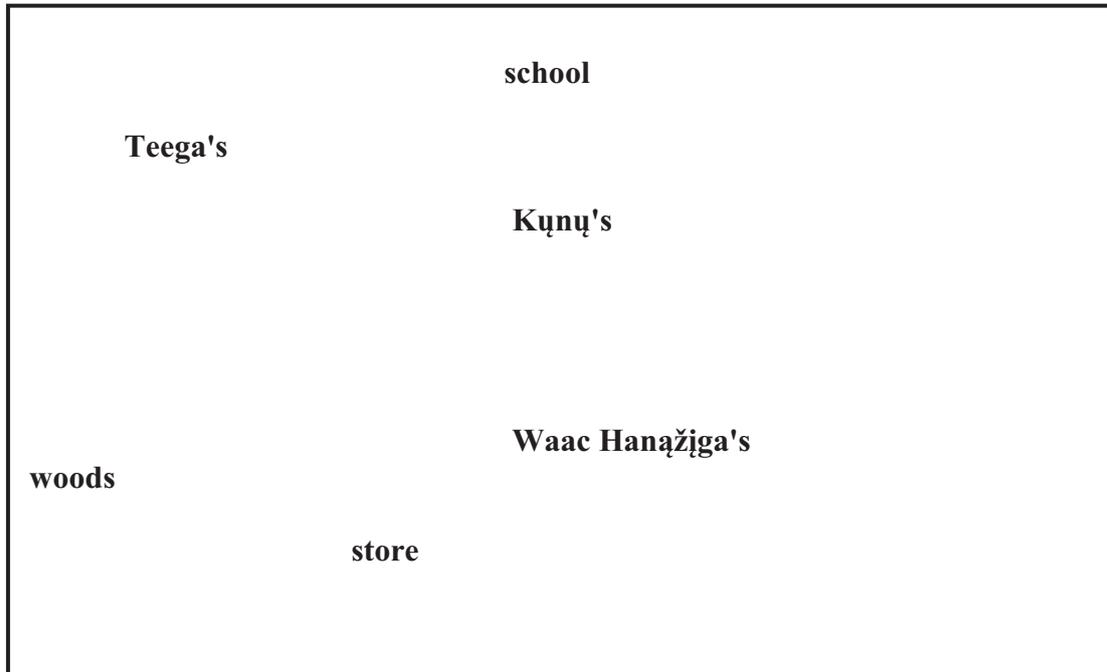

- the woods.

Figure 1 shows the map-like setting that was used in both recording sessions.

---

<sup>3</sup> We would like to thank Waac Hanažiga (Cecil Garvin) for his participation and patience during these sessions.

**Figure 1. Map-like setting used in the elicitations**

The consultant was asked to imagine himself living and acting in this setting. The first recording session tried to elicit the use of the DMVs in a narrative-like context. Hence the researcher was telling a story in English and simultaneously moving the manikins around accordingly, while the consultant was asked to translate / tell the same story in Hocak. The whole conversation/narration together with the manipulation of the manikins was video-taped. All possible and expected semantic parameters in DMVs and their oppositions were integrated in a coherent story of movements. This allowed the situation to be considered more natural to the speaker. All possible configurations and combinations of semantic features [+/- Deictic Center and +/- Base] were thus tested and recorded. The design of this session was more oriented towards the onomasiological approach in linguistics.

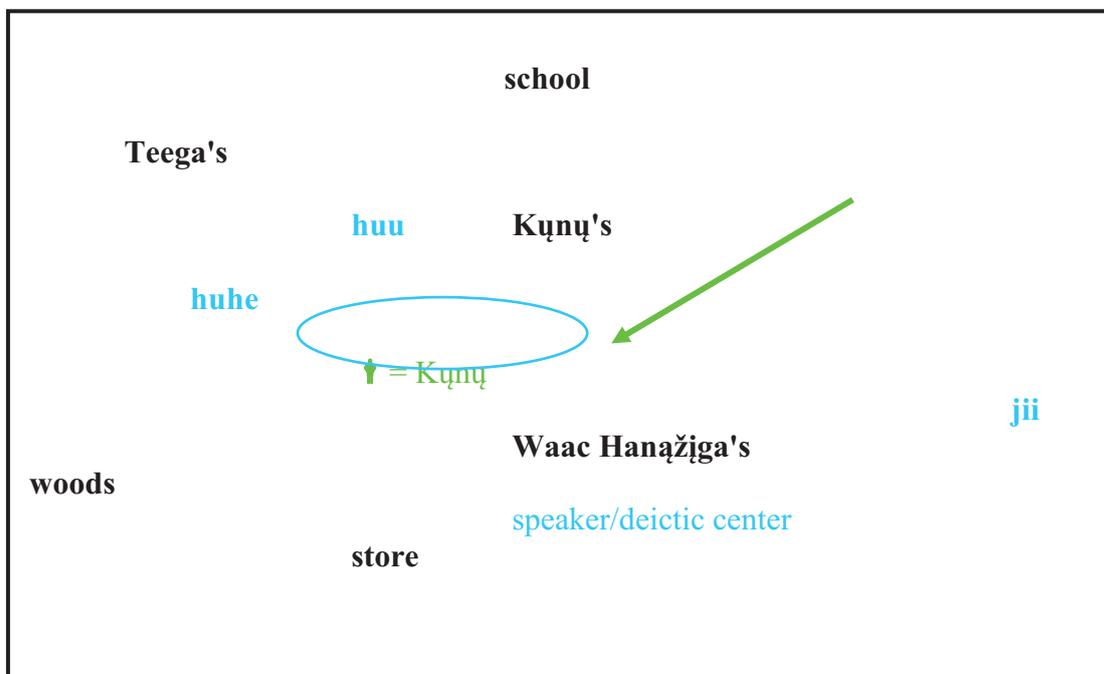

In the second session, which was recorded a day after the first one, the same speaker was asked to take a more active role and was now the one moving the manikins around. The same map-like setting was used, because now the speaker was already familiar with it. This time he was asked to tell a story himself with the given setting. The researcher participated in so far as to give the speaker a word (in this case an inflected form of one of the DMVs) and ask him to make up a sentence with it and show the movement of the characters on the map-like setting at the same time. For each sentence the researcher gave the speaker a new word that he'd be expected to use. Even though the DMVs were given in a specific form by the researcher, there were no instructions given as to which character the speaker should move, or which character the speaker would let speak at the time. This allowed the speaker to play a more creative part in the session. All DMVs in all their inflections were used during the session most of them were used more than once, so that later comparisons would be possible. They were given to the speaker in random order, so that he would have to react spontaneously

and could not anticipate what form or verb would be coming next. The design of this session was more oriented towards the semasiological approach in linguistics. Both sessions (overall over two hours of recordings) were then transcribed and compared by the researcher.

### 3.2.1 Minimal pairs

Figure 2 illustrates the use of the DMVs expressing the three different aktionsarten mentioned earlier in this paper (cf. videoclip CG1\_01). In this part of the session Waac Hanažiga was the deictic center. Kunu is the traveler moving towards the deictic center and away from his home base. Sentences E 1 a-c show how the DMVs were used by the speaker.

**Figure 2. The aktionsarten: START - PROGRESSIVE - ARRIVE**

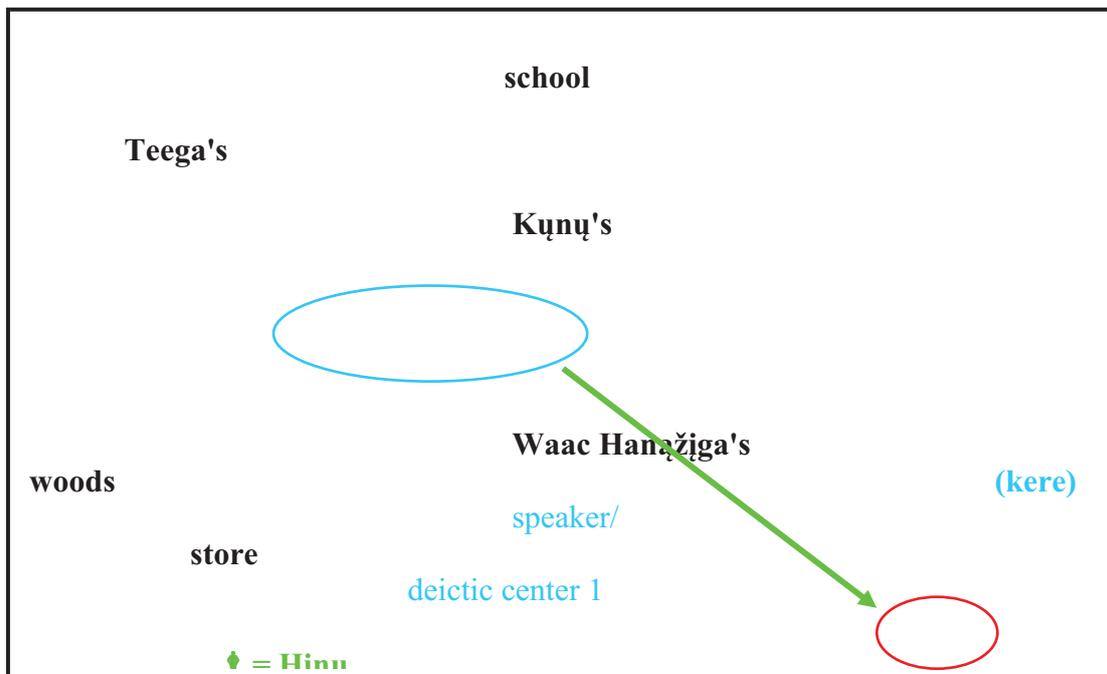

**E 1 (CGI\_01) Speaker+DC Waac Hanažiga:**

- a. Kunuğa huukjane.  
 Kunu-ğa **huu**-kjane  
 Kunu-PROP                    come(SBJ.3SG)-FUT  
 'Kunu is going to come (over to my place/here).'
  
- b. Kunuğa huhe.  
 Kunu-ğa **huhe**  
 Kunu-PROP                    be.coming(SBJ.3SG)  
 'Kunu is coming (over to my place/here).'

- c. Kunuḡa jii.  
 Kunuḡ-ga **jii**  
 Kunu-PROP arrive.here(SBJ.3SG)  
 'Kunu (just) got here.'

Figure 3 illustrates the expression of motion towards the deictic center versus that of motion away from the deictic center (cf. videoclip CGI\_05b). When Waac Hanaḡiḡa functions as the deictic center, asking Hinuḡ if she made it back home, he has to use the DMV *gii* [motion –DC, +Base]. When Hinuḡ replies (thus turning her into the DC), she has to use *kiri* [motion +DC, +Base]. Note that Hinuḡ is at her home Base when they talk about it. In English the difference would be expressed by using *there* vs. *here* (Did you get there? vs. I got here.).

**Figure 3. Motion towards Deictic Center and away from Deictic Center**

**E 2 (CG1\_05b) Speaker +DC Waac Hanaḡiḡa:**

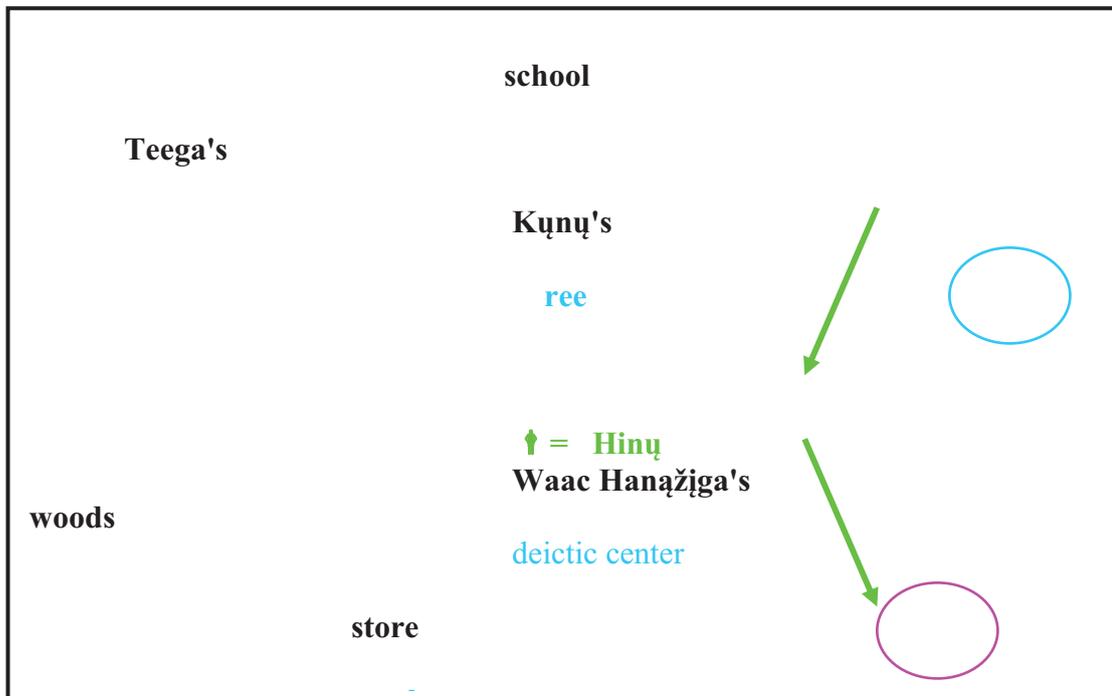

- a. Rakere waš'uḡawaḡ?  
 ra-**kere** wa<š>'u-ša-waḡ  
 2.A-go.back.there <2.A>do/be-2.A-POS.HOR  
 'Are you (Hinuḡ) (still) going back home?'
- b. Keenḡ ragiinḡ?  
 keenḡ ra-**gii**-nḡ  
 ANT.IN 2.A-arrive.back.there-ANT.FIN  
 'Did you (**Hinuḡ**) get home yet?'

**E 3 Speaker +DC Hinu:**

Hakiri.  
 ha-**kiri**  
 1E.A-arrive.back.here  
 'I (**Hinu**) just got back home.'

An illustration of motion towards the Base vs. motion away from the Base is shown in Figure 4. When Hinu says that she is heading out to the store (which is not her Base) she has to use the DMV *ree* (cf. videoclip CGI\_9a), whereas when she talks about heading back home she will have to use *kere* (cf. videoclip CGI\_9b). In E4-6 the full sentences are given.

**Figure 4. Motion towards Base away from Base**

**E 4 (CGI\_09a) Speaker+DC Hinu at Kunu's:**

 ka keenj 'eeja howe-**tee** wa<ha>'u-mak-šana  
 no not.yet there go.about-go.there\1E.A 1E.A>do/be-POS.HOR\1E.A-  
 DECL  
 'No, not yet, I'm (**Hinu**) going to the store (now).'

**E 5 (CGI\_09b) Speaker+DC Waac Hanažiga asking Hinu (cell phone)**

Rakaraginj was'uşawak?  
 ra-**kere**-ginj wa<ş>'u-şa-wak  
 2.A-go.back.there-already <2.A>do/be-2.A-POS.HOR  
 'Are you going back home now?'

## E 6 Speaker+DC: Hinu (on the way)

Hakere waa'umakšana.

ha-**kere**

1E.A-go.back.there

'I'm going back home.'

wa<ha>'u-makšana

<1E.A>do/be-POS.HOR-DECL

Overall, the two recording sessions allowed the researcher to witness and better understand how all of the DMVs are used in context, something the text corpus didn't. The map-like setting and the different characters worked well as stimuli and created a comfortable setting for the speaker, so that he could demonstrate the use of the DMVs not only through speech but also through the movements of the different characters.

### 3.2.2 Usage of DMVs in third person narrations

In narrations and stories DMVs are used differently, which is also why a full understanding of the DMVs is not possible just from looking at narrations alone. The DC is often transferred to a discourse participant with which the narrator is emphatic or which plays a significant role in a certain stretch of discourse. In the following example from one of our texts, the DC is shifted from the narrator to the home/Base of the Traveler which was the place where the preceding important events of the story had happened; cf. E 7.

## E 7 CHT010c

Ĝáak naççégera teekjže, ha ké

haakjá cii

ĝáak naççé-**ra** teek-xjž- že ha ké

haakjá cii

cry heart-DEF ache-INTS-QUOT NEG.IN back

house

'éja kirinjra.

'eeja **kiri-nj-ra**

there **return-NEG.FIN-DEF**

'He was crying with a broken heart, he did not **return to the house.**'

The house is the home of the boy from which he was expelled by his father for educational reasons. Since the house is not the narrator's home Base one would expect him to use *gii* [-DC, +Base]. However, the narrator uses *kiri* which is translated here as 'return'. The semantic features are: [+motion to home base]; [+motion toward DC] and [arrival]. Thus, the DC of this usage of *kiri* coincides with the home base of the character the story is about.

## 4. Conclusions

The main conclusion to be drawn from the study of deictic motion verbs in Hocak is that there is no such thing as a pure principled documentation of an individual language that may serve as a sufficient data base for all kinds of linguistic research let alone descriptive linguistics.

It is not possible to expect that a language description consists only of generalizations on the primary data of the language documentation.

If a language documentation should serve as a repertoire of primary data for a grammatical or lexical description, it has to be enriched with all the data the descriptive linguist needs for the generalizations; language documentation and language description have to go hand in hand to some degree. Good language documentation needs reference to descriptive linguistics.

# Interrogatives in Sri Lankan Sign Language

Kano Mitsuru

Nagaoka University of Technology

asti@vos.nagaokaut.ac.jp

## Abstract

This paper examines both manual and non-manual ways of forming polar and content questions in Sri Lankan Sign Language in comparison with Indo-Pakistan Sign Language in terms of the paradigm of question words, the ways of expanding the paradigm, the spread of non-manual question marking and the position of question words in sentence. Both languages pattern together in terms of head position with respect to non-manual marking for the distinction between polar and content questions. The spread of non-manual marking is more restricted in SLSL than IPSL. The use of mouth in the question-word paradigm is more prevalent in SLSL than IPSL. The placement of question words in sentence is much less constrained in SLSL than IPSL.

**Keywords:** interrogatives, polar questions, content questions, non-manual marking, Sri Lankan Sign Language.

## 1. Introduction

Signed languages are natural human languages used by deaf people throughout the world. Unlike the spoken languages that use an oral-auditory modality, signed languages use a visual-manual modality in which manual signs, facial expressions, and body movements and postures all convey complex linguistic information.

Zeshan (2004, 2006) and Šarac et al. (2007) provided a cross-linguistic comparison of interrogatives in many signed languages. Zeshan (2000, 2006) discussed that based on the comparisons of lexicon and grammatical structures, there is only one signed language used in various regions of India and Pakistan and refers to this signed language as Indo-Pakistani Sign Language (IPSL). Sri Lanka is also one of other regions of Indian subcontinent. And there may be only one signed language in various regions of Sri Lanka because deaf people of various regions have no difficulty of communicating with each other. I refer to this signed language as Sri Lankan Sign Language (SLSL). It is of great interest to see the similarities and differences between

IPSL and SLSL.

In this paper I use the data of the dialect of Colombo area, where is the center of politics, education and economy in Sri Lanka. This research has been conducted based on elicited data as well as data that have been collected by video recording natural discourses and translations from Sinhala with a deaf consultant's cooperation.<sup>1</sup> He is a native signer of Colombo dialect and grew up in Deaf family where SLSL was the primary language used in the home. The data and observations regarding IPSL are cited from Zeshan (2000, 2004, 2006).

Zeshan (2004) investigated interrogative structures based on data from 35 signed languages around the world since the functions of interrogative sentences play an important role of the grammar of any language. Zeshan found that both content (wh-questions) and polar questions (yes/no questions) are mainly marked by non-manual characteristics. Some signed languages also have manual polar signs and most of the signed languages have manual question signs.

Similar to other signed languages, interrogative constructions in SLSL consist of both manual and non-manual components. Manual components are lexical items, which consist of the combinations of hand, movement and location. Non-manual components consist of special facial expressions such as brows up, head and body postures such as chin up and down, body leaning forward, eye gaze toward the addressee and mouth patterns. In this paper, I examine both manual and non-manual ways of forming two basic types of questions, polar questions and content questions in SLSL in terms of the paradigm of question words, the ways of expanding the paradigm, the spread of non-manual question marking and the placement of question words in sentence, compared with IPSL.

## **2. Polar questions**

### *2.1. Non-manual marking*

As shown in (1), SLSL is a verb/predicate-final language like IPSL.

- (1) INDEX<sub>1</sub> BANANA EAT  
“I eat bananas”

In SLSL, a polar question differs from the corresponding affirmative sentence by the

presence of non-manual marking ‘chin down’ as exemplified in (2). I use a conventional gloss notation which involves the use of capitalized English words to represent signs in signed languages. Subscript numbers refer to points in the signing space that are used in pronominalization. The spread of a non-manual marking is indicated by a line on top of the sign glosses in capital letters.

- (2) a. INDEX<sub>2</sub> DEAF INDEX<sub>2</sub>  
 “You are deaf.”
- b. INDEX<sub>2</sub> DEAF  $\overline{\text{INDEX}}_2$   
 chin down  
 “Are you deaf?”

In addition to head position, i.e. chin down, brow position, i.e. brows up, is also used to mark polar questions. In (3), the sign EAT is marked by brows up, whereas in (4) there is no brows up and the sign CLOSE is marked by chin down only, which is also used in polar questions of IPSL (Zeshan 2004: 20). The eye gaze toward the addressee and a hold following the sign in clause-final position are obligatory. In (2-4), the final sign in each sentence accompanied with eye gaze is followed by a hold. Although IPSL and SLSL have the same feature of non-manual marking that differentiates between a polar question and the corresponding affirmative sentence, they differ in terms of the spread of non-manual marking. It is notable that in SLSL the head movement ‘chin down’ does not spread over the entire sentence which has no topicalised constituents and marks the sign CLOSE only, whereas in IPSL it spreads over the entire sentence minus any topicalised constituents according to Zeshan (2004: 20).

- (3)  $\overline{\text{EAT}}$   
 brows up/chin down  
 “Did you eat?”
- (4) NOW TIME 6  $\overline{\text{CLOSE}}$   
 chin down  
 “Is it around 6’oclock?”

## 2.2. Question Particle

Besides non-manual marking, SLSL has a question particle for marking polar questions, whereas IPSL does not have any question particle (Zeshan 2006: 340). The question particle is articulated by beginning with one or two open hands with the fingers and thumb extended, palm facing down and fingers pointing forward, held in front of the body, and then twisting the hand at the wrist so that the palm faces up while moving forward slightly. It is optionally used in polar questions, alternative questions, tag questions and content questions, and occurs in clause-final position only. Example (5) illustrates that the question particle (QP) occurs in clause-final position following the sign CAN.

- (5) INDEX<sub>1</sub> TIME LONG MEDICINE DRINK LONG NEED CAN QP  
“Will I have to drink medicine for a long time?”

When used in content questions, the question particle occupies the clause-final position following a question word, as shown in (6).

- (6) INTERROG-A QP  
“Why?”

### **3. Content questions**

#### *3.1. Non-manual marking*

As shown in the above examples (2b)-(4), the polar questions are marked by chin down. In contrast to that, the content questions are primarily marked by chin up in (7) and (8) like IPSL (Zeshan 2006: 309). Thus in terms of head position, IPSL and SLSL have the same typological feature with regard to non-manual marking for the distinction between polar and content questions. In terms of the status of non-manual marking involving brow position, i.e. brow furrow and brows up, however, they seem to differ from each other. In SLSL brow furrow is primarily associated with the general question word INTERROG-B accompanied by a round, open mouth gesture, but not primarily with other question words, whereas it is used for secondary non-manual marker in IPSL (Zeshan 2006: 310). In SLSL, brows up functions as a secondary non-manual marker because it is not used as illustrated in (7) and (8), whereas in IPSL it functions as a primary non-manual marker (Zeshan 2006: 310). In SLSL brow position does not

appear to be crucial for marking content questions in that it is also used for marking polar and content questions that are formed in the absence of non-manual marking involving brow position. The statuses of these non-manual markers and the differences among them have not yet been studied.

Besides chin up, mouth patterns and slight headshake are also used to mark content questions in SLSL. In (9) and (10) mouth patterns accompanied with the question word are ‘how’ in English. With respect to head position, chin up functions as a primary non-manual marker and head shake functions as a secondary non-manual marker.

- (7) INDEX<sub>2</sub> TODAY LATE INTERROG-A  
chin up  
“Why are you late today?”
- (8) INDEX<sub>2</sub> INTERROG-A  
chin up/mouthing  
“Who are you?”
- (9) COCONUT PICK INTERROG-A  
mouthing/head shake  
“How do you pick coconuts?”
- (10) SEE BEFORE NOW INTERROG-A  
mouthing/head shake  
“Seeing you after a long time! So how?”

As for the spread of non-manual marking, unlike IPSL, the examples (7)-(9) mentioned above show that the non-manual marking by chin up is limited to the question word only. In IPSL the non-manual marking spreads over the entire question minus any topicalised constituents whereas in SLSL only a question word is typically marked by non-manual marking, although in some cases the adjacent constituent to a question word is also marked. Example (11) illustrates that the sign GIVE is also marked by brows up and chin up. It seems that the spread of non-manual marking for polar and content questions in SLSL is more constrained than IPSL. Much more research will be needed on the conditions of the spread of the non-manual marking.

- (11) A: SIGN INDEX<sub>2</sub>  
“What is your name sign?”  
B: NAME-SIGN

“My name sign is this.”  
 A: NS GIVE INTERROG-A  
 chin up/brows up  
 “Who named you the name sign?”

### 3.2 Basic Paradigm of Question Words

According to Zeshan (2004: 22), "Paradigms of question words can be radically different from one signed language to another, in terms of both size and the distinctions that are lexicalized as question words. Indo-Pakistani Sign Language basically has a minimal paradigm with only one question word that covers the entire range of interrogative meanings", i.e. 'what, who, why, and where'. In contrast to IPSL, SLSL has four basic monomorphemic question words (see Table 1), and thus has a larger paradigm of question words than IPSL.<sup>2</sup> Among the basic questions words, two content words are general question words, i.e. INTERROG-A and INTERROG-B, that cover the wide range of meanings. The sign INTERROG-A with all fingers curled and palm facing left involves a pivoting movement of the elbow held in front of the right shoulder and is articulated by a short double to-and-fro movement. The sign INTERROG-B is articulated by beginning with the index finger extended and other fingers curled against the palm, palm facing down and the index finger pointing forward, held in front of the chest, and then wiggling the index finger.

There are several differences between INTERROG-A and INTERROG-B. First, INTERROG-A is a basic and general term for ‘what’ in terms of frequency and usage, whereas INTERROG-B is more specific. Second, INTERROG-A is marked by mouth patterns derived from English and Sinhala content words such as ‘who’ in English and ‘æyi’ (why) in Sinhala, whereas INTERROG-B is marked by mouth gesture formed from within in SLSL (See 3.3.1 for the use of mouth). Third, INTERROG-B can be used to differentiate human entity from non-human by movements of eyes such as eye gaze toward the addressee and ‘look down’. Example (12) illustrates that when INTERROG-B is marked with the eye gaze toward the addressee, it refers to human entity. In contrast, INTERROG-B is marked with the eye movement ‘look down’, it refers to non-human entity such as animal, thing and activity. In (13), it refers to an activity.

(12) WORK INTERROG-B  
 brows up/chin up/mouth gesture

- “Who is working?”  
 (13) WORK INTERROG-B  
 brow furrow/mouth gesture  
 “What are you doing?”

It is well known that languages vary in the way they manifest animacy. Examples (12) and (13) indicate that in SLSL animacy concept is reflected in the domain of question words through an interaction of manual and non-manual components.

Fourth, unlike INTERROG-A, INTERROG-B combines with other elements of movement. As shown in (14) involving the situation for picking up something, the dominant hand forming INTERROG-B stretches forward and moves from left to right as if searching for something. Example (15) illustrates that INTERROG-B stretches towards the upper right direction as if incorporated into the index finger representing 3rd person pronoun.

- (14) BOOK LIKE INTERROG-B  
 brow furrow/chin up/mouth gesture  
 “Which book do you like?”  
 (15) ASOKA GO INTERROG-B  
 brow furrow/chin up/mouth gesture  
 “Whom does Asoka go with?”

In addition to the general question words INTERROG-A and INTERROG-B, specific question words for ‘where’, ‘when’ and ‘how many’ also form the basic paradigm of the question words in SLSL. The two-handed sign WHERE involves an orientation change and is articulated by beginning with the fingers and thumb extended, palms facing down and fingers pointing forward, held in front of each side of the body, and then twisting the hands at the wrists so that the palms face up. The sign HOW-MANY has two meanings, i.e. 'how many' and 'when'. It involves an internal hand shape change and is articulated by beginning with all of the fingers and thumb curled, palm facing in, held in front of the chest, and then moving downward while flicking the fingers and thumb open quickly.

Table 1. Basic paradigm of monomorphemic question words

	SLSL	IPSL
--	------	------

Monomorphemic question words	1. INTERROG-A ‘what, who, why, how’ 2. INTERROG-B ‘what, who, which, what for’ 3. WHERE ‘where’ 4. HOW-MANY ‘how many, when’	1. INTERROG ‘what, who, why, where, etc.’
------------------------------	--	--

### 3.3. Expanding the basic paradigm of question words

SLSL has several devices to expand the basic paradigm of question words by the use of three formational means: mouth patterns accompanying the manual question signs, complex question word formation and using non-interrogative words as question words.

#### 3.3.1 Mouth patterns

Since the basic question words have several meanings, for disambiguation mouth patterns are used to specify them in SLSL. On the other hand, IPSL does not seem to have the use of mouth for disambiguation in interrogative constructions, because Zeshan (2000, 2001, 2004, 2006) did not report that. According to Braem and Sutton-Spence (2001: 2-3), signed languages have at least two types of mouth patterns. One may be derived from a spoken language and the other may be formed from within the sign languages and have no relation to the mouth movement of a spoken language. I refer to the former with mouthing and to the latter with mouth gesture, according to Braem and Sutton-Spence.

SLSL also has two types of mouth patterns.<sup>3</sup> One is mouth patterns derived from English and Sinhala question words. The same manual sign INTERROG-A can be accompanied by mouthing of different words such as ‘who’ in English and ‘æyi’ (why) in Sinhala, resulting in separate question signs in SLSL. For expressing the meaning of ‘who’, INTERROG-A is accompanied by the mouth movement of rounding lips. For ‘æyi’ (why), INTERROG-A is accompanied by stretching the mouth wide. Mouthing may have a lexical function and be part of the lexical component of interrogative constructions. And the other is mouth patterns formed from within SLSL which do not have any relation with English and Sinhala question words. In contrast to the mouthing, the round and open mouth gesture accompanying INTERROG-B does not function

specifying each meaning of INTERROG-B because INTERROG-B always associates with the same mouth gesture, i.e. the round, open mouth gesture.

### 3.3.2 *Complex question word formation*

Another device for expanding the basic paradigm is a complex question word formation that consists of non-interrogative sign in combination with INTERROG-A. Non-interrogative nouns are used as question words by combining with INTERROG-A, such as WATCH + INTERROG-A/B ‘what time’, TIME + INTERROG-A/B ‘what time’ and MONEY + INTERROG-A ‘how much’. In IPSL this word formation is a disambiguation strategy, because IPSL has only one question word that covers the whole range of question words in other languages and is ambiguous. In contrast, the word formation does not function specifying the meanings of the general question signs in SLSL, because INTERROG-A cannot mean ‘what time’ and ‘how much money’ in the absence of the signs WATCH and MONEY respectively. As for the sign WATCH, note its repeated movement when forming a content question as shown in (16). The sign WATCH is a two-handed sign. When the extended index finger of the dominant hand with slight to-and-fro movement points twice at the wrist of the non-dominant hand or touches it one time in (17), the sentence means ‘what time’. By pointing at the wrist one time in the absence of to-and-fro movement, it means ‘whose watch?’.

(16) WATCH  $\overline{\text{INTERROG-A}}$

chin up

“What time is it?”

(17) TIME  $\overline{\text{INTERROG-B}}$

chin up

“What time is it?”

(18) MONEY  $\overline{\text{INTERROG-A}}$

chin up

“How much is it?”

### 3.3.3 *Non-interrogative words as question words*

As question words some nouns are used by marking them with non-manual components such as mouthing, head movement, brows up or a combination of these. SLSL has two nouns, i.e. TIME and MONEY, used as question words, whereas IPSL

does not use this strategy. In (19) the sign TIME is accompanied by the open and close mouth movement of imitating the pronunciation of English word ‘time’. In (20) the sign MONEY is accompanied by the mouth movement of imitating the pronunciation of English word ‘money’. Notice that the non-interrogative sign AGE can be used without mouthing, head movement or brows up, although it accompanies eye gaze toward the addressee and a hold in clause-final position. The use of AGE as a question word without non-manual marking appears to be due to the effect of frequency. Since the phrase unit INDEX2 AGE is frequently used, it is easily predictable and identifiable from the context even if it has no non-manual marking, and may become conventionalized.

- (19)  $\bar{T}\bar{I}\bar{M}\bar{E}$   
mouthing/chin up  
“What time is it?”
- (20)  $\bar{M}\bar{O}\bar{N}\bar{E}\bar{Y}$   
mouthing  
“How much?”
- (21) INDEX2 AGE  
“How old are you?”

Table 2 shows the expanded paradigm of question words both in IPSL and SLSL. Note that the use of mouth is prevalent in SLSL than IPSL in the domain of the formation of interrogative construction.

Table2 The expanded paradigm of question words

	SLSL	IPSL
Monomorphemic question words	1. INTERROG-A	1. INTERROG
	2. INTERROG-B	
	3. WHERE	
	4. HOW-MANY	
	(mouth patterns)

	2. MONEY INTERROG-A	2. PLACE INTERROG
	(mouth patterns)	3. TIME INTERROG
		4. NUMBER INTERROG
Non-interrogative words as question	1. TIME	

words	2. MONEY	
	3. AGE	
	(mouth patterns)	

### 3.4 Syntactic position of question words

Unlike in IPSL that allows only clause-final placement of question words, in SLSL the syntactic positions for question words are clause initial, clause final, or doubled and in situ, although the clause final position is strongly preferred in the data. In (22) the question word INTERROG-A occupies in-situ position. In (23), the question word WHERE appears in the clause final position. On the other hand, in (24) it occupies the clause initial position. Notice that WHERE in the clause initial position is not marked by eye contact with the addressee but by chin down. It will require more research on the relation between the position of a question word and non-manual making.

(22) INDEX<sub>2</sub> REMOVE ELSE INTERROG-A WANT INDEX<sub>2</sub>

chin up

“What else do you want?”

(23) YOUNGER-BROTHER GO WHERE

chin up

“Where did younger brother go?”

(24) WHERE YOUNGER-BROTHER GO

chin down

“Where did younger brother go?”

Unlike IPSL, SLSL has multiple content questions that contain more than one content question word. Example (25) illustrates that the same question words occupy both clause-initial and clause-final position and it is a construction with doubling of constituents. The two different general question signs, i.e. INTERROG-A and INTERROG-B, can also appear in the clause-initial and clause-final position as shown in (26).

(25) INTERROG-A MONK INDEX<sub>3</sub> INTERROG-A

chin up

chin up

“Which monk is that?”

- (26)  $\overline{\text{INTERROG-A}}$  DO  $\overline{\text{INTERROG-B}}$   
chin up chin up/brow frown/mouth gesture  
“What are you doing?”

In example (27) and (28), there are two different question signs INTERROG-B and WHERE that sequentially co-occur in clause-final position. The examples differ from each other in that in (27) they undergo a phonological reduction indicated by the notation ‘~’, behave like a one unit and express the meaning ‘where’, whereas in (28) each content sign denotes its inherent meaning. Examples (29) and (30) also illustrate that two different general question signs INTERROG-B and INTERROG-A undergo a phonological reduction, behave like a one unit and mean ‘why’ in (29) and ‘who’ in (30).

- (27) ASOKA GO  $\overline{\text{INTERROG-B~WHERE}}$   
chin up/mth chin up  
“Where did Asoka go?”
- (28) ASOKA GO  $\overline{\text{INTERROG-B}}$   $\overline{\text{WHERE}}$   
chin up/mth chin up  
“What is Asoka’s job and where does he work?”
- (29) ASOKA GO  $\overline{\text{INTERROG-B~INTERROG-A}}$   
chin up/mth chin up  
“Why did Asoka go?”
- (30) MONK  $\overline{\text{INTERROG-B~INTERROG-A}}$   
chin up/mth chin up  
“Who is the monk?”

While it is possible to elicit multiple content questions such as (31), they do not appear to occur spontaneously.

- (31) ASOKA GO WHERE WITH  $\overline{\text{INTERROG-A}}$  WATCH  $\overline{\text{INTERROG-A}}$   
chin up chin up  
“When and where did Asoka go with whom?”

According to Zeshan (2004: 25), American Sign Language and Japanese Sign Language allow split interrogative constituents. IPSL allows it in the composite interrogative expressions as shown in (32). Examples (33) and (34) exemplify that SLSL also permits the construction.

- (32) INDEX2 FRIEND PLACE SLEEP INTERROG (Zeshan 2006: 316)  
 “Where is your friend (going to) sleep?”
- (33) COLOR LIKE INTERROG-A  
 chin up  
 “What color do you like?”
- (34) TIME GO INTERROG-B  
 chin up/mouth gesture  
 “What time will you go?”

#### 4. Conclusion

The paper focuses on several typological features in order to find out the similarities and differences between IPSL and SLSL. In terms of head position, SLSL patterns with IPSL with respect to non-manual marking for the distinction between polar and content questions. Both languages use chin down for polar questions and chin up for content questions, although they are different from each other with respect to the use of brow position. Regarding the basic paradigm of question words, SLSL has a larger paradigm than IPSL in terms of size and the distinctions lexicalized as question words. With respect to the spread of non-manual marking, it is restricted in SLSL more than IPSL. The use of mouth in the question-word paradigm is more prevalent in SLSL than IPSL. The placement of question words in sentence is much less constrained in SLSL than IPSL. Such findings reveal the similarities and differences between two languages.

Further research will be needed on the extent of the spread of non-manual marking, the functions of the non-manual markers and mouth patterns, and the constraints on the placement of question words. This type of research could make a descriptive contribution to our knowledge of the signed languages of Indian subcontinent.

#### Notes

1. I am very much indebted to my informant Asoka Abeysekera. Without his patient help this research would not have been possible.
2. According to Rohana Special School (2007), Matara dialect has a larger basic paradigm of question signs than Colombo dialect studied here. It has WHO ‘who’,

WHAT 'what', WHY 'why', HOW 'how', WHERE 'where', WHEN 'when', HOW-MANY 'how many' and WHAT-TIME 'what time'

3. The use of mouth patterns is influenced by several factors, i.e. personal background, educational background, communication situation, and text type. The exact functions of mouth patterns in SLSL need considerable further research based on the sociolinguistic factors.

# Clitic and its Tonal Behavior in Akan

Kyoko Koga

Kochi University  
2-5-1 Akebonocho, Kochi City, Kochi 780-8520, Japan  
koga@kochi-u.ac.jp

## Abstract

This paper aims to show how justification for the syntactic category clitic can be seen in its tonal behavior in Akan. We focus here on what I call enclitics, namely, =*i*, =*no*, =*bi*, =*ni*, =*ha*, =*fo-ɔ*, and =*nom*. Although they presumably originate from nouns, they have been equated with suffixes by the researchers. However, what has been gained from this research is, that some enclitics behave differently tonally from suffixes. There are three types tonally: one is the same as nouns, a second the same as suffixes, and the third the same as both nouns and suffixes. It is concluded that the presence of these three types reflects the fact that they originate from words, and are shifting toward affixes.

**Keywords:** Akan, tone, clitic, word, affix.

## 1. Introduction

Akan is a Niger-Congo, Kwa language spoken mainly in Ghana. According to Gordon ed. (2005), there are nine dialects: that is, Asante, Fante, Akuapem, Agona, Dankyira, Asen, Akyem Bosome, Kwawu, and Ahafo. The dialect dealt with in this paper is Asante, and all the data presented here is collected by the author from a native speaker.<sup>1</sup>

Akan is a tone language, and there are two tonemes: one is H(igh), and the other is L(ow) (see (1)). Phonetically, there is mid tone which appears only after H, which is a little lower than H but not as low as L (see (2)). We call this Downstepped H(igh), because it is considered that it appears when both L and H are realized in one syllable. In this paper,  $\acute{\phantom{x}}$  represents H tones,  $\overset{\sim}{\phantom{x}}$  Downstepped H tones, and L tones are unmarked.

- (1) a.  $d\acute{a}$                        $da$   
          “to lie”                    “ever”

b. <i>papá</i>	<i>papa</i>	<i>pápá</i>
“father”	“fan”	“very good”

(2) <i>ɔbɔ́fóó</i>	<i>ɔbɔ́!fóó</i>
“creator”	“messenger”

## 2. Tone of suffixes

Let us first look at the behavior of suffixes. As shown in (3), nominal suffixes (-o, -ɔ, -õ, -e, -ε, -ẽ)<sup>2</sup> always bear the H tone, regardless of the tone of the root ( - representing morpheme boundaries).

(3) <i>a-pú!pú-ó</i>	<i>a-paso-ó</i>	<i>n-sõ-õ</i>
“shellfish”	“scissors”	“ash”
<i>nantwí-é</i>	<i>a-taadé-é</i>	<i>kyénsẽ-ẽ</i>
“cow”	“clothes”	“pan”

## 3. Tone of roots

Let us take a look at the tonal behavior of noun roots here. They always retain their original tones as in the sentences and compounds shown in (4) (= representing clitic boundaries. In this paper, unless shown separately, the tones of morphemes in words or sentences have not changed from the original tones).

(4) a. <i>ɔ=wo</i>	<i>siká</i>
3sgSC=have	money
“S/he has money.”	
b. <i>ɔ=wó</i>	<i>fufú-ó</i>
3sgSC =pound	fufuo
“S/he pounds on fufuo.”	

- c.  $\text{ɔ}=\text{bó}$       *dúku*  
 3sgSC =wear scarf  
 “S/he wears a scarf.”
- d.  $\text{ɔ}=\text{tó}$       *pí!ǎ*  
 3sgSC =throw lance  
 “S/he throws a lance”
- e. *twíí-ká!sá*  
 Twi-language  
 “Twi language”
- f. *naná-maamé*  
 grandparent-elder woman  
 “great-grandmother”
- g.  $\text{ɔ}=\text{mán-fáráńkaá}$   
 nation-flag  
 “national flag”

When a noun has a L tone prefix, usually the prefix is deleted when it is preceded by another word or root.<sup>3</sup> But the tone of the prefix is preserved therefore when the preceding root-final tone and the initial tone of the root to which the prefix is attached are both H, the initial H tone changes into Downstepped H tone as in the sentence and compound shown in (5).

- (5) a.  $\text{o}=\text{twá}$       *!dwán*      cf. *o-dwán*  
 3sgSC =cut sheep      “sheep”  
 “S/he kills the sheep.”
- b. *a-wú-!dúró*      cf. *a-dúró*  
 PREF-die-medicine      “medicine”  
 “poison”

An interesting tonal phenomenon is seen exclusively in some compounds. In the examples shown in (6), the original tones of the preceding roots are lost, and they

appear with L tone throughout (tones of the following roots do not change).

- |                           |                     |                 |
|---------------------------|---------------------|-----------------|
| (6) a. <i>dade-pɔnkɔ́</i> | cf. <i>dadé-é</i>   | <i>ɔ-pɔnkɔ́</i> |
| iron-horse                | “iron”              | “horse”         |
| “bike”                    |                     |                 |
| b. <i>nantwi-nám</i>      | cf. <i>nantwí-é</i> | <i>ε-nám</i>    |
| cow-meat                  | “cow”               | “meat”          |
| “beef”                    |                     |                 |
| c. <i>e-fun-dá!ká</i>     | cf. <i>e-fúnú</i>   | <i>a-dá!ká</i>  |
| corpse-box                | “corpse”            | “box”           |
| “coffin”                  |                     |                 |

#### 4. Tone of enclitic

Now let us look at the tonal behavior of enclitics. The enclitics presented here are demonstrative enclitic =*i*, determiner enclitic =*no*, indefinite enclitic =*bi*, agent enclitic =*ni*, demonstrative enclitic =*ha*, agent enclitic =*fo-ɔ*, and plural enclitic =*nom*. Although =*i*, =*no*, =*bi*, and =*ha* clearly originate from nouns *weí* ‘this’, *ε-no’* ‘it’, *e-bí* ‘something’, and *a-há* ‘here’ respectively, they have been equated with suffixes by the researchers (e.g. Christaller 1964, Dolphyne 1988). However, what has been gained from this research is, that some enclitics behave tonally differently from suffixes. These enclitics are categorized tonally into three types: one is the same as nouns, a second the same as suffixes, and the third the same as both nouns and suffixes.

##### 4.1 =*i*, =*no*, =*bi*,

As shown in (7) and (8), demonstrative enclitic =*i*, determiner enclitic =*no*, and indefinite enclitic =*bi* always bear the H tone regardless of the tone of the roots as nominal suffixes do.

- (7) a. *a-nadwo=í*                      *sófi=í*  
           night=DEMC                      shovel=DEMC  
           “tonight”                          “this shovel”
- b. *a-nadwo=nó*                      *sófi=nó*  
           night=DETC                      shovel=DETC  
           “the night”                        “this shovel”
- c. *a-nadwo=bí*                        *sófi=bí*  
           night=INDC                      shovel=INDC  
           “a certain night”                “a certain shovel”
- 
- (8) a. *a-kókó=í*                            *prá!kó=í*  
           hen=DEMC                        pig=DEMC  
           “this hen”                         “this pig”
- b. *a-kókó=nó*                        *prá!kó=nó*  
           hen=DETC                        pig=DETC  
           “the hen”                         “the pig”
- c. *a-kókó=bí*                        *prá!kó=bí*  
           hen=INDC                        pig=INDC  
           “a certain hen”                 “a certain pig”

#### 4.2 =ni

In contrast with the three clitics presented in 4.1, agent enclitic =ni behaves just like a noun with a H tone root and a L tone prefix. When the root-final tone is L, it bears the H tone as shown in (9), but when the root-final tone is H, it bears the Downstepped H tone as shown in (10). This tonal phenomenon indicates that =ni originates from a noun with a L tone prefix.

- (9) *o-krísto=ní*                            *gáána=ní*  
       PREF-Christ=AGC                      Ghana=AGC  
       “Christian”                            “Ghanaian”

- |                         |                   |
|-------------------------|-------------------|
| (10) <i>ɔ-wari'=!ní</i> | <i>o-tié'=!ní</i> |
| PREF-marry=AGC          | PREF-listen=AGC   |
| “married person”        | “listener”        |

Furthermore, as in (11), some roots to which =*ni* is attached appear with the L tone throughout, regardless of the original tone of these roots, as preceding roots in compounds do.

- |                          |                  |
|--------------------------|------------------|
| (11) a. <i>o-sika=ni</i> | cf. <i>sika'</i> |
| PREF-money=AGC           | “money”          |
| “rich person”            |                  |
| b. <i>o-kua=ni</i>       | cf. <i>ku'á</i>  |
| PREF-farming=AGC         | “farming”        |
| “farmer”                 |                  |
| c. <i>o-kuro=ni</i>      | cf. <i>kúró</i>  |
| PREF-town=AGC            | “town”           |
| “citizen”                |                  |

#### 4.3 =*ha*, =*fo-ɔ*, =*nom*

Demonstrative enclitic =*ha*, agent enclitic =*fo-ɔ*, and plural enclitic =*nom* show a mixed behavior. As shown in (12), when the preceding root-final tone is L, they bear the H tone. But when the preceding root-final tone is H, they bear the Downstepped H tone in some cases as shown in (13), and the H tone in other cases as shown in (14). Furthermore, while the tones of the roots to which =*ha* is attached never change, some roots to which =*fo-ɔ* and =*nom* are attached appear with L tone throughout as in the compounds shown in (15).

- |                        |                          |
|------------------------|--------------------------|
| (12) a. <i>ɔ=te=há</i> | <i>o=gyina=há</i>        |
| 3sgSC=live=DEMC        | 3sgSC=stand=DEMC         |

brother/sister=PLC  
“brother/sister”

cf. *a-núa'*  
“brothers/ sisters”

## 5. Conclusion

To sum up, all the enclitics mentioned in this paper appear to originate from words consisting of a H tone root and a L tone prefix. The enclitic which behaves the same as nouns is *=ni*, since whenever the root-final tone is H, the enclitic always bears the Downstepped H. This suggests that it originates from a word with a H tone root and a L tone prefix.

Contrastively, the enclitics which behave the same as suffixes are *=i*, *=no*, and *=bi*. Although these enclitics seem obviously to originate from nouns with a H tone root and a L tone prefix, downstep never occurs when the root-final tone is H, but these enclitics always appear with H.

The enclitics which behave like both nouns and suffixes are *=ha*, *=fo-ɔ*, and *=nom*. When the root-final tone is H, there are cases where these enclitics appear with the Downstepped H like words with a H tone root and a L tone prefix, and there are cases where these enclitics appear with the H like suffixes. Furthermore, among these three enclitics, *=fo-ɔ* and *=nom* behave more like words than *=ha*. This is because in several cases the roots to which *=fo-ɔ* or *=nom* is attached appear with the L tone throughout regardless of the original tone of these roots, just as in some compounds.

To conclude, there are three types of enclitics tonally: one is the same as nouns, a second the same as suffixes, and the third the same as both nouns and suffixes. The presence of these three types reflects the fact that clitics originate from words, and are shifting toward affixes. The enclitics dealt with in this paper can be placed on the transitional phase as shown in (16).

# Possessor Raising and Noun Incorporation: A Case of Alutor in Russian Far East

Yukari Nagayama

Research Institute for Languages and Cultures of Asia and Africa  
Tokyo University of Foreign Studies  
nagayama@aa.tufs.ac.jp

## Abstract

In Possessor Raising (PR) in Alutor (Chukchi-Kamchatka language family), the noun is placed outside the verbal complex as a possessor and the incorporated noun, as a possessee. The aim of this paper is to demonstrate all possible situations that allow PR in Alutor. In many languages, PR occurs when the possessor noun and the possessed noun indicate inalienable (often body parts) possession. In contrast, PR in Alutor is not restricted to inalienable possession, but can occur in the case of many other relations. Nevertheless, there are certain restrictions. In this paper, I will show that the following three parameters control PR in Alutor: 1) Property of nouns, 2) Affectedness of a verb, 3) Beneficialness of the action.

**Keywords:** possessor raising, incorporation, transitivity, affectedness, beneficialness.

## 1. Introduction

Alutor involves a process known as Noun Incorporation (NI). By incorporating a direct object, a transitive verb reduces its valence and follows the intransitive conjugation pattern. However, there are also some cases in which a transitive verb incorporates its direct object and retains its transitivity. One of these cases is associated with Possessor Raising (PR); these sentences have both the noun outside the verbal complex as a possessor (1a. dog) and the incorporated noun as a possessee (1a. whisker). In this study, I will term constructions like (1a) as PR with transitive NI.

- (1) a. *un<sup>[J]</sup>un<sup>[J]</sup>u-ta      <sup>[H]</sup>ət<sup>[H]</sup>-ə-n      na-lalu-<sup>[G]</sup>itəl<sup>[J]</sup><sup>[Q]</sup>*  
*at-ə-tkə-n*  
child-ERG    dog-E-ABS.SG    LOW.A-whisker-pull-E-IPFV-3SG.P

“The children pull the *dog’s* whiskers.” (*lit.* the children whisker-pull the dog)

b. *un*[\$J]*un*[\$J]*u-ta*      *[\$H]ət[\$H]-ina*      *lalu-wwi*  
 child-ERG    dog-POSS.3PL    whisker-ABS.PL  
*na-[\$G]itəl[\$J]at-ə-tkə-na*  
 LOW.A-pull-E-IPFV-3pl.P  
 “The children pull *dog’s* whiskers.”

Cross-linguistic studies show that PR is often restricted to inalienable possession. However, PR in Alutor is used for broader possessive relations. The goal of this presentation is to demonstrate all possible situations that allow PR with transitive NI.

## 2. General information about Alutor

- Alutor belongs to the Chukchi-Kamchatkan language family and is spoken in Kamchatka Peninsula, Russia, by about 200–300 speakers.
- Alutor is an agglutinating, polysynthetic, and ergative language. Transitive subjects (A) are encoded in the ergative case (2), while intransitive subjects (S) and direct objects (O) are encoded in the absolutive case (2, 3).

(2) *[junjunawət-nak]A*    *[\$G]-etu-lin*      *[un[\$J]un[\$J]u-pil[\$J]]O*  
 PSN-ERG.SG      RES-give.birth-RES.3SG.P      child-DIM.ABS.SG

(3) *teloŋ*    *qət-ə-jji*      *[miti]S*  
 to.there    go-E-PFV.3SG.S    PSN.ABS.SG  
 “M went there.”

- Transitive and intransitive verbs show different conjugation patterns and are easily distinguishable from each other.
- The word order is fairly free.
- The subject and/or object are often omitted because the person and the number of these participants are obligatory marked on verbs by affixes.

(4) *[əlla[\$Q]-a]A*      *iv-nin*

mother-ERG      say-PFV.3SG.A/3SG.P  
 “Mother told him.”

### 3. Overview of NI in Alutor

When a transitive verb incorporates its direct object, the performer of the action is moved to the absolutive position, and the verbal complex takes the intransitive conjugation pattern. In (5a), the word “boots” takes the absolutive case, and the verb “crumple,” the transitive conjugation. In contrast, in (5b), the nominal stem “boot” is incorporated into the verb, and the verbal complex “boot-crumple” take the intransitive conjugation pattern.

- (5) a. *ɲavakka-ta              pəlak-u              tavamjat-ə-tkə-nina*  
 daughter-ERG      boot-ABS.PL      crumple-E-IPFV-3SG.A/3PL.P

 daughter.ABS.SG      boot-crumple-E-IPFV.3SG.S  
 “(My) daughter softens *boots*.” (*lit.* Daughter boot-crumples.)

- According to general tendency for NI provided in Mithun (1984: 856), in Alutor, NI often refers to general, habitual activities or ‘activities directed at an unspecified portion of a mass’.
- Alutor does not allow the incorporation of two objects.
- No modifier of a noun can be incorporated.
- Transitive verbs that have corresponding lexical affixes (e.g., “to eat” and “to make”) usually do not incorporate their direct objects. Thus, the NI in (6a) is ungrammatical, and sentences with a lexical suffix, such as (6b), are preferred.

- (6) a. \**ɬ[G]əmmə      t-əvənɬ[Q]-ə-nu-tkən*  
 I.ABS      1SG.S-berry-E-eat-IPFV

 I.ABS      1SG.S-E-berry-eat-IPFV  
 “I eat berries.” (*-u* is a lexical suffix that means “to eat/drink”)

In (8a), the noun “parka” is incorporated into the verb “tear,” and its possessor “father” is the direct object of the verbal complex.

[clothes]

- (8) a. *un*[\$J]un[\$J]u-ta      **alla**[\$G]-ə-n  
 child-ERG    father-E-ABS.SG

*t-ə-sima-v-nin*  
 CAUS-E-tear-CAUS-3SG.A/3SG.P[PFV]  
 “The child tore father’s parka.”

In (9a), the noun “cat” is incorporated into the verb “to kill,” and its possessor “mother” is shown as the direct object of the verbal complex.

[domestic animals]

- (9) a. *un*[\$J]un[\$J]u-ta      **alla**      \$[G]a-koška-nm-ə-lin  
 child-ERG    mother.ABS.SG    RES-cat-kill-E-RES.3SG.P  
 “The child killed the *mother’s* cat.” (lit. the child cat-killed *mother*)
- b. *un*[\$J]un[\$J]u-ta      \$[G]a-nm-ə-lin      *koška*  
 child-ERG    RES-kill-E-RES.3SG.P    cat.ABS.SG  
**alla**[\$Q]-in  
 mother-POSS.3SG  
 “The child killed mother’s cat.”

Similarly, in (10a), the noun “cup” is incorporated into the verb “to break,” and its possessor “father” is the direct object of the verbal complex.

[other inanimate objects]

- (10) a. *qaj-un*[\$J]un[\$J]u-ta      **alla**[\$G]-ə-n  
 DIM-child-ERG    father-E-ABS.SG

*na-syat-ə-n*  
 LOW.A-break-E-3SG.P[PFV]  
 “The boys broke *father’s* cup.”

In contrast, kinship terms functioning as a possessee are not incorporated. In (11 a), the noun “child” is incorporated into the noun “to scold,” and his mother is the direct object. It is regarded incomprehensible or interpreted as “I scolded my sister for her son.” That is, the action is directed not toward the incorporated noun “child,” but toward the direct object “sister.” In the same manner, (12a) is incomprehensible.

[Kinship terms]

## 4.2. Affectedness

Affectedness—the degree to which an action is transferred to a patient (Hopper and Thompson 1980: 252)—is also related to the occurrence of PR with transitive NI.

All verbs in the abovementioned examples show a high degree of affectedness (“to cut open,” “to tear,” “to kill,” “to break”). On the other hand, the same construction using verbs of lower affectedness is regarded ungrammatical. Compare the following examples:

- (13) \**un*[\$J]*un*[\$J]*u-ta*      *\$/H/ət\$/H/-ə-n*      *\$/G/a-ŋujŋ-ə-la\$/H/u-lin*  
 child-ERG      dog-E-ABS.SG      RES-tail-E-see-RES.3SG.P  
 “The child saw a *dog’s* tail.” (*lit.* the child tail-saw a *dog*)
- (14) *un*[\$J]*un*[\$J]*u-ta*      *\$/H/ət\$/H/-ə-n*      *\$/G/a-ŋujŋ-akmil-lin*  
 child-ERG      dog-E-ABS.SG      RES-tail-clutch-RES.3SG.P  
 “The child clutched a *dog’s* tail.” (*lit.* the child tail-clutch a *dog*)

Example (13), which uses the verb “to see,” is ungrammatical, while (14), which uses the verb “to clutch,” is grammatically correct. The only difference between these sentences is in the verbs used. This shows that the affectedness of the verbs determines the acceptability of PR with transitive NI.

Let us consider some other examples with verbs of lower affectedness. Sentences (15), (16), and (17) are all ungrammatical. However, if we use the verb “to break” in place of each verb, all the sentences are regarded to be grammatical.

That is, “I broke my friend’s pot,” “The child broke the mother’s pot,” and “The child broke the mother’s leg” are all grammatical.

- (15) \**t-ə-kuka-java-n*      *tum\$/G/-ə-tum*  
 1SG.A-E-pot-use-3SG.P[PFV]      friend-E~ABS.SG  
 “I used (my) *friend’s* pot.” (*lit.* I pot-used my *friend*)
- (16) \**un*[\$J]*un*[\$J]*u-ta*      *əlla*      *\$/G/a-senik-ə-ntəmŋiv-lin*  
 child-ERG      mother.ABS.SG      RES-teapot-E-lose-RES.3SG.P  
 “The child lost the *mother’s* teapot.” (*lit.* the child teapot-lost *mother*)
- (17) \**un*[\$J]*un*[\$J]*u-ta*      *əlla*      *\$/G/a-\$/G/ətka-nit\$/Q/ajav-lin*  
 child-ERG      mother.ABS.SG      RES-leg-wet-RES.3SG.P  
 “The child wet the *mother’s* feet.” (*lit.* the child foot-wet *mother*)

The acceptability of verbs with regard to affectedness is shown in Table 1. As we have already seen, the verbs of higher affectedness, “to kill,” “to cut open,” and “to tear,” can be used in PR with transitive NI. However, the verbs of lower affectedness cannot be used in this manner.

Table 1. Acceptability of verbs in PR with transitive NI.

Affectedness	Verbs	Acceptability
High	tm/nm- ‘kill’	A
	svi- ‘cut’	A
	-rra- ‘cut open’	A
	m̩la- ‘break’	A
	s̩ŋa- ‘break’	A
	simav- ‘tear’	A
	j̩[G]u- ‘bite’	A
	akmit- ‘clutch’	A
	k̩pl- ‘hit’	A
	keŋa- ‘kick’	A
	java- ‘use’	U
	-nit̩[Q]ajav- ‘we t’	U
-ntəm̩ŋiv- ‘lose’	U	
Low	la̩[H]u- ‘see’	U

A: acceptable; U: unacceptable

#### 4.3. Beneficialness of the action

When the action expressed by a verbal complex is beneficial for its direct object, the direct object is not interpreted as a possessor of the incorporated noun, but as a beneficiary of the action. Compare the following two examples:

(18) un̩[J]un̩[J]u-ta      əlla      [G]a-koška-nm-ə-lin  
(=9)

child-ERG      mother.ABS.SG      RES-cat-kill-E-RES.3SG.P

“The child killed *mother’s* cat (*lit.* the child cat-killed *mother*).”

(19) un̩[J]un̩[J]u-ta      əlla[G]-ə-n      [G]a-qura-nm-al-lin

child-ERG father-E-ABS.SG RES-reindeer-kill-SUFF-RES.3SG.P  
 “The child killed reindeers for the *father*.” (*lit.* the child reindeer-killed *father*)

Killing a pet cat is not beneficial for its owner. However, killing reindeers is beneficial because it helps one get reindeer meat and fur that are absolutely imperative for Alutor people. Thus, in (19), the direct object “father” is interpreted as a beneficiary, rather than a possessor, of the incorporated noun “reindeer.” Another related example is given in (20): Here, the direct object “mother” is also interpreted as a beneficiary, rather than a possessor. If we use the verb “to break” in place of the verb “to take, to buy,” the direct object “mother” would be interpreted as a possessor of the incorporated noun “dish.”

(20) *ɲavakka-ta*      *ʃ[G]a-qama-ʃ[Q]akmil-lin*      *alla*  
 daughter-ERG RES-dish-take-RES.3SG.P mother.ABS.SG  
 “The daughter bought a dish for the *mother*.” (*lit.* the daughter dish-took *mother*).

When an incorporated noun refers to a body part, the direct object is interpreted as a possessor. Compare the following two examples: In (21), the incorporated noun “hand” is a body part term; therefore, the direct object of the verbal complex, “child,” is interpreted as the possessor of the “hand.” In contrast, in (22), the incorporated noun “shirt” does not indicate a body part, and the direct object of the verbal complex is interpreted as a beneficiary.

(21) *ʃ[G]əmnan*      *unʃ[J]unʃ[J]u*      *t-ə-mənʃ[G]-ə-nmət-ə-tkə-n*  
 daughter-ERG child.ABS.SG 1SG.A-E-hand-E-wash-E-IPFV-3SG.P  
 “I wash (my) *child’s* hands.” (*lit.* I hand-wash my *child*)  
 (22) *ʃ[G]əmnan*      *unʃ[J]unʃ[J]u*      *t-urvaq-ə-nmət-ə-tkə-n*  
 daughter-ERG child.ABS.SG 1SG.A-E-shirt-E-wash-E-IPFV-3SG.P  
 “I wash the shirt for (my) *child*.” (*lit.* I shirt-wash my *child*)

## 5. Concluding remarks

PR with transitive NI is preferred in the following cases:

- when an incorporated noun and a direct object of a verbal complex exhibit i

inalienable possessive relation (body parts)

- for a verb with a high degree of affectedness

PR interpretation does not occur in the following cases:

- The incorporated noun is a kinship term
- The affectedness of a verb is low
- The action expressed by a verbal complex is beneficial for the direct object

## Language Policy for China's Minorities: Orthography Development for the Yi

David Bradley

La Trobe University, Australia

### 1. The Yi

The Yi nationality of southwestern China is a composite group of nearly eight million people speaking various related languages; a very small number also live in northern Vietnam and northeastern Laos. There are nearly a hundred languages of the Ngwi subgroup of the Burmic or Southeastern branch of Tibeto-Burman (Bradley 1997a, 2007). Of these, over sixty (and probably others still unreported) are spoken by people classified as members of the Yi nationality in China.

The term Yi was introduced in the early 1950s to replace the earlier Chinese term Lolo, now regarded as pejorative; it is said that Chairman Mao himself selected the character now used in Chinese for the Yi nationality, which is homophonous with another character formerly used to refer to groups speaking Dai languages and now classified as Zhuang and Buyi nationality. The nationalities classification was undertaken rather quickly in the mid-1950s, and simply follows the earlier Chinese practice of lumping numerous distinct groups with different languages into larger nationalities.

Four groups within the Yi nationality have distinct logographic traditions, Nosu, Nasu, Nisu and Sani. Like Chinese characters, the original basis of these systems was pictographic, but they subsequently developed into logographic systems by the use of pictographic characters in their phonetic value for homophones, and modifications to distinguish these characters from the original pictographs. Like Chinese, the Ngwi languages do not have affixal morphology and so each character represents a syllable with a meaning.

My term Ngwi is derived from the traditional autonym of many groups speaking Ngwi languages. In these languages, cognates derived from the Tibeto-Burman etymon \*d-ŋul<sup>1</sup> originally meaning 'silver' are used as an autonym, and the etymon \*plu<sup>2</sup> meaning 'white' elsewhere in Tibeto-Burman has generalised to mean 'silver' as well. In the Burmese cognate /ŋwe<sup>22</sup>/ as in other non-Ngwi Burmic or Southeastern Tibeto-Burman languages, the cognates of this etymon reflect the original form and original meaning 'silver'. One of the older Chinese terms for minority groups of the southwest was Man, and there were Bai Man 'White Man' and Wu Man 'black Man' subgroups in what is now Yunnan Province, usually taken to be the ancestors of groups later called Lolo and now Yi; perhaps the descriptive term 'white' here also reflects the Ngwi autonym. The traditional autonym for the Nosu is /ni<sup>21</sup>/, for Nasu it is /nu<sup>21</sup>/ and similar forms, and for the Eastern Yi Sanguie language spoken just west of Kunming city, the autonym remains /sq<sup>21</sup> ŋwe<sup>21</sup>/ or changes in some dialects to /sq<sup>21</sup> ɲε<sup>21</sup>/ (Bradley 2005); we also see the same name and the same Chinese prefix in the Sani autonym /nɪ<sup>21</sup>/, in the second syllable of the autonym of the related Southern Ngwi group Hani and in the autonym Zani found in the traditional songs of the Akha, and so on. Like the Akha, the Nosu, Nasu and Nisu also have newer autonoms; all three literally mean 'black people'.

There is extreme confusion of Chinese names among groups classified as Yi. Hei Yi 'black Yi' often refers to various formerly unassimilated groups, Bai Yi 'white Yi' is a widespread term for formerly partly assimilated groups, and Gan Yi 'dry Yi' refers to various more fully assimilated groups with a lifestyle like that of the Han Chinese majority. Various other colour and descriptive terms are also combined to refer to specific groups, such as Huang Yi 'yellow Yi', Hong Yi 'red Yi', Shui Yi 'water Yi', Shuitian Yi 'irrigated field Yi'

and so on. Among the Nosu, the leading former aristocratic clans are known as ‘black’, while the former non-aristocrat but non-slave clans are known as ‘white’. Some of the most assimilated groups no longer have any remembered autonym other than a general Chinese term such as Bai Yi. Prior to the introduction of the new term Yi in the early 1950s, all these were Lolo: Bai Lolo and so on. Just to confuse matters even further, there is a very large group classified as Yi whose autonym remains Lolo, and another whose autonym is Lalo.

Chinese linguists classify Yi into six major clusters, including Central Yi (Lolo plus a few other languages) and Western Yi (Lalo and some related languages) respectively, neither of which has a traditional writing system. Of the four groups with writing systems, the Nosu are classified as Northern Yi, the Nasu are classified as Eastern Yi, the Nisu are classified as Southern Yi, and the Sani are one of various groups classified as Southeastern Yi. Chinese linguists call the whole Ngwi subgroup of Tibeto-Burman the Yi Branch. Bradley (1979) classified this into Northern, Central, Southern and Southeastern subbranches. The Ngwi languages linguistically classified in the Southern Ngwi subbranch are spoken by people mostly classified as Hani nationality in China. Speakers of languages in the Central Ngwi subbranch include groups classified as Yi such as the Lolo, Lalo and others, as well as all those classified as Lisu and Jinuo, nearly all the Lahu and some of the Nu. Most groups whose languages are within the Northern Ngwi and Southeastern Ngwi subbranches are classified as Yi, but one such group, the Kazhuo of Tonghai, is classified as Mongol.

The Nosu number over 2.3 million people, mostly in the Liangshan Yi Autonomous Prefecture of southwestern Sichuan Province, but also in Ninglang County which is the continuation of the same mountain area in northwestern Yunnan. Since 1950, the Nosu have also spread widely across the rest of northwestern Yunnan. The Nosu are by far the largest group within the Yi nationality, their language is very well maintained among the population and Nosu leaders have frequently proposed that their language should be the standard for all Yi in all provinces of China. This was even agreed at a conference of Yi Studies held in Sichuan five years ago, but has not been implemented. Nosu has an extremely wide range of published research materials, including several dictionaries including bilingual ones such as Mahei et al. (1989) and monolingual ones such as Zhu et al. (1990), as well as numerous grammatical studies, but all are based on the new syllabic writing system, not the older traditional script (see discussion below in 3.1). While quite a lot of text material has been published, much has been edited so that it contains much less variation than was found in real traditional texts, or more often so that it conforms exactly to the new syllabic standard discussed below. One fortunate exception is Vermander (1998). There are still many traditional religious practitioners (hereafter ‘shamans’) who use traditional writing, including some younger ones in some areas, and many mother tongue linguists doing extensive research.

The Nasu are widely scattered across northeastern Yunnan and northwestern Guizhou provinces, and number about one million speakers and many more ethnic group members who do not speak the language. Not all Nasu subgroups have retained a literary tradition; two major clusters which have are in Wuding and Luquan counties just north of Kunming in Yunnan, and in various counties in northwestern Guizhou, notably Bijie and Dafang counties. A large number of traditional Nasu texts in original or edited form with Chinese translation have been published in China in the last twenty years, especially material from Guizhou but also from elsewhere. However, the number of fully literate shamans who can read traditional materials is small and rapidly decreasing, and there are few scholars working on Nasu. Notable dictionaries include Ma et al. (1991) on the Guizhou dialect, Bai et al. (1995) on the Wuding dialect, with further data on the Shuangbai dialect of Nisu as well as Lipo and Lolo, and Zhang et al. (1999) on the Luquan dialect. Apart from the literary dialects of Nasu, there are many other closely related languages classified within Eastern Yi by Chinese linguists.

Nisu or Southern Yi is also rather diverse; in addition to about 800,000 speakers, there are many nonspeaker members of the group. It has a wide range of dialects, with Northern and Southern dialects. Speakers of the northernmost Northern Nisu dialect in Yimen, Jinning, Hongta and northern Eshan counties or districts south of Kunming actually use the autonym Nasu (not to be confused with the Eastern Yi Nasu). The other subdialect of Northern Nisu is spoken in Xinping, Shuangbai, Yuanjiang, Mojiang and Shiping counties. Southern Nisu is spoken in Jianshui, Honghe, Luchun and other counties of south central Yunnan and in Vietnam. The main differences between Northern and Southern Nisu are in the reflexes of \*ak which is /a/ in the Nasu subvariety of Northern Nisu, /i/ in the rest of Northern Nisu, and /iɛ/ in Southern Nisu; also the reflexes of medial \*l clusters in words such as ‘white/silver’, Yang (Forthcoming), and retroflex affricates and fricatives, present in Southern Nisu, allophonically present before back vowels in northernmost Northern Nisu, and absent elsewhere. Traditional literate shamans are found in many of these areas, but their numbers are declining, and relatively few young shamans are being trained in the traditional way. There are also some Nisu scholars and intellectuals who have some literacy in traditional Nisu, but much less complete than that of the older shamans. A few Nisu live in Vietnam where they are known as Lolo; these Nisu had at least one literate shaman when they arrived in Vietnam more than 150 years ago, but by the time French colonial administrators visited in the 1880s, literacy had disappeared and the remaining manuscripts were collected by the French and eventually taken to Paris. A surprisingly large number of Nisu manuscripts is in overseas libraries in France, the UK and elsewhere, partly due to the colonial efforts of the French in southern Yunnan while building a railway from Hanoi to Kunming in the early twentieth century. There is an excellent Northern Nisu dictionary, Pu Zhangkai et al. (2005), which is very comprehensive and makes a systematic attempt to list all alternative forms of characters, and substantial scholarly publication of traditional texts.

Sani is the main speech form of the Yi nationality in Shilin ‘stone forest’ County, formerly known as Lunan but renamed after its major tourist attraction, and is also spoken in a number of surrounding counties by a total of about 120,000 people. The autonym of this group is actually Ni; Sani is a Chinese exonym containing the first syllable ‘sa’ so widespread in Chinese names for Yi groups around Kunming. The Shilin County government promotes the use of traditional Sani logographic characters and research on Sani topics, notably the Ashima and other traditional stories. There are fewer Sani manuscripts overseas, despite the fact that the French Catholic missionary Vial did extensive work on it starting over a hundred years ago. There are two dictionaries, Vial (1909) using a type font with only 450 characters, and Jin et al. (1984) with over 1300 distinct handwritten head entry characters and some alternative forms given. Vial was limited by the availability of a restricted font of Sani characters, while Jin et al., representing a slightly different dialect, shows some of the wide range of additional variant characters actually used.

## 2. Yi Writing Systems

The traditional writing systems were known to and used almost exclusively by shamans for life cycle, divination and healing rituals, keeping historical and genealogical records, and among the Sani for writing traditional semihistorical stories such as the well-known Ashima story. These practitioners are known in the ethnographic literature as *bimo*, from the romanisation of the Nosu word /pi<sup>33</sup> mo<sup>44</sup>/; Nasu /pe<sup>55</sup>/, Nisu /pu<sup>55</sup>/ and Sani /pi<sup>21</sup>/ are cognate with the first syllable of the Nosu term. While these four writing systems are ultimately related, they differ greatly.

The original orientation of all four systems was most likely similar to Chinese: written from top to bottom. Most Nasu texts are written starting at the top right. The Nosu are relatively recent arrivals in Sichuan, having come from the east and thus across the upper

Yangtse River from the adjacent Nasu area of northeastern Yunnan only a few hundred years ago. At some point, the Nosu started to turn their texts 90 degrees counterclockwise, and now read them from left to right starting at the top. This means that Nosu characters are rotated 90 degrees counterclockwise, when compared to the characters of the other three traditions. Both Nisu and Sani are written starting at the top left.

Traditional books are hand-written on handmade paper, bound into books with handmade cloth covers, and usually stored rolled. Traditionally, each shaman would train a son or nephew to succeed him, and the successor would recopy all of the books of his mentor, and as many other books as he could find. All literate shamans were men; female religious healing practitioners did not use writing. There is also a small corpus of inscriptions on stone or on bronze bells, of hotly debated dates but probably no more than 600 years old. Some Yi scholars claim a 6000 year history for Yi writing, antedating Chinese, but this is implausible. The principle of logographic writing and the form of some Yi characters clearly derive from Chinese. The Chinese were a major force in the Yunnan area for over two millennia, long before any surviving datable Yi inscriptions.

It is easy to distinguish Nisu and Nasu manuscripts, because after each line of five, seven or however many syllables, there is a dividing mark (to mark the pause in chanting). The Nisu dividing mark is an equilateral triangle resting on one base, with a horizontal line going to the left from the top. This is often filled in in red, while the rest of the text is in black. The Nasu dividing mark is a small circle at the bottom right or left of the last character in a line, out of alignment with the characters. A similar mark is sometimes used in Sani, but the form of many Sani characters is quite different, so a limited familiarity with some basic frequent characters suffices to distinguish these. The manuscripts usually have section titles written horizontally in a colophon above the beginning of each section; thus a Nosu manuscript has the title and the text reading in the same direction, while the other three traditions have the text reading vertically but the titles reading horizontally, most often left to right. The end of each section of a Nisu manuscript is marked by an equilateral triangle standing on its apex, with ornamental lines, sometimes partly in red, radiating downward. Sections are also sometimes separated from the following section by a black line. Some Nisu manuscripts have ruled borders and even ruled lines between vertical columns of text. Manuscripts often contain pictures, and the orientation of the pictures also shows which way the text is to be read and thus whether it is Nosu or one of the other three.

A partial exception is seen in some divination books, which may have full-page illustrations upside down facing the text, so that the person whose fortune is being told can see the picture while the shaman reads the text. These books typically have an even number of pages, 24 to 60 (and reportedly up to a maximum of 70, though no book of this size is currently known). Each page of these divination books has an attached string with a copper coin at the end; the person chooses a coin, and the shaman then reads relevant parts of that page to the person. Such books are fairly widespread among the Nisu where they are known as Baileshu, less frequently found among the Nasu, and not used by the Nosu and Sani; two collections of the illustrations from these divination books have recently been published: Zhang (2003) and Pu Xuewang et al. (2005); our translation of two such divination books in European libraries is forthcoming.

Books are sometimes dated, usually according to the Chinese emperor and the year of his reign in which the book was first written or when it was copied. It is said that the older style of ritual text has five syllables per line, while the newer style has seven, and indeed many of the texts with seven-syllable lines are recognisably derived from Chinese models, though usually still several hundred years old.

Due to the mode of transmission, the forms of the characters within each major tradition show substantial internal differences. Unlike Chinese, there has never been an

education system spreading and standardising these scripts. Also, as the shamans made their living by chanting texts, there was a desire to keep the texts as opaque as possible. For this reason, many frequent words have multiple alternative written forms. These are usually edited out of recently published materials, but not always.

In all four traditions, the texts have been transmitted for many generations by recopying, and so textual differences have developed. Also, various parts of the text can still be read phonetically but are ambiguous or impossible to understand, so even the most knowledgeable shamans cannot explain everything.

A local variant of the Nasu script has been used in some scholarly publications in Guangxi, where there are some Yi, especially in Longlin County in the northwestern corner. Nasu script has also been learned by a few shamans speaking other languages: there is a Sanguie shaman just west of Kunming who uses it for his Eastern Yi language, there were formerly some Samei shamans who used it to write their Eastern Yi language spoken just east of Kunming, and there are still a few Azhe shamans in Mile County southeast of Kunming who use it for their Southeastern Ngwi language. It is also reported that some Lolo who speak a Central Ngwi language but were in contact with Nasu formerly wrote using this orthography. Similarly, a few Pula and Muji shamans who speak their own Southeastern Ngwi languages, but are bilingual in Nisu, use Nisu script.

Various other Ngwi groups have retained traditional oral ritual texts which follow the same structural pattern as most Yi ritual texts: pairs of lines with parallel structure and meaning but alternative lexicon, mostly with five or seven syllables and always with an odd number of syllables; there is no requirement for internal rhyme or syllable structure constraints as in some forms of Chinese poetry, but pairs of lines often end with the same grammatical element and thus may rhyme, but this is not necessary. Divination, historical and story texts do not follow this fixed pattern, neither in the various Yi nonritual texts nor in the oral texts of other groups such as the Lisu, Hani and others speaking Ngwi languages but without old writing systems.

### **3. Standardisation of Yi**

Language policy for minority languages in China follows the usual Stalinist model: each nationality in principle has one language, and one standard dialect should be chosen which is a central dialect intelligible to speakers of other dialects, with a large number of speakers who are socially advanced within the group. This one dialect should become the standard for the development or reform of writing, for educational implementation, and for wider use within the society. In China in the 1950s, there was also a push for the use of romanisations instead of traditional orthographies, for Chinese as well as minority languages, but this was dropped at the end of the 1950s.

During the 1950s, there were several attempts to implement romanisations to replace the Yi orthographic traditions. Vestiges of these romanisations survive in libraries around China, but none was ever accepted by any Yi group. It is interesting that indigenous literary traditions which were so restricted in their users and uses up to that time nevertheless were central enough to group identity that community members simply refused to accept these romanisations, intended to smooth the way for learning Chinese through its *pinyin* romanisation.

After the end of the Cultural Revolution and the fall of the Gang of Four in the mid-1970s, there was an explosion of work on minority languages. Firstly, a massive quantity of primary ethnographic and linguistic research material collected in the late 1950s was finally published. Secondly, the shamans who had managed to save their books from the Red Guards brought them out from hiding and started to perform traditional rituals again. Thirdly, a new generation of young scholars and shamans started to be trained. Finally, the new 1982

constitution clearly stated the right of each nationality to maintain and develop its language and culture. Many local governments in minority autonomous areas all over China took full advantage of this liberalisation. In recent years this push has slowed greatly, but local authorities still deploy their traditional culture as a tourist drawcard.

As in some other areas, the imposition of a single standard variety for an entire nationality has not really been attempted for the Yi; each province with a substantial Yi population has followed a different path.

### **3.1 The Nosu Syllabary**

The first and most successful reformed writing system for a Yi language was the Nosu syllabary. Mahei (1985) provides a detailed account of the process of its development, from the perspective of a leader in the process. This syllabary was devised starting in 1974 and was fully approved on 17 December 1980. It selects one of the many alternative variant characters for each of the 819 syllables which occur in the speech of the Central variety of Nosu (also known as Shengza from its autonym) as spoken in Xide County, and uses only that one character, rather than different logographic or variant forms, for every other homophone regardless of meaning. It also adds a diacritic, a semicircle above the mid tone form, to indicate the lower-high sandhi tone found in that local dialect but not previously distinguished in the orthography; there is one additional symbol to indicate that a particular syllable is repeated. Not surprisingly, this syllabary is written from left to right starting at the top, like traditional Nosu script and like modern Chinese.

Thus this orthography is a phonetic syllabary based on one dialect, not a logographic system neutral between dialects. This of course means that speakers of other varieties of Nosu, including Northern Yino and Lindimu and Southern Sondi and Adur, must learn the Central Shengza dialect in order to become literate. As these other Nosu varieties, including the Southern ones not mutually intelligible with Shengza Nosu, have different tone sandhi patterns (Bradley 1997b) and other phonological differences, major lexical differences and some syntactic differences, becoming literate is much easier for the approximately half of the Nosu who speak a Central dialect, including all those in northwestern Yunnan.

Training for teachers of Nosu has long been carried out in the Nosu area at Liangshan University in Xichang and Zhaojue Normal Institute in Zhaojue, and elsewhere at the Southwest University of Nationalities in Chengdu and at the Central University of Nationalities in Beijing. In the early 1980s, the Yunnan Institute of Nationalities brought teachers from Sichuan to teach Nosu to students from northwest Yunnan, but since the mid-1980s Nosu students from Ninglang County have been sent to Sichuan to study Nosu instead. A huge number of monolingual books in Nosu, including textbooks at all levels up to university, original research on Nosu language and society, traditional and modern literature, health, agricultural, political and other materials translated into Nosu from Chinese, magazines, scholarly journals and many other things have been published, starting in draft versions in the late 1970s and since 1980 in really amazing quantity and quality, mostly through the Sichuan Nationalities Press. There is also a newspaper in Nosu, the Liangshan Daily, which started in January 1978 with three issues a month and has been a daily for many years. Initially all Nosu materials were typeset and printed at a plant in Xichang, but now everything is computer-generated and there is a Unicode standard.

Claims of literacy achieved in this Nosu syllabary range up to nearly 100% in the core Shengza areas where it is the local speech, and nearly as high in other Shengza areas with slight dialect differences, such as Yanyuan County where /h/ has merged with /x/. Signs in public places such as train stations, roads, signboards and notice boards throughout Liangshan are bilingual. Many members of other nationalities in Liangshan are also able to speak Nosu: some members of the Tibetan nationality with first languages such as Pumi and

Namuyi and the local Mongol and Naxi with first languages Na and Naxi can speak Nosu in addition to their own language. There are even some Han Chinese and a few foreigners who have learned Nosu and its syllabary.

### **3.2 Nasu Characters**

In Guizhou starting in the early 1980s, the traditional Nasu logographic script was standardised and brought back into use, firstly with literacy primers and textbooks such as Guizhou Nationalities Commission & Guizhou Nationalities Research Institute (1982-83) and Language Office, Guizhou Nationalities Commission (1984) and subsequently with a great deal of traditional text material published by the Guizhou Nationalities Press and by the Sichuan Nationalities Press. This was intended to use the local pronunciation of each area, but with a single standardised set of logographic characters without graphic variation. That is, unlike Sichuan, the Nasu in Guizhou were not expected to learn to use another dialect in order to write, but only to learn a single set of standard characters. This is more analogous to the earlier Chinese situation, in which people used local pronunciation when reading, unlike the modern Chinese situation in which the standard *Putonghua* pronunciation is used for reading throughout China. Modern Nasu in Guizhou is written from left to right starting at the top left, as is modern Chinese, and not like traditional Nasu; even published versions of traditional Nasu books are printed this way.

The dissemination of this Nasu script has been led by the Guizhou Institute of Nationalities, training teachers, scholars and administrators in Nasu from the late 1970s. There is also an institute for Nasu writing at Bijie, which carries out much of the research work, and uses a slightly different standard as seen in Ma et al. (1991). As about half of the Yi nationality in Guizhou, especially younger people, do not speak Nasu or any other kind of Yi, chances for long-term success with this script are lower than in Sichuan.

The dialect differences within Nasu in Guizhou are not too large, but the speech of western Weining County is actually more similar to the speech of many of the Nasu in northeastern Yunnan, and the speech of Pan County in the southeast is much more distinct, though still considered Eastern Yi by Chinese linguists.

### **3.3 Yunnan Reformed Yi**

As we have seen, all four of the traditional Yi writing systems are found in Yunnan. Thus, no one system could be implemented province-wide, unlike Sichuan and Guizhou where the internal linguistic differences between the languages included in the Yi nationality are much less substantial, and only one traditional Yi orthography was present.

In response to this, the Yunnan Nationalities Commission directed its Nationalities Language Commission to create a new composite logographic system. A work group representing the four literary varieties of Yi was set up, and worked from September 1983 to late 1985 creating a completely new composite logographic orthography of over 1600 characters, with some of its characters derived from each of the four established scripts. The Nosu work group member left after one year, and the Nosu component is small. Like modern Nosu and Nasu, Yunnan Reformed Yi is written from left to right starting at the top; unlike Nosu, none of the characters is turned on its side. A conference to report on and discuss this work was held in Kunming in March 1986.

The intention in this Einbau process (Fishman 2006) was to have majority rule: if a single character was used in three of the four scripts, or two out of four with the other two each different from each other, then the majority character was meant to be chosen. Given that Nosu, Nasu and Nisu orthographies are on the whole more similar to each other, and Sani is more distinct, this would have meant relatively few uniquely Sani characters would

have been chosen, so the work group attempted to give Sani characters somewhat greater representation than would have resulted from the majority principle.

Notice that this means that the Yunnan Reformed Yi characters are purely logographic; in principle they cannot be used in their phonetic value, as they have no inherent phonetic value. Each is meant to be pronounced according to local speech; thus it is also suitable for Yi areas where there was no traditional script, such as in western Yunnan among the Lolo and Lalo, or where there are speakers of more than one type of Yi; or for that matter where children do not speak Yi, and can be taught some variety using the materials provided.

The first stage was approved for implementation at the province level in February 1987. Over a further two years, the work group devised an additional 600 logographic characters and a syllabary to represent borrowed words or words for which there is no logographic character available. Initially, provincial Nationality Affairs Commission subsidies were available for educational implementation of the system in schools, and various textbooks were prepared. A literacy volume had the largest print run, with 6,000 copies printed in August 1991 from hand-written characters (Yunnan Nationalities Language Commission & Yunnan Reformed Yi Work Group 1991). A revised edition of 5,000 copies using a computer font for both Yi and Chinese came out in May 1997 (Yunnan Nationalities Language Commission & Yunnan Reformed Yi Work Group 1997) and an expanded edition (Bi et al. 2000) came out in December 2000 in a print run of 10,000. The total printing of 21,000 copies over ten years for a group with nearly five million people in the province shows how limited the actual implementation has been; if anything, the print runs exaggerate the extent of use, as in each case the new printing was made to improve the earlier edition, before that had been sold out.

There was a serious attempt by Zhang Chunde of the Yunnan Institute of Nationalities to implement this script. He led and taught a two-year program for Yi cadres from all over Yunnan, with a few from other provinces, to learn it; this included participants from groups with and without traditional writing, and also trained participants in the Nosu script from Sichuan. Over a number of years, Zhang also taught Yunnan Reformed Yi to students of the Yi language class in the Yunnan Institute of Nationalities, using his own Luquan Nasu as the model pronunciation; students were also trained in phonetics so that they could represent their own speech and relate it to the characters. Since he retired at the end of 2001, this training has stopped. Another centre for learning this script was in Chuxiong, the capital of the only Yi autonomous prefecture in Yunnan, at the Chuxiong Normal Institute; it is claimed that this has produced 340 qualified teachers since 1987. Since most Yi in Chuxiong either have no tradition of literacy or are Nasu and prefer traditional Nasu script, teaching has not been well-received (Cao 2001). In the Honghe Hani and Yi Autonomous Prefecture in southern Yunnan, a six-month class for teaching this script was held in 1989 with 36 of 74 participants passing, and six teacher training classes were run between 1991 and 1998 with 208 teachers trained. This was implemented during the 1990s in seven preschools and twenty primary schools (Liang 2001), but has now lapsed.

The Yunnan Reformed Yi writing system has encountered very serious problems. Some Yi in Yunnan Province, including some in areas with languages other than the four having orthographic traditions, have started to use the Yunnan Reformed Yi script for symbolic purposes such as public signs, letterheads and tourist-oriented materials, but its educational implementation has stalled, and authorities in Nisu, Sani and Nasu areas have strong reservations about its use, all preferring their own traditional scripts. Nosu in Ninglang have never switched to it, but continued to use the Sichuan Nosu syllabary.

While the Yunnan Nationalities Press continues to publish materials in Yunnan Reformed Yi, including new primary school textbooks in a province-wide series for all nationalities that have an established orthography, these Yi textbooks are hardly used.

#### 4.4 Traditional Yi

In every area, printed versions of traditional texts are arranged as in modern Chinese; that is, starting at the top and going from left to right. Line breaks in ritual and other similar texts are not represented by the original diacritics, but by starting a new line of text. Nearly all of what is printed also has an introduction in Chinese and a translation of the text into Chinese, sometimes with phonetic transcription of each syllable, word-by-word glosses and extensive footnotes to explain cultural background and other information. Most such books are printed in fairly small press runs and quickly go out of print. Sometimes the publication of a volume is supported by a local government, in which case that government may take almost the entire press run and gradually give it out to visitors, and such books are almost immediately unavailable from the publisher.

In Yunnan, local authorities in the Nisu, Nasu and Sani areas have attempted to document their traditional orthographies and publish materials in traditional characters, usually through the Yunnan Nationalities Press. There is also a lot more material internally published by various universities, teaching institutes and research institutes; in principle this is meant to be for restricted use inside China. Some of this appears years later in openly published editions; for example, Guo & Ding (1984) which eventually became Guo et al. (1993), with very similar content.

The most extensive efforts to teach a traditional system to new shamans have been in the Honghe Yi and Hani Autonomous Prefecture in southern Yunnan. There, many Nisu shamans have taught informal classes since the early 1980s; a more formal program was run in primary schools of one village in Xinping County of Yuxi Prefecture in the mid-1990s, but stopped when funding from the Ford Foundation ran out. Many Nosu shamans in Sichuan also run informal classes, mainly for their male relatives. In addition, extensive study of traditional Nosu, Nasu, Nisu and Sani written materials is carried out by scholars at what are now the Central University of Nationalities, the Southwest University of Nationalities, the Yunnan University of Nationalities and the Guizhou Institute of Nationalities; all of these institutions have also trained many students in traditional scripts.

#### 5. Conclusion

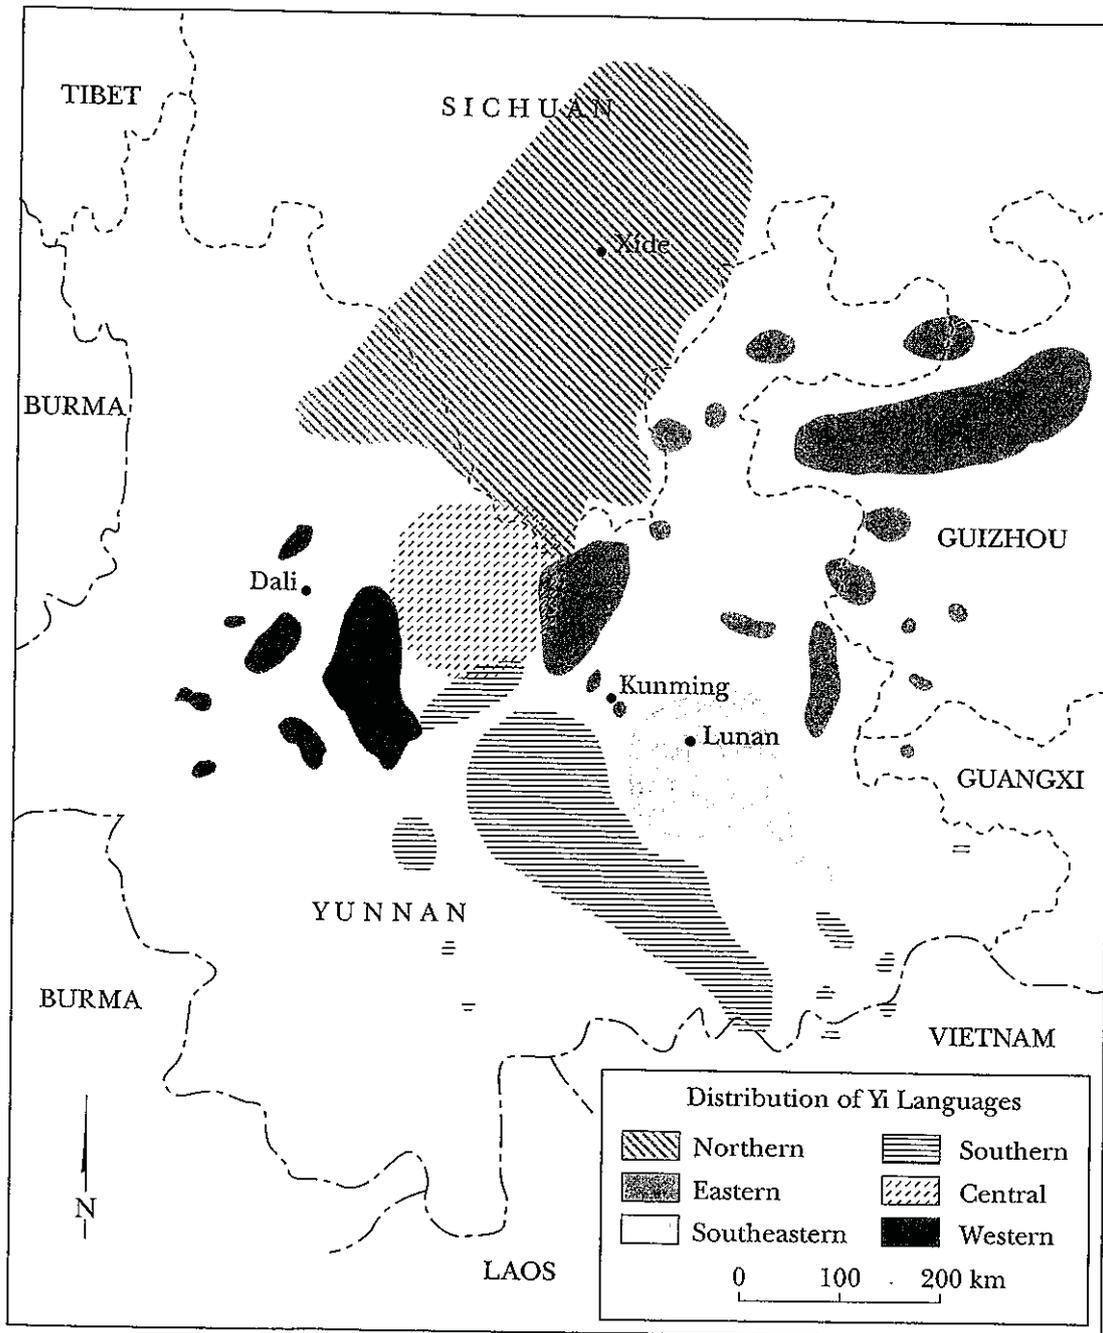

The Yi orthography reforms have been very successful for Nosu in Sichuan, less so for Nasu in Guizhou, and rather unsuccessful in Yunnan. At the same time, efforts are being made to document and preserve traditional written materials, and in some areas to continue to train traditional shamans.

# Discrepancies between Sounds and Graphs in Chinese Characters

Ik-sang Eom

Hanyang University  
Seoul, 133-791, Korea  
[eom@hanyang.ac.kr](mailto:eom@hanyang.ac.kr)

## Abstract

This article attempts to analyze the causes of the irregular readings of Chinese characters both in Madarin and Sino-Korean, Korean pronunciations of Chinese characters. Cultural taboo, avoidance of confusion and residues of historical and/or regional sound change were the main causes for irregular readings in Chinese. Semantic readings, euphony, mismatched palatalization, confusion and erroneous readings were the main reasons in Sino-Korean among many others. This article examines also how well the graph of a Chinese character conveys the sound if it is a phonetic compound, which consists of a phonetic element and a semantic element. It points out that the function of conveying the exact pronunciation of a Chinese character is not so reliable unlike DeFrancis' (1984) claim.

Key Words: discrepancies, sounds, graphs, Chinese, Sino-Korean, characters, erroneous readings, irregular readings, Mandarin

## 1. Introduction

As a writing system, Chinese characters are known as logographic while English and Korean alphabets are phonemic. However, it is merely a misconception that a Chinese character can convey a meaning graphically beyond a few limited examples. Even the most typical examples of pictographs shown in (1) still require one's rich imagination to figure out their exact meanings.

- (1) a. 日            sun  
      b. 月            moon  
      c. 山            mountain  
      d. 木            tree

In that sense, Hannas (1997:109) is right to reject the notion that Chinese characters represent 'ideas' divorced from language. It is similarly erroneous to believe that a Chinese character can convey sound graphically although DeFrancis (1984) emphasizes the phonetic function of Chinese characters over semantic function. He (1984:84) points out that the ratio of phonetic compounds had increased from 34% in the oracle bone period to 97% by the 18th century.

(2)		16-11th C BC	2nd C AD	12th C	18th C
	Non-phonetic (%)	66	18	7	3
	Phonetic (%)	34	82	93	97

So called the phonetic compound, a term which was first coined by Karlgren (1923:16),

refers to a Chinese character that consists of one phonetic element and the other semantic element. The examples in (2) show that phonetic compounds are overwhelmingly the major component of Chinese characters nowadays. It is fortunate that a Chinese character has indicators for its meaning and pronunciation.

What is unfortunate, however, is that the meaning and sound indicators may not function properly all the time. According to DeFrancis (1984:106), the accuracy of phonetic elements in phonetic compounds can be summarized as follows:

- |     |                              |       |
|-----|------------------------------|-------|
| (3) | a. Completely Identical      | 24.6% |
|     | b. Identical except for tone | 17.0% |
|     | c. Partially Identical       | 23.4% |
|     | d. Total                     | 65.0% |

Some examples of (3a-c), quoted from DeFrancis (1984:102-103) with modifications, are as follows:

- |     |          |       |                     |
|-----|----------|-------|---------------------|
| (4) | MM       | SK    | Gloss               |
| a.  | 皇 huang2 | hwang | an emperor          |
|     | 惶 huang2 | hwang | afraid              |
|     | 煌 huang2 | hwang | brilliant           |
|     | 凰 huang2 | hwang | female phoenix      |
| b.  | 馬 ma3    | ma    | a horse             |
|     | 媽 ma1    | ma    | mother              |
|     | 瑪 ma3    | ma    | agate               |
|     | 馮 ma4    | ma    | clamp               |
| c.  | 堯 yao1   | jo    | a legendary emperor |
|     | 驍 xiao1  | hjo   | fine horse          |
|     | 翹 qiao2  | kjo   | tail feather        |
|     | 曉 xiao3  | hjo   | dawn                |
|     | 燒 shao1  | so    | burn                |

The statistics in (3) above demonstrate that only 65% of phonetic compounds are useful as indicators of the proper pronunciations to a certain degree. This means that the remaining 35%, which comprise approximately 34% of all Chinese characters, have no clue for their sounds in their graphs. The percentage of 34-35% takes a considerable portion of the whole Chinese characters, which exceed more than 55,000 in number.

This paper originally planned to explore those phonetic compounds, whose pronunciations are totally different from the readings of their phonetic components. However, since this type of discrepancy was created by historical sound changes, one has to further examine whether the sound change was regular. If it was a systematic change that took place in a group of characters, which had the same pronunciation, it is no longer an irregular change. The *fanqie* is a crucial criterion for determining whether the pronunciation of a character is correct. The *fanqie* was a more analytic and scientific means than earlier methods because the first character of a set of two represented the onset of the character in question, and the second represented the rhyme, such as the

glide, nucleus and coda. Accordingly, this paper will examine the causes of irregular readings of Chinese characters, both in modern Mandarin Chinese and modern Sino-Korean. The emphasis, however, will be on the analysis of Sino-Korean data because of the quantity of the data collected for this study.

## 2. Irregular Readings of Modern Mandarin

### 2.1 Initials

In this paper, PY, OC, MC, FQ, OM, MM and SK stand for pinyin (PY), Old Chinese (OC), Middle Chinese (MC), fanqie of the Guangyun (FQ), Modern Mandarin (MM) and Sino-Korean (SK) respectively. OC and MC reconstructions were cited from Guo (1986) and Li and Zhou (1993), with slight modifications, both of which are based upon Wang Li's reconstructions. For typographical reasons, S, c, Y and E in this article denote the voiceless postalveolar, the voiceless alveolo-palatal fricative, the palatal lateral approximant and the open-mid front vowel respectively. The following characters are examples of irregular readings of Chinese characters in Modern Mandarin:

(5)

CR	PY	OC	*OC	MC	*MC	FQ	OM	MM	Crrt	SK
鳥	niao3	端幽	tiau	端篠開4II效	tieu	都了	niau	niao3	diao3	tSo
秘	mi4	幫質	piet	幫至開3IV 止	pi	兵媚	Pi	pi4/mi4	bi4	pi
溪	xi1	溪支	khie	溪齊開4I蟹	khiei	苦奚	khi	ci1	tc <sup>h</sup> i1	kje
捐	juan1	余元	Yiwan	余仙合3I山	jiwen	與專	iuEn	tcyen1	yan1	jøn
鉛	qian1	余元	Yiwan	余仙合3I山	jiwen	與專	iEn	tc <sup>h</sup> ien1	yan1	jøn

The character for ‘bird’ is *niao3* in Modern Mandarin. It is a unique pronunciation because it cannot have a nasal onset in a historical sense. The modern Sino-Korean reading, co [tSo] is a palatalized form of the Middle Sino-Korean [tjo] (Gweon 2005:374). Since it belonged to the OC and MC alveolar stop initial group, it is supposed to have an alveolar stop [t-]. However, it changed to [niau] in Old Mandarin while other characters which belonged to this initial group remained the same. The reason why was that [tiau] referred to the male sexual organ in some Chinese dialects. This is an example of how taboo caused a change in pronunciation.

The second character in (5) is read as [mi] instead of [bi] as in *mimi* 秘密, ‘secret’ and *mishu* 秘書, ‘secretary.’ The bilabial nasal onset in these words has no theoretical basis. The third character *xi1* [ci] 溪 for ‘stream’ had an aspirated velar stop so its palatalized form would be *qi* [tc<sup>h</sup>i]. Both *mi4* and *xi1* are erroneous readings, and I cannot explain the causes of such irregular changes.

The fourth and fifth characters, 捐 and 鉛, should have had the zero initial as in SK. However, they have palatal affricates in MM. Where was the consonantal onset derived from? Qu (2006) presents Li Fangkuei's OC reconstruction of *juan1*, \*grj- as the source of *juan1*. She claims that compilers of rhyme books did not record the actual

sound with a velar initial due to the conservative nature of rhyme books. Qu might be right but her claim stands on the premise that Li's reconstruction is colloquial while Wang Li's reconstruction is literary. Since it is not certain such a premise can be accepted, it is still questionable whether the character in question had a velar onset during the OC period. Qu presents the *Hebing zixue bianyun pianlan* (1606) as the first book which recorded the *fanqie* of *juan1* as 居然. It indicates that the character *juan1* acquired a velar onset in some dialects for unknown reasons and changed to a palatalized affricate later on. The character for *qian1*, meaning 'lead,' had the same pronunciation as *juan1* until OM, so the same explanation could be given for this character. These characters seem to be the historical and/or regional residues of sound change.

## 2.2 Finals

The only example at hand is the character for 'cancer.' It is ai2 癌 in MM while it is am in SK. The OC, MC and OM are uncertain.

(6)

CR	PY	OC	*OC	MC	*MC	FQ	OM	MM	Crrt	SK
癌	ai2			疑咸開2I咸				ai2	jEn2	am

In the *Mathew's Chinese-English Dictionary* (1931, 1943) this character is listed only under yen2, which is the same as yan2 in *pinyin* system. In the *Xinhua zidian* (1990 edition) it is listed only under ai2. This indicates that the standard pronunciation has been officially changed in recent years on purpose. Considering SK am and SJ kan, yan2 ought to be the correct pronunciation. If so, why did they change it to an incorrect sound? According to Liu Zemin (2008 personal communication), yan2 for 'cancer' can be easily confused with yan2 炎 for 'inflammation.' It makes sense not to make 'inflammation' 炎症 easily confused with 'cancer' 癌症 for both patients and doctors. This is an example of how a pronunciation has been artificially changed for a practical reason.

## 3. Irregular Readings of Sino-Korean

### 3.1 Initials

There are many more examples of irregular readings in SK although SK demonstrates considerably similar correspondence with Chinese, MC in particular. There were internal changes within the domain of SK but they underwent very systematic changes. Accordingly, it is not so difficult to discover irregular readings although the lists below, of course, are not complete or exhaustive. In his article, the palatalized alveolar stop and the open back vowel are denoted as T and A for typographical convenience.

(7) Koreanized Readings

CROC	*OC	MC	*MC	FQ	MM	SK	Crrct	
串	昌元	Thiwan	昌線合3III山	tchiwEn	尺絹	chuan4	tShən/kot	tShən
寧	泥耕	nieŋ	泥青開4I梗	nieŋ	奴丁	ning2	(n/r)jəŋ	(n)jəŋ
拏	泥魚	neA	泥麻開2I假	na	女加	na	na/ra	Na
異	余職	Yiək	余志開3去止	jiə	羊吏	yi4	i/ri	i

The first character is a very rare example of semantic reading of SK at present, as is used in *Jeongotgyo* or *Salgoji dari*, which is an old stone bridge near Hanyang University (See the picture below). Chuan4 means ‘to string together.’ SK kot(<kkot) is the stem of the Korean verb equivalent to chuan4.

(8) *Jeongotgyo*

Ning2 for ‘peaceful’ is read yeong word initially. It changes to nyeong after a consonant or to ryeong after a vowel at a non-word initial position as in *Changnyeong* 昌寧 and *Euiryeong* 宜寧. The r- onset in SK, however, has no theoretical basis at all because the character never has had an r- onset throughout the history of Chinese.

What is interpreted as so called ‘euphony’ has no Chinese background either. The la sound in *Halla-san* 漢拏山 and the ri in *Chiri-san* 智異山 have nothing to do with Chinese pronunciations. The former has an n- onset and the latter has no onset in Chinese.

Data (9) presents some examples of mis-matched palatalization between Mandarin and Sino-Korean. In the following tables, D and O denote the voiced palatalized alveolar stop and the rounded open-mid back vowel respectively:

(9) Mis-matched Palatalization

CROC	*OC	MC	*MC	FQ	MM	SK	
丁	端耕	Tieŋ	端青開4I梗	tieŋ	當經	ding1	tSəŋ
店	端談	Tiam	端木忝開4III咸	tiem	都念	TiEn4	tSəm
卓	端藥	teauk	知覺開2IV江	TOk	竹角	zhuo1	thak
撞	定東	deoŋ	澄絳開2III江	DOŋ	直絳	zhuang4	taŋ
濁	丁屋	deok	澄覺開2IV江	DOk	直角	zhuo2	thak
宅	定鐸	deAk	澄陌開2IV梗	DAk	瑒伯	zhai2	thEk

As was reported in Eom (2000, 2003), Chinese and Korean underwent totally

different paths for palatalization. MC palatalized or retroflex stops changed to palatal affricates while MC alveolar stops remain unchanged in Chinese. On the other hand, MC palatal of retroflex stops of grade 3 and alveolar stops of grade 4 changed to affricates while most of MC alveolar and palatal stops of grades 1 and 2 remained unchanged in SK. This caused great discrepancies between MM and Modern SK. The examples shown in data (8) are all irregular sounds from a Chinese perspective. For typographical reasons, X and Z are used to denote the voiced velar and alveolo-palatal fricatives in this article.

(10) Confused Readings with Similar Characters with Identical Elements

The SK readings in (10) are the most commonly found errors. It is predictable that the Korean people tend to guess the pronunciation of a character from the seemingly phonetic component. The SK readings of the characters in the right-most column seem to have triggered such erroneous readings. These examples, the largest in number, demonstrate that how risky to solely rely on the phonetic element of a phonetic compound to pronounce it correctly.

(11) Erroneous Readings of the Characters with Multiple Readings

CR	OC	*OC	MC	*MC	FQ	MM	SK	errct	Meaning
行	匣陽	XAn	匣唐開1I宕	XAn	胡郎	hang2	hEn	han	a store
行	匣陽	XeAn	匣庚開2I梗	XAn	戶庚	xing2	hEn	hjəŋ	to go
便	並元	bian	並線開3IV山	biEn	婢面	bian4	phjən	pjən	convenient

便	並元	bian	並仙開3I山	biEn	房連	pian2	pjən	phjən	cheap
豸	定支	die	澄蟹開2II蟹	Dai	宅買	zhi4	t(S)hE		lgndry animal
豸	定支	die	澄紙開3II止	Die	池爾	zhi4	tShi		legless insect

The three characters in (11) had different *fanqie* in MC depending on meaning. The distinctions, however, were not made clearly in SK. *Eunhaeng*, 銀行 ‘bank,’ should be read as *eunhang* in SK. However, SK does not make such distinction at all as one can see in *Yuhan yanghaeng*, 柳韓洋行 a pharmaceutical company and *juhaeng*, 走行 ‘running.’

SK usage of the second character is clear as is shown in (12):

- (12) a. [phən]: 便安 便利 便宜 方便  
 b. [pjən]: 大便 小便

However, such distinction is not identical in Chinese, where *pianyi* has an aspirated ph- while others have an unaspirated p-.

The last character, zhi4, has one pronunciation in MM but has two different meanings: one is a legendary animal that eats fire, the other is a feetless insect. MC differentiated its pronunciation depending on the meaning, the former Dai and the later Die. Such distinctions were well preserved in SK but SK pronunciations are problematic. It became a keen issue because Seoul Metropolitan Government announced “Haechi” as the new symbol of Seoul in 2008 (See the picture below). “Haechi” means an insect without feet. If the Seoul Metropolitan Government meant the legendary animal of which stone statues are often found in front of a palace or an entrance of a city in Korea, it should be called “Haetae” or “Haeche.”

(13) The New Mascot of Seoul

As the *fanqie* of zhi4 豸 indicates, this character belonged to the *zhi* 知 series of grade 2. More than 70% of these characters did not undergo palatalization in the pre-modern Korean period (Eom 2000:227, 2003:210). Accordingly, it is mostly provable and correct to read it “Haetae [hEthE].” It was recorded as [thi] for the insect in the *Sinjeung ryuhap* (1576) (Gweon 2005:430). According to Nam (1995:563), Middle SK dictionaries list it as [chi] and [chai] since the eighteenth century.

(14) Erroneous Readings for Other Various Reasons

CR	OC	*OC	MC	*MC	FQ	MM	SK	crct	rmks
畜	曉覺	xiauk	曉屋合3IV通	xiuk	許竹	xu4	chuk	hok	MM
畜	透覺	thiuk	徹屋合3IV通	Thiuk	丑六	0	chuk	chuk	SK
畜	透幽	thiu	徹宥開3III流	Thiəu	丑救	0	chu	chu	
旭	曉覺	xiauk	曉燭合3IV通	xiwok	許玉	xu4	uk	hok	
丑	透幽	thiəu	徹有開3III流	Thiəu	敕九	chou3	chuk/chu	chu	
革	見職		見麥開2IV梗	kæ k	古核	ge2	hjak	kjak	
姬	見之		見之開3I止	kiə	居之	ji1	hli	ki	
系	匣錫		匣霽開4III蟹	Xiei	胡計	xi4	kje	hje	
頤	匣質	Xiet	匣屑開4IV山	Xiet	胡結	jie2	kil/hil	hil	頤頤
輒	端葉		知葉開3IV咸	TiEp	陟葉	zhe2	tShəp	tSəp	asp
陟	端職		知職開3IV曾	Tiək	竹力	zhi1	tShək	tSək	asp

The first character, xu4 should be read as hok [hok] in SK instead of chuk [tShuk] if following MC. However, the SK pronunciation is not basis. This character had two additional pronunciations in OC and MC, as shown in (14). SK followed the second *fanqie* while MM followed the first *fanqie*. At this point, it is not certain if there were differences in meanings and why they took different paths.

The second character, xu4 should not be [uk] but [huk] in SK if strictly following the *fanqie*. It is not certain why this character acquired the zero initial since Middle SK. The third character, chou3, has two readings in SK, chuk and chu. The consonantal coda of chuk has no basis from a Chinese perspective because it has been an open syllable throughout the history of Chinese. It might be a trace of Old SK, of which coda system was under the process of development. One may refer to Eom (1999:39) for detailed discussion.

The following four characters demonstrate interchange between h- and k-. The initial aspiration on the last two characters is without basis. I will not discuss this issue further because mismatch in aspiration is not a rare phenomenon between Chinese and SK.

### 3.2 Finals

It is not easy to generalize the causes for the erroneous readings in SK finals. One apparent tendency is a preference of a low vowel [a] over a high front vowel [i], as shown in (15):

#### (15) High Vowel → Low Vowel

CR	OC	*OC	MC	*MC	FQ	MM	SK	crct
蔘	山侵	Siəm	山侵開3I深	Siem	所今	shen1	sam	sim
師	山脂	Siei	山脂開3I止	Si	疏夷	shi1	sa	si
寺	邪之	ziə	邪志開3IV止	ziə	詳吏	si4	sa	si
私	心脂	Siei	心脂開3I止	si	息夷	si1	sa	si
四	心質	Siet	心至開3去止	si	息利	si4	sa	si

士	崇之	dZiə	崇止開3III止	dZiə	鉏里	shi4	sa	si
子	精之	tsiə	精止開3II止	tsiə	卽里	zi3	tSa	si
雌	清支	tshie	清支開3I止	tshie	此移	ci1	tSa	tS(h)i

It is interesting to note that a high front vowel in Chinese changed to a low vowel in the above examples of SK.

There are some additional examples that demonstrate vowel lowering in SK. The following table (16), which are based upon Daesan (1940:8), also presents a variety of vowel mismatches between Chinese and SK:

(16) Vowel Lowering

CR	OC	*OC	MC	*MC	FQ	MM	SK	errct
魅	明物	miət	明至開3IV至	mi	明秘	mei4	Me	mi
畏	影微	iwəi	影未合3III止	iwe	於胃	wei4	∅	wi
母	明之	Mə	明厚開1II流	məu	莫厚	mu3	Mo	mu
乞	溪物	khiət	溪迄開3IV臻	khiət	去訖	Qi3	kəl	kɪl
阮	疑元	ŋiwan	疑阮合3III山	ŋiwan	盧遠	ruan3	wan	wən

What follows are counter examples, which I quoted from Daesan (1940:8) and Yang Seuk(2008 personal communication):

(17) Vowel Raising

CR	OC	*OC	MC	*MC	FQ	MM	SK	errct
繡	幫蒸	pəŋ	幫耕開2I梗	pəŋ	北萌	beng1	puŋ	pjəŋ
諸	章魚	TiA	章魚開3I遇	tcio	章魚	zhu1	tSe/tSə	tSə

Over all, it seems to be apparent that SK preferred lower vowels for the reasons that I cannot figure out at this point.

#### 4. Conclusion

This paper attempted to present the causes of the irregular readings in Chinese and Sino-Korean. In Chinese cases, cultural taboo, avoidance of confusion, and possibly residues of historical and/or regional sound change were the main causes for the irregular readings. These factors, however, did not trigger the irregular readings of SK. A variety of reasons caused the irregular readings in SK. They include semantic readings, euphony, mismatched palatalization, confused readings of phonetic elements or similar characters, erroneous readings of the characters with multiple readings, a tendency for vowel lowering and, of course, unknown reasons. Among these, the most critical reason turned out to be the confused readings with similar characters with identical elements. This fact demonstrates that the function of conveying the exact pronunciation of a phonetic compound is not so reliable unlike DeFrancis' expectation. The results of this study can eventually shed light on the mechanisms of discrepancies

between sounds and graphs both in Chinese and Sino-Korean although the current study was limited in that sense due to insufficient data.

# The Nurigeul Writing System for Preliterate Chepang

In Bean Lim

Department of Linguistics, Korea University  
Anam-dong, Sungbuk-gu, Seoul, Korea  
inbean75@korea.ac.kr

## Abstract

In this paper, the phonemic system of Chepang is analyzed and the Nurigeul writing system for Chepang is proposed. There are two needs for literacy. The first is a strong need for an easier writing system. The other is the chance for formal education. Nurigeul is a writing system that is easy to learn and teach. It fits perfectly for the purpose of spreading a new writing system. A font for Chepang is provided for the use on a computer. Education of teachers to spread the writing system must continue; for this purpose, reading materials should be prepared. Different methodologies that can be used in temporary education organizations like night study groups and Hangul schools are also proposed.

**Keywords:** Chepang, Aspiration, Nurigeul, Hangul, writing system

## 1. Introduction

The purpose of this study is to establish the phonemic system of Chepang, a preliterate language used in Nepal, and to point out unsatisfactory points in the phonemic system proposed by Caughley (1969).

Chepang is a language used by a minority tribe living in Nepal, representing one of endangered languages without proper writing system. The Chepang tribe lives in high mountainous regions located in Chitwan province, Nepal. The population is about 130 thousands, an approximate number in that they rarely register new-born babies. People of Chepang started living in mountainous regions in their efforts to escape from epidemic diseases and invasion of the Arian and they still live in the same region even after the dangers of Malaria or the Arian disappeared. Due to this reason, they were able to maintain their unique characteristics as a minority tribe.

They earn a livelihood by the gathering and the slash-and-burn field agriculture; most of them do not receive public education. Population growth seems rapid as they usually marry in their late 10's and have babies without birth controls. Most of males are able to use both Chepang

and Nepali language while females usually use only Chepang. Illiteracy rate is over 95% for females and over 80% for males (Panta 2005).

Chepang belongs to the Tibeto-Burman language family. It lacks retroflexed stops and affricates, which are common in Nepali and Hindi. It also lacks double articulation phonemes and nasal vowels. Instead, however, Chepang is distinguished from Nepali in that it has glottal stops.

## 2. Previous Research

Caughley(1969) provides a list of phonemes in Chepang. In his paper, names of palatal and glottal sounds are not listed as shown in <Table 1>.

<Table 1> The Phonemic System of Chepang (Caughley, 1969)

	<b>Bilabial</b>	<b>Dental</b>		<b>Velar</b>	
<b>Stops</b>	p b	t d		k g	ʔ
<b>Affricates</b>			c j		
<b>Fricatives</b>			s		h
<b>Liquids</b>		r l			
<b>Nasals</b>	m	n		ŋ	
<b>Non-syllabic Vocoids</b>	w		y		
<b>Vowels</b>			i e	ə a	u o

While Caughley acknowledged that Chepang is a Tibeto-Burman language, he did not follow the fourfold stop/affricate system specific to the Tibeto-Burman language family, i.e. voiceless unaspirated, voiceless aspirated, voiced unaspirated, and voiced aspirated sounds. He has done a detailed analysis in other aspects of Chepang, but aspiration of stops and affricates still remains unexplained. He instead treated aspirated stops and affricates as a sequence of stops/affricates plus a /h/ sound.

As aforementioned, the fourfold stop/affricate system is a unique characteristic to the Tibeto-Burman language family. Speakers of Chepang recognize aspirated and unaspirated sounds as different phonemes. It is not a /h/ sound following stop/affricate sounds, but one sound with aspirated/unaspirated characteristics. It seems that the fourfold stop/affricate system exists in this language. Therefore, in the stop/affricate system of Chepang, aspirated sounds act as phonemes.

### 3. Research Process

In order to analyze the phonemic system of Chepang, we visited the residential zones of Chepang four times, from February, 2004 through August, 2007. In each visit, the duration of stay ranged from a week to a month. In the first visit, basic words and phrases were investigated to see the fourfold system. The second visit was paid to prepare for the analysis of a phonemic system of Chepang by comparison with the phonemes of the Nepali language, along with a phonetic transcription of Chepang.

In the third visit, we investigated the fourfold system out of the sounds of Chepang using words and phrases to identify the sounds which the speaker recognized or failed to recognize as phonemes. In the last visit, we recorded the sounds of Chepang to verify the problems in the previous research, which were found during the third visit, with respect to the stop/affricate system.

We first transcribed the phonetic sounds of Chepang to identify the phonemic structure of the language. While recording, we transcribed the sounds on a notebook by using IPA symbols and later confirmed the transcription results. To this end, native speakers of Chepang and a translator helped us. No one from Chepang was able to speak English, so it was impossible to communicate in English with them. Because many males were able to speak both Chepang and Nepali we hired a Nepali translator who could speak English to communicate with Chepang males.

Later we asked the native speakers to speak in short sentences and transcribed the sounds as precisely as possible. We transcribed all the sounds at the level of the allophone so that we would not accidentally omit phonemes by treating phonemes as allophones. Then later on we differentiated phonemes from allophones.

### 4. Phonemes and Matching Words

We found phonemes and matching words based on phonetic transcription data. Phonemes are found in accordance with the general procedure for phoneme identification used mainly by structural linguistics, focusing on the matching structure of the fourfold system and their free variations. Particularly, we relied heavily on the natural sense of the native speaker of Chepang in this process.

<Table 2> Consonants and Vowels of Chepang and Matching Words<sup>1</sup>

---

<sup>1</sup> To maintain objectivity in the recording, the subjects (3 males and 2 females) were asked to pronounce the words twice. In this way, transcriptions of words were confirmed. Given below are the names and personal information on the subjects.

<2-1> Consonants of Chepang and Matching Words

## <2-2> Vowels of Chepang and Matching Words

Phoneme	1	2	3	4	5	6
ʔə	ʔək̃ (prise up)	ʔəm̃ (decrease)				
ʔa	ʔag̃ <sup>h</sup> (tradition)	ʔapa (father)	ʔama (mother)	ʔal̃ (go)	ʔay (grandmother)	ʔaysayʔ (cucumber)
ʔi	ʔiçi (this small)	ʔihaŋ̃ʔ (here)				
ʔu	ʔum̃ (egg)	ʔuh (that)	ʔus (crop)			
ʔe	ʔeñʔ (sleep)	ʔer (large)				
ʔo	ʔohaŋ̃ʔ (there)	ʔoyk̃ (powder)				

5 matching words are selected for each phoneme and are double-checked to see if the sound is not an allophone. The phonemes and corresponding matching words, transcribed in IPA, are listed in <Table 2>. The phonemes and the corresponding matching words, transcribed narrowly in IPA, are listed along with English meanings.

### 5. Aspirated Sounds of Chepang

Taking a look at the phonemic system of Caughley, we found that he did not distinguish unaspirated sounds from aspirated ones, and that distinctions were made between voiced and voiceless sounds. However, in the structure of Chepang, aspiration is one of the distinctive features and thus aspirated versus unaspirated sounds must be distinguished.

First of all, Chepang speakers are aware that there are fourfold matching pairs in Chepang classified by the qualities of aspiration and voicedness. This fact was confirmed by the interviews with 5 Chepang native speakers in that they all recognized aspirated stops or affricates as independent phonemes.

Second, by observing the minimal pairs of phonemes in Chepang we can see that aspirated sounds are used independently from unaspirated sounds. Table 3 presents an IPA transcription of minimal pairs of stops/affricates and their English meanings.

<Table 3> Minimal Pairs of Chepang Stop/Affricate Structure

	Voiceless		Voiced	
	Unaspirated	Aspirated	Unaspirated	Aspirated
<b>Velars</b>	/kəŋ/ 'earring'	/k <sup>h</sup> əŋ/ 'skin face'	/gəŋ/ 'trough for pigs'	/g <sup>h</sup> əŋ/ 'fall on face'
<b>Palatals</b>	/čə/ 'be pulled'	/č <sup>h</sup> ə/ 'favour'	/ʃəmɰ/ 'prepare tobacco'	/ʃ <sup>h</sup> əmɰ/ 'die away'
<b>Alveolars</b>	/tək/ 'hoe'	/t <sup>h</sup> ək/ 'make hole'	/dəŋ/ 'settle'	/d <sup>h</sup> əŋ/ 'descend'
<b>Bilabials</b>	/pən/ 'bedbug'	/p <sup>h</sup> ən/ 'ritual smoking'	/bəŋʔ/ 'bamboo tube'	/b <sup>h</sup> əŋʔ/ 'burst out'

As we can see in <Table 3>, for each stop/affricate sound there are minimal pairs between aspirated and unaspirated sounds. Therefore, we can argue that aspiration is one of the distinctive features, separating aspirated sounds from unaspirated ones.

Third, <Table 4> below presents the Nepali system of stop/affricate sounds, which belongs to the Tibeto-Burman language family and is closely related to Chepang. The Nepali system of stop/affricate sounds is composed of the fourfold oral sounds, based on the qualities of voicedness and aspiration, and a nasal stop sound. The table is constructed with the help of Mr. Nava Raj Panta,<sup>2</sup> a Nepali student studying in Korea.

---

<sup>2</sup> Nava Raj Panta, 42, Ph.D course student, Kyunghee University, originally from Chitwan, Nepal

<Table 4> The Stop/Affricate System of Nepali language

23 ब ङ	b	bəhadɔɾ	Brave
24 भ ङ	b <sup>h</sup>	b <sup>h</sup> əkəri:	Store
25 म ङ	m	mə	I

Fourth, looking at the transcribed data, the syllabic structure of Chepang is a CVC type with obstructed sounds appearing at the finals. Consonant clusters may appear at the finals, but cannot possibly appear at the onset position. Based on these observations, we can treat an aspirated sound at the onset position as a phoneme, not as a /h/ followed by stop/affricate sounds.

In investigating the phoneme structure of Chepang, we focused mainly on the aspiration structure of stop/affricate sounds, for results of the study, except for this part, are in agreement with those of the previous research by Caughley(1969). As presented in detail above, the aspiration structure of Chepang is not just the matching pairs of voiced vs. voiceless sounds, but the fourfold matching pairs of voiceless unaspirated, voiceless aspirated, voiced unaspirated, and

voiced aspirated sounds. Based on this observation, the correct phonemic system of Chepang, therefore, is presented in <Table 5> below.

<Table 5> The Phonemic System of Chepang

	Bilabial	Alveolar	Palatal	Velar	Glottal
<b>Stops</b>	p b p <sup>h</sup> b <sup>h</sup>	t d t <sup>h</sup> d <sup>h</sup>		k g k <sup>h</sup> g <sup>h</sup>	ʔ
<b>Affricates</b>			č ʃ č <sup>h</sup> ʃ <sup>h</sup>		
<b>Fricatives</b>			s		h
<b>Liquids</b>		r l			
<b>Nasals</b>	m	n		ŋ	
<b>Glides</b>	w		y		
<b>Vowels</b>			i e	ə a	u o

If we compare the stop/affricate system with that of Caughley (1969), the results are shown in <Table 6>.

a	ʔat	one
i	ʔihaŋʔ	here
u	ʔuyhle	formerly
e	ʔewerŋ	still, calm
o	ʔohaŋʔ	there

The far left column in <Table 7> is an alphabetic transcription of the sounds in IPA notation. In the second column from the left are examples in broad transcription, corresponding to the phonemes. In other words, examples are transcribed using the phonemes of Chepang, using IPA. We selected the examples with the corresponding phoneme in the onset position. For vowels, however, we selected the words starting with a glottal stop sound [ʔ], as there is no word starting with a vowel.<sup>3</sup> The last column presents the meanings of the examples.

## 6. Nurigeul Writing System for Chepang

The Nurigeul writing system for Chepang is made based on the Korean alphabet system, Hangul. The writing system is established on the standard list of phonemes. The system does not indicate stress or intonation, for they do not cause changes in meaning, but it does clearly indicate segments. <Table 8> below is the Nurigeul writing system for Chepang.

---

<sup>3</sup> Transcribed data show that glottal stop sounds clearly exist as phonemes, but some Chepang speakers did not recognize the preceding glottal stop sounds as consonants. The relationship between glottal stop sounds and vowels is beyond the scope of this paper and thus is not treated in detail.

<Table 8> The Nurigeul writing system for Chepang

Devanagari Alphabet – Nurigeul for Chepang			
Devanagari Alphabet	Sample words	Meaning	Nurigeul Alphabet
<b>Velars</b>			
1 क क	기하사	see	기
2 ख ख	카하러	can not	ㅋ
3 ग ग	기하	kidney	ㄱ
4 घ घ	기하	hole	ㄱ
5 ङ ङ	하	I	ㅇ
<b>Palatals</b>			
6 च च	차하	saw	ㅈ
7 छ छ	차하	whisper	ㅊ
8 ज ज	자하	mosquito	ㅉ
9 झ झ	자하	hope	ㅊ
<b>Linguals</b>			
10 त त	타하	head	ㄷ
11 थ थ	타하	begin	ㅌ
12 द द	다하	why	ㄸ
13 ध ध	다하	dust	ㄷ
14 न न	나하	you	ㄴ
<b>Bilabials</b>			
15 प प	파하	good	ㅍ
16 फ फ	파하	sky	ㅍ
17 ब ब	바하	stone	ㅂ
18 भ भ	바하	pressure	ㅂ
19 म म	마하	human	ㅁ
<b>Liquids/Lateral</b>			
20 य य	야하	fly	ㅇ
21 र र	라하	shame	ㄹ
22 ल ल	라하	bread	ㄹ
23 व व	와하	walk	ㅇ

Sibilants			
24	स र	ㄱ ㄴ	insect
Glottal			
25	ह ह	ㅎ ㅅ	nausea
Vowels			
1	अ	ㅏ ㅑ	mend
2	आ ɪ	ㅓ ㅕ	Let's go
3	इ ɪ	ㅓ ㅕ	this way
4	ऊ ॊ	ㅗ ㅛ	that way
5	ए ॑	ㅛ ㅜ	here
6	ओ ॑	ㅜ ㅠ	there

Some letters are not found in the Korean writing system. Letters with a small circle at the lower left corner are the voiced sounds of the corresponding voiceless sounds.<sup>4</sup> Also, in contrast to no distinction between ‘r’ and ‘l’ in the Korean alphabet, there is a clear distinction in Vajao and so we used ‘r-ㄹ’ and ‘l-ㄹ’ matching. ‘o’ in Korean has different sounds between the onset position and the coda position. Thus, we used ‘o’ to indicate /ŋ/ instead of ‘o’.

Moreover, for /ʔ/, a glottal stop sound, we used a medieval Korean letter ‘ㅇ’; for ‘y’ and ‘w’ there are no corresponding letters in the Korean alphabet, so we used ‘y’ and ‘w’. These two letters have the qualities of both vowels and consonants; thus we used ‘o’ to denote consonants and ‘j’ and ‘l’ to denote the sound value of each letter.

## 7. Suggestions for the Establishment of the Writing System

The first way that we can support the native speakers of Chepang is to help in designing their keyboard layout to make relevant fonts. It would be helpful for the users to produce documents using Nurigeul, which would in turn promote the use of Nurigeul.

The layout of the keyboard is designed around the current layout of the Roman alphabet and additional letters occupy the empty spaces on the keyboard. Diphthongs, especially, are arranged in the positions of capital letters, i.e., the typing positions of ‘shift+alphabet,’ so that one stroke may produce the diphthongs. <Figure 1> below shows the keyboard layout.

<sup>4</sup> Korean plosive/affricate system does not have voiced sounds.

### Recommended Keyboard Layout for Chepang Font<sup>1</sup>

#### Meaning of the Keys

Shift + Key	
Normal Key	English key Location

Figure 1: Recommended keyboard layout for Chepang Font

The current author designed the letter shapes and keyboard design; font design and production of the program for the computer processing of the Chepang language have been done by Sandoll Communications. When Nurigeul phonemes and sample words for Chepang are complete, we can produce educational materials to teach Nurigeul to users and cultivate teachers of Nurigeul. We may first recruit and educate potential teachers who can later teach the Nurigeul writing system for Chepang to others.

According to the personal experiences of the author from 2004 through 2006, after only 2 to 3 hours of training, using the production principles of Nurigeul, students were able to write simple words such as their names and village names. Among these early students a few grew very comfortable in using Nurigeul alphabets and became teachers who went on to educate others.

Using the indigenous people as teachers of Nurigeul could save effort and money in spreading Nurigeul to the users. Users in the indigenous society prefer to have indigenous teachers as they do not need translators.

One of the ways to help the Chepang people use Nurigeul is to produce and supply books and reading materials. The most welcome reading materials which may please the elders and the leaders of the tribe are traditional fairy tales or materials preserved by oral tradition.

We may first teach children Nurigeul alphabets for the Chepang people and produce reading materials in Nurigeul, displaying them in public places where people might come and read the materials freely. We believe that it would be advantageous for the users of Nurigeul alphabets to have traditional fairy tales, short Biblical stories, and educational materials that

children love. This will eventually influence the eradication of illiteracy and promotion of Nurigeul alphabets.

Traditional Chepang fairy tales have never been translated or published. From the position of the national leaders, it is lamentable for the traditional fairy tales to disappear due to the lack of a writing system. Therefore, preservation of traditional fairy tales would be another reason for the development and spread of the Nurigeul writing system for Chepang.

Hangul was disseminated through Summer Bible School and make-shift night schools for the poor. In this way, we can say that Korean Christianity has prospered through Hangul. Many people got involved in the production and dissemination of the Bible written in Hangul and thus escaped from illiteracy. Likewise, the Nurigeul writing system for Chepang should be provided to eradicate illiteracy through temporary education organizations such as make-shift night schools and churches.

## **8. Conclusion**

In this paper, we investigated the aspirated sounds of Chepang, a language without a proper writing system. Our study is centered around the phonemic system presented by previous research done by Caughley(1969) and proposed an updated version of the structure. We especially looked at the aspiration structure of stop/affricate sounds.

The previous study of Chepang (Caughley, 1969) seems to contain incorrect observations in the stop/affricate system. There are matching structures of phonemes by aspiration quality, which can be explained in several different ways, including speakers' intuition, the structure of syllables, a comparison with the Nepali language that belongs to the same language family, and most importantly the minimal pairs and spectrogram. We showed that minimal pairs exist at the phoneme level in voiced and voiceless stop/affricate sounds. Analysis by spectrogram provides enough evidence that voiced stop/affricate sounds are not a sequence of stop/affricate sounds and a /h/ sound, but form a single phoneme.

In order to analyze the phonemes of Chepang, we transcribed words and sentences and separated phonemes and allophones using the intuition of the speakers. Subsequently, we searched and provided the sample words that include the phonemes for the learners of Chepang to use as education materials.

This paper makes a proposition for Nurigeul as a universal writing system. Nurigeul is so easy to learn and also to teach that it is apt for Nurigeul to be used and remembered as the basic alphabet is shaped after the shapes of speech organs. Moreover, Nurigeul writing provides a one-

to-one relationship between sounds and letters that users can write precisely, without any confusion. For these reasons, we suggest using Nurigeul as the writing system for Chepang.

We also provide keyboard layouts and fonts to be used on computers for the convenience of the users. This is supported by education programs for teachers and the production of educational materials such as traditional fairy tales and reading materials. As an education method, we suggested the use of temporary education organizations such as make-shift night schools or summer schools for the education of the Nurigeul writing system.

# Ambiguity in Homographic *Kanji* and Disambiguation through *Okurigana*

Keisuke Honda

## Abstract

In Japanese, a large number of *kanji* graphemes are homographic at two levels, namely the *morpheme level* and the *word-form level*. They are ambiguous because their intended readings are not predictable from the orthographic representation per se. Previous work has suggested that these graphemes are disambiguated by *okurigana*, i.e. post-*kanji hiragana* graphemes used to phonemically spell out a section of the written word. This paper presents a critical appraisal of the actual effectiveness of the disambiguating function. It is argued that while *okurigana* disambiguate homographic *kanji* fully at the word-form level, their effectiveness is severely limited by several restrictions at the morpheme level.

**Keywords:** Homographic *kanji*, Ambiguity, *Okurigana*, Disambiguation, Effectiveness.

## 1. Introduction

One striking feature of the current Japanese writing system is that it incorporates a large number of homographic *kanji*, i.e. graphemes of the *kanji* script that have several readings.<sup>[1]</sup> These graphemes are inherently ambiguous, since the intended readings are not predictable from the orthographic representation (see section 2). This type of ambiguity can be observed at two levels (Kondō 2005, Honda 2007, in press). At the *morpheme level*, on one hand, a single grapheme may encode several Native Japanese (NJ) morphemes, several Sino-Japanese (SJ) morphemes, or both (1a).<sup>[2]</sup> At the *word-form level*, on the other, a single grapheme may be used for varying forms of inflectional words (1b). As these two levels are not mutually exclusive, *kanji* graphemes can be ambiguous at both levels, with a large number of candidate readings.

- (1) a. 食 → {*tabe-*, *kuw-*, *kuraw-*, *SYOKU*, *ZIKI*}  
b. 食 → {*tabe-ta* ‘eat-PAST’, *tabe-ro* ‘eat-IMP’, *tabe-nai* ‘eat-NEG’, . . . }

Previous work has shown that *okurigana* reduce ambiguity by disambiguating

homographic *kanji* (Hoshina 1949, Hayashi 1977, Kondō 2005, Honda, in press). *Okurigana* are post-*kanji hiragana* graphemes used to spell out inflectional endings and/or a section at the end of various NJ free morphemes and stem morphemes. As most *hiragana* graphemes encode individual morae through biunique correspondences, *okurigana* can be seen as reliable sources of phonemic information. So if they are applied to a homographic *kanji*, and if the phonemic information matches that of only one candidate reading, then this candidate is logically specified as the intended reading (2).<sup>[3]</sup> In this sense, *okurigana* have the potential to disambiguate homographic *kanji*.

(2) ORTH	a. 食	べ	た	b. 食	べ	ろ
TRANSLIT	<i>tabe-</i>	<i>be</i>	<i>ta</i>	<i>tabe-</i>	<i>be</i>	<i>ro</i>
GLOSS	tabe-ta ‘eat-PAST’			tabe-ro ‘eat-IMP’		

At first glance, the disambiguating function of *okurigana* seems to provide an effective solution to the prevalent problem of homography-induced ambiguity. This is particularly true if it is seen from a qualitative perspective, as in the previous studies mentioned above. However, little effort has been made at examining the *actual effectiveness* of this function, that is, the amount of homographic *kanji* that they can really disambiguate. This issue deserves particular attention because if *okurigana* fail to disambiguate many graphemes, a large amount of ambiguity persists in the *kanji* script and, in turn, the Japanese writing system as a whole.

This paper presents a critical appraisal of the actual effectiveness of the disambiguating function of *okurigana* from a quantitative perspective. In section 2, the notions of homographic *kanji* and their ambiguity are elaborated. In section 3, the disambiguating function of *okurigana* is formalised. In section 4, it is argued that this function is subject to various restrictions at the morpheme level. In section 5, a survey of 1,945 official *kanji* graphemes demonstrates that these restrictions limit the effectiveness of morpheme disambiguation to a considerable degree. Finally in section 6, a conclusion is drawn.

## 2. Ambiguity in homographic *kanji*

### 2.1. Homographic *kanji*

Homography is a situation in which a single unit of writing corresponds to two or more units of language (Vance 2002, Rogers 2005). By definition, homographic representations do not change their forms according to the distinctive contrasts existing

between the corresponding linguistic units (Rogers 2005). If, say, an element is added to or deleted from a given representation to express such contrasts graphically, this necessarily creates separate representations and thus resolves homography. Put differently, the constancy of homographic representations implicates that these representations do not point to the intended reading in a graphically distinctive manner.

As has been already mentioned in section 1, *kanji* graphemes can be homographic at two levels. At the morpheme level, many *kanji* graphemes encode multiple NJ morphemes, multiple SJ morphemes, or both. With regards the current official *kanji* inventory *Jōyō Kanji Hyō* (Cabinet 1981a; see section 5.1), 1,249 out of 1,945 graphemes (64%) encode two to 12 morphemes (Nomura 1981).

The prevalence of morpheme-level homography can be ascribed to two historical events that took place in the course of adopting *kanji* into Japanese.<sup>[4]</sup> First, both *kanji* graphemes and their corresponding morphemes were borrowed from various parts of China over a long period of time. As a result, many graphemes came to accommodate an accumulation of morphemes of varying origins (e.g., 食 → *SYOKU*, *ZIKI* ‘eating, food’). Second, *kanji* graphemes were gradually adapted to represent not only the original SJ morphemes (*on*) but also their NJ equivalents (*kun*). In many cases, the graphemes were given a variety of NJ translations, many of which have been preserved in the lexicon of the present-day Japanese (e.g., 食 → *tabe-*, *kuw-*, *kuraw-* ‘eat’).

In addition to the morpheme-level, homography is also found at the word-form level. Japanese has a relatively rich inflectional and derivational morphology, implemented mainly by suffixation. While SJ items are not inflectional, NJ verbs, adjectives and adjectival verbs take a wide range of inflectional suffixes denoting tense, modality, aspect and so forth. These properties are underrepresented in *kanji*, since graphemes remain the same irrespective of the varying word-forms (e.g., 食 → *tabe-ta*, *tabe-ro*, *tabe-nai*, . . .). Regarding the *Jōyō Kanji Hyō*, 1,230 out of the 4,087 official readings (30%) classify as NJ inflectional items (Nomura 1981).

*Kanji* graphemes can be homographic at the morpheme level and the word-form level simultaneously. That is, a single grapheme may encode several morphemes, and some or all of these morphemes may be inflectional. Consequently, many *kanji* graphemes are highly homographic, associated with large sets of candidate readings (3).

- (3) 食 →  $\left\{ \begin{array}{llll} \textit{tabe-} & \textit{kuw-} & \textit{kuraw-} & \textit{SYOKU} \quad \textit{ZIKI} \\ \textit{tabe-ta} & \textit{kuw-ta} & \textit{kuraw-u} & \\ \textit{tabe-ro} & \textit{kuw-e} & \textit{kuraw-e} & \\ \textit{tabe-nai} & \textit{kuw-anai} & \textit{kuraw-anai} & \\ \dots & \dots & \dots & \end{array} \right\}$

## 2.2. Homography-induced ambiguity in kanji

The constancy of homographic representations gives rise to the problem of ambiguity. When units of writing are actually employed in a particular text, they are in principle intended for specific readings. This is also true for homographic representations, irrespective of how many candidate readings they may potentially have. Yet, the intended readings are not predictable from these representations per se, since they are not differentiated from other candidate readings in a graphically distinctive manner. In this sense, homographic representations are *potentially* ambiguous.

To be precise, it is important to observe that not all homographic representations are *actually* ambiguous. For one example, in English <c> has two readings, namely the phonemes /k/ and /s/. As /s/ occurs only when this grapheme is immediately followed by <e>, <i> or <y> (Venezky 1970: 39), the intended reading can be regularly predicted from the adjacent grapheme.<sup>[5]</sup> Contrastively, the intended reading for the English <s> is unpredictable from the orthographic representation: it can be /s/, /z/ or zero, and in many cases the occurrence of each reading is lexically specified (e.g., *virus*, *as*, *corps*) (Venezky 1970: 83). This grapheme is therefore inherently ambiguous, and the intended reading can be accessed only by making reference to individual, lexically specified spelling-to-sound correspondence rules. Following this line of thought, this paper assumes that homographic representations are ambiguous if the intended readings are not regularly predicted from the surrounding orthographic environment.

Viewed in this light, homographic *kanji* graphemes are ambiguous at both morpheme and word-form levels. At the morpheme level, which particular morpheme constitutes the intended reading is lexically specified, and is therefore unpredictable from the orthographic representation. For instance, 海 encodes two distinct morphemes, namely *umi* and *KAI* ‘sea’, both of which are entitled to occur in many words (4). The relative frequency of NJ versus SJ readings is not a useful clue because it differs from grapheme to grapheme. Even though there are some rules of thumb (e.g., ‘SJ is more likely in *kanji-kanji* strings’), they are subject to many counterexamples and fail to offer reliable grounds for prediction (as in (4a)).

- (4) a. 海      蛇                      b. 海      水  
    *umi*    *hebi*                      *KAI*    *SUI*  
    *umi+hebi* ‘sea+snake’      *KAI+SUI* ‘seawater’

The intended word-form is also unpredictable from the information embedded in the orthographic representation. This is simply because the occurrence of a particular word-form is licensed by syntactic, semantic, and other linguistic factors. As the

orthographic representation provides only implicit information about these factors, the word-form must be inferred indirectly from the context.

The prevalence of homographic *kanji* indicates that the *kanji* script incorporates a large amount of ambiguity. This, in turn, implies that the Japanese writing system is potentially highly ambiguous because the *kanji* script constitutes an integral component of this system. In short, the existence of many homographic *kanji* poses a serious threat to the transparency of Japanese text.

### 3. The disambiguating function of *okurigana*

In the literature, it has been suggested that *okurigana* serve to reduce the problem of homography-induced ambiguity at both morpheme and word-form levels.

As has been outlined earlier, *okurigana* are post-*kanji hiragana* graphemes used to spell out inflectional endings and/or a portion of NJ free morphemes and stem morphemes. Current conventions for *okurigana* orthography have been stipulated by a body of official guidelines called *Okurigana no Tsukekata* (Cabinet 1981b). Despite the non-binding nature of these guidelines, the use of *okurigana* is virtually obligatory in both casual and formal writing. Accordingly, *okurigana* should be regarded as an indispensable part of the current Japanese writing system.

When *okurigana* are used for inflectional endings, they are applied to *kanji* graphemes in a way that they spell out all relevant suffixes. As *hiragana* graphemes relate to individual morae quite regularly, this means that *okurigana* assign a unique representation to each distinct word-form, indicating its phonemic form clearly and invariably (Hoshina 1949, Hayashi 1977, Sampson 1985, Coulmas 2003, Kondō 2005, Honda, in press, and many others). This is applicable to all word-forms, even morphologically highly complex words such as *mi-sase-rare-tagar-anai* ‘do not want to be made to see’ (5).

(5) 見 さ せ ら れ た が ら な い  
mi- sa se ra re ta ga ra na i  
mi-sase-rare-tagar-anai ‘see-CAUS-PASS-want-NEG’

Besides, the word-form disambiguation is not only exhaustive but also surface-oriented in terms of the level of abstraction (Honda, in press). In Japanese, there are morphophonological processes collectively known as *onbin*, wherein some stem-final consonants alternate with other segments when concatenated to certain inflectional suffixes. To illustrate, when the stems *kak-* ‘write’, *yom-* ‘read’ and *tor-* ‘take’ are

followed by the past tense suffix *-ta*, they become *kai-*, *yoN-* and *toQ-*, respectively (6a-c).<sup>[6]</sup> In each case, *okurigana* represent the surface phonemic forms rather than the more abstract morphophonemic forms. Based on the exhaustive and surface phonemic representation, the intended word-forms can be regularly predicted from the orthographic representation. This way, *okurigana* disambiguate *kanji* graphemes altogether at the word-form level.

- (6) a. 書 い た      b. 読 ん だ      c. 取 っ た  
*kak- i ta*      *yom- N da*      *tor- Q ta*  
ka[i]-ta ‘write-PAST’      yo[N]-da ‘read-PAST’      to[Q]-ta ‘take-PAST’

Several studies have suggested that *okurigana* also contribute to the disambiguation of *kanji* graphemes at the morpheme level. First, Kaiser (1995) points out that the presence of *okurigana* implicates that the intended reading is NJ: there are orthographic requirements restricting *okurigana* to NJ nominals (see section 4).<sup>[7]</sup> This is illustrated below, where *べ* distinguishes the NJ compound *tabe+mono* ‘food’ (7a) from the near-synonymous SJ compound *SYOKU+MOTU* ‘food’ (7b).

- (7) a. 食 べ 物      b. 食 物  
*tabe- be mono*      *SYOKU MOTU*  
tabe+mono ‘eat+thing’      SYOKU+MOTU ‘eat+thing’

Second, the phonemic information of *okurigana* contributes to a more explicit form of disambiguation. Hoshina (1949) and Hill (1967) point out that when *okurigana* spell out inflectional endings phonemically, they also specify the intended morpheme as well as the intended word-form. Sampson (1985) and Coulmas (2003) provide more specific description with regards the so-called C-verbs. In Japanese, verb stems are divided into two groups, namely those ending with a vowel (V-verbs) and those ending with a consonant (C-verbs). For C-verbs, the convention is that *okurigana* should start from the unit comprising the stem-final consonant and the suffix-initial vowel, which is then followed by the inflectional ending. According to Sampson and Coulmas, this specifies the intended morpheme by spelling out its final consonant. This is exemplified by 歩, which encodes (among others) *aruk-* ‘walk’ (8a) and *ayum-* ‘walk’ (8b).

- (8) a. 歩 く      b. 歩 む  
*aruk- ku*      *ayum- mu*  
aruk-u ‘walk-NON.PAST’      ayum-u ‘walk-NON.PAST’

Honda (2007) points out that the same logic holds for similar cases where *okurigana* repeat a section at the end of morphemes. Within the range of *Okurigana no Tsukekata*, this applies to stems of V-verbs (9a) and many adjectives (9b), as well as various free morphemes such as non-derived adverbs (9c) and conjunctions (9d).

Moreover, in some exceptional cases *okurigana* are also applied to NJ nominals (9e), despite the orthographic requirements mentioned above. For these morphemes, *okurigana* provide partial but reliable phonemic information, which may be utilised for predicting the intended morphemes. It is therefore reasonable to conclude that *okurigana* have the potential to disambiguate homographic *kanji* at the morpheme level.

- |          |                        |              |      |                         |          |      |                   |
|----------|------------------------|--------------|------|-------------------------|----------|------|-------------------|
| (9) a. 食 | べ                      | る            | b. 悲 | し                       | い        | c. 最 | も                 |

|          | tabe-ru ‘eat-NON.PAST’ |              |      | kanasi-i ‘sad-NON.PAST’ |          |      | mottomo ‘most’    |
| d. 且     | つ                      |              | e. 幸 | せ                       |          |      |                   |
|          | <i>katu tu</i>         |              |      | <i>siawase se</i>       |          |      |                   |
|          | katu ‘besides’         |              |      | siawase ‘happiness’     |          |      |                   |

#### 4. Restrictions on morpheme disambiguation

In the previous section, it was shown that *okurigana* disambiguate *kanji* graphemes fully at the word-form level, specifying all word-forms without exception. Contrastively, such perfection cannot be expected for disambiguation at the morpheme level. From a qualitative perspective, *okurigana* certainly provide a vital clue for predicting the intended morpheme (Honda, in print). At the same time, it is also true that morpheme disambiguation is subject to heavy restrictions. As will be discussed below, the existence of these restrictions gives rise to an empirical question about the actual effectiveness of morpheme disambiguation.

Let us start by elaborating on the restrictions which limit the applicability of morpheme disambiguation. These restrictions derive from two orthographic requirements, which have been already mentioned in section 3. The first requirement stipulates that *okurigana* can be added to *kanji* graphemes – no matter they are homographic or non-homographic – only when the intended reading is NJ. In other words, *okurigana* are powerless over SJ items (10a). This is a major drawback because SJ items account for a large proportion of the entire vocabulary.<sup>[8]</sup> Similarly, the second requirement bans the use of *okurigana* for NJ nominals, except for nominal derivatives of inflected words (e.g., 歩む *ayum-u* ‘walk’ → 歩み *ayum-i* ‘progress’) (10b). While *Okurigana no Tsukekata* permits *okurigana* for a small number of non-derived NJ nominals (e.g., 幸せ *siawase* ‘happiness’), these exceptions do not undermine the general principle.

- (10) a. *Okurigana* should not be used for Sino-Japanese items.

- b. *Okurigana* should not be used for NJ non-nominals (ex. nominal derivatives and other exceptions)

Essentially, the orthographic requirements (10a, b) are concerned with the type of readings for which *okurigana* can be used. Three restrictions on the applicability of the morpheme-level restriction are generated when the type factor is combined with another factor, namely the number of candidate readings. First, it follows from (10a) that *okurigana* cannot fully disambiguate homographic *kanji* that encode two or more SJ morphemes, irrespective of the number of NJ morphemes. *Okurigana* cannot specify the intended reading if it is SJ, since they are not applicable to SJ items in general. Consequently, if there are multiple SJ items, and if one of these items constitutes the intended reading, it is unpredictable from the orthographic representation. Thus, the problem of homography-induced ambiguity remains unsolved (11).

- |   |                |             |
|---|----------------|-------------|
| (11) a. 質 → { <i>SITU</i> , <i>SITI</i> } | b. 質           | c. 質        |
|   | <i>SITU</i>    | <i>SITI</i> |
|   | SITU ‘quality’ | SITI ‘pawn’ |

Similarly, it follows from (10b) that *okurigana* cannot fully disambiguate homographic *kanji* that encode two or more NJ nominals, irrespective of the number of SJ items and NJ non-nominals. *Okurigana* are powerless if one of the NJ nominals constitutes the intended reading (12).

- |  |               |             |
|--|---------------|-------------|
| (12) a. 角 → { <i>kado</i> , <i>tuno</i> , ...} | b. 角          | c. 角        |
|  | <i>kado</i>   | <i>tuno</i> |
|  | kado ‘corner’ | tuno ‘horn’ |

By the same token, it follows from (10a) and (10b) that *okurigana* cannot fully disambiguate homographic *kanji* that encode one or more SJ morpheme(s) and one or more NJ nominal(s) at the same time (13).

- |   |               |           |
|---|---------------|-----------|
| (13) a. 印 → { <i>sirusi</i> , <i>IN</i> } | b. 印          | c. 印      |
|   | <i>sirusi</i> | <i>IN</i> |
|   | sirusi ‘mark’ | IN ‘seal’ |

In addition to the three restrictions on applicability, morpheme disambiguation is subject to yet another restriction which limits its sufficiency. In some cases, *okurigana* fail to prevent homographic representations even if they do accompany *kanji* graphemes. Some *kanji-okurigana* combinations produce identical representations in all word-forms (14), while others become homographic in certain word-forms (15). In either case, *okurigana* do not spell out morphemes to the extent that the intended item can be specified invariably.

- (14) a. 開 → {*ak-*, *hirak-*, ...}

- |   |  |
|---|--|
| b. 開            <<br><i>ak-~hirak-</i> <i>ku</i><br><i>ak-u~hirak-u</i> ‘open-NON.PAST’ | c. 開            い た<br><i>ak-~hirak-</i> <i>i</i> <i>ta</i><br><i>ai-ta~hirai-ta</i> ‘open-PAST’ |
|---|--|
- (15) a. 行 → {*ik-*, *okonaw-*, ...}
- |  |  |
|--|--|
| b. 行            <<br><i>ik-</i> <i>ku</i><br><i>ik-u</i> ‘go-NON.PAST’ | b. 行            つ た<br><i>ik-~okonaw-</i> <i>Q</i> <i>ta</i><br><i>iQ-ta</i> ‘go-PAST’~ <i>okonaQ-ta</i> ‘do-PAST’ |
|--|--|

To sum up, morpheme disambiguation does not work on homographic *kanji* which violate any of the Applicability Restrictions (16a-c) or the Sufficiency Restriction (16d). In view of these restrictions, the empirical question arises: How effective is morpheme disambiguation, or, more specifically, what is the proportion of homographic *kanji* that actually qualify for it? In addition, a secondary but equally important question is, which restriction or restrictions constitute(s) the chief obstacle to morpheme disambiguation?

(16) *Kanji* graphemes must not have:

- a. Two or more SJ morphemes;
- b. Two or more NJ nominals (ex. nominal derivatives and other exceptions);
- c. One or more SJ morpheme(s) and one or more NJ nominals (ex. nominal derivatives and other exceptions); or
- d. Two or more morphemes that take identical forms of *okurigana*.

## 5. Survey

### 5.1. Aim

To answer the questions raised in the previous section, the author conducted a survey of *jōyō kanji*, i.e. *kanji* graphemes listed in the official *Jōyō Kanji Hyō* (‘List of Characters for General Use’; Cabinet 1981a). The inventory consists of 1,945 graphemes and 4,087 associated morphemes, which are “recommended” to be used for everyday purposes. Just like *Okurigana no Tsukekata* (Cabinet 1981b; see section 3), *Jōyō Kanji Hyō* has no legal binding power whatsoever. Besides, it is not an exhaustive list of all *kanji* graphemes, even though it covers a large proportion of the graphemes that are currently in use. Nonetheless, the inventory stands out as a de facto standard adopted in official and legal documents, approved textbooks, major dailies and various other publications. It is therefore reasonable to regard the *jōyō kanji* set as representative of the current

*kanji* script.

## 5.2. Material and method

Among the 1,945 *jōyō kanji*, 1,249 graphemes classify as homographic, with the number of associated morphemes ranging from 2 to 12. These graphemes and morphemes were sorted out using a computer-readable database developed by Tamaoka and his colleagues (Tamaoka et al. 2000). This database is prepared in Excel 2000 and can be downloaded from the Oxford Text Archive free of charge (as of October, 2008). It describes various properties of *jōyō kanji* graphemes using 27 variables, such as grapheme structures, associated morphemes, transliterations, English translations, etc. The author downloaded the database in June, 2007, and extracted the relevant data for the present survey.

The accuracy of the data was checked against two hardcopy databases of *jōyō kanji* (Nomura 1981, Kai & Shinozaki 2006). As a result, it was discovered that Tamaoka et al. (2000) incorrectly classified 気 as a grapheme with one NJ and two SJ morphemes. In reality this grapheme encodes only SJ morphemes (*ki* and *ke*), and the database itself does not show the claimed NJ morpheme. Apart from some minor typographic errors, this was the only flaw that came to the author's attention.

After the checking, the data were reorganised to make a 'Check Table'. Using this, the author checked the 1,249 homographic *jōyō kanji* against the four restrictions (16a-d) one by one. Each violation was marked in the Check Table and the total number was counted. As for the Sufficiency Restriction (16d), *kanji* graphemes were judged as violating the restriction if they took identical *okurigana* for two or more morphemes in some or all word-forms. The survey covered all and only those morphemes shown in *Jōyō Kanji Hyō*. This included a number of items specifically marked as "special or of limited use" in the inventory. Strictly speaking, some of these items were in fact not distinct morphemes but allomorphs of the same morpheme.<sup>[9]</sup> Yet, the author treated all items equally, as long as the inventory identified them as separate readings.

A sample of the Check Table is reproduced here as Table 1, which has been partly modified from the original to enhance clarity. Each line consists of an exemplar *kanji*, violations against the restrictions (16a-d), and the morphemes associated with the grapheme in question. Abbreviations are used to denote the four restrictions; see the accompanying note for clarification. The first four lines illustrate violations against the respective restrictions, citing the examples (11), (12), (13) and (14) from section 4. Notice that the second example 角 commits multiple violations: it encodes two NJ

nominals as well as one SJ morpheme. The fifth and sixth lines exemplify cases of non-violation.

The graphemes which did not violate any restriction were identified as qualifying for morpheme disambiguation. Finally, the total number of these graphemes was divided by the total number of homographic *jōyō kanji* (1,249) to calculate their ratio within the entire set.

Table 1. A sample of the Check Table

Kanji	Violations				Associated Morphemes	
	2+ SJ	2+ NJ Nom	1+ SJ & 1+ NJ Nom	Identical	NJ	SJ
質	X				—	<i>SITU, SITI, TI</i>
角		X	X		<i>kado, tuno</i>	<i>KAKU</i>
印			X		<i>sirusi</i>	<i>IN</i>
開				X	<i>ak-, hirak-, ake-, hirake-</i>	<i>KAI</i>
届					<i>todok-, todoke-</i>	—
運					<i>hakob-</i>	<i>UN</i>

NOTE: 2+ SJ = Two or more SJ morphemes (16a); 2+ NJ Nom = Two or more NJ nominals (16b); 1+ SJ & 1+ NJ Nom = One or more SJ morpheme(s) and one or more NJ nominals (16c); Identical = Two or more NJ morphemes that take identical forms of *okurigana* (16d); X = violation.

### 5.3. Results and discussion

The survey brought about the following results.<sup>[10]</sup> Firstly, 569 graphemes were identified as qualifying for morpheme disambiguation. They amounted for only 45.5% of all homographic *jōyō kanji* graphemes. This clearly demonstrates that the effectiveness of morpheme disambiguation is severely limited, so much that the intended morphemes can be specified in less than half of homographic *kanji*.

Secondly, there were 755 cases of violation in total; among these, 728 (96.4%)

were violations against the Applicability Restrictions (16a-c). Recall that these three restrictions are all derived from the same orthographic requirements which prohibit *okurigana* for SJ items and NJ nominals (10a, b). This point has particular significance for the actual effectiveness of morpheme disambiguation in several respects.

To begin with, SJ items count for more than half of all vocabulary items (Miyajima et al. 1987: 60; see fn. 6). In view of this fact, the failure of morpheme disambiguation for SJ items implicates that a considerable amount of graphemes remain ambiguous in actual texts. Second, formal texts (e.g., legal documents, academic materials, etc.) tend to have more SJ items than less formal texts do (e.g., general magazines, light novels, etc.). Again, the prohibition of *okurigana* for SJ items leaves much ambiguity unresolved. To be sure, the learned reader must be able to specify the intended morphemes without much difficulty. However, this by no means alters the amount of ambiguity inherent to these texts. Finally, NJ nominals also occur quite frequently, particularly in casual texts, primary school textbooks and materials intended for a young readership.

In sum, *okurigana* fail to provide a drastic solution to the problem of homography-induced ambiguity at the morpheme level, leaving a significant amount of ambiguity in Japanese texts. Considering the preponderance of *kanji* graphemes and their indispensability, this indicates that a large amount of ambiguity remains unresolved in the current Japanese writing system and their products.

## 6. Concluding remarks

This paper has discussed the problem of ambiguity in homographic *kanji* graphemes and the effectiveness of *okurigana* as a solution to this problem. First, it was shown that many *kanji* graphemes are homographic at the morpheme level and/or the word-form level, and that this causes a potentially large amount of ambiguity. Second, previous work was reviewed to outline the way *okurigana* may disambiguate homographic *kanji* at both levels. Third, it was argued that while disambiguation works out fully at the word-form level, morpheme disambiguation is subject to several heavy restrictions. These restrictions were classified into two types, namely Applicability Restrictions and a Sufficiency Restriction. Finally, a survey of the current official *kanji* inventory demonstrated that these restrictions limit the actual effectiveness of morpheme disambiguation to a considerable degree.

The limited effectiveness of *okurigana* at the morpheme level suggests that

ambiguity remains largely unsettled in the *kanji* script and, by extension, the entire Japanese writing system. Consequently, the task of disambiguating homographic *kanji* is left to the reader's ability to infer the intended morphemes by making reference to lexical knowledge and other extra-orthographic factors. In this respect, the problem of homography-induced ambiguity has a fundamental effect on the operational principle of the current Japanese writing system.

## Notes

\* The author wishes to express his cordial thanks to Prof. Sang-Oak Lee, who chaired the special workshop 'Writing Systems and the Linguistic Structure' at the 18<sup>th</sup> International Congress of Linguists. This paper benefitted greatly from discussions with and comments from many participants in the workshop. Special thanks go to Prof. Stefan Kaiser for his invaluable comments and suggestions.

[1] The current Japanese writing system is a "multiscriptal" system (Smith 1996), substantiated by several scripts that constitute subcomponents of the entire grapheme system. The scripts of particular importance are *kanji* and *hiragana*. Roughly, *kanji* primarily encodes morphemes, and is mainly used to represent Native Japanese and Sino-Japanese lexical elements (free morphemes, stems, roots, etc.). *Hiragana*, on the other hand, encodes morae and is chiefly used for Native non-lexical elements (affixes, particles, postpositions, etc.). Usually both scripts are employed to compose a text, each assigned to the particular linguistic elements just described.

Following Sproat (2000) and Rogers (2005), this paper uses *grapheme* to refer to the basic unit of writing, without committing to the theoretical debate on the appropriateness of this traditional term (Daniels 1991, 1994, Herring 1994a, b). For *kanji*, it is used to denote the so-called *character*, not its *component*.

[2] Throughout this paper, examples are transcribed morphophonemically using the *Kunreisiki* romanisation system (Cabinet 1954), with a few minor modifications. Upper case indicates Sino-Japanese items.

[3] The labels ORTH, TRANSLIT and GLOSS stand for 'orthographic representation', 'transliteration' and 'gloss', respectively. To save space, these labels are omitted in the remainder of this paper.

[4] For more detailed accounts of the historical background written in English, see Miller (1967), Sampson (1985) and Seeley (2000/1991), among others.

[5] Details about the behaviour of this specific grapheme in polygraphs (e.g., *church*)

and loans (e.g., *cello*) is not relevant to the point being made.

[6] Here, the elements shown in square brackets denote the surface phonemic forms.

[7] In contrast, the absence of *okurigana* does not necessarily implicate that the intended reading is SJ: it can be either a SJ item or NJ nominal (Vance 2002).

[8] According to Miyajima et al. (1987: 60), a survey of a general dictionary revealed that 31,839 out of 60,218 headwords (52.9%) classified as SJ. Even though many of these headwords are presumably non-standard or rarely used words, this figure substantiates the predominance of SJ items in the lexicon of the present-day Japanese.

[9] For example, *Jōyo Kanji Hyō* identifies *ame* and *ama* as distinct items associated with 雨 ‘rain’. As a matter of fact, the latter is an allomorph generated by a morphophonological alternation (e.g., *ame* ‘rain’ + *oto* ‘sound’ → *ama+oto*).

[10] For full details of the survey result, see Honda (2007).

# Choice of Voices in Maya Hieroglyphic Writing

**Kosuke Matsukawa**

State University of New York at Albany  
Dep. of Anthropology, SUNY at Albany 1400 Washington Ave., Albany, NY 12222  
km7470@albany.edu

## **Abstract**

Maya hieroglyphic writing was the prestigious writing system of the Maya civilization and had been used mainly during the Classic Period (ca. AD 250-900). In Maya hieroglyphs, three types of voices (active voice, passive voice and mediopassive voice) have been identified until now. These three voices are not used randomly and usually one of the three voices is preferably chosen for each verb. The choice of voices in Maya hieroglyphs seems to be constrained by the contextual nature of texts as historical records and the nature of an agent and a patient. In this paper, I will analyze what kinds of factors constrain the choice of voices in Maya hieroglyphic writing.

**Keywords:** Maya Hieroglyphs, Writing System, Voices, Mayan Languages.

## **1. Introduction**

Maya hieroglyphic writing was the prestigious writing system mainly used during the Classic Period (ca. AD250-900) in the Maya area (Guatemala, Mexico, Honduras and Belize). In Maya hieroglyphs, three types of voices have been identified until now: active voice, passive voice and mediopassive voice (Stuart et al. 1999; Houston et al. 2000). These three identified voices are not used randomly and usually one of the three voices is preferably chosen for each verb.

In the texts of Maya hieroglyphs, usually an important person of a site is the main character of the texts and the texts recount the historical events happened at the site (e.g. birth, accession, death, war, period-ending, capture of a captive, ceremonies, dedication of a building & monument). This contextual nature of the texts as historical records and the nature of an agent and a patient (human vs. non-human & specific vs. non-specific) seem to restrict the choice of voices in Maya hieroglyphs. In this paper, I will show how the three voices are chosen for each verb and analyze what kinds of factors constrain the choice of voices in Maya hieroglyphic writing.

## 2. Voices in Maya Hieroglyphs

Stuart et al. (1999) and Houston et al. (2000) have identified three types of voices in Maya hieroglyphs: active voice, passive voice and mediopassive voice (or -Vy intransitive). In addition to these three types of voices, Kettunen and Helmke (2005) also list an antipassive voice in Maya hieroglyphs. In this section, I will summarize how an active voice, a passive voice, a mediopassive voice and an antipassive voice are represented in Maya hieroglyphs.

### 2.1. Active voice (*transitive verb*)

The active voice of a transitive verb is represented by a *-wa* syllabic sign (syllabogram) in Maya hieroglyphs. The *-wa* syllabic sign is suffixed to a CVC root and CVC-*wa* is phonetically interpreted as CV<sub>1</sub>C-V<sub>1</sub>w. This *-wa* suffix is attached to a verb root in both incomplete and complete aspects.

### 2.2. Passive voice

A passive voice is represented by a *-ja* suffix in Maya hieroglyphs. In an incomplete aspect, *-ja* is suffixed to a CVC root and CVC-*ja* is phonetically interpreted as CV(h)C-*aj*. This *-ja* suffix is interpreted as a morpho-syllable (Stuart et al. 1999) and is read as *-aj* instead of *-ja*.<sup>1</sup> Like modern Ch'olan languages (see 3.2.), probably *h* was infix to a CVC root in Maya hieroglyphs but *h* cannot be represented in the spelling convention of Maya hieroglyphs. In a complete aspect, a passive voice is represented by *-ji-ya* suffixes and CVC-*ji-ya* is phonetically interpreted as CV(h)C-(a)*j-iiy*. In this case, *a* of the passive voice suffix *-aj* cannot be represented in Maya hieroglyphs either.

### 2.3. Mediopassive voice (*-Vy intransitive*)

The third voice in Maya hieroglyphs is a mediopassive voice. This voice is also called a -Vy intransitive verb because the marker for this voice is represented by a -Vy suffix. A syllabic sign *-yi* is used for a mediopassive voice and it is suffixed to a CVC root. In an incomplete aspect, a mediopassive voice is represented as CVC-*yi* and it is phonetically interpreted as CV<sub>1</sub>C-V<sub>1</sub>y. In a complete aspect, a mediopassive voice is represented as CVC-*yi-ya* and it is phonetically interpreted as CV<sub>1</sub>C-V<sub>1</sub>y-*iiy*.

## 2.4. Antipassive voice

Whether Maya hieroglyphs have an antipassive voice or not is still uncertain. Stuart et al. (1999) and Houston et al. (2000) do not list an antipassive voice, but Kettunen and Helmke (2005) list it. According to Kettunen and Helmke (2005:61), a *-wi* syllabic sign is an antipassive voice marker in Maya hieroglyphs and CVC-*wi* is phonetically interpreted as CV<sub>1</sub>C-V<sub>1w</sub>: e.g. *tzutz-uw* (TZUTZ-*wi*) ‘(s/he) finished’.<sup>ii</sup> Kettunen and Helmke (2005:61) also list *-wa(?)* as an antipassive voice marker and CVC-*wa(?)* is phonetically interpreted as CV<sub>1</sub>C-V<sub>1w</sub>: e.g. *chuk-uw* (*chu-ku-wa(?)*) ‘(s/he) captured’.<sup>iii</sup> Kettunen and Helmke (2005) do not mention whether an antipassive voice has different markers for different aspects.

If *-wa* is used as an antipassive voice marker as well as an active transitive marker in Maya hieroglyphs, only difference between an antipassive voice and an active transitive verb is an ergative marker: an antipassive voice does not take an ergative marker and an active transitive verb takes an ergative marker. However, both an ergative marker and the *-wa* suffix are often omitted in Maya hieroglyphs. Therefore, whether the lack of an ergative marker represents the difference between an antipassive voice and an active transitive verb in Maya hieroglyphs is questionable. Besides, antipassive voice markers in modern Ch’olan languages are different from -V<sub>1w</sub> (see 3.4.). Therefore, whether *-wi* and *-wa(?)* are antipassive voice markers in Maya hieroglyphs is still uncertain. Even if *-wi* and *-wa(?)* are antipassive voice markers in Maya hieroglyphs, their distribution is very limited and they will not affect the main argument in this paper.

The identified voices in Maya hieroglyphs are summarized below (see Figure 1).

	<b>Incomplete</b>	<b>Complete</b>
<b>Active (Transitive)</b>	CV <sub>1</sub> C-V <sub>1w</sub> (CVC-wa)	CV <sub>1</sub> C-V <sub>1w</sub> (CVC-wa)
<b>Passive</b>	CV(h)C- <i>aj</i> (CVC- <i>ja</i> )	CV(h)C-( <i>a</i> ) <i>j-iiy</i> (CVC- <i>ji-ya</i> )
<b>Mediopassive</b>	CV <sub>1</sub> C-V <sub>1y</sub> (CVC- <i>yi</i> )	CV <sub>1</sub> C-V <sub>1y-iiy</sub> (CVC- <i>yi-ya</i> )

<b>Antipassive?</b>	CV <sub>1</sub> C-V <sub>1</sub> V <sub>1</sub> w?	CV <sub>1</sub> C-V <sub>1</sub> V <sub>1</sub> w?
	(CVC-wi/wa?)?	(CVC-wi/wa?)?

**Figure 1: Voices in Maya Hieroglyphs**

### 3. Voices in Modern Ch'olan Languages

Ch'olan languages are composed of four languages (Ch'olti', Ch'orti', Chontal and Ch'ol) and subclassified into Eastern Ch'olan languages (Ch'olti' and Ch'orti') and Western Ch'olan languages (Chontal and Ch'ol).<sup>iv</sup> Stuart et al. (1999) and Houston et al. (2000) hypothesized that the language of Maya hieroglyphs was most similar to the proto-language of Eastern Ch'olan languages, which they named Classic Ch'olti'an. Mora-Marín (2004) hypothesized that the language of Maya hieroglyphs was closer to Proto-Ch'olan than Classic Ch'olti'an. Although which hypothesis is better is still under debate, it seems doubtless that a kind of a proto-language of Ch'olan languages was the language of Maya hieroglyphs. In this section, I will show how the four voices are represented in modern Ch'olan languages and analyze whether the markers for the identified voices in Maya hieroglyphs can be linguistically reconstructed based on modern Ch'olan languages.

#### 3.1. Active voice (transitive verb)

An active transitive verb takes a status maker after a CVC root in modern Ch'olan languages (see Figure 2).

#### (Incompletive Aspect)

<b>Ch'olti':</b>	CVC-V <sub>1</sub>
<b>Ch'orti':</b>	CVC-i/-e
<b>Chontal:</b>	CVC-e'
<b>Ch'ol:</b>	CVC-∅

#### (Completive Aspect)

<b>Ch'olti':</b>	CVC-V <sub>1</sub>
------------------	--------------------

<b>Ch’olti’:</b>	CVC-i/-e
<b>Chontal:</b>	CVC-i
<b>Ch’ol:</b>	CVC-V <sub>1</sub>

(Kaufman and Norman 1984:100)

### Figure 2: Active Transitive Voice Markers in Ch’olan Languages

In Ch’olti’ (in both aspects) and Ch’ol (in a completive aspect), a status marker for an active transitive verb is represented by a harmonic vowel -V<sub>1</sub>. Although the active transitive verb marker in Maya hieroglyphs is -V<sub>1</sub>w, it seems likely that w of -V<sub>1</sub>w had been lost in Proto-Ch’olan and -V<sub>1</sub> became more specifically -i/-e in Ch’orti’ and Chontal.

#### 3.2. Passive voice

A passive voice in modern Ch’olan languages are represented as follows (see Figure 3).<sup>v</sup>

<b>Ch’olti’:</b>	CVjC-a	
<b>Ch’orti’:</b>	CVjC-a	
<b>Chontal:</b>	CVC-k	(Knowles 1984:142-144)
<b>Ch’ol:</b>	CVjC (when a final consonant is a non-fricative)	

(Kaufman and Norman 1984:107-109)

### Figure 3: Passive Voice Markers in Ch’olan Languages

Although Eastern Ch’olan languages (Ch’olti’ and Ch’orti’) do not have j after a passive voice suffix -a, it seems likely that j of -aj in Maya hieroglyphs was lost in Eastern Ch’olan languages or at the stage of Proto-Ch’olan. Both Ch’olti’ and Ch’orti’ retain a j infix.<sup>vi</sup> In Ch’ol, the passive voice suffix -aj was lost but the j infix is retained. Although data on a passive voice in Chontal are unavailable in Kaufman and Norman (1984), Knowles (1984) lists -k as a passive voice marker in Chontal. Since the passive voice marker in Chontal is different from those in other Ch’olan languages and the j infix does not exist in Chontal, the -k passive voice marker seems to be an innovation in

Chontal.

### 3.3. Mediopassive voice

Although Kaufman and Norman (1984) do not list mediopassive voice markers in Ch'olan languages, MacLeod (2004) lists those in Ch'olan languages (see Figure 4).

#### (Incompletive Aspect)

<b>Ch'olti':</b>	-el / -p-a(h)-el / -k'-a(h)-el	
<b>Ch'orti':</b>	-p-a / -k'-a	
<b>Chontal:</b>	m-a-n	-Vl (in Acalan Chontal)
<b>Ch'ol:</b>	CVjC-el	

#### (Completive Aspect)

<b>Ch'olti':</b>	-p-a / -k'-a	
<b>Ch'orti':</b>	-p-a / -k'-a	
<b>Chontal:</b>	m-i	-p-i (in Acalan Chontal)
<b>Ch'ol:</b>	CVjC-i(y)	

(MacLeod 2004)

**Figure 4: Mediopassive Voice Markers in Ch'olan Languages**

Although CVjC-i(y) in Ch'ol (in a completive aspect) is similar to the -V<sub>1</sub>y suffix in Maya hieroglyphs, other mediopassive voice markers in modern Ch'olan languages are different from -V<sub>1</sub>y. Houston et al. (2000:332) proposed that the -V<sub>1</sub>y suffix had derived from a positional verb marker -\*V<sub>1</sub>l and an intransitive positional marker -\*er in Common Mayan (see Figure 5).

<b>Common Mayan</b>	-*V <sub>1</sub> l (positional), -*er (intransitive positional)
<b>Common Wasteko-Ch'olan</b>	-*V <sub>1</sub> y (intransitive positional)
<b>Common Ch'olan</b>	-*V <sub>1</sub> y (intransitive positional)
<b>PreClassic Ch'olti'an</b>	-*V <sub>1</sub> y (passive)
<b>Classic Ch'olti'an</b>	-V <sub>1</sub> y (mediopassive)

(Houston et al. 2000:332)

### **Figure 5: Origin of Mediopassive Voice Markers in Maya Hieroglyphs**

According to their hypothesis, a positional verb marker  $-*V_1l$  and an intransitive positional marker  $-*er$  in Common Mayan were merged into a  $-*V_{1y}$  intransitive positional marker in Common Wasteko-Ch'olan. Then, the  $-*V_{1y}$  intransitive positional marker was functionally sifted to a passive voice maker in PreClassic Ch'olti'an and it became a mediopassive voice marker in Classic Ch'olti'an (language of Maya hieroglyphs). However, their hypothesis is still suspicious and more historical linguistics analysis is necessary to clarify the origin of the  $-V_{1y}$  mediopassive voice marker in Maya hieroglyphs.

#### *3.4. Antipassive voice*

Although neither Kaufman and Norman (1984) nor MacLeod (2004) list an antipassive voice marker, Knowles (1984) lists an antipassive voice marker in Chontal. According to Knowles (1984:150), an antipassive voice in Chontal is represented by an  $-n$  suffix. In Ch'ol, an antipassive voice marker is an  $-oñ$  suffix (Coon 2004:45). In Ch'orti', an antipassive voice marker is a  $-san$  suffix (Martinez 1994:72). Since antipassive voice markers in modern Ch'olan languages are different from  $-V_{1w}$ , the antipassive voice marker  $-V_{1w}$  in Maya hieroglyphs is suspicious.

### **4. Choice of Voices in Maya Hieroglyphs<sup>vii</sup>**

In this section, I will show how the identified three voices (active voice, passive voice and mediopassive voice) are actually used for each verb in Maya hieroglyphs. The data on Maya hieroglyphs are from the sculptured monuments (e.g. stelae, altars, lintels, plates, tablets, hieroglyphic stairways, zoomorphs, thrones, slabs) of most of the major Maya sites (e.g. Aguateca, Caracol, Copan, Dos Pilas, Naranjo, Palenque, Piedras Negras, Quirigua, Seibal, Tikal, Tonina, Yaxchilan) and some other minor sites. The following eleven verbs will be analyzed in this section: *chok* ('to throw/scatter'), *ch'am* ('to grasp/receive'), *chuk* ('to seize/grasp/capture'), *muk* ('to bury'), *naw* ('to adorn'), *jub'* ('to take down/bring down'), *pul* ('to burn'), *k'a'* ('to terminate'), *k'al* ('to

bind/tie/wrap’), *tz’ap* (‘to plant upright’) and *tzutz* (‘to end/finish/terminate’). Since the existence of the *-wi* and *-wa(?)* antipassive markers is still uncertain, an antipassive voice is not included in the analysis bellow.

#### 4.1. *Chok*

The verb *chok* means ‘to throw/scatter’ and is usually used with *ch’aj* (‘drops of liquid’). Although *chok* is used in a passive voice on the Stela F of Quirigua, *chok* is usually used in an active voice (see Table 1). In many cases, an ergative marker and *-wa* are not written. Without *-wa*, *chok* might be treated as a nominalized verb (‘throwing/scattering’). In Table 1, *chok* without an ergative marker or *-wa* is not included.

#### 4.2. *Ch'am*

The verb *ch'am* means 'to grasp/receive' and is usually used with *k'awiil* (name of a deity) or a specific name of a scepter. *Ch'am* is always used in an active voice (see Table 2). However, an ergative marker and *-wa* are not written in many cases. Without *-wa*, *ch'am* might be treated as a nominalized verb ('grasping/receiving'). In Table 2, *ch'am* without an ergative marker or *-wa* is not included.

4.9. Other verbs (*k'al*, *tz'ap* & *tzutz*)

Although other verbs like *k'al* ('to bind/tie/wrap'), *tz'ap* ('to plant upright') and *tzutz* ('to end/finish/terminate') are used in two or three voices, they also show some preference (see Table 9). *K'al* is usually used with *tun* ('year/stone') or (*sak*) *jun* ('(white) headband').<sup>viii</sup> Although *k'al* is used in a passive voice on the Palace Tablet of Palenque and the Box of Tortuguero, *k'al* is usually used in an active voice. An ergative marker and the active transitive marker *-wa* are not written in many cases. In Table 9, only samples with both an ergative marker and *-wa* are counted and *k'al* without an ergative marker or *-wa* is not included. *Tz'ap* expresses the erection of a stela/monument. *Tz'ap* is usually used in a passive voice but sometimes *tz'ap* is used in an active voice too. *Tzutz* means 'to end/finish/terminate' and is usually used to express the termination of a period (e.g. *b'aktun*, *k'atun*, *tun*).<sup>ix</sup> *Tzutz* is usually used in a mediopassive voice, but sometimes it is also used in an active voice or a passive voice.

**5. Analysis of the Data**

Judging from the data in the previous section, each voice does not seem to be chosen randomly for each verb and usually one of the three voices is preferably used for each verb. In this section I will analyze why one of the three voices is preferably chosen for each verb and discuss whether it is possible to make generalization for the choice of voices in Maya hieroglyphs.

According to the data in the previous section, *chok* ('to throw/scatter'), *ch'am*

(‘to grasp/receive’) and *k’al* (‘to bind/tie/wrap’) are usually used in an active voice. The agent of these verbs is an important person and a patient is a non-human. More specifically, patients are drops of liquid for *chok*, *k’awiil* or a specific name of a scepter for *ch’am* and a year/stone or a (white) headband for *k’al*. Since an agent is more important than a patient in these contexts, the choice of an active voice seems to be reasonable. The verb *yak* (‘to give’) is similar to *chok*, *ch’am* and *k’al*. *Yak* is usually used in an active voice. Since an agent is an important person and a patient is a specific thing given by the person, the choice of an active voice seems to be reasonable too.

The verbs *muk* (‘to bury’), *naw* (‘to adorn’) and *chuk* (‘to seize/grasp/capture’) are usually used in a passive voice. With *muk* and *naw*, a patient is an important person and probably an agent is a person (or persons) who buried or adorned the patient. Since an agent is an unidentified person (or persons) and a patient is a specific person, the choice of a passive voice seems to be reasonable.

In the case of the verb *chuk*, usually both an agent and a patient are mentioned in a text and both of them are important persons: a captor is an important person of the site and a captive is an important person from other site. Since an agent is obviously more important than a patient in this context, an active voice seems to be more preferable to a passive voice. However, a passive voice is usually chosen in this context. Since a patient is more emphasized than an agent in a passive voice, the choice of a passive voice seems to be somewhat odd in this context.

Although *tz’ap* (‘to plant upright’) is preferably used in a passive voice, sometimes it can be used in an active voice too. An agent is a non-specific person (or persons) who built a stela/monument and a patient is the stela/monument. Since an agent is uncertain (might be a ruler) and the stela/monument is a specific thing on which the text is carved, the choice of a passive voice might be reasonable. In an active transitive sentence, the agent who built a stela/monument is clarified (usually a ruler) and the agent is more emphasized.

The verbs *jub’* (‘to take down/bring down’), *pul* (‘to burn’), *k’a’* (‘to terminate’) and *tzutz* (‘to end/finish/terminate’) are usually used in a mediopassive voice. Both *jub’* and *pul* metaphorically imply a war event. Probably, an agent is an unidentified person or a site itself and a patient is a specific site or place. *K’a’* is used with *sak nik ’ik’-il* (‘white flower soul’) and metaphorically expresses the death of a person. Although a deceased person is mentioned in a text, an agent who terminated a white flower soul is uncertain because of the metaphoric nature of the text (might be a deceased person). In the case of *tzutz*, an agent is uncertain (might be a ruler) and a patient is a period of time (e.g. *b’aktun*, *k’atun*, *tun*). The verb *tab’* (‘to rise up/ascend/present’) expresses the

dedication of a building and is usually used in a mediopassive voice too. An agent is a non-specific person (or persons) and a patient is a specific building. Since an agent is a non-specific person (or persons) or non-human and a patient is a specific non-human (site/place, period of time, white flower soul, building) with these verbs, the choice of a mediopassive voice seems to be reasonable.

Based on these analyses, it seems possible to make generalization for the choice of voices in Maya hieroglyphs. When an agent is a specific person and a patient is a non-human, an active voice is preferred: e.g. *chok*, *ch'am*, *k'al*, *yak*. When a patient is a specific person and an agent is a non-specific person, a passive voice is chosen: e.g. *muk*, *naw*. When both an agent and a patient are specific persons, a passive voice is preferred for some reason: e.g. *chuk*. When an agent is a non-specific person or non-human and a patient is a non-human, a mediopassive voice is chosen: e.g. *jub'*, *pul*, *k'a'*, *tzutz*, *tab'*.

As a result, the following generalization for the choice of voices based on the nature of an agent and a patient (human vs. non-human & specific vs. non-specific) can be made in Maya hieroglyphs (see Table 10).

	<b>(Patient)</b>	<b>Specific Person</b>	<b>Non-human /Non-specific Person</b>
<b>(Agent)</b>			
<b>Specific Person</b>		Passive	Active
<b>Non-human /Non-specific Person</b>		Passive	Mediopassive

**Table 10: Generalization for the Choice of Voices in Maya Hieroglyphs**

Usually, the texts of Maya hieroglyphs recount the life history of an important person of a site (e.g. birth, accession, death) or historical events happened at the site (e.g. war, period-ending, capture of a captive, ceremonies, dedication of a building & monument). Therefore, the main character of a text is usually an important person of the site. Because of this contextual nature, the choice of voices seems to be highly constrained by the nature of an agent and a patient (human vs. non-human & specific vs. non-specific) in Maya hieroglyphs. In the case of *tz'ap*, *tz'ap* is most preferably used in a passive voice. Since usually an agent is a non-specific person and a patient is a non-human (stela/monument), *tz'ap* does not follow the generalization (following the generalization, *tz'ap* should be in a mediopassive voice). Therefore, the generalization is not absolute and sometimes different contextual factors or constraints may override this

generalization.

## 6. Conclusion

In Maya hieroglyphs, three types of voices (active voice, passive voice and mediopassive voice) have been identified until now (e.g. Stuart et al. 1999; Houston et al. 2000). The active voice of a transitive verb is represented by  $-V_1w$  in both incomplete and complete aspects. A passive voice is represented by  $-aj$  in an incomplete aspect and  $-(a)j-iiy$  in a complete aspect. A mediopassive voice is represented by  $-V_1y$  in an incomplete aspect and by  $-V_1y-iiy$  in a complete aspect. Although Kettunen and Helmke (2005) list an antipassive voice marker in Maya hieroglyphs, whether  $-V_1w$  is actually an antipassive marker or not is still uncertain.

Among the identified three voices in Maya hieroglyphs, an active transitive voice marker and a passive voice marker seem to be reconstructible based on the data on modern Ch'olan languages. Although Houston et al. (2000) proposed that a mediopassive voice marker  $-V_1y$  in Maya hieroglyphs had derived from a positional verb marker  $-*V_1l$  and an intransitive positional marker  $-*er$  in Common Mayan, their analysis is suspicious and more detailed historical linguistics analysis is necessary.

In this paper, I analyzed the choice of the three identified voices for eleven verbs (*chok*, *ch'am*, *chuk*, *muk*, *naw*, *jub'*, *pul*, *k'a'*, *k'al*, *tz'ap* and *tzutz*) in Maya hieroglyphs. As a result, each voice is not chosen randomly for each verb and usually one of the three voices is preferably used for each verb. The choice of voices seems to be mainly constrained by the nature of an agent and a patient (human vs. non-human & specific vs. non-specific). When an agent is a specific person and a patient is a non-human, an active voice is preferred: e.g. *chok*, *ch'am*, *k'al*, *yak*. When a patient is a specific person and an agent is a non-specific person, a passive voice is chosen: e.g. *muk*, *naw*. When both an agent and a patient are specific persons, a passive voice is preferred for some reason: e.g. *chuk*. When an agent is a non-specific person or non-human and a patient is a non-human, a mediopassive voice is chosen: e.g. *jub'*, *pul*, *k'a'*, *tzutz*, *tab'*.

Thus, the nature of an agent and a patient seems to constrain the choice of voices in Maya hieroglyphs and the generalization using human vs. non-human and specific vs. non-specific (see Table 10) seems to explain the choices of voices in Maya hieroglyphs. However, the generalization is not absolute and may be overridden by other contextual factors or constraints (e.g. *tz'ap*). Although Maya hieroglyphic writing is not as eloquent as the writing systems of modern languages, sometimes the contextual nature of a

writing system may influence and constrain its grammatical structure like Maya hieroglyphic writing.

---

<sup>i</sup> Morph-syllables are represented by the same glyphs as syllabic signs but morpho-syllables are read as VC instead of CV: e.g. *-aj*, *-il*, *-ib'* (Stuart et al. 1999).

<sup>ii</sup> Although Kettunen and Helmke (2005:61) interpret *TZUTZ-wi* as *tzutz-uuw* ('s/he finished'), they interpret *chu-ku-wa* as *chuk-uw* ('s/he captured'). Therefore, the vowel length of  $V_1w$  is inconsistent. For consistency, I chose the short vowel variant  $-V_1w$  here because the vowel of the active transitive marker  $-V_1w$  is also treated as a short vowel with the same *-wa* suffix.

<sup>iii</sup> Since Kettunen and Helmke (2005:61) put a question mark after *-wa*, *-wa* as an antipassive voice marker seems to be still uncertain for them.

<sup>iv</sup> Ch'olti' is a deceased language.

<sup>v</sup> Although Ch'olti', Ch'orti' and Ch'ol have a few other passive voice markers too, I list only passive voice markers most closely related to the decipherment of a passive voice in Maya hieroglyphs.

<sup>vi</sup> In Maya hieroglyphs and Proto-Ch'olan, the /j/ infix was /\*h/. Although both /\*h/ and /\*j/ can be reconstructed in Proto-Ch'olan (Kaufman and Norman 1984), /\*h/ and /\*j/ were merged into one phoneme /j/ in modern Ch'olan languages.

<sup>vii</sup> In the data on Maya hieroglyphs, the following abbreviations are used: Alt. = altar, COM = completive aspect, Frag. = fragment, INC = incompletive aspect, HS = hieroglyphic stairways, L. = lintel, M. = monument, St. = stela, T = temple, Thr. = throne, Zo. = zoomorph.

<sup>viii</sup> Sometimes, *k'al* is used with *may* ('deer hoof'). Since the meaning of the phrase *k'al may* is uncertain, *k'al* with *may* is not included in the data.

<sup>ix</sup> *B'aktun*, *k'atun* and *tun* correspond to 144,000 days, 7,200 days and 360 days respectively.

# The Emblematic Script of the Aztec Codices as a Particular Semiotic Type of Writing System

Ludmila L. Fedorova

Institute of Linguistics, Russian State University for Humanities

Moscow

[lfvoux@yandex.ru](mailto:lfvoux@yandex.ru)

## Abstract

Aztec manuscripts give examples of an early stage of phonetic writing used for inscriptions in the whole frame of textogram representing an event. The inscriptions have the character of emblems, where pictorial images have phonetic meaning. This type of writing may be called Emblematic script – a stage in the morphosyllabic writing. Among the factors constraining the development of the script the language structure factor should be noted. It may be the polysynthetism of the structure of the Nahuatl language, which allowed long series of syllables within an incorporative complex. An emblem with its restricted number of positions might not have had technical resolution for guarding the strict order in such a long file as a predicative phrase, so only name phrases could be written.

**Keywords:** Aztec script, Emblematic writing, textogram, polysynthetism.

## 1. The Phoneticism of the Aztec Script

### 1.1. Did the Aztecs have phonographic writing?

It is generally accepted that Aztec codices represent a transitional stage from pictography to phonography, to morphosyllabic writing, or, rather, a stage of ideography with the rudiments of phonography. Already the first investigator of Aztec manuscripts Joseph Aubin, in 1849, gave examples of syllabic spellings of personal names (*itz-co-atl*, *mo-cauah-zo-ma*) and the place name Teocaltitlan (*te-o-cal-tlan*, with the omission of syllable *-ti-*).

These examples could not convince the majority of scientists that there was an Aztec tradition of elaborated phonography.

Nevertheless in the 20<sup>th</sup> century the idea of a developed phoneticism of Aztec script was seconded by Nickolson (Nickolson 1973) and at present by Alphonso

Lacadena (Lacadena 2003). As he shows, place names and personal names mostly have a phonetic transcription: the scribes used not only ideographic, but also syllabic signs, and their combinations, with the main conventions of morphosyllabic writing: rebus substitutions, redundant phonetic indications, pure syllabic spellings. Lacadena also succeeded in showing that in the Aztec script there was a set of syllabic signs, and it was regularly used by the scribes of different local schools. This brought him to the conclusion that the Aztec script in its essential features doesn't differ from other ancient morphosyllabic systems – Sumerian or Egyptian.

Yet most scholars consider the phonological component as minimal and developed under Spanish influence.

### *1.2. Writing tradition in Mesoamerica*

Now after Knorozov's decipherment of the Maya writing and the discovery of Zapotec and Olmec monuments with inscriptions, the ingenious nature of the Mesoamerican writing tradition is out of doubt.

The Aztec script can be regarded in this tradition as one of several coexisting forms: Mixtec, Zapotec, Olmec, Maya. They are all different, but have some shared graphic images. Mixtec may be rather ideographic, Maya is morphosyllabic, Zapotec and Olmec are not deciphered yet, but presumably morphographic.

## **2. The Aztec Script at the Very Beginning of Proper Writing**

### *2.1. The Aztec script as a separate stage in the evolution of writing*

We are inclined to regard the Aztec script as a separate stage in the evolution of writing and as a particular semiotic type, different from ideography and from proper morphosyllabic writing. If we consider pictography and ideography (following Gelb as well as Dyakonov) as Proto-writing, and the consistent phonetic component in the text as the main characteristic of proper writing, then we should assume that the Aztec script must be placed at the very beginning of proper writing. What distinguishes it from the preceding stage, which is represented, e.g., in the Winter Counts and other monuments of North American writing or maybe in the Mixtec manuscripts, is the stable phonetic component.

What distinguishes it from the morphosyllabic stage is the following:

1) The peculiar function of phonetic spelling in the structure of *textogram* (Dyakonov's term): it is subordinate to the pictographic representation of events or descriptive subjects; this is a function comparable to that of a caption;

2) The absence of phonetic spellings of predicate phrases – only of name phrases: place names, personal names;

3) Writing of names in the form of an emblem composed of a restricted number of elements in no strict order (their arrangement could be interpreted logically as well as phonetically);

4) Syncretism of the images: only one symbol could stand for a sequence of two morphemes;

5) The absence of signs for semantic determinators, a function proper to developed morphosyllabic writing.

Yet the use of conventions of morphosyllabic writing and the very fact of a stable tradition of such conventions allow us to consider this script as a peculiar, distinct beginning stage in the evolution of proper writing. We propose naming this type of writing the Emblematic script – because it is the emblem with its compound structure of meaning and graphic combination that is its main unit. This type may be characterized as “writing of inscriptions”, or as “illustrative writing”. Probably this stage is common to historical writing systems. At this stage the picture is prominent and conserves its fascinating power.

These characteristics shall be considered in more detail.

## 2.2. *Function of phonetic signs*

The Aztec codex can be compared to a children's book, where the main content is represented in the picture and the text is only an inscription. In adults' books the proportion is the opposite: the main content is given in the text and the picture is only an illustration, an additional expressive means. The Aztec codex differs from a children's book in the form of signs – as for iconic, so for index signs they are the same.

In Aztec manuscripts pictures accomplish two kinds of functions:

– iconic – representation of events (conquests of towns, births, marriages, deaths of rulers, their feats and so on) or of descriptive subjects (tributes, penalties and so on), on the one hand, and

– indexical (after Pierce) – fixation of their concrete circumstances (dates, locations, titles and names, number of objects).

These two functions are supported with a peculiar structure of the pictorial sign.

### 2.3. Semiotic structure of the Aztec pictorial sign

We can see the semiotic structure of the Aztec pictorial sign in its stages from a picture to a writing sign.

At first it is a visual representation of an object. It may function just as a picture and it may have several interpretations: *Ayotl* – ‘Turtle’, ‘The Place of turtles’.

When the metonymical interpretation becomes generally accepted, the structure of *signatum* becomes more complex: the Word becomes the *signatum* of the 2<sup>nd</sup> level.

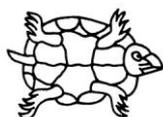

Gradually the word becomes a *signatum* of the 1<sup>st</sup> level, and the object a *signatum* of the 2<sup>nd</sup> level.

At last the connection of the picture with the object-signatum is lost and the connection with the sound-signatum is fastened – the sign again has its simple structure.

The Aztec writing sign may use the last and the preceding stages of development.

### 2.4. Emblems in nominations – name phrases

A proper name can be written with a sign-pictogram or with a combination of pictograms as an emblem. We find examples in (Berdan 1992):

a) *AYOTLAN* – (*Ayo-tl*) + *tlan* – “Where there are many turtles” (*-tlan* is omitted).

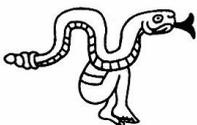

b) *AYOTZINTEPEC* – (*Ayo-tl* + *tzin* + *Tepe-tl*) + *c* – “On the Hill of the Little Turtle”, where ‘little turtle’ is expressed syncretically in one image, locative suffix *-c* is omitted.

c) *AYUTUCHCO* – “On the Armadillo” (*Ayo-tl* + *Toch-tli*) + *co* = ‘On the Turtle-rabbit’ (‘armadillo’ is a rabbit in the armour of a turtle) + *A-tl* (‘water’) – phonetic complement.

### 2.5. The absence of a strict order of components

The logical incompatibility of components in emblems of personal names and names of places can indicate the combination of phonetic and ideographic signs:

d) *COATZINCO* – “On the Small Snake” (*Coa-tl* + *tzin*) + *co*  
*coa-tl* – ‘snake’, *tzin-tli* – ‘rump’, *tzin* – ‘small’ (rebus substitution), *co* – ‘on’ (omitted).

The graphic structure may have no direct correspondence with the components of the composite:

e) *YACAPITZTLAN* – “Where There are Many Pointed Things” (*Yacapitz-auah*) + *tlán*:

*Yaca-tl* – ‘nose’, *Petz(o-tli)* – ‘insect’, *Yacapitz(a-uac)* – ‘smth pointed’ (rebus spelling), *tlán* – ‘abundance of’ (omitted).

Hill (graphic base) + Nose + Insect.

f) *COYUACAN* – “Place of the Lean Coyotes” (*Coy-otl* + *hua-cqui*) + *can*:  
*Coyo(tl)* – ‘coyote’, *Coyo(ctic)* – ‘hole’ (phonetic complement), *huacqui* – ‘lean, hungry’, *can* – ‘pertaining to a place’ (omitted).

### 2.6. *Syncretism of the image*

The use of one glyph for two morphemes (as *b*, *c*) may be even more creative:  
*MIXCOAC* – “On the cloud snake” (*Mix-tli* + *coa-tl* + *c*), *Mixtli* – ‘cloud’, where *mix-tli* (“cloud”) is drawn as a blue snake with curls forming the upper line of the coat’s image. The blue colour and the curling line represent a cloud. But the same place name is composed with two glyphs (a snake and a cloud) in cod. Santa Maria Asuncion.

### 3. The textogram as a frame

Now we can see how the whole composition is made in Aztec Manuscript. On the page consecrated to Itzcoatl – ‘The Snake with arrows’ – his conquests are shown: the emblem of war is in the centre, destroyed cities with their emblems are around it, the years of his reign as calendar glyphs are in blue at the border.

So the textogram corresponds to a situation, representing it as a frame with acting participants, where the participants’ positions are determined by the coordination of the principal, central, and secondary, subordinate. For the archaic culture the cyclic

repetition of certain events is principal, and new, changing factors are regarded as secondary, though necessary circumstances. The subordinate function of emblems as marks, signs of circumstances in a textogram is expressed in their particular position.

The structure of the textogram doesn't prescribe the order of reading; it represents the semantic, deep level of text, which is known from the oral tradition.

E. Boone (Boone 1998) speaks about the "visual thinking" of the Nahua, comparing their pictorial documents to musical or mathematical notations that could be "read" without words.

#### **4. Factors constraining the development of script**

Finally about the factors constraining the development of Aztec script. We see three such.

- 1) Cultural factor: it was just a choice of communicative strategy (A. Davletshin, private discussion), based upon "visual thinking" (E. Boone).
- 2) Sociolinguistic factor: it was the Spanish influence. The situation with the Aztec (and Maya) script in collision with Spanish culture may be compared with that of Egypt in the emergence of Hellenism, when Coptic writing arose. "Firstly, in Egypt and elsewhere, it is a script, rather than the language, that becomes a symbol of "heathendom", of the old religious order which a new revealed religion aims to overcome; secondly, the alphabetic system is not an inevitable outcome of a writing system ..." (Lopriene 1995, 237).
- 3) Language structure factor: it may be the polysynthetism of the structure of the Nahuatl language, which allowed long series of syllables within an incorporative complex (up to 32, often 8–9). A proper word for Nahua could be a name with its stable morphemic structure; a predicate is a variable incorporative combination. There lies the border between language and speech. An emblem with its restricted number of positions could not have the technical resolution for guarding the strict order in such a long file; it should be unfolded to a chain. Yet we have the example of the Maya hieroglyphic script, where the problem was resolved for a language with elements of polysynthesisism. But before the pictorial sign became phonetic, the number of components in hieroglyphic block was restricted and the proper order of writing/reading was determined.

# **The Emblematic Principle in the Evolution of Writing Systems**

**Ludmila L. Fedorova, Elena N. Kondratyeva**

Institute of Linguistics, Russian State University for Humanities  
Moscow

[lfvoux@yandex.ru](mailto:lfvoux@yandex.ru), [chicco@mail.ru](mailto:chicco@mail.ru)

## **Abstract**

The paper addresses the use of emblems in the representation of language units in writing systems. The emblem is conceived as a complex graphic unit which creates a new meaning by means of differentiation of reference. The proper function of the emblem is nomination, so it appears in the representation of proper names in historical writing systems. The stage of Emblematic writing may be placed at the very beginning of proper writing; the Aztec manuscripts show the most typical examples of it. An emblem can be formed by one symbol, but more often it has two components. The relations between them can be compared with those in compound words: they can be symmetrical or subordinating. The emblematic principle is used in modern writing along with the linear principle: while the latter unroll the text in the consequent order, the former represents hierarchic information as an integral graphic composition.

**Keywords:** Historical Writing systems, Emblem, Symbol, Differentiation.

## **1. Acknowledgements**

I appreciate greatly the opportunity to present our paper, Elena Kondratyeva's and mine, kindly granted by Organizing Committee and Dr. Lee Sang-Oak. I thank Professor Lee personally for his assistance.

I represent here the Russian State University for Humanities, where Dr. Kondratyeva teaches Korean language at the Institute for Oriental and Classical Studies and I lecture in History and Theory of Writing, Semiotics and Sociolinguistics.

I've permitted myself to widen the announced theme of the paper (The Emblematic principle in Korean Writing) in the absence of Dr. Kondratyeva, who is much more competent in Korean. So I'll speak about the Emblematic principle in the evolution of writing systems, not only in Korean writing.

## **2. Some Preliminary Definitions and Assumptions**

### *2.1. Writing system*

We define *a writing system* as a semiotic system, with a set of graphic (pictorial or linear, symbolic) signs for expressing a certain content. So a calendar system, a counting system, any system of notation (musical, mathematical and so on) can be regarded as a writing system. We regard as a language writing system any system of writing based on language units.

### *2.2. The emblematic principle of writing*

My first comprehension of the emblematic principle was as follows: the emblematic principle of writing presupposes that a complex semantic unit – such as a proper name (personal name, name of tribe, place name, etc.) – has an appropriate external, graphic structure, which represents the combination of its elements as a whole. Presumably its semantic structure includes a pair of components as immediate constituents.

### *2.3. Assumptions*

We presuppose that the use of emblem may be extended to the common principle of writing, along with the linear principle.

The nature of the emblem can vary, but its main features are the combination of pictorial images in a whole, not in a linear order (integration), and some sort of semantic relation between them.

The linguistic emblem is a readable sign, representing a (compound) language unit.

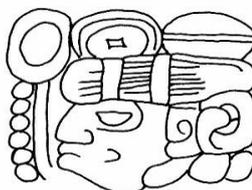

### 3. The Term Emblem in the History of Writing

In the history of writing the term emblem was used by Heinrich Berlin in his investigation of Maya place names (Berlin 1958). Yet his comprehension of emblem presupposed an iconographic and not linguistic nature, so the emblem was regarded not as readable sign, but as sign requiring interpretation.

Consider these examples of compound Maya glyphs for the settlements Palenque and Tikal:

*Palenque*

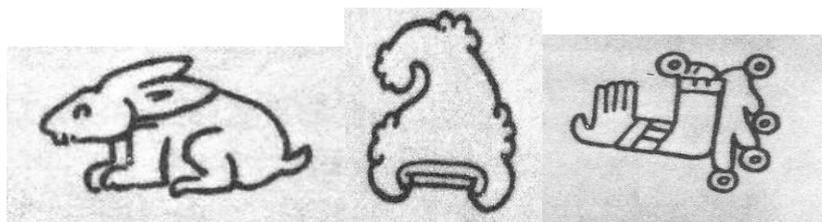

*Tikal*

We can compare them with simpler glyphs for Aztec place names (pre-Hispanic place signs), which presumably have phonetic reading:

a rabbit for *Tochpan* – *toch-tli* ('rabbit') + locative postfix;

a curved hill for *Colhuacan* – *colhua*<sup>1</sup> is represented as *col-tic* (*tepetl*) 'curved' ('hill'), (while *colhua*<sup>2</sup> is a group living in the Valley of Mexico) + locative postfix = 'place of *colhua*', with a rebus spelling;

*Acolman* (*Acolhuacan*?) – *a-tl* ('water') + *acol-li* ('shoulder') + locative postfix, where *atl* is used as a redundant phonetic indicator (phonetic complement).

*Tochpan*

*Colhuacan*

*Acolman/Acolhuacan*

So there are compound as well as simple signs. Simple signs can be emblems when they correspond to a distinct referent.

#### 4. The Difference between Emblem and Symbol

It is obvious that a writing emblem has much in common with an ordinary graphic or pictorial symbol with semantic reference (whether verbalized or not), such as we can see in modern advertisement, or as we use in e-mail letters:

*I ♥ Nescafe Gold*

*I √ Stream*

*We are waiting for you at the hotel ☺*

They are merely simple pictograms or ideograms. An important point is that they presuppose some intelligible semantic (not phonetic) reference (we can read: *I choose Stream, I prefer Stream, I vote for Stream*), so they belong to a different level of structure than the surrounding signs. The context makes their meanings more definite.

Yet the difference between Emblem and Symbol as semiotic category consists in the definite reference of the Emblem and indefinite reference (or even infinity of possible references) of the Symbol.

Reference becomes the most definite in nominations, in proper names.

So the main feature of a writing emblem is not its 2-component structure, but its function – that is a different way of reference: 1) it is a semantic reference, 2) it is a distinct reference, restricted with a language unit in its proper sound image.

The emblems are in contrast to the rest of the pictorial composition or of the text – or they may be prominent in vacuum, holding the quintessence of meaning. For the blank field, *tabula rasa*, is in full opposition to a meaningful symbol. The use of emptiness as a generative power is a philosophical principle in Oriental Art, and it reveals its value in Proto-writing.

## 5. Simple Symbols as the Bases of the Writing system

In the history of invention of writing systems there are examples when simple signs, symbols, make the basis of the whole system. The simpler the primary signs are, the deeper the sense they could convey.

The Korean *Hankyl* is the most evident example. It has 3 main signs for vowels, which symbolize the neo-Confucian ideas:

- – Point or circle – for Heaven,
- – Horizontal line – for Earth,
- ┃ – Vertical line – for Man

Another example is the Slavic Glagolitic writing, where 3 signs found the graphic images of the letters. They are symbols of Christianity:

- – Circle, which symbolizes the Infinity of the Universe,
- △ – Triangle, which symbolizes the Holy Trinity, and
- ✝ – Cross, which indicates Christ's Passion.

The main difference is that the Korean signs have their own phonetic value, and among the Glagolitic only the Cross signifies /a/ by itself. But the others form combinations corresponding to sounds. So these simple signs could be regarded as symbols, but not as true emblems.

## 6. Pictograms and Ideograms: the Ambiguity of Terms

At the beginning of writing we have more often not symbolic signs with global meanings, but pictorial signs with concrete meanings, e.g.: ☀ 'sun', ▲ 'mountain'.

They have an iconic reference to the object. Traditionally they are called pictograms, while a term of ideogram is used for a sign with indirect reference. But a

picture can represent an idea as well as an object – so there is no definite distinction between a pictogram and an ideogram:

	
‘sun’	‘daylight’
	‘day’
	‘God’

So some scholars avoid the last term (H. Rogers uses ‘abstract pictograms’ for ideograms (Rogers 2005)).

The ambiguity proceeds from the fact that the terms are based upon different aspects of the sign. The picture (*picto-*) is a *signans* of a sign, while the idea (*ideo-*) is its *signatum*.

While the principle of pictography is iconic – the use of visible, direct reference, – the principle of ideography is the use of indirect reference, metonymic or metaphoric. They are supplementary to each other, so pictograms and ideograms can coexist in the same ideographic system.

## 7. The Ways of Differentiation of an Emblem

The evolution of writing (if there is any) can be considered as a way of optimization of the system: from Proto-writing with iconic direct representation of a situation to proper writing with graphemes representing language units, from radical-morpheme writing to morphosyllabic writing, and so on, always through differentiation to a new integration. Any mark of differentiation serves to restrict reference in the syntagmatic representation at any stage of the process. At the very beginning of proper writing an emblem is differentiated from the whole pictorial composition, *textogram* (Dyakonov’s term. (Dyakonov 1979)), representing a situation and referring to a canonical text. Thus proper names, dates, numerals can be recorded. This is a stage of Emblematic writing.

Then, at the advanced stage of writing emblems remain among linear signs and get a differentiating mark.

An emblem can be marked among other signs:

– with a diacritic:

we can see an example in the Egyptian writing, where a stroke marks an ideogram in the status of an emblem: p-r = ‘house’, kA = ‘soul’ (the stroke can be considered as a second, subordinate structural – semantically empty – component of an emblem); later the cartouche served as a diacritic of compound emblem: it had a role of escutcheon, a coat of arms, and within it a special, honorific order of signs was permitted. Also a line above a letter (letters) marks its numeral meaning or abbreviation (“titlo” in Slavic); so the name *Iisus* (Jesus) is written in abbreviated form as an emblem.

*p-r* 'house'; *son of Ra, Tutankhamen* [imn-t-w-t-anx]; *IS* (Jesus)

*kA* 'soul';

– by its size:

ciphers, numerals among the letters; a majuscule in proper names which can be considered as the relict of an emblem mark; maybe even a long line or hook under or above the line in many consonant letters as a mark of a syllable in minuscule alphabetic writing, as Dr. Manfred Kripke supposed (in private discussion);

– by the heterogeneity of its structure:

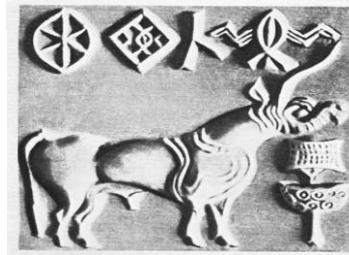

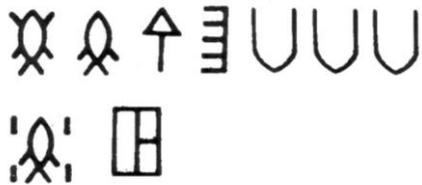

Chinese characters among Korean syllables or Japanese kana;

나무는 德을 가지고 있다

(‘Even a tree has its virtue’)

– sometimes with symmetrical or balanced organization of compound signs, which acquire an appearance of an emblem:

Indus, or Kharappa, writing, not deciphered yet, gives examples of symmetry in ligatures; also as an emblematic relict may be considered the rule of a square of Egypt and Chinese calligraphy, where graphic elements are situated within an invisible square, and they can be enlarged or diminished, stretched or compressed; we can also see these graphic techniques in the Korean syllabograms, especially with patchims;

*sign of fish in ligature with IIII; sign of fish in ligature with waves in a tablet (Kharappa)*

– by its position:

at last, it may have no external mark, as Sumerian ideograms in the Akkadian cuneiform (Dyakonov calls them *heterograms* (Dyakonov 1979); but it can be marked with its position. This is the case with the stable position of a determinative.

These are the ways of external differentiation. They are more often morpheme-operations than segmental morphemes, as we have seen. They mark emblems as signs of another level among the rest.

## 8. Ways of restriction of reference

The use of an emblem serves to restrict the reference.

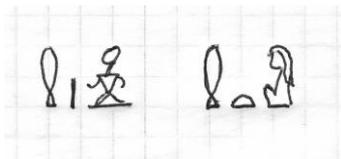

In morphographic writing a sign-radical can be referred to any element of a semantic field. So its content can be restricted in some ways, e.g.:

– by a semantic determinative, indicating a class of reference – the determinative is an emblem marked by its position:

Sumerian (in conventional form):

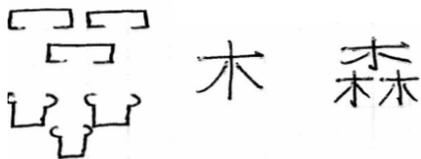

Aššur<sup>Country</sup>, Aššur<sup>Town</sup>, Aššur<sup>God</sup>;

Egyptian (the combination of signs creates a new integrated image):

*'slave'-id. + Det. 'man'; 'slave' + [t] fem. + Det. 'woman'*

– by a reduplication of the ideogram. The reduplication can give way to a new meaning, the new integration gives a new emblem:

*Pl. ('house');*      *'tree' – 'grove' (Ch.)*

*Pl. ('soul') (Eg.);*

As we can see, a new integrated meaning appears in the semantic compound, so reduplication may be the first archaic way of visual representation of a grammatical meaning, such as the plural.

A new meaning appears not only in the case of reduplication, but in combinations of ideograms:

*'man' + 'tree' = 'rest', 'relax' (Ch.)*

This is a new step of integration going along with differentiation.

All these means make for a more intelligible reference and a more sophisticated expression of the meaning.

## 9. The proper Function of Emblems is Nomination

The word becomes actual in the nomination, so personal names, place names, names of tribes, calendar names are the first stable names – proper names – and real stable phrases worthy of notation. Proper names are names with fixed reference, and the ancient names have an appropriate semantic structure. Such a name may contain a single word (Turtle, Fox, Bear, Cloud, etc.), which is expressed by a pictogram. But more commonly there is a differentiated name (a word combination) that creates an individual image (Turtle Following His Wife, Dark Cloud, etc.). This is already an attempt of sound writing with iconic images, because the *signatum* is a sounding word, not an object, – a scribe wrote the name. We can see such writing in Mixtec codices

(Smith 1973), in North-American annual records.

We can find more elaborated emblems of names in Aztec manuscripts, where a redundant phonetic indicator or rebus spelling may be evidence of sound writing.

The emblematic principle works at the early stages of writing as a transition to morphosyllabic writing. We can suggest that emblematic writing was an important stage in the development of writing. This principle is represented most completely in the Aztec manuscripts. The phono-emblems function as subtitles or inscriptions to the pictorial compositions of common content, such as war, battle or death, marriage. They mark on the background calendar dates, lords' names, toponyms and other concrete information, which is subordinate to the main content given in the centre. They use the devices of phoneticism (Nickolson 1973, Berdan 1992). The same principle may be found in Egyptian in Narmer's Palette where *Narmer* is a phono-emblem with two glyphs.

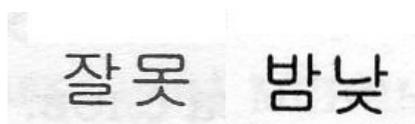

## **10. Relations between Components of a Compound Emblem**

For the one-sign emblem we can regard the mark of differentiation as its second component, so the relation between the first and the second is quite technical (with a functional meaning).

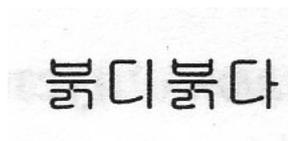

At first I assumed that there must be subordination between the immediate constituents of an emblem (Aztec place names give examples). Now I see that this is not necessary. There can be different possibilities, and other, non-linguistic material gives good examples of coordinative relation; one of them illustrates the *yin-yang* emblem, which constitutes the balance of male and female, light and dark.

I think that some parallels with language word-composition could be established: the possible relations between components in a compound word resemble the relations within an emblem. We have not only bahuvrihi, but also dvandva composites in many languages, often giving not only the sum of meanings, e.g., in adjectives of colour (*red-blue*), or the sense of intensification, but new nominations: so we have in Armenian *arev-tur* = 'take-give' for 'market'; in Greek *ἄψε-σβήσε* 'fire-blow' (imperative) = 'in a flash'; in Nahuatl we have more often not compound words, but binomial word-combinations (the words are in their free form): *in atl in tepetl* as set expression or *atltepetl* as a composite – 'water, hill', the whole means 'settlement'; *in cozcatl in quetzalli* – 'necklace, feather of quetzal' – that is 'treasure'.

Korean gives many examples of composites and binomial compounds:

*cal-mos* = ‘good, not’ (‘mistake’), *pam-nac* = ‘night, day’ (‘24 hours’);  
reduplications for intensification:

*pulkti-pulcta* = ‘red-red’ (‘scarlet’);

especially many reduplications with onomatopoeic function: *acang-acang* (for a child’s first steps), *panccak-panccak* (about glint, with intensification), or

*khung-khung* ‘din-din’ (Lee 2005).

We have thus word-emblems – words that change their function and reference in composition.

In a more common sense a compound word may be regarded as a semantic emblem because the semantic relations between its components are frozen or neutralized (for example, *forget-me-not* or the Nahuatl greeting *mixpantzinco* (*m(o)-ix-pan-tzin-co* – ‘in your reverend presence’), as in the most part of compound word etiquette formulae; *leap-day* or *leapfrog* – on the other hand, with indefinite grammatical functions of its components). But this is a subject of further research.

## 11. The Lay-out of a Semantic Unit

The lay-out of a semantic unit is a logical task; it is resolved by the coordination of the central and the marginal (the positions around a centre), the main and the subordinate (positions behind the main) or by the balanced coordination of components. The whole composition is a task of integration.

A complex language unit has an underlying logical structure. A complex writing unit has an emblematic structure, which is governed not only by the structure of

language unit, but by the logical order, graphical possibilities and fantasy of the author. So we can see fantastical images: a tree with teeth or with a mouth and a speech scroll, a snake with knives or lips in the channel. On the other hand, the components of an emblem can be combined in a logical way: where a house stands on the hill, a snake goes out of the house. In every case a scribe tries to make the composition into a whole, even if it is a fantastic image.

The lay-out of the phonetic chain needs linear order, and the linear principle indicates the unrolling in time of the sequence of symbols, the order of reading. This is a way of differentiation.

## **12. The Emblematic Principle in Korean Writing**

The language system may determine the ways of writing.

The Korean writing combines the emblematic principle in the representation of morphemes and the linear order in the spelling of words.

The Korean writing follows the emblematic principle in 2 points:

1) in the use of Chinese characters as emblems of words with strict meanings or radical morphemes in the chain of phonetic signs (a Chinese word is rather a semantic emblem);

2) in the composition of a syllable, using alphabetical signs.

The first case is a relict of morphographic writing, which may be conserved to a certain degree – as long as it makes for laconism of expression and helps understanding and as long as it doesn't create great difficulties for reading. It is a matter of tradition and of reasonable extent.

The second case reveals many details. Some of them – the balanced organization of a syllable as a whole – were already mentioned. We can add two things: 1) the use of a zero-sign, indicating the absence of an initial consonant, so that the whole syllable reserves its canonical two-component structure; 2) the division of the word into syllables which shows its morphemic structure – so that the syllable borders coincide with the morphemic borders in the word.

So a Korean word may be regarded as a phono-emblem, rather than a phonetic chain.

### 13. Is the Emblematic Principle an Obsolete Survival?

– It coexists with the linear principle in creation of monograms, ligatures, abbreviations:

£ & @ Æ

– It corresponds to the creative, combinatory capacity, due to which we have such emblems as “?” and “!” created in Latin writing by using a vertical order of components (Q and o, I and o):

Quaestio > Qo > ?

Io > !

– Even in writing numerals we can find the coexistence of two ways of representation: linear (1 : 3) and emblematic ( $\frac{1}{3}$ ). Other examples can be found in mathematical, chemical and musical notations (in the last a chord is a harmonic emblem and a melody progresses note by note in linear order).

In conclusion, we must remark that the emblematic principle can unite signs of different levels or different status in the historical writing systems. This doesn't mean that emblematic principle is an obsolete survival. An emblem of any kind is a way of visual representation of hierarchic information in compact form; it is a way to break the importunate chain of linear order. And its energy is multiplied in emptiness.

# A Formal Model of Writing: Writing Systems, Scripts, Writing Standards, Orthographies and their Interactions

Oliver Streiter

National University of Kaohsiung,  
Nanzi, Kaohsiung, Taiwan  
ostreiter@nuk.edu.tw

## Abstract

Starting from the observation that writing systems are vaguely defined and thus offer a loophole for national ideologies, we propose a formal description of writing systems. Such a formal description can be used to identify ideologies in linguistic discourse or a data structure for OCRs and text-handling modules. Key-notions such as *script*, the *writing standard* and the *orthography* are newly defined, so that established classifications can now be formally defined. New research questions arise from the proposed formalization, helping to advance our knowledge of this intricate field.

**Keywords:** Writing systems, writing standards, formal modeling, ideologies

## 1. Writing Systems: From classification to conceptualization

Writing systems have for a long period been ignored as object of scientific study. Writing might have been thought to be too closely related to linguistic prescription and thus not to be a suitable subject for science. Writing systems is still largely banned as a research field from linguistic curricula and, with few recent exceptions, from conferences and journals. The new interest in writing is partially due to a series of systematic studies. e.g. by Cardona (1986), Sampson (1990) and Daniels and Bright (1996), that established classifications and new terminology for the description of writing systems.

Our knowledge of writing systems however still lacks behind that of other linguistic domains, such as phonology or morphology. We know details about specific writing systems, but have no general theories in the same way as we have phonological theories. As a consequence, we lack a conceptual framework that, in widely accepted terms, allows thinking and reasoning about writing systems. This is due to the gap in research on the one hand, and the extraordinary diversity and complexity of writing systems on the other: Writing systems are compromising, in different ways, political power, national identity, religious identity, tradition, learnability, readability, writability, digitalizability, the phonological system of a language, the phonetics of a language and a culture's aesthetics. A theory of writing that does not integrate linguistic, psycholinguistic, anthropology, sociology and sociolinguistics will thus remain fragmentary.

This inherent complexity however does not mean that the current state of knowledge is all we can achieve, or even, that writing systems are unsuitable for a scientific study. In this paper we thus want to support the claim that scientific approaches can be applied to writing systems and illustrate this through a minimal formalization, actually, implemented in the framework of a relational database.

Second, we claim that the entire field of linguistics without a rich theory of writing system will remain unscientific, in the same way as a psychology without the notion of environment is unscientific. The unscientific nature of a linguistics that does not integrate a theory of writing becomes apparent when contrasting current linguistic discourse to a formal model of writing systems. This discourse, we claim, can be linked directly to the extinction of languages and cultures that we are currently facing (cf. Crystal 2002).

## **2. Writing Systems: Playground for Ideologies**

We claim that the lack of a theoretical framework for writing systems discredits the entire field of linguistics and threatens, as one factor among others, languages and cultures. In the absence of writing systems from the conceptual space of the linguist, there is no structural opposition between 'writing system' and 'language'. As a consequence, phenomena that should be described by the linguist at the level of writing systems are described as if belonging to the level of language. The discourse of a linguist is thus similar to that of biologist that talks about algae as if they were plants.

One might wonder whether linguists are basically aware of the difference and just employ a sloppy discourse. But how sloppy are linguists allowed to be? No chemist would call NaCO<sub>3</sub> (Sodium Bicarbonate) "Sodium", but which linguists wouldn't call a text written in English, Swahili or Russian "English", "Swahili" or "Russian". A denominations like "English" actually seem to be innocent, but this identification with a language ignores at the same time the (obvious) script, the (less obvious) writing standard, the (nameless) orthography and the (obvious) writing direction or even the fundamental distinction between a language and a written representation of it. How far would a chemist come if he systematically calls a salt by the name of the metal?

The term "English-Chinese Machine Translation", used by, for example, but not only, Siu and Meng (2001), is another example of a perverted linguistic discourse. Here, the term "English" refers to a language. Which writing system of English is translated is not specified through the term. Might it be American English written in Desert?. "Chinese", the second linguistic term, refers to a language family including, but not limited to, Modern Standard Mandarin. A second meaning of the term is the Chinese script. This script has been applied to a variety of languages, including Korean, Japanese, Vietnamese, Cantonese and Taiwanese Minnan. Which language is actually involved in the translation is thus left unspecified in both interpretations of the term "Chinese", as language family and script are compatible with more than one language and even the intersection of both remains ambiguous. Maybe Cantonese is actually aimed at, as the authors work in Hong Kong. Maybe. Maybe not. "Translation", finally thought of a mapping between languages is a misconception in the same way, as input and output of the Machine Translation systems is usually a text which can be linguistically classified as belonging to one or another writing system of which the language is one attribute. But whatever meaning a linguist might give to the term "language", as I-Language, E-Language (c.f. Chomsky 1986) or others, none of them will fit the concept of "translation". Translated are, at best, written, spoken, signed or other linguistic productions of which the language is one attribute.

Do we witness just a deplorable habitus (Elias 1939/1992) in an otherwise correct linguistic field? We don't think so. It is easy to show (c.f. Streiter & Voltmer forthcoming), that such an apparently meaningless discourse transmits ideologies, mostly that of nation states and their national languages, e.g. Spanish and Standard Mandarin, but also of non-central languages, the advocates of which use similar ideological means to compete with national language in their strive for power, e.g. Catalan and Taiwanese Minnan..

The transmission of the ideology through the linguistic discourse works as follows: If presented with such a meaningless expression, the addressee is forced to make subconsciously assumptions which allow to make the discourse meaningful. Such assumptions might be 'there is only one Chinese language written' or 'all Chinese languages are written in Chinese characters'. When presented sufficiently often with material which requires this assumption, the assumption is implemented in the cultural body of unconscious knowledge that has been built in the same way, cf. (Fairclough 1989). The more the discourse simplifies, the more default assumptions the addressee is supposed to make. As the linguist author might also make subconsciously assumptions about which default assumptions the addressee is most likely to make, he or she will fall back on those assumptions that he or she shares with the addressee, e.g. those assumptions propagated in Kindergarten and elementary education, which in most countries are mainly concerned with standardizing the kids' linguistic production according to national curricula for the establishment of national identities.

Linguists that in their discourse do not carefully distinguish the concept of 'language' from the concept of 'writing system' become, knowingly or unknowingly, henchmen and executors of prevailing ideologies, contributing with each analysis of "English", "Russian" or "Swahili" to the death of a language somewhere else. Linguists, through their discourse, ensoul and transmit a nationalistic discourse and thus affect the formation of identities, language attitudes and language politics. Whether or not representatives of central and non-central languages want to use these means to promote their language under the surface of a linguistic analysis, is left to their conscience. However, as this ideological linguistic discourse falls again into the area of linguistics, linguists have the right, the means and maybe the obligation to identify the ideologies and their mechanisms that invade their field.

Our proposal is thus to formalize writing systems as far as possible and to use this as conceptual framework with which linguistic discourse can be contrasted, showing where the ideological discourse creates unmotivated implications.

### **3. Writing Systems: Towards a Formal Model**

#### *3.1. Writing Systems: Axiom and Principles*

In our formal model, we start from an axiom that linguist might agree upon and a few principles that build on the axiom to derive theorems. Second, we need mechanisms to check the validity of the theorems against the reality of written texts. Third, through the logic of the formal model new research questions arise. Possible answers to this

question having the same validity should be ranked by the principles. If no ranking of competitive answers is possible, the principles are too weak and should be refined.

The endeavor to formalize writing systems started in the framework of XNLRDF (Streiter & Stuflesser 2006). In this project we describe writing systems of the world one by one in a formal way. While doing so we developed, adapted and validated a formal model. The model is said to be *inadequate* if it cannot distinguish different writing systems; it is *invalid* if the properties of a text do not match those of the associated writing system. Fundamental thus is the question what properties texts have and which of these properties motivate a distinction into different writing systems. The axiom we start from is derived from the discourse we criticize, i.e. the identification of language and writing system. If this identification represents common linguistic discourse, we can assume that linguists might agree to it.

**Axiom:** *When the language of a text changes, the writing system changes as well.*

**Example 1:** *Two writing systems separated by the language.*

- 1a)** Luxembourgish: *Eise Papp am Himmel*  
                           Our Father in heaven  
**1b)** Plautdietsch: *Ons Voda em Himmel*  
                           Our Father in heaven

(Translation of the Lord's Prayer 2008)

We define the concept of *language* as homogeneous form of expression used by a specific community in a specific time across different activities. Although different definitions of the concept of language are possible, they will possibly have no influence on the acceptability of the proposed axiom.

Second, we formalize a writing system as an *attribute value matrix* (AVM), e.g. [a=b,d=[e=f]], where the value to an attribute can be another AVM. AVMs should describe a homogeneous set of texts, identified by attributes like *time period*, *standard*, *language*, *writing direction*, *orthography*, *script* and *word separators*. How to define and organize these attributes and represent the interrelations of their values is part of this modeling. A first model of writing systems identifies the writing system with the language spoken by a community, thus merging the axiom and our definition of language, c.f. Listing 1:

**Listing 1:** *A first model of writing systems.*

---

```
[language=[language_name=,
          syntax_rule=*,phonology_rule=*,morphology_rule=*,
          time_from1=, time_to1=,
          community=*[community_name=,
                      time_from2=,time_to2=,
                      locality=,
                      language_activity=*[activity_name=,
                                          person=*[person_name=,
                                                  proficiency=,attitude=]]]],
channel],
person=*[person_name=,birth_date=,gender=, ethnicity=].
```

---

In this model, the Kleene-star '\*' marks that the value is a set instead of a single value. There is thus a one-to-many relations, e.g. between a language and a community. If we would not use the Kleene-star, the formalization would mean that each community has another language, or in other words, that the community is defined by the language. While '\*' marks the set when represented as type, we use <[.],[.],...> to mark an instance of a set.

*The channel* describes the form of linguistic expression like *spoken, whistled, signed, drummed* or *written*. We will return below to the discussion of the channel. The *proficiency* and *attitude* refer to the specific language activity. These latter values characterize a writing system, but do not define it.

Coming back to the axiom, one might object that the axiom we stipulate might go uncontested for Western Languages, but maybe not for texts in Chinese script that can be read in different Chinese languages. Isn't this a counterexample to the axiom, i.e. one writing system in many languages? We don't think so. This Chinese writing, might either be a specific Chinese language that incidentally can be vocalized in another language, or a written macro language (dach-sprache) that allows a comprehensible vocalization in different languages. In any of these cases we have, admittedly, at least two different languages. But from the partial identity of two writing systems we cannot deduce their identity. Although a Tang poem can be vocalized in Mandarin, written Mandarin is not the same writing system as the writing system of the Tang poem. A single character, a single sentence marker, a single spelling variance is sufficient to prove a difference. In written Mandarin, for example, we find the character '她' (/ta/, female 3<sup>rd</sup> person pronoun) that is not part of the writing system of the Tang poem. Thus, although these writing systems are related and their relation can be systematically analyzed and represented, they are not the same.

With this axiom we use two general principle that allows to distinguish writing systems and chose among alternative models. Principle 1 looks for systematic differences in two texts. It claims that if what is said is the same, but texts looks systematically different, different mechanism in coding and decoding are at stake. Random variations in not-standardized writing systems, thus, do not allow to speak of a different writing system. The writing system should thus provide all the information necessary for text understanding that is not provided by proper linguistic components, such as syntax or morphology modules. A formalized writing systems should be a component of OCRs, text-to-speech systems or any other text-handling facility.

**Principle 1:** *Any systematic difference in two texts that express the same wording in the same language reflects a difference in their writing systems.*

Principle 2 states that we want to constraint our model as much as possible and do that using hierarchical structure wherever possible. Hierarchical structures however should not serve the beauty of the representation, but allow for a calculus and through this calculus constrain the values of higher or lower levels in the hierarchy.

**Principle 2:** *A model that uses hierarchical structures and inheritance schemes it to be preferred over flat list of attributes.*

## 3.2 Writing Systems: Theorems

### 3.2.1. The script

The definition of a writing system in Listing 1, however is *inadequate* as it over-looks another, obvious systematic difference of texts, i.e. the *script*. When the *script* changes, the appearance of texts changes radically. A *script* is defined through a set of *characters* that get into usage in a certain *time* plus a set of functions that operate on the characters. Contrary to common assumptions, we assume, that these characters have no pronunciation and no meaning within the script. Pronunciation or meaning are defined in mappings between the script and a specific language. The only alternative to this assumption would be to include a language within the definition of a script, something impossible if at least one script is used to write more than one language. Of course, one might, in a historical perspective try to assign a proto-meaning or proto-sound to a character, but in a synchronic perspective, there is no uniform meaning or pronunciation in a script.

**Theorem 1:** *When the script of a text changes, the writing system changes as well.*

**Example 2:** *Two writing systems separated by the script.*

2a) Serbo-Croatian, Cyrillic script: *српскохрватски језик*

*serbocroatian language*

2b) Serbo-Croatian, Latin script: *srpskohrvatski jezik*

*serbocroatian language*

The Latin character 'u', for example, is pronounced /ü/ in Dutch, as /u/ in Italian. The Chinese character 緊 has in Cantonese a specific meaning it does not have in Mandarin or Taiwanese Minnan, i.e. expressing in Cantonese an ongoing action. To save the traditional assumption, one might argue that the Dutch script and the Italian script are not the same, as some characters are different. This might actually be true. But to take this as an argument for the inclusion of meaning and pronunciation into the script would mean, whenever two scripts have characters with different pronunciation or meaning, they also have to have different character sets, a claim that can be easily falsified. In addition if the script is freed from meaning and pronunciation we can, following Principle 2, set up hierarchies, allowing a script to inherit characters from its mother script. Such an inheritance might be expressed as in Listing 2. According to this model, one script can inherit from more than one script. In addition, single characters to be removed, added ex nihil or transformed.

**Theorem 2:** *A script is a set of characters. Pronunciation or meaning are assigned characters in language-specific mappings.*

**Listing 2:** *A possible formalization of inheritance in scripts.*

script\_A ::= [script\_B (v=>u) + \*script\_C (...=>...) - [x,y,w] + [ü]]

A script, in addition, has mappings to variants of a character, e.g. upper case characters, if these mapping prove to be language-independent. The ordering of characters, however is language-dependent most of the time. One can find even within one lan-

guage different systems of ordering for different purposes.<sup>1</sup> We thus tentatively associate the mapping of characters with the script, the ordering with the writing system.

**Listing 3:** *A first model of scripts.*

---

```
[script_name=,
 basics=[script_B (...=>..., ...=>...)
        + *script_C (...=>..., ...=>...)
        - [...]
        + [...]],
 up(a)=A, up(b)=B, ...
 time_from=...,
 time_fromB < time_from,
 time_fromC < time_from.
```

---

**Listing 4:** *A second model of writing systems including scripts.*

---

```
[language=[language_name=,
          syntax_rule=*,phonology_rule=*,morphology_rule=*,
          time_from1=,time_to1=,
          community=*[community_name=,
                    time_from2=,time_to2=,
                    locality=,
                    language_activity=*[activity_name=,
                                       person=*[person_name=,
                                               mode=,
                                               proficiency=,attitude=]]]],
 channel=,
 sorting=<[pos(a)=1],[ pos(b)=2],[...]>,
 script=[script_name=],
 script=*[script_name=,basics=, time_from3=],
 person=*[person_name=, birth_date=, gender=, ethnicity=]
```

---

Interestingly, our argumentation against language-specific attributes in the script does not prevent general linguistic values to be assigned within the script, if the values are valid for all usages of the script. These linguistic attributes, should be organized in hierarchies so to be compatible with a hierarchical organization of scripts, resulting in a more constraint model of scripts. At the moment we simply assume that, for example, characters for syllables can be described as 'syllable(...)' and characters that can be used as numbers as 'numbers(...)', e.g. in the case of Armenian (c.f. Nakanishi 1980).

---

<sup>1</sup> The new official German orthography, for example, while listing the character of the German alphabet, puts 'ä' after 'z', saying later on, that 'ä' should be ordered with 'a' (Duden 1996:860).

**Listing 5:** A second model of scripts, allowing characters to be linguistically classified.

---

```
[script_name=,  
basics=[script_B (...=>..., ...=>...)  
+ *script_C (...=>..., ...=>...)  
- [...] + [...]],  
up(a)=A, up(b)=B, ..  
vowel(a,e,i,o,u,...),  
consonant(b,d,f,g,..),  
plosive(b,d,g,...),  
number(a,b,...),  
time_from=...],  
time_fromB < time_from,  
time_fromC < time_from.
```

---

### 3.2.2. Time and place

As apparent from the above, a writing system has a temporal attribute, i.e. the temporal overlap of the other time periods.

**Theorem 3:** Texts written in a very different time and place belong to different writing system.

**Example 3:** Two writing systems separated by time.

**3a)** Old English, ca. 1000, Latin script: *Fæðer ūre þū þe eart on heofonum*

**3b)** Middle English, ca. 1384, Latin script: *Oure fadir þat art in heuenes*  
(Translation of the Lord's Prayer 2008)

**Listing 6:** A third model of writing systems, including time and space.

---

```
[MAXIMUM(time_from1,time_from2,time_from3)  
< MINIMUM(time_to1, time_to2),  
language=[...]]  
...
```

---

### 3.2.3. The Writing Standard

Every language has potentially a large number of writing systems. There are those used by communities, those proposed or implemented as national standards, or those used by linguists for the transcription or annotation of language activities. The notion of 'writing system' thus is not equivalent to that of a 'written language', as the former includes, for example, API/IPA transcriptions. Two writing systems of a language can be combined into a third, such as ([我們]/[wōmen]). These combined writing systems assume a central position in the formalization of mixed *spellings* (see below). Given one writing system, we can specify other writings system by the way they map to this writing system.

Mappings between writing systems that linguists are most familiar with are *transliterations*. A *transliteration* is defined as mapping of one writing system to another writing system of the same language. More precisely, in a *transliteration* characters or

combinations of characters are mapped one-to-one onto characters or combination of characters. Linguist, for example, transliterate a Russian Cyrillic text into a Russian Latin text, following one-to-one mapping rules, losing no information during this process. A *transliteration* might be specified in a general *standard*, e.g. the Cyrillic scientific transliteration in (ISO 9: 1995, 2002). Transcribing Modern Standard Mandarin in Hanyu Pinyin (Yin and Felley 1990), is another standard, although not a transliteration in the strict sense. One Hanyu Pinyin Romanization can be mapped onto more than one Chinese character.

The type of mapping between *writing systems* of the same *language* is called the *standard* or *writing standard*. We assume for each language the possible existence of a phonetic (e.g. API/IPA transcription), phonological (e.g. Signwriting, c.f. Gangel-Vasquez & Sutton 1998), morphological, syntactic or semantic writing system, each of them being linguist's inventions. If we assume that writing systems themselves are *typed* (*phonetic transcription, phonological transcription, morphological transcription, semantic transcription, syntactic transcription, transliteration, common writing*), the standard specifies how a *writing system* is defined by its mapping to another *typed writing system*, starting potentially from a close phonetic transcription. The *standard* for transcriptions might be the annotation guidelines developed within an annotation project, starting possibly from a *common writing* (e.g. Babko-Malaya 2005). The *standards* can be defined for a *language* or a group of languages (e.g. the Epp standard is specific to lower German languages), or a *script* or a group of scripts (e.g. the Epp standard is specific to the Latin script) and the *writing type* of the *writing system* (*phonetic transcription* etc.) mapped to.

**Listing 7:** *A fourth model of writing systems, including the writing type.*

---

```
[MAXIMUM(time_from1,time_from2,time_from3)
 < MINIMUM(time_to1, time_to2),
 writing_type,
 language=[...]]...
```

---

We hypothesize that the writing standard has three components, a *header*, a *rule-type definition* and *rules*. The header of a *writing standard* specifies the range of writing systems that can be mapped as illustrated in Listing 8.

**Listing 8:** *An example of the header of a writing standard.*

---

```
[standard_name=,
 standard_header=[language=Low German language,
                  script=Latin script,
                  writing_type=common writing] <=>
 [script=IPA/API script,
  writing_type=phonological transcription,
  standard=IPA/API standard]
 ...].
```

---

The rule-type definition gives the rule-format in a general form as shown in Listing 9. The third component, the set of more specific mappings are instantiations of a rule type. A rule might map, for example, the character 'm' to the IPA/API symbol /m/. In this notation the brackets '()' marks those elements that are actually mapped, similar to the notation of substitutions with regular expression in Perl (Larry Wall et al. 2000). Those elements outside the brackets '()' describe the context necessary for the rule to apply. The elements outside the brackets are not mapped. In case of not mapped contextual elements, the mapping is not bijective.

**Listing 9:** *An example of the rule type and rules in a writing standard.*

---

```
[standard_name=,
rule_type=<[*vowel]<=> (vowel),rule=<['(a)' <=> /(a)/],[ ...]>]
      [(consonant) <=> (consonant), rule=<['(m)' <=> /(m)/,['(n)' <=>
/(n)/]>>].
```

---

Established classifications can now be defined formally through in the *standard*, e.g. by reference to the writing type (1.-3.), the script (4., 5.) or the language (5.), as specified in the header of the *standard*. Most standards however are mixed (6.)

1. 'Phonemic orthography' ::= [common writing] <=> [phonemic transcription].
2. 'Phonetic orthography' ::= [common writing] <=> [phonetic transcription].
3. 'Ideographic writing' ::= [common writing] <=> [semantic transcription].
4. 'Chinese Romanization' ::= [Latin script] <=> [Chinese script].
5. 'Romanization of Japanese' ::= [Latin script] <=> [Japanese language].
6. 'Chinese mixed phonetic and ideographic writing' ::= [Standard Modern Mandarin, Chinese script, common writing] <=> [semantic transcription/phonological transcription].

Another classification can be re-defined on the basis of the rule-types of the *standard* and the references herein to the linguistic classification within scripts.

7. 'segmental' ::= <[\* (vowel) <=> \*(IPA vowel symbol)],  
 [\* (consonant) <=> \*(IPA consonant symbol)]>;
8. 'syllabic' ::= [(syllable) <=> (IPA consonant symbol, IPA vowel symbol)];
9. 'abugida' ::= <[(character) <=>  
 (IPA consonant symbols), IPA default vowel symbol],  
 [(character)(vowel symbol to be merged) <=>  
 (IPA consonant symbol), (IPA not default vowel symbol)]>;
10. 'consonantal' ::= [(character) <= (IPA consonant symbols), IPA vowel symbol];
11. 'impure consonantal' ::= <[(character)(vowel symbol to be merged)] <=>  
 (IPA consonant symbol),(IPA vowel type A);  
 [(character) <=  
 (IPA/API consonant symbol), IPA vowel type B]>;

Theoretically, the two types of standards, i.e. the types defined on the writing systems mapped and the other on the basis of the rule types are independent. De facto, however, not all combinations are found in writing systems. Although we find a seg-

mental Chinese Romanization, e.g. (Yin and Felley 1990), and a consonantal transliteration in Latin characters of the Ugaritic script, e.g. (Pope 1975), we have no consonantal Chinese Romanization, as this would be of limited help. Other limitation on theoretically possible combinations reflect the historical development of languages, scripts and standards and their interactions.

*Standards* can thus potentially be hierarchically organized in a multiple inheritance model. A formal definition of the hierarchy of *standards* has not been attempted yet, but would clarify fundamental properties of writing systems. As, in addition the standard restricts the range of scripts and languages, the writing system is represented as in Listing 10, where the language name and the script name of the writing standard have to unify with the set of language names and script names of the *standard*, marked formally as superscript, where the unification, especially of hierarchical terms has to be defined more precisely.

As a different *channel* requires different *standard* for transcriptions or transliterations, even if the same language is involved, a different channel will result in a different writing system. As for the differences of a written whistled language and its written spoken language counterpart, c.f. (Trujillo 2005:56).

**Listing 10:** *A third model of writing systems including the writing standard.*

---

```
[...
writing_type=,
language=[language_name=1],
script=[script_name=2],
sorting=<[pos(a)=1],[pos(b)=2],[...]>,
standard=[standard_name=],
*script=[...],
*person=[...],
*standard=*[standard_name=,
channel=,
standard_header=[language_name=1,
script_name=2,
writing_type3]
time_from4=,
standard_inherited_from=[standard_header=[language_name=1,
script_name=2,
writing_type=3]],
rule_type=*[rule]].
```

---

**Theorem 4:** *Texts written in a different standard belong to different writing system.*

**Example 4:** *Two writing systems separated by the writing standard.*

**4a)** Arabic language, Arabic script, pure consonantal: ذَبَح

**4b)** Arabic language, Arabic script, impure consonantal: ذَبَّح

(Abjad 2008)

A *standard* can be validated by comparing mapping rules at its lowest level of the hierarchy of *standards* to the entities mapped between a text of the writing system and a text of the target writing system, unless these entities are covered by the *spelling*. Entities mapped by the *spelling* can be validated in the same way, requiring in addition a check whether the spelling rules correspond to the standard. All this leads us directly to the definition of the *spelling*.

#### 3.2.4. The Spelling

The *spelling* maps between words or morphemes of different *writing systems* of the same *language*. The *spelling* can overwrite the mapping rules as defined in the *standard* by reference to words and morphemes. To what extent the spelling rules can violate the rule types so that the system becomes *invalid*, is difficult to judge. A writing system that does not specify the spelling, however, would clearly remain *inadequate* as it cannot account for the differences in Example 5.

**Theorem 5:** *Texts written in a different spelling belong to different writing system.*

**Example 5:** *Two writing systems separated by the spelling.*

Russian language, Cyrillic script, segmental, spelling 1709: *гражданскій шрифтъ*

Russian language, Cyrillic script, segmental, spelling 1917: *гражданский шрифт*

*Spellings* are linked to only one *language*, one *script*, and one *standard*. Within the domain of the one *language*, one *script*, and one *standard*, a hierarchy of orthographies might be possible. The spelling of English refers to a mixed semantic/phonetic writing system. Rules map either words or morphemes with word-rules overwriting morpheme-rules.

- photograph <=morpheme=> [“SEMIOTIC”] / [/'fotəgræf /].
- photographer <=word=> [“PERSON”]/[fə'tagrəfər/].  
(c.f. English Orthography 2008)

For the praxis of reading and writing the *spelling* rules have to be mastered, in the same way as text-to-speech or speech-to-text systems have to master these rules. The size of the body of *spelling* rules which have to be added to a *writing standard* in order to describe a writing system is an indicator for its learnability.

**Listing 11:** *A first model of spelling.*

---

```
[spelling_name=,  
language_name=1,  
time_from5=,  
script_name=2,  
rule=*,  
standard=[...]].
```

---

**Listing 12:** *A third model of writing systems including the spelling.*

---

```
[MAXIMUM(time_from1,time_from2, time_from3, time_from4,time_from5)
< MINIMUM(time_to1, time_to2), ...,
  spelling=[spelling_name=,
            time_from5=,
            rule=*,
            language=[language_name=1],
                    script=[script_name=2],
                    standard=[standard_name=,
                              standard_header=[language_name=1, script_name=2]],
            *script[script_name=2,basics,...],
            *language[language_name=1]
            *person[person_name, birth_date...],
            *standard[standard_name,
                      language_name=1,
                      script[script_name=2],
                      standard_inherited_from [language_name=1, script_name=2]]
```

---

### 3.2.5. The Orthography

Our notion of *spelling* is different from that of *orthography*. While the *spelling* maps characters to create morphemes and words, the *orthography*, through rules and sets of symbols, e.g. the characters, word separation markers, sentence markers etc., accounts for the spelling, hyphenation, quotation, punctuation, enumeration, numbers, formulas, dates, thus turning phrases and sentences into a text. Some of these subsystems of the orthography, one might argue, are writing systems on their own, e.g. numbers or mathematical formulas. Actually, writing system can include, like a function call, other writing systems.

**Theorem 6:** *Texts written in a different orthography belong to different writing system.*

**Example 6:** *Two writing systems separated by the orthography.*

**6a)** Standard High German, Latin script, segmental, orthography before 1998: *Er versprach, heute zu kommen.*

**6b)** Standard High German, Latin script, segmental, orthography after 1998: *Er versprach heute zu kommen.*

**Listing 11:** *A first model of orthography.*

---

```
[orthography_name=,
  time_from6=,
  spelling=,hyphenation=,quotation=,enumeration=,date=,time=,number=, ...].
```

---

### 3.2.5. The Writing Direction

As obvious as are changes of the script are changes in the writing direction. The knowledge of the writing direction and its implication is absolutely necessary to decode a text.

**Theorem 7:** *Texts written in a writing direction belong to different writing system.*

**Example 7:** *Two writing systems separated by the writing direction.*

**7a)** Chinese script, right to left, as written on tombstones: 安南

**7b)** Chinese script, left to right: 南安

(Streiter et al. 2007)

As the changes in the writing direction may imply changes in the characters of the script (e.g. in Mandarin Chinese, traditional characters has different realizations of the character 理 for top-to-bottom or left-to-right writing) and affect punctuation, quotation, enumeration and numbers, the writing direction is most likely to be an attribute of the orthography. Thus, when the writing direction changes, the orthography changes with it, allowing then, all other subsystems of the orthography, such as hyphenation, to change. A writing in boustrophedon, such as found, for example, in Ancient Greek, obviously challenges our formalization. What would be need would be a mirroring operation that operates over a line in a text, mirroring along the horizontal axis and/or the vertical axis. Such operations should be defined as part of the orthography as the notion of 'line' is available only at this level. If defined this way, boustrophedon would not be among the writing directions. This, however is reasonable, as with a boustrophedon the orientation of the characters changes, while a changing writing direction does not change the orientation of characters.

**Listing 12:** *A second model of orthography.*

---

```
[orthography_name=,  
...,  
vertical_mirror=,  
horizontal_mirror=,  
writing_direction=].
```

---

### 3.2.5. *The Rotation*

Texts, finally can be turned at an angle of 90 or 270 degree, especially if a left-to-right writing, e.g. in Latin or Cyrillic characters) is integrated into a top to bottom writing, e.g. traditional Chinese or traditional Mongolian. As the angle does not interfere with any other attribute or value, it can be represented outside the orthography. The model of writing thus is summarized in Listing 13.

## 4. Summary and Conclusions

In this paper we have tried to argue that linguists that do not carefully conceptualize writing systems, damage the entire field of linguistics. If the opposition between the notion of language and the notion writing systems collapses within the conceptual space of the linguist, his or her discourse becomes essentially meaningless and a transmitter of prevailing ideologies that ultimately contribute to the extinction of languages and cultures. Although we cannot provide here a full analysis of linguistic discourse, we can estimate the large amount of information that has to be inferred if we compare Listing 1, a possible model of standard linguistic discourse, to Listing 13, a more advanced model. While the first model explains a writing system by reference to a language, people, a region and a time, the last model highlights the arbitrary choices that contribute to the wri-

                                                                    writing_type=3]]
                      rule_type=*[rule]].
```

---

ting system, such as the choice of the alphabet, the writing standard and the orthography, contrasting the current state with other theoretical possible or historical states or historical decision that have been made.

Then we have tried to illustrate a formal approach to the description of writing systems. Starting from the inadequate description of a writing system we identify the attribute that varies in the inhomogeneous set of writings. We then arrange this attribute in the model such that the model is as constraint as possible, e.g. through the usage of hierarchical structures, but still valid. We thus assume the same conceptual structure for all writing systems and arrange the model so that it is valid for all writing systems. This theoretical model then projects dimensions, seeming regularities or categories onto the linguistic material which have gone unobserved for writing systems. We conjecture that finding the relation between these categories and the writing systems of the world will propose new insights in writing systems, writing in general and human cognition, demanding through the empirical validation an ever increasing specification.

If we assume that there are arbitrary constraints and linguistically motivated constraints on writing systems, theory formation in writing systems thus transforms seemingly arbitrary constraints into linguistically motivated constraints. For example, one might observe the fact that writing systems using the Cyrillic and Latin alphabet have a *segmental writing standard*. One then might then check the validity of the observation, and observe that it is only valid for *common writings*. The transformation of this finding into a general rule provokes a number of new questions. One might for example hypothesize that if more than one mapping between writing systems is possible, the mapping with the least information loss is chosen. This is a quite high level abstract constraint that, if put onto our model, would explain a great number of seemingly arbitrary constraints. Thus, if the phonological transcription (let us for a short while assume that there is one) has vowels and consonants and the available script can represent vowels and consonants, the segmental mapping is the preferred one. For any syllable-based mapping there might be not sufficient characters in the script and consonantal writings or other ambiguities of default vowels create ambiguities. If we cannot assume a phonological transcription from which to be mapped, we can assume at least a phonological awareness, which is formed or influenced by writing systems known by people in a certain time in a certain place. To represent these states of phonological awareness will be a challenge on its own. This relation between the phonological awareness and the available script would help to explain, for example, the slow development of, *segmental* writings in the history of writing. One might even try to reconstruct the phonological awareness of extinct languages from the modification of writing systems.

Finally we claim, that this formal exercise does not only have its practical benefits for archiving, data management and computational linguistics, but allows to derive and define the notions we should use when talking about languages and writing systems. It shows us new research directions, e.g. the construction of hierarchies for scripts, standards and orthographies and shows us where our knowledge and understanding is still insufficient, e.g. when facing seemingly arbitrary constraints on writing systems.

A last remark. Writing systems are important for the formation of identities and identities are indispensable for humans to survive. It is not our purpose to remove this important component from the discourse on writing. However we try to replace the fre-

quently dark nationalistic shades in the discourse by shedding light on the human and cultural development at the root of writing, something all people can be equally proud of.

# The Korean Alphabet: An Optimized Featural System with Graphical Ingenuity

Sang-Oak Lee

Seoul National University

[sangoak@snu.ac.kr](mailto:sangoak@snu.ac.kr)

## 1. Introduction

The basic structure of the Korean alphabet named as **Hangeul** is logical and systematic. The vowel letters are based on the three philosophical symbols for the trinity: Heaven · , Earth — , and Human | . These are typically the limited set of strokes (vertical, horizontal, and short lines = dots) frequently used in many other alphabets. All the vowels in the Korean language are combinations of dots, horizontal and vertical lines. These signs are balanced into the *Yang* (bright) sounds and *Yin* (dark) sounds for harmony, which according to Taoism are the universe's two opposing energies.

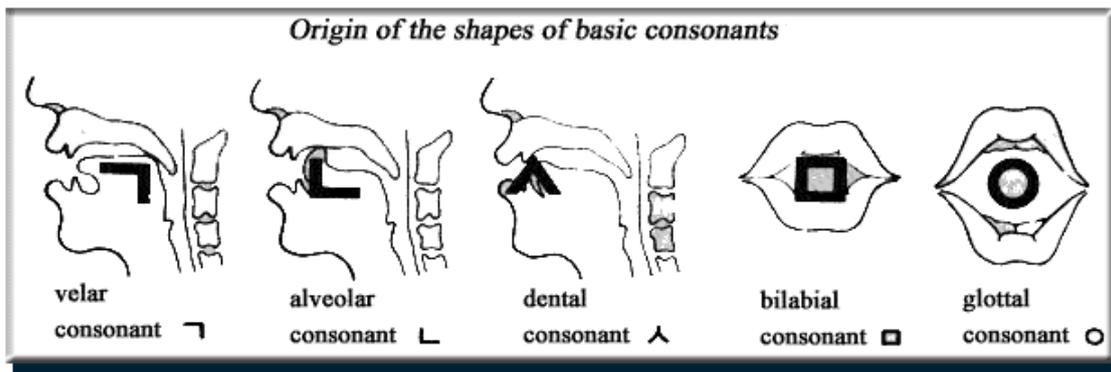

The Heaven	The Earth	The Human
( <i>Yang</i> bright, male)	( <i>Yin</i> dark, female)	(neutral)
Round dot	Level	Standing
· · ·	— — —	

King **Sejong**, inventor of the Korean alphabet in 1443, created a separate symbol for each vowel phoneme. There are eleven vowels shaped after symbols that represent the most important elements in eastern cosmology. This remarkable accomplishment is as important as the figurative representation of consonant features: prior to the 15<sup>th</sup> century, no writing system with a full representation of the vowels was known in all of Asia. Indian alphabets, for example, which were familiar to Koreans through Buddhism, incorporate the vowel "a" into the consonant symbols and represent other vowels with diacritics. The importance and significance of the vowel was a discovery unprecedented in East Asia. The analysis of a syllable by tripartite C-V-C (onset-nucleus-coda, where

C represents "consonant" and V "vowel") was creatively made breaking from the long tradition of bipartite C-rhyme(=VC) fundamental to Chinese phonology.

It is an undisputable fact that the consonant letters are based on the shapes of various speech organs. This is very innovative idea with the articulatory phonetic explanation which is better than Bell's *Visible Speech* in the West. Although some scholars have attempted to draw coincidental and nonsystematic connections between a few of the letters in **Hunmin jeongeum** (the original name of the Korean alphabet when it was first proclaimed) and those of neighboring writing systems, these apparent similarities are the result of the limited nature of the set of strokes (vertical, horizontal, and slanted lines, and circles) frequently used in an alphabet.

Ledyard (1966) and Yu Chang-gyun (1966) have suggested 'Phags-pa script as a possible model for the Korean alphabet, in particular, the 'Phags-pa consonants [d] for Korean [t]. However, other letter shapes, like Korean ㅅ[s], ㅆ[č], and ㅈ[tʰ], do not have the same sound value as the similar 'Pahags-pa letters ㅅ[o], ㅆ[o], and ㅈ[j]. With only this much coincidental similarity, nobody can fairly claim that there is systematic correspondence. The phonetic background of the script **Hunmin jeongeum** is clearly explained in the book *Hunmin jeongeum haerye* ("Explanations and Examples of the Correct Sounds for the Instruction of the People") the basic consonant symbols are schematic drawings of the speech organs articulating the sound.

Consonants articulated at the same place in the mouth share the same basic graph. Then, if one of these consonants has the added feature of aspiration, the symbol for that consonant is written with an additional stroke. Compare, for example, the symbols of the Roman alphabet: nothing in the shapes of the letters indicates how the phonemes are articulated. For example, pairs of letters such as *t* and *d* provide no clue that the two sounds they represent are related in any way. Both are articulated in the alveolar region.

The unique characteristics of the Korean alphabet are as mentioned above 1) the

creation of related letters by the addition of strokes to basic letters, and 2) writing words in syllabic units, combining more than two letters within two or three blocks in a square as found in Chinese characters, for example, 珀 or 碧.

However, **hangeul** also stood in stark contrast with the complex and flowing lines of Chinese characters. No one looking at this original work could fail to be impressed by the difference. Unlike the letters of other alphabets, **hangeul** symbols are not written side-by-side; rather, the individual letters are arranged into syllabic units. There are typically several different positions where a letter may occur. The shape of vowels may be affected by the presence of glides or final[=coda] consonants, and the shape of consonants by the vowel, the glide, or the presence of final consonants.

When we write individual letters in a syllabic unit for actual writing, there are six syllabic layouts. As illustrated in the following diagram, the individual letters are arranged and proportioned to fit neatly into a square box, and are always read from left to right, then top to bottom. As shown in Figure 1, there are several degrees of density in paralleling the strokes: six strokes in the horizontal direction and seven in the vertical direction are the most complex.

Vowels that are "vertical", like ㅏ, go to the **right** of the first consonant in a syllable. Vowels that are "horizontal", like ㅑ, go **under** the first consonant in a syllable. All of this is done to make sure that syllables fit into a square box.

가    ㄱ    ㅋ    ㆁ    ㆁ    ㄴ  
 ㅏ    ㅑ    ㅓ    ㅕ    ㅗ    ㅛ  
 ㅜ    ㅠ    ㅡ    ㅜ    ㅝ    ㅞ  
 ㅟ    ㅠ    ㅡ    ㅟ    ㅠ    ㅡ  
 ㅢ    ㅣ    ㅤ    ㅥ    ㅦ    ㅧ  
 ㅨ    ㅩ    ㅪ    ㅫ    ㅬ    ㅭ

		Bright	Dark	Neutral
	Vertically Oriented	ㅏ   ㅑ   ㅓ   ㅕ	ㅜ   ㅠ   ㅡ   ㅞ	ㅠ
	Horizontally Oriented	ㅑ   ㅕ	ㅟ   ㅡ	ㅢ

	Mixed-Orientation	나 내 니	겨 게	ㄱ
---	-------------------	-------	-----	---

Fig. 1. How to compose ‘Syllabic Units’

A maximal Korean syllable structure is CVCC. While C is optional, V is obligatory. The Korean syllable structure can therefore be re-written as (C) V (C) (C). All the possible combinations of the syllable occurrences are exemplified as the following:

V : 아, 와, 왜    VC : 얼, 음, 은    VCC : 앓, 엷, 읊

CV : 가, 보, 뛰    CVC : 낙, 뿔, 광    CVCC : 값, 뭇, 뽕

In addition to these characteristics, some calligraphic principles are applied. They are 3) writing from left to right and from top to bottom, 4) maintaining equi-distance in adding strokes and in creating syllabic units, and 5) limiting the size of syllabic units to the inside of squares in equal sequence. All these give a feeling of symmetry and stability based on calligraphic beauty (see Fig. 1).

Each syllable is symmetrical and balanced, much as one would say for Chinese characters. But these are not characters, they are syllables, or perhaps better morpho-syllables, consisting of alphabetic symbols representing the individual sounds, arranged according to the morpho-phonological rules involved.

Hangeul can be written both horizontally and vertically. The latter method is traditional, akin to the Chinese style. The former style was promoted since the twentieth century, and has become overwhelmingly preferred. Within each word, syllables are written right next to each other. Between words, however, there are spaces. This way even quickly and messily written hangeul will be legible to Koreans.

Hitherto uninvestigated aspects of the Korean writing system include graphemes and calligraphy.

## 2. How were the Graphemes of the Korean Alphabet Designed?

The question that has never been asked is *how* King Sejong the Great, who invented the alphabet, experimented with various possible strokes and characters on a

blank piece of paper. I assume that the king was the initiator of all ideas, since an individual should come up with an embryonic idea at the outset.

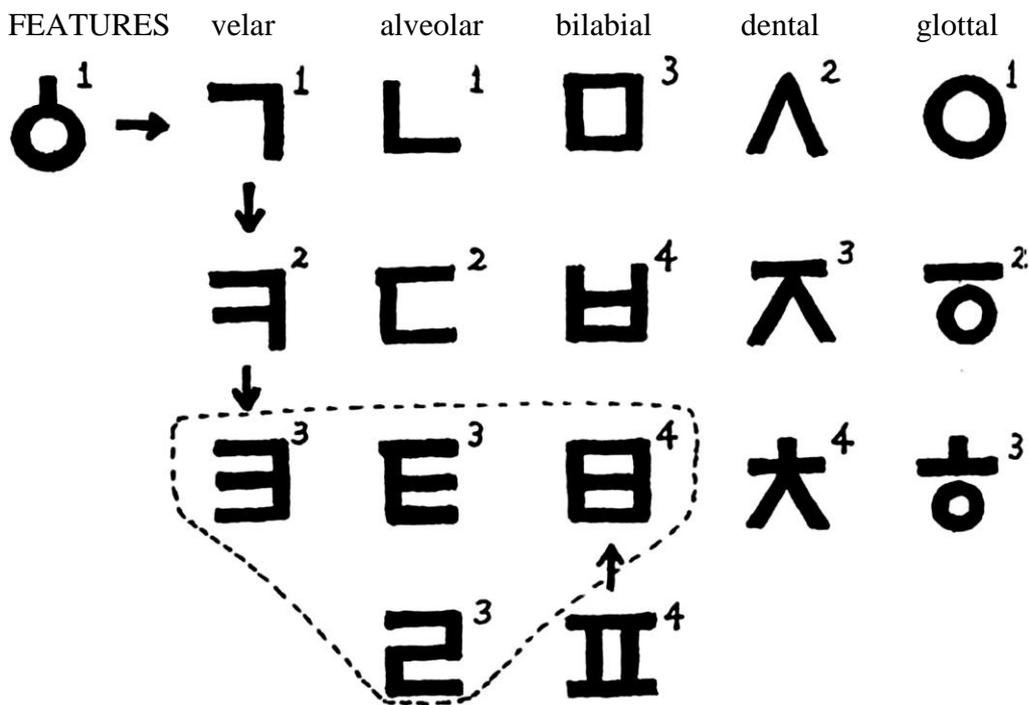

In this sequence of preparation, I am sure that he used the “trial and error” method, and was not mysteriously inspired with a mature idea for the entire set of characters all at once. It means that he used a brush to draw a draft of scripts and felt the difficulty of writing dots but in the initial period stuck to the philosophical symbol of round dot for Heaven and later changed to short strokes from the impractical dots in brush writing and plate carving on the wooden blocks.

### *2.1. Economy of Calligraphy*

In the case of ㄱ, ㅋ and ㆁ, the reason why he did not choose ㄱ, ㅋ and ㆁ is that the latter require one more stroke apiece in brush writing. This may be regarded as another calligraphic principle: 6) minimization of strokes. Another interesting example of economy of calligraphy is the latter development of shapes in 入, 丩, ㄹ with a visible reduction in the number of strokes from original 2, 3, 4 to 1, 2, 3.

### *2.2. Avoiding Calligraphic Similarity*

When King Sejong invented the consonant letters, he may have ended up with several similar characters, as marked by a dotted line in Fig. 2. It is well known that ㅞ and ㅟ printed in small type are often misread even today. Two problem areas were avoided: one is ㅞ and the other ㅟ. Thus, 7) calligraphic similarity must be avoided by introducing different shapes.

Velar	○ (ŋ)	ㄱ (g)	ㅋ (k)	ㆁ (kk)	
Alveolar		ㄴ (n)	ㄷ (d)	ㄸ (tt)	ㄹ (r, l)
Bilabial	ㅁ (m)	ㅂ (b)	ㅃ (p)	ㅍㅍ (pp)	
Dental	ㅅ (s)	ㅈ (j)	ㅊ (č)		
Glottal		ㅎ (h)			

Fig. 2. A Hypothetical and Preliminary Draft for Designing the Korean Alphabet

It is my assumption that King Sejong avoided the graphic jam by eliminating ㄷ, shifted ㄱ and ㅋ down to fill a blank, and newly introduced ㅇ as an exceptional measure of avoiding the graphic jam, an interpretation more in line with other ingenious aspects of the Korean Alphabet (Hunmin Jeongeum).

Many scholars believe that ㅍ has two additional strokes on the top of ㅍ but it is totally wrong. ㅍ has three strokes and ㅑ simply four in brush writing. Thus, there is not two, but one additional stroke.

As for ㅌ, this shape looks not only like the Chinese character 日 but also like the other Korean letters ㅌ, ㅎ, & ㄷ. Therefore, to avoid this jam in the dotted line of Fig. 1, ㅌ was introduced probably turning ㅌ by 90 degrees. ㅌ is a more natural way of adding strokes to ㅍ & ㅑ, but may have had problems in composing shapes like ㅌㅌ (the first ㅌ as a consonant, the second ㅌ as a vowel).

### 2.3. Graphemes with Maximal Distinction

Last but not least, ㄱ was chosen over ㄲ to avoid the probable confusion with ㅋ. ㄲ is one possible way to add a stroke to ㄱ. Likewise, ㅌ is one possible way to add a stroke to ㄴ. It is likely that either the set ㄱ & ㅋ or the set ㄲ & ㅌ would be selected to keep 8) maximal distinction between graphemes. Maximal distinction together with avoidance of calligraphic similarity is aspects of a general principle of calligraphic distinctiveness.

### 3. An Optimized Featural System

De Francis (1989) claims that Bell's "Visible Speech(VS)" is featural because it consistently takes a C-shaped symbol for *consonant*. As a result this *consistent* iconic alphabet ends up with shapes that prove equivocally confusing for laymen and cannot be used as a universal phonetic writing system in any practical cases. Although VS was a faithful featural script, Bell failed to understand where to leave this faithfulness and adhere to principle, but King Sejong knew how to make the system optimally workable. Sproat (2000) classified Hangeul(Hankul) as \_ an intelligently constructed segmental alphabet," but fairly speaking beyond taxonomic nomenclature, I believe it should be viewed as an **Optimized Featural System: a segmental system that come close to being\_ a featural system but intentionally avoids becoming completely featural.** As I explained above, King Sejong had "a tight spatiogeometrical constraint of having to represent characters in mutually distinctive shapes, each with no more than a few strokes."(Kim 1997)

In addition, the Korean vowel script retains the more vertical strokes for the statistically frequent vowel group (cf. Lee Sang-Oak, 1997), and it is easier to move our fingers and hand vertically well with a brush. Whether Sejong were aware of this relationship between the frequency of sounds and the assignment of vertical strokes, he invented the most optimal system anyhow, probably with the help of the Heaven.

# A Syntax-Semantics Interface Study of Predicative *Shi* in Mandarin Chinese Copular Construction

Li, Larry Hong-lin

Department of English, National Taiwan Normal University  
162 He-Ping East Road Sec. 1, Taipei 106, TAIWAN, R.O.C.  
[lion6688@ms36.hinet.net](mailto:lion6688@ms36.hinet.net)

## Abstract

This research points out that, in the Mandarin predicative NP1-*shi*-NP2 construction, NP2 cannot independently serve as the syntactic predicate. That is, the syntactic predicate consists of *shi* and NP2. Furthermore, the syntactic realization of *shi* is determined by two semantic conditions. First, when NP2 denotes a specific meaning, *shi* can be covert. Second, when the sentence conveys a general reading with respect to the temporal reference and the perspective of referring, *shi* is not obligatory to be realized. This research concludes that in exploring the syntactic behavior of language, the semantic dimension must be taken into consideration.

**Keywords:** copula, predicate, specific meaning, temporal reference, perspective of referring

## 1. Introduction

From a syntax-semantics viewpoint, this paper explores the conditions determining the syntactic presence of the copula *shi*, a necessary part of the predicate in the NP1-*shi*-NP2 construction. It is clarified that in this construction the predicate is composed of *shi* and NP2. In addition, the fact that *shi* can be covert concerns two semantic conditions. The first concerns the denotation of NP2, namely, whether NP2 denotes an entity whose property is well characterized and classified. The second condition concerns the semantics of the sentence containing *shi*, namely, whether the sentence is interpreted under a generic reading and involves an unrestricted frame of reference in which properties are valued. Of these two semantic conditions, the first applies before the second one does. This research indicates language universal that the overt manifestation of Mandarin predicative *shi*, as those of the copular verbs in many other languages, is bound to semantic properties.

In most of the predicative NP1-*shi*-NP2 sentences, the copula *shi* must be present as shown in (1). However, it is well-known that there are examples in which *shi* does not have to occur. In other words, what we see is an apparent NP1-NP2 sequence as shown in (2).

- (1) Zhangsan \*(shi) xuesheng.  
 Zhangsan be student  
 ‘Zhangsan is a student.’
- (2) a. Zhangsan (shi) hao xuesheng.  
 Zhangsan be good student.  
 ‘Zhangsan is a good student.’
- b. Zhangsan (shi) zhongxuesheng.  
 Zhangsan be middle-school student  
 ‘Zhangsan is a middle school student.’

In view of this phenomenon, this article is motivated to identify the conditions constraining the syntactic presence of the copula *shi*. More specifically, we propose that the syntactic behavior of *shi*, on a par with copular verbs in many other languages, is tied to semantic values. These semantic constraints on the syntactic distribution of *shi* include, firstly, the reference denoted by NP2 and, secondly, the meaning conveyed by the sentence with respect to the temporal reference and the perspective of referring.

This paper is organized as follows. Section 2 reviews the previous works exploring *shi* in its predicative use. Section 3 discusses how *shi* can be covert when the denotation of properties of NP2 is specific enough. Section 4 addresses how the temporal denotation of the sentence and the perspective of referring condition the lexical realization of *shi*. Section 5 demonstrates the ordering of the application of the two semantic conditions and section 6 concludes this article.

To the best of our knowledge, all the previous analyses of this NP1-NP2 construction (e.g. Tang 2001; Wei 2004a, b; Hsieh 2005b) are based on the same assumption that NP2 alone can be predicative of NP1, serving as a nominal predicate. However, under their analyses, a problem arises: why *shi* has to occur in the sentence which refers to a specific location in time or denotes an entity based on a relativized set of reference. Thus, this research proposes to survey why and when *shi* can be implicit by looking into the semantic dimensions of the sentence containing *shi*.

## 2. Problems of Previous Analyses

In this section, we review three analyses proposed for the predicative NP1-(*shi*)-NP2 construction in the literature and point out theoretical and empirical problems that they suffer.

To begin with, Wei (2004a,b) claims that in copula-less sentences, NP2 is licensed as a nominal predicate only when it conforms to a modifier-modifiee pattern

at or above the phrase level. As shown in (3a) and (3b), *hao* ‘good’, an AP, and *xuesheng* ‘student’, an NP, form such a modifier and modifiee relationship at the phrasal level, which thus licenses absence of the copula *shi*.

- (3) a. \*Xiaohua xuesheng.  
       Xiaohua student  
       b. Xiaohua haoxuesheng.  
       Xiaohua good student  
       ‘Xiaohua is a good student.’

However, it is questionable that *hao* ‘good’ indeed modifies *xuesheng* ‘student’ in (3b) as claimed. According to McCawley (1992), such a sequence should be taken to be a compound rather than a combination of an adjective phrase and a noun phrase since an adjective phrase should be able to ‘expanded’ as in (4) but the sequence at issue cannot co-occur with degree expressions and comparative phrases as shown in (5), contrary to expectation.

- (4) a. He is a good boy.  
       b. He is a very good boy.  
       c. He is a better boy than you.  
       (5) a. Ta shi yige hoaxuesheng.  
           He be one-*Cl* good student.  
       b. \*Ta shi yige hen haoxuesheng.  
           He be one-*Cl* very good student  
       c. \*Ta shi yige bi ni haoxuesheng.  
           He be one-*Cl* than you good student

Furthermore, under Wei’s analysis, NP2 in (6) is expected to serve as a nominal predicate because it conforms to the required pattern with *henduo* ‘many’ as modifier and *xuesheng* ‘student’ as modifiee. This expectation, however, is not borne out.

- (6) \*Tamen henduo xuesheng.  
       They very many student

These unacceptable examples, therefore, show that a modifier-modifiee internal structure of NP2 is not the right generalization to capture the licensing of copula-sentence sentences.

Another account for the copula-less constructions is provided by Hsieh (2005b). It is pointed out that the occurrence of *shi* in the predicative NP1-*shi*-NP2 structure is conditioned by two factors related to the nominal phrase: whether there is an empty indefinite determiner and whether there is an internal licenser for the empty indefinite

determiner. Witness sentences in (7).

- (7) a. Ta (shi) [<sub>DP</sub> hen hao de [<sub>DP</sub> yi-ge [e] xuesheng]].  
He be very good *De* one-*Cl* student  
'He is a very good student.'
- b. Ta \*(shi) [<sub>DP</sub> yi-ge [e] [<sub>NP</sub> hen hao de xuesheng]].  
He be one-*Cl* very good *De* student  
'He is a very good student.'
- c. Zhangsan [<sub>NP</sub> shagua].  
Zhangsan fool  
'Zhangsan is a fool.'

According to Hsieh (2005a), in (7a), the modifier *hen hao de* 'very good', either adjoined to D' or DP, marks the existence of DP. This modifier serves as the internal licenser for the indefinite D. Thus *shi* is not required to be present since the indefinite D has been internally licensed. On the other hand, *shi* is required to occur in (7b) when the empty indefinite determiner needs external licensing with *shi* being the external licenser. The modifier *hen hao de* 'very good' in (7b) is adjoined to N' or NP and does not mark the existence of DP. Therefore, *shi* has to function as the external licenser and is required to be present in (7b).

Under closer scrutiny, however, the contrast in (7a) and (7b) is actually not as sharp as claimed by Hsieh. This casts doubt on simply relying on the word order difference between the adjective and the classifier to account for distribution of the copula *shi*.

Moreover, according to Hsieh (2005b), when there is no projection of D as in (7c), no licensing is required and therefore *shi*, as an external licenser, does not have to occur. However, when (7c) is compared to (8a) and (8b) as follows, it can be found that *shi* is required to occur although, as in (7c), there is no projection of D in (8a) and (8b).

- (8) a. Xiaolin \*(shi) yisheng.  
Xialin be doctor  
'Xiaolin is a doctor.'
- b. Laoliu \*(shi) jingwei.  
Laoliu be guard  
'Laoliu is a guard.'

From the comparison between (7c) and (8), it is suggested that the occurrence of *shi* is not relevant to the syntactic factors as Hsieh proposes but the semantic reading of NP2.

Finally, we consider Tang's (2001) account for the absence of *shi* in this construction. According to Tang, required by a focus anchoring principle, *shi* necessarily appears if the expression itself serves as a focus of message, based on a contrast with another piece of information in the mind of the speaker. Therefore, according to this analysis, the reason why NP2 *xinlaoshi* 'a new teacher' in (9) can be a predicate is that it is anchored by the focus through a contrast with 'an old teacher'. Likewise, the pair of NP2's in (10) can serve as predicates because of being a focus of information, set in a pair of contrastive sentences.

- (9) a. \*Zhangsan laoshi.  
       Zhangsan teacher  
       b. Zhangsan xinlaoshi.  
       Zhangsan new teacher  
       'Zhangsan is a new teacher.'
- (10) Zhangsan jingcha; Lisi junren.  
       Zhangsan policeman Lisi soldier  
       'Zhangsan is a policeman; Lisi is a soldier'

This account, however, fails to explain why *shi* is required to occur in (11a) and (11b).

- (11) a. Jiang ayi congqian \*(shi) haotaitai. (xianzai, bu shi.)  
       Jiang aunt before be good wife. (now not be)  
       'Aunt Jiang was a good wife before. (Now, she is not.)'
- b. Lisi yinggai \*(shi) haoyisheng. (Danshi shijishang ta bu shi.)  
       Lisi should be good doctor. (but in-fact he not be)  
       'Lisi should be a good doctor. (But, in fact, he is not.)'

According to Tang's analysis, in (11a) and (11b), the omission of *shi* should be allowed since the two sentences denote a contrastive meaning: in (11a) a contrast between the state of the present and that of the past; in (11b) a contrast between the expectation of the speaker and the reality. In spite of such contrastive reading, the copula *shi* is still required to occur in (11a) and (11b), thus casting doubt on this focus approach to copula-less sentences.

Additionally, under Tang's analysis, the fact that the copula *shi* may be absent in a small clause as in (12a) is because copula-less sentences are permitted in a context with "epistemic modality" but not in a factual context; an epistemic context, but not a factual one, provides a contrastive reading, which thus allows *shi* to be elided.

- (12) a. Wo dang Zhangsan (shi) xuesheng. (Tang 2001)  
       I consider Zhangsan be student

- ‘I consider Zhangsan a student.’
- b. Wo zhidao Zhangsan \*(shi) xuesheng. (Tang 2001)  
 I know Zhangsan be student  
 ‘I know that Zhangsan is a student.’

This account for the contrast in (12), however, is problematic. First, it remains a question whether *dang* takes a small clause as its complement. In fact, (12a) does not sound as acceptable as claimed by Tang with the absence of *shi*. If we look into more data, it can be found that the presence of *shi* in the complement clause should be required. Identify (12a), (12c) and (12d).

- (12) a. Wo dang Zhangsan ?(shi) xuesheng.  
 I consider Zhangsan be student  
 ‘I consider Zhangsan a student.’
- c. Wo dang Zhangsan \*(shi) kouzhuajia.  
 I consider Zhangsan be month-foot painter  
 ‘I consider Zhangsan a month-foot painter.’
- d. Wo dang Zhangsan \*(shi) baoxiantuixiaoyuan.  
 I consider Zhangsan be insurance salesperson  
 ‘I consider Zhangsan an insurance salesperson.’

Second, as Rothstein (2001: 275) stresses, the presence or absence of *shi* leads to distinct interpretations. Witness (12e) and (12f) below.

- (12) e. I consider Ken to be a nice doctor.  
 f. I consider Ken a nice doctor.

In (12e), the small clause denotes an existential eventuality, whereas in (12f) it refers to a characterizing property. Such a distinction can also be seen in the small clause complement taken by *dang* if we accept Tang’s analysis of *dang* as taking a small clause complement. Observe the contrast between (12a) and (12g) as follows.

- (12) a. Wo dang Zhangsan (shi) xuesheng. (Tang 2001)  
 I consider Zhangsan be student  
 ‘I consider Zhangsan a student.’
- g. Wo dang Zhangsan xianzai \*(shi) xuesheng.  
 I consider Zhangsan now be student  
 ‘I consider Zhangsan to be a student now.’

In (12g), the complement clause denotes an eventuality in present time and *shi* is not allowed to be absent. Last but not the least, the copula *shi* can and, in fact, must occur

in contexts denoting modality as shown in (13).

- (13) a. Huang xiaojie yinggai \*(shi) haomama.  
Huang miss should be good mother  
'Miss Huang should be a good mother.'
- b. Wang xiansheng hoaxing \*(shi) minghuajia.  
Wang mister seem be famous painter  
'Mr. Wang seems to be a famous painter.'

Based on the two pairs of counterexamples, those containing overt temporal expressions in (11) and those containing modal expressions in (13), we thus conclude that Tang's account that hinged on focus is not on the right tract. It is crucial to note that these two sets of data also constitute important counterexamples for Wei's (2004a, b) and Hsieh's (2005b) accounts as well. It is not immediately clear why the absence of the copula *shi* is not licensed since the modifier-modifiee relationship proposed by Wei and the licensing of the empty D proposed by Hsieh supposedly is satisfied within the internal structure of NP2. The fact *shi* has to be present in these contexts suggests that the licensing of the absence of the copula *shi* should go beyond the syntactic concerns provided by Tang, Wei and Hsieh.

Behind the analyses of *shi* given by Tang (2001), Wei (2004a, b) and Hsieh (2005b) is the assumption that NP2 in the NP1-*shi*-NP2 construction can be an independent nominal predicate. However, both theoretically and empirically, this assumption is not without problems. First, from the theoretical viewpoint, Timberlake and Nichols (1991) pinpoints that the copula reports a state or a change of state denoted by NP2 for NP1. Additionally, Rothstein (2001: 299) clarifies that English copula *be* is a grammatical formative although it is not a content word like any other lexical verbs. It actually bears a packaging and locating function, which presents a non-countable property denoted by the semantic predicate as a countable eventuality and then locates this eventuality in time. Since a predicational sentence ascribes either an inherent property or an existential eventuality to NP1, copula *be* plays a crucial semantic role in the NP1-*be*-NP2 construction.

In addition to the theoretical weakness, the analyses of Tang, Wei, and Hsieh can not account for why the sentence allowing *shi* to be elided requires a pause between NP1 and NP2.

Empirically speaking, all the sentences analyzed by Tang (2001), Wei (2004a, b) and Hsieh (2005b) as allowing *shi* to be elided require a pause between NP1 and NP2. Witness the following sentences.

- (14) a. Xiaochen haofuqin.  
Xiaochen good father

- ‘Xiaochen is a good father.’
- b. Xiaochen (shi) haofuqin.  
 Xiaochen is good father  
 ‘Xiaochen is a good father.’
- (15) a. Lisi daxuexiaozhang.  
 Lisi university president  
 ‘Lisi is a university president.’
- b. Lisi (shi) daxuexiaozhang.  
 Lisi is university president.  
 ‘Lisi is a university president.’

From (14) and (15), it can be seen that (14b) and (15b) which read with a pause between NP1 and NP2 sound more natural than (14a) and (15a).<sup>1</sup> According to Crystal (2003), a pause functions as a grammatical marker and plays a part in structure. For instance, an empty position left by a movement forms a syntactic gap. This syntactic gap constitutes a phonologically empty category and reads with a silent pause. In addition to Crystal, Cooper and Paccia-Cooper (1980) points out that a prosodic boundary often occurs where a syntactic deletion has taken place.<sup>2</sup> According to Crystal and Cooper and Paccia-Cooper, such a silent pause or a prosodic boundary indicates that there should be an empty position occurring between NP1 and NP2. Another indirect piece of evidence is mentioned by Feng (1993), studying the copula in classical Chinese. Feng points out that in classical Chinese there is a pause position between the subject and the semantic predicate, which serves as a place holder and can be filled by semantically empty particles. Thus, the pause occurring between NP1 and NP2 suggests that there indeed exists a slot left by *shi* being covert.

To summarize, from the theoretical and empirical point of view, in the NP1-*shi*-NP2 construction, NP2 cannot be a nominal predicate. Furthermore, the appearance of *shi* should be explored from the semantic perspective. Therefore, this research proposes to analyze *shi* as a necessary constituent in this construction, whereas it should be overtly realized in certain situations under the intervention of semantic factors.

---

<sup>1</sup> Most of the speakers consulted by the researchers accept as more natural the sentence with a silent pause between NP1 and NP2 as in (14b) and (15b). However, according to the speakers surveyed, when two predicative sentences are juxtaposed with a pause in between, the pause occurring NP1 and NP2 can be elided.

<sup>2</sup> According to Cooper and Paccia-Cooper (1980), in (i), there should be a prosodic boundary, as marked by ‘#’, between *John* and *to Sue* since *gave a book* has been deleted and left an empty position.  
 (i) Sam gave a book to Mary and John # to Sue.

### 3. *Shi* and Semantic Property of NP2

#### 3.1. *Shi* as a semantically null verb

According to the modern linguistic view of the copular verb (Narahara 2002), *shi* functions to be a copula which makes no contribution to the semantic interpretation. Narahara cites Bach (1967) as employing the selectional restriction in testing whether the copula is semantically empty: the predicate nominal imposes a selectional restriction on the subject nominal as regular verbs do on their arguments. Such a test can serve to demonstrate that *shi* is a semantically null verb. Witness the contrast in (16).

- (16) a. Zhangsan shi Taipei ren.  
Zhangsan be Taipei man  
'Zhangsan comes from Taipei.'  
b. \*Zheben shu shi Taipei ren.  
This-*CI* book be Taipei man.

The acceptability contrast in (16) indicates that *shi* does not effect the proposition but the second NP does. Such being the case, it is NP2 that ascribes a property and thus is semantically predicated of the subject NP1. NP2, as Napoli (1988, 1989) explicates, is the semantic predicate. The semantic values of semantic predicate and its interaction with the copula is elucidated in the following subsection.

#### 3.2. *Shi* as a reporter of the semantic property of NP2

Timberlake and Nichols (1991) note that the copula is responsible for reporting the state denoted by NP2 for NP1. Moreover, the variation in the semantic value denoted by NP2 may be morphosyntactically correlated with the form of the copula. Compare (17a) and (17b) below.

- (17) a. John is a good guy.  
b. John seems a good guy.

In (17a), by virtue of the copula *be*, the property of being a good guy is neutrally reported for NP1, *John*, whereas in (17b), by the copula *seem*, the same property is assigned to *John* with a judgment involved. With regard to the semantic predication of NP2, Napoli (1988, 1989) clarifies that NP2 conveys a subjective and an evaluative judgment towards NP1. As illustration, consider (18a) and (18b).

- (18) a. Mr. Wang is a responsible doctor.

b. Peter is the best man I have met in the world.

(18a) and (18b) both express a subjective opinion and assign a property to the subject NP. In addition to the evaluative description, Timberlake and Nichols (1991) stress that NP2 specifies the semantic properties to be assigned to NP1 by individualizing NP1 into a certain class and characterizing NP1 by its distinctiveness from other individuals. By individualization and characterization, it means that the denotation of NP2 points to the classification of NP1 into a member of a kind (Carlson 1977) or characterizes NP1 by its properties. Witness (19a) and (19b) shown below.

(19) a. Smith is a teacher.

b. John is a genius.

NP2 in (19a) specifies the property of NP1 of being in the capacity of the typical member of some class of individuals while NP2 in (19b) features NP1 by the property of being talented. Given the analyses of the semantic value of NP2 provided by Napoli (1988, 1989) and Timberlake and Nichols (1991), we sort the predicative nature of NP2 into two types in terms of objectivity and subjectivity. In the objective sense, NP2 denotes a classification in which the entity denoted by NP1 is classified into a proper kind, as in (19a); in the subjective sense, NP2 denotes a characterization in which it points to the characteristic of NP1 involving the judgment and evaluation of the speaker as in (18) and (19b).

Based on the semantic function of the copula and the predicative nature of NP2, we assume that the syntactic manifestation of *shi* is determined by the semantic value denoted by NP2: when NP2 assigns a property to NP1 in a specific sense, *shi* can be syntactically covert. In the follow-up, let us scrutinize the correlation between the realization of *shi* and the specificity of the semantic property denoted by NP2.

### 3.2.1. Objective classification

This section examines whether the explicitness of *shi* is related to how well the referent of NP1 is classified. Witness (20), (21), and (22) in the following.

(20) a. Wei xiansheng Zhongguoren.

Wei mister Chinese

‘Mr. Wei is Chinese.’

b. \*Wei xiansheng ren.

Wei mister man

(21) a. Zhangsan xiaozhang; Lisi zhuren.

Zhangsan principal Lisi director

‘Zhangsan is a principal; Lisi is a director.’

- b. \*Zhangsan xiaozhang.  
 Zhangsan principal
- (22) a. Zhang xiaojie mishu jian daziyuan.  
 Zhang miss secretary and typist  
 ‘Miss Zhang is a secretary and typist.’
- b. \*Zhang xiaojie mishu  
 Zhang miss secretary

In (20a), *Zhongguoren*, analyzed by Tang (2001) as referring to a subset of a presupposed set and by Wei (2004a, b) as subject to the modifier-modifiee pattern, refers to a class of all the peoples in the world. Yet, in (20b) NP2 is not properly classified. In (21a), according to Tang (2001), the contrast between two readings licenses the omission of *shi*. However, by the definition of individualization (Timberlake and Nichols 1991), the denotation of the different identities of two persons individualizes the two persons into separate classes of the kind. In (21b), NP2, denoting one single property, does not express well individualized meaning. Likewise, in (22a), *jian* denotes two properties of one individual (Li 2001), which sufficiently specifies the characteristic of NP1. However, compared to (22a), (22b) is not specific in characterizing the property possessed by NP1. Therefore, as can be seen in the examples given above, *shi* does not have to be syntactically overt in (20a), (21a), and (22a) since they meet the requirement of property assigning.<sup>3</sup>

### 3.2.2. Subjective characterization

In addition to the classifying predicative nature, NP2 expresses the characteristic of NP1 in a subjective sense. Consider the contrast between (23a) and (23b).

- (23) a. Xiaoming (shi) huaihaizi.  
 Xiaoming be bad kid

---

<sup>3</sup> We thank Ray Huang for offering a scenario in which *shi* does not have to be overt even though the property denoted by NP2 is not well individualized, as in (i) below.

(i) A: Zhangsan shi zuo sheme de?  
 Zhangsan *Shi* do what *De*  
 ‘What does Zhangsan do?’

B: Zhangsan (shi) xuesheng a!  
 Zhangsan be student *A*  
 ‘Zhangsan is a student!’

In this case, the individualized reading is provided by the context. Before speaker A gives the question, he actually presupposes *Zhangsan* is in a profession of some kind. Such a presupposition can be revealed by an extended interpretation attached to the question. Witness (ii).

(ii) Zhangsan shi zuo sheme de? (Laoshi haishi xuesheng?)  
 Zhangsan *Shi* do what *De* (teacher or student )  
 ‘What does Zhangsan do? (A teacher or a student?)’

Given the individualized interpretation brought about by the context, *shi* can be dropped.

- ‘Xiaoming is a bad kid.’  
 b. \*Xiaoming haizi.  
     Zhangsan kid

According to Tang (2001), *shi* can be omitted since (23a) involves a contrastive focus but (23b) does not. As for Wei (2004a, b), *shi* can be elided in (23a) but not (23b) since it fits the modifier-modifiee standard.<sup>4</sup> However, according to Napoli (1988, 1989), NP2, as semantic predicate, should voice a specific and an evaluative judgment.<sup>5</sup> Along this line of thinking, (23a) is better than (23b) in evaluating the property of NP1. As evident in (23), *shi*, functioning to report a property for NP1, can be covert when the property denoted by NP2 is more specifically and judgmentally expressed.<sup>6</sup>

In summary, when the property denoted by NP2 is specific and precise, *shi* can be syntactically dropped.

Aside from the correlation between the syntactic realization of *shi* and the semantic value of NP2, the behavior of *shi* is bound to another two semantic conditions, namely the temporal reference and the frame of referring of the sentence. The correlation between these two semantic facets and the copula is spelt out in the following.

#### 4. *Shi* and Temporal Reference and Perspective of referring

##### 4.1. *Instantiating function of copula and temporal reference*

---

<sup>4</sup> In section 2, sentence (6) as repeated as follows is cited to counter Wei’s analysis. As we can see, even though *henduo xiesheng* is semantically more specific than *xiesheng* alone, *shi* is obligatory to occur in this sentence. The unacceptability of (6) seems to be a counter example against the analysis of this research. In fact, despite the specific reading of *henduo xiesheng*, *henduo* specifies the quantity rather than the property; hence the ungrammaticality of (6).

(6) \*Tamen henduo xuesheng.  
     They very many student

<sup>5</sup> However, it remains unsolved to what degree the denotation of a property can be specific. This question can be saved for further discussion.

<sup>6</sup> It must be noted that in sentences as (i), *shi* is obligatory to be present in spite of the specific and judgmental meaning.

(i) Zhangsan \*(shi) henhaode xuesheng.  
     Zhangsan be very good student  
     ‘Zhangsan is a very good student.’

Based on Simpson (2001) on DP in Chinese, *henhaode xuesheng* is a DP and thus cannot serve as semantic predicate.

According to Rothstein (2001: 299), English copula *be* is not a content word, but a grammatical formative. She defines *be* as the instantiation function. By this function, *be* bears a packaging and locating operation, which turns a non-countable property denoted by the semantic predicate into a countable eventuality and then locates this eventuality in time. For illustration, consider (24) as follows.

(24) Jane was clever last Monday.

In (24), *be* presents the non-countable property of being clever as a countable eventuality and then locates this eventuality in a specific time denoted by *last Monday* in which Jane had the cleverness property. Following this line of thinking, Rothstein suggests that the instantiating function of *be* is associated with the tense feature, namely [+tense] [+/-past] or [-tense], contained by Infl(ection). Witness the sentences in (25) as follows.

- (25) a. Lucy is a pretty girl.
- b. Lucy was a pretty girl.
- c. I consider Lucy to be a pretty girl.
- d. I consider Lucy a pretty girl.
- e. Lucy will be a pretty girl.

In (25a) and (25b), *be* instantiates the property denoted by NP2 in time since the Infl node contains [+tense] [-past] and [+tense] [+past] features respectively. In (25c) with the occurrence of *be*, the subject NP1 *Lucy* is interpreted as having an existential eventuality of being a pretty girl, whereas in (25d) NP1 is interpreted as having the generic property of being a pretty girl. As for (25e), even though the tense feature is underspecified in Infl in the future tense, the modal auxiliary *will* subcategorizes for a VP. That is, in (25e), it is a syntactic necessity that *be* should occur.

However, the association of the instantiation of *be* with the grammatical tense feature specified in Infl is not without problems. As Radford (1997) points out, the correlation between the present and past distinction and time reference is not a perfect one. Witness the example provided by Radford as follows.

(26) If I went there tomorrow, would you come with me? (Radford 1997: 531)

In (26), the past tense verb *went* is specified as [+tense] [+past], but the sentence refers to a location in time. Therefore, adopting the definition of copula offered by Rothstein, we propose that the instantiating function of copula should be associated with the temporal reference of the sentence. In order to classify temporal reference of sentences, we appeal to the distinction between characterizing and situation-descriptive sentences (Ramchand 1996), which is presented as follows:

A characterizing sentence is defined as a sentence referring to a generic property, which cannot be located in time; a situation-descriptive sentence is a sentence referring to a property of a being a certain type of event, which denotes an existential closure in time (Ramchand 1996). Given this division of characterizing and situation-descriptive sentences, the instantiation of copula can be associated with the temporal reference of the sentence: *be* instantiates an eventuality in time in a characterizing sentence, whereas this function does not come into play in a situation-descriptive sentence. In such an analysis, English copula *be* in (25b), (25c) and (25e) presents the property denoted by *a pretty girl* as an eventuality and locates it in time. In (25d), with the manifestation of *be*, *a pretty girl* is assigned as an inherent property to *Lucy*. Refer to (25b), (25c), (25d) and (25e), repeated as follows.

- (25) b. Lucy was a pretty girl.  
 c. I consider Lucy to be a pretty girl.  
 d. I consider Lucy a pretty girl.  
 e. Lucy will be a pretty girl.

As for (25a), the sentence denotes a generic property of being a pretty girl and thus is a characterizing sentence. However, *be* is obligatory to occur. The fact that *be* must be present is attributed to the syntactic concern: in English, Infl must take a VP as its complement (Haegeman 1994; Rothstein 2001) and, additionally, copula *be* must be attached with the tense feature (Doron 1983); hence, the obligatory occurrence of *be*.

We assume that *shi*, as does English copula *be*, functions to instantiate an eventuality and this instantiating function concerns the reference of the sentence to temporal locations. When the sentence containing *shi* denotes temporally unrestricted locations, it does not have to be overtly realized; when the sentence containing *shi* refers to a temporally restricted location, *shi* is obligatory to be manifested.

#### 4.2. *Shi* and temporal reference

Given our assumption of the syntactic realization of *shi*, let us examine the sentences in (27) as follows.

- (27) a. Lisi zhongxuelaoshi.  
 Lisi middle-school teacher  
 ‘Lisi is a middle-school teacher.’  
 b. Lisi shi zhongxuelaoshi.  
 Lisi be middle-school teacher  
 ‘Lisi is a middle-school teacher at the moment.’  
 c. Lisi yiqian \*(shi) shuxuelaoshi.

- Lisi before be math teacher  
 ‘Lisi was a math teacher before.’
- d. Lisi nianqing shi \*(shi) lanqoujiaolian.  
 Lisi youth moment be basketball coach  
 ‘Lisi was a basketball coach when he was young.’
- e. Lisi xianzai \*(shi) lanqoujiaolian.  
 Lisi now be basketball coach  
 ‘Lisi is a basketball coach now.’
- f. Lisi yizhi \*(shi) lanqoujiaolian. (yiqian shi, xianzai ye shi.)  
 Lisi constantly be basketball coach (before be now too be)  
 ‘Lisi has been a basketball coach. (He was one before and he is one now)’

(27a) is a sentence describes a property which refers to unrestricted locations in time and is classified as a characterizing sentence. It is demonstrated that *shi* can be covert in (27a). In (27b), with the syntactic manifestation of *shi*, the sentence denotes a temporally instantiated eventuality. This is to say, the instantiating function of *shi* leads to the interpretation that *Lisi* is a middle-school teacher at the right moment. (27c), (27d), and (27e) denote a restricted location in time and is known as a situation-descriptive sentence. As (27c), (27d), and (27e) illustrate, if the sentence refers to an existential eventuality, *shi* has to be overtly realized. As for (27f), the sentence seemingly denotes unrestricted locations in time and therefore *shi* should be allowed to drop. However, with the occurrence of adverb *yizhi*, we can afford the interpretation that in every individual situation, the eventuality of being a basketball coach is being ascribed to NP1, *Lisi*. Since the situation-descriptive reading is available in (27f), *shi* is obligatory to be present.

In summary, *shi* is required to be explicitly realized in the sentence denoting a temporally restricted location.

#### 4.3. *Shi* and perspective of referring

In addition to the temporal reference of the sentence, the syntactic behavior of *shi* concerns modality, namely the perspective of referring of the sentence. The perspective of referring can be incorporated into the concept of possible worlds. First, witness the sentences in (28).

- (28) a. Tom is a pianist.  
 b. Tom seemed to be a pianist. (But today, I found he is not.)

(28a) denotes the truth, based on an unrestricted frame of reference, whereas (28b) contrasts the truth with a possibility, founded on a relativized perspective of referring. In terms of possible worlds semantics (Kripke 1980), a relativized frame of referring entertains two situations, namely the actual world and a possible world. These two worlds, as Thomason (1984) notes, are bound to converge in time. For instance, in (28b), the actual situation and the possible situation merge in the temporal location denoted by *today*. In other words, a sentence involving a relativized reference frame definitely denotes a restricted location in time.

Along these lines, we assume that *shi* has to be overtly manifested in a sentence based on a relativized perspective of referring. Such an interaction of the syntactic behavior of *shi* and the perspective of referring is illustrated in the following sentences:

- (29) a. Xiaohua yinggai \*(shi) guaihaizi. Shishishang, ta bu shi.  
 Xiaohua should be nice kid actually he not be  
 ‘Xiaohua should be a nice kid. Actually, he is not.’
- b. Tingshuo Huang buobuo \*(shi) minggeshou. Danshi, ta bu xiang.  
 It-is-said Huang uncle be famous singer but he not like  
 ‘It is said that uncle Huang is a singer. But he does not look like one.’
- c. Ta hen xiang \*(shi) renzhen de laoshi. Keshi, hen xiang you  
 bu shi.  
 He very like be responsible *De* teacher But very like again  
 not be  
 ‘He seems to be a writer. But somehow it appears that he is not one.’

The sentences in (29) prove that the realization of *shi* is obligatory if the referring of the sentence is founded on a relative set of reference. In (29a), (29b) and (29c), the properties are valued founded on a contrastive set of reference and thus *shi* has to be fulfilled.

To summarize, when the sentence containing *shi* involves a relativized perspective referring, *shi* can be covert.

#### 4.4. Cross-linguistic data for copula

In fact, in many languages, the behavior of the copular verb is tied to the temporal reference of the sentence: in some of these languages, the distinction between the characterizing and situation-descriptive sentences determines the realization of copula; in the others, the characterizing/situation-descriptive distinction conditions the choice of different copular elements. To begin with, in Swahili, Yagua,

Hungarian, and Bengali, as shown in (30), (31), (32), and (33) the copula in the characterizing interpretation is not necessary to be overtly realized.

(30) Swahili (Schachter 1985)

- a. Hamisi mpishi.  
Hamisi cook  
'Hamishi is a cook'
- b. Hamisi alikuwa mpishi.  
Hamisi was cook  
'Hamisi was a cook'
- c. Hamisi atakuwa mpishi.  
Hamisi will be cook  
'Hamisi will be a cook'

(31) Yagua (Payne 1997)

- a. Máchituru ráy.  
Teacher 1SG  
'I am a teacher.'
- b. ra-vyicha-núú-yanu máchituru  
1SG-be-CONT-PST3 teacher  
'I used to be a teacher.'
- c. rá-á vicha machituru  
1SG-FUT be teacher  
'I am going to be a teacher.'

(32) Hungarian (Kiefer 1968)

- a. Péter katona.  
Peter soldier  
'Péter is a soldier.'
- b. Péter katona volt.  
Peter soldier was  
'Péter was a soldier.'
- c. Péter katona lesz.  
Peter soldier will-be  
'Péter will be a soldier.'

(33) Bengali (Finch 2001)

- a. ram Sukhi.  
Ram happy  
'Ram is (a) happy (person).'
- b. ram Sukhi achhe.

Ram happy be-3O<sup>7</sup>  
'Ram is (certainly) happy (at present).'

With regard to the different choice of the copular element, we first consider the copular verbs in Scottish Gaelic as in (34).

(34) Scottish Gaelic (Adger and Ramchand 2003)

- a. Is                      tidsear    Calum.  
COP-PRESENT    teacher Calum  
'Calum is a teacher (by vocation).'
- b. Tha                      mi    'nam    thidsear  
Be-PRESENT    I    in-1SG    teacher  
'I am a teacher.'

In Scottish Gaelic, *is* is required in the characterizing sentence as in (34a) and *tha*, an inflected form of *bith*, occurs in the situation-descriptive sentence as in (34b). Apart from the copular element in Scottish Gaelic, Spanish exhibits a distinct selection of the copular verb depending on the temporal reference of the sentence. Compare (35a) and (35b).

(35) Spanish (Querido 1976)

- a. Juan es            médico.  
Juan ser.3S doctor  
'Juan is a doctor.'
- b. Juan está        de    médico.  
Juan estar.3S of    doctor  
'Juan is a doctor.'

In (35), the copula verb *es*, an inflected form of *ser*, is employed in the characterizing sentence; in (35b), *está*, an inflected form of *estar*, is required since it is a situation-descriptive sentence (Querido 1976). In addition to Scottish Gaelic and Spanish, let us scrutinize the use of the copular element in Modern Hebrew. What is worth noting with respect to the copular element in Hebrew is that, when the sentence denotes a restricted location in the past and present time, the verbal copula *h.y.y* must be employed. However, in the sentence under a generic reading, a pronominal copula can either appear or be omitted (Doron 1986; Rapoport 1987). Wintess (36) as follows.

(36) Modern Hebrew

- a. Dani more.

---

<sup>7</sup> According to Finch, in Bengali, 'O' is the ordinary form, distinct from 'H', the honorific form.

- Dani teacher.  
 ‘Dani is a teacher.’  
 b. Dani hu        more.  
    Dani *Pron* teacher  
    ‘Dani is a teacher.’

Regarding the presence and omission of *hu* in (36), Doron (1986) and Rapoport (1987) claim that the pronominal element is only a phonetic realization for the person and number features and it is optional in the predicational sentence. That is, this pronominal element does not correlate with meaning. However, Greenberg (1999) defines this element as a pronominal copula and argues that it indeed interacts with a difference in meaning: when *Pron* is present, the sentence has a more individual level reading, and when *Pron* is absent, it has more of a stage level interpretation. If Greenberg’s analysis is on the right track, it can be found that the manifestation of Hebrew verbal copula and pronominal copula concerns the characterizing/situation-descriptive interpretation.

The cross-linguistic data presented above for the copular verb demonstrate that the syntactic behavior of the copular verb is bound to the temporal reference of the sentence.

## 5. A Cyclic Application

Notice that when the semantic values denoted by NP2 and the temporal reference and the perspective of assigning the properties to NP1 are taking effect on the overt realization of *shi*, the cyclicity principle must be respected (Radford 1988). That is, the precondition that *shi* can be covert when the sentence has an imperfective interpretation or evaluates a situation by an unlimited set of reference is that the denotation of NP2 must meet the criteria of being well classified and bound to an evaluative characterization. Consider the following sentences:

- (37) a. \*Lisi (shi) laoshi. Ta dasuan zai jiao wu nian cai tuixiu.  
       Lisi be teacher. He plan more teach five year just retire  
    b. \*Zhangsan (shi) yanyuan. Zhejian shi dajia dou zhidao.  
       Zhangsan be actor this-*CI* fact everyone all know

From the two examples shown above, it is evident that (37a) and (37b) are ungrammatical even if the sentences do meet criteria required of the implicitness of *shi* regarding the temporal reference and the perspective of referring. The reason is

that NP2 in (37a) and (37b) does not express a specific reading.

## 6. Concluding Remarks

This paper points out the overt realization of *shi* is bound to semantic facets. There are two semantic conditions determining the syntactic behavior of *shi*. The first is that the information conveyed by NP2 must be specific and evaluative enough. The second is that the sentence must be in characterizing reading and denotes the situation founded on an unrestrained frame of reference. Furthermore, the two semantic conditions apply in an ordered fashion. From this research, we can learn that Mandarin *shi* plays a role as an indicator, the syntactic manifestation of which points to the semantic values of the NP2 and the temporal denotation and the perspective of referring of the sentence. Meanwhile, this research implies that the exploration of the syntactic dimension can not be independent of the investigation of the semantic structure of language. Last but not least, this research shows that the behavior of *shi*, as that of the copular verb in many other languages, correlates with certain semantic attributes.

This research, however, leaves unspecified the syntactic structure of the NP1-NP2 sequence. It is not clear whether in this sequence NP2 along serves as the syntactic predicate as claimed by the previous analyses or it is actually a construction with *shi* dropping on the surface structure. Such an issue needs further pursuing.

Aside from the construction being explored in this research, it is noted that there are other types of the NP1-NP2 construction. One of them can be illustrated in the following:

- (38) Zhangsan niurou mian, Lisi zhurou mian.  
Zhangsan beef noodles, Lisi pork noodles  
'Zhangsan wants beef noodles and Lisi pork noodles.'

As we can see, the sentence in (38) is an NP1-NP2 sequence. However, in this sequence, NP2 is not a semantic predicate since it does not ascribe a property to NP1. It appears that the occurrence of this type of NP1-NP2 constructions is restricted to certain contexts, for instance, the ordering of food in a restaurant. The NP1-NP2 construction can be a possible topic for future studies.

# Syntax and Semantics of Negation

Suwon Yoon

University of Chicago  
1010 E. 59th St. Chicago, IL 60637 USA  
suwon@uchicago.edu

## Abstract

The current study suggests a set of new diagnostics to examine narrow and wide scope negation, based on Korean data with two overtly distinct (short and long) forms of negation. The contrast between narrow and wide scope negation will be discussed in terms of metalinguistic negation, expletive negation, *again*-test, coordination construction, *try to V*-construction, and two Klima's (1964) tests -- namely *deliberately*-test and tag-question.

**Keywords:** negation, narrow/wide-scope, diagnostics

## 1. Introduction

The current study attempts to suggest a novel argument for the co-existence of two types of negation based on empirical evidence found from narrow scope versus wide scope negation in Korean. With respect to the debate on negation, Korean is of particular importance because it is equipped with two overtly distinct forms of negation marking different scopes: so-called Short form negation (S-Neg) and Long form negation (L-Neg). Starting from the hypothesis that the two types of Korean negation truly represent two distinct syntactic and semantic scopes of negation, the current paper sheds light on the nature of negation by rigorously investigating a complex array of facts in this domain: first, I suggest a set of new diagnostics for distinguishing narrow scope from wide scope negation in section 2. The basic syntactic structures of S-Neg & L-Neg will be proposed in section 3. Conclusion is given in section 4.

## 2. Proposal: Scope Diagnostics

In this section, crucial evidence will be provided for clarifying the semantic interpretations and the syntactic structures in the two types of negation. For this purpose,

I suggest that the following properties distinguish wide scope negation from narrow scope negation, in addition to Klima's diagnostics for negation scope in (1g,h):

(1) Diagnostics for Negation Scope

- a. Adverbial Jumping is available only with wide scope negation.
- b. Metalinguistic Negation is available only with wide scope negation.
- c. Expletive Negation is available only with wide scope negation.
- d. *Again*-test shows ambiguity only in wide scope negation.
- e. Coordination shows ambiguity only in wide scope negation.
- f. *Try to* V-construction shows ambiguity only in wide scope negation.
- g. *Deliberately*-test shows ambiguity only in wide scope negation (Klima 1964).
- h. Tag-question shows ambiguity only in wide scope negation (Klima 1964).

Although most of these tests were originally suggested for different purposes, they are uniformly applicable to diagnosing scope as well.

2.1. Test 1: "Adverbial Jumping" (only for L-Neg)

Two possible interpretations in (2) below show that English adverbials in negative sentences reveal peculiar behaviors. That is, a natural interpretation is that the negative targets the adjacent VP 'wear a jacket' as in (2a), meaning that he does not wear a jacket and it is because the weather is hot. However, another interpretation in (2b) is also available where, instead of the adjacent VP 'wear a jacket', the adverbial part 'because of the weather' is negated via a semantic scope transform, called 'jumping' (Gabbay and Moravcsik 1978; see also Johnston 1994). Hence (2b) states that it is the case that he wears a jacket but it (his wearing a jacket) is not because the weather is cold (but because he wants to be polite).

(2) He does not wear a jacket because of the weather.

a. He does not [(wear a jacket) because of the weather].

b. He wears a jacket not (because of the weather).

→ 'jumping'

Note, however, that such jumping is available only with L-Neg in Korean. The lack of jumping effects in S-Neg shows that the inherently low location of the negative prevents the negative from combining with an adjunct at higher position.

- (3) *Swuni-nun nalssi-ttaymwuney cakeys-ul ip-ci an-ess-ta.*<sup>1</sup>  
 Swuni-TOP weather-because of jacket-ACC wear-CI L-Neg-PST-DECL  
 R1: Swuni does not [(wear a jacket) because of the weather].  
 R2: Swuni wears a jacket not (because of the weather). → ‘jumping’
- (4) *Swuni-nun nalssi-ttaymwuney cakeys-ul an-ip-ess-ta.*  
 Swuni-TOP weather-because of jacket-ACC S-Neg-wear-PST-DECL  
 R1: Swuni does not [(wear a jacket) because of the weather].  
 R2: # Swuni wears a jacket not (because of the weather). → \*‘jumping’

2.2. Test 2: Metalinguistic Negation (only for L-Neg)

More surprisingly, a particular set of adverbial NPIs, summarized in Fig 1, is only licensed by L-Neg.

Fig 1. Adverbial NPIs in Negation

adverbial NPIs	S-Neg	L-Neg
norm-denying NPI: <i>potong, yekan, com</i> ((not)...at the normal standard)	*	√
expectation-echoing NPI: <i>byello</i> ((not)... particularly)	*	√
up-denying NPI: <i>cenhye, tomwuci</i> ((not)... at all/ ever)	*	√

The ungrammaticality of (5a) indicates a clear scope distinction between S-Neg and L-Neg.

- (5) a. \**Swuni-nun kongpu-lul potong an-coaha-y.*  
 Swuni-TOP study-ACC normally S-Neg-like-DECL
- b. *Swuni-nun kongpu-lul potong coaha-ci an-a.*  
 Swuni-TOP study-ACC normally like-CI L-Neg-DECL
- ‘It is not the normal degree that Swuni likes studying.’ (=she extraordinarily likes it)

Lee (2005) argues that the above cases are metalinguistic negation in Horn’s (1989) sense – “a device for objecting to a previous utterance on any grounds whatever, including the conventional or conversational implicata it potentially induces, its morphology, its style or register, or its phonetic realization.” His claim seems to be on

the right track because it corresponds to another obvious case of metalinguistic negation (6) where only L-Neg is grammatical.

- (6) a. *Swuni-nun ku-lul coaha-ci an-a. salangha-y.*  
 Swuni-TOP him-ACC like-CI **L-Neg-DECL** love-DECL
- b.# *Swuni-nun ku-lul an-coaha-y. salangha-y.*  
 Swuni-TOP him-ACC **S-Neg-like-DECL.** love-DECL  
 ‘Swuni does not like him. (she) loves him.’

Given that (6) shows that only L-Neg can have metalinguistic use, I argue that these asymmetries in metalinguistic negation are naturally predicted from the distinct syntactic scopes in each type of negation. That is, the metalinguistic negation requires a syntactic wide scope in which a focus phrase can be dominated by a higher (wide scope) negation, so the semantic interpretation can be structured as ‘it is not the case that Swuni likes him, but it is the case that she loves him.’ In contrast, a syntactic narrow scope S-Neg (6b) is only interpretable as ‘it is the case that Swuni does not-like her’, which makes its following sentence ‘Swuni loves her’ sound anomalous. Furthermore, I assume that the structure for wide scope negation can be interpreted either as simple propositional negation (external negation à la Russell 1905) or as the metalinguistic one above.

### 2.3. Test 3: Expletive Negation (only for L-Neg)

As in many other languages such as Old/Middle English, Spanish, French, Italian, Catalan, Russian, Polish, Dutch, Modern Hebrew, etc. (see van der Wouden 1994; Tovena 1996; Brown and Franks 1995; Portner and Zanuttini 2000; Abels 2002), Korean negation has an expletive use in exclamatives and the embedded clauses of adversative predicates. Another type of scopal asymmetry comes from the expletive negation<sup>2</sup>: (7) shows that L-Neg expressed in the form of an exclamative does not have a negative meaning. Note, however, this usage is unavailable with S-Neg (8).

- (7) *ney-ka aisukurim-ul ta mek-ci an-ess-ni !*  
 you-NOM ice cream-ACC all eat-CI **L-Neg-PST-DECL**
- (8) # *ney-ka aisukurim-ul ta an-mek-ess-ni !*  
 you-NOM ice cream-ACC all **S-Neg-eat-PST-DECL**  
 ‘You ate up all the ice cream!’

According to Portner and Zanuttini's (2003) analysis, expletive negation in exclamatives triggers a scalar implicature. Thus, in (7), an epistemic speaker assumes a likelihood scale (Scale = 'you ate all ice cream' < 'you didn't eat all ice cream') and the expletive negative implicates that the proposition with a low likelihood (i.e. you ate all ice cream) was out of the speaker's expectation. In this respect, the oddity in (8) arises presumably because, while the wide-scoped L-Neg in (7) affirms the fact that the addressee ate all the ice cream and the speaker expresses a surprise about the fact, the narrow scope nature of S-Neg in (8) forces an unintended interpretation where the speaker affirms the fact that the addressee did not-eat the ice cream.

#### 2.4. Test 4: *Again-test*

The *again-test* has been suggested as a diagnostic for object position (von Stechow 1996, Beck and Johnson 2004 for German; Ko 2005 for Korean). However, I suggest that it indicates not only the syntactic location of the object but the syntactic domain of negation as well. First, let's observe the interpretation pattern of *again* in affirmative sentences:

- (9) *Swuni-ka*            *mun-ul*            *tasi*            *yel-ess-ta.*  
 Swuni-NOM            door-ACC        again            open-PST-DECL  
 (i) 'Swuni opened the door again, and that had happened before.' (repetitive)  
 (ii) 'Swuni opened the door again, and the door had been open before.' (restitutive)
- (10)a. *Swuni-ka*            *tasi*            *mun-ul*            *yel-ess-ta.*  
 Swuni-NOM            again            door-ACC        open-PST-DECL  
 'Swuni opened the door again, and that had happened before.' (repetitive)
- b. *tasi*            *Swuni-ka*            *mun-ul*            *yel-ess-ta.*  
 again            Swuni-NOM            door-ACC        open-PST-DECL  
 'Swuni opened the door again, and that had happened before.' (repetitive)

Example (10) shows that the adverbial *again* adjacent to the verb allows for both repetitive and restitutive interpretation as in von Stechow's (1996) German data. However, (11) illustrates that the object is located higher than the domain of restitutive *again* in Korean. Given this, the (simplified) D-structure in Korean can be posited as the following:

irrespective of the location of *again*.

### 2.5. Test 5: Ambiguity in Coordination

The highest scope of L-Neg II is manifested by the scopal ambiguity in coordination structure. Consider the scopal ambiguity of NegP in the coordinated sentence (15) in English.

- (15) John cannot turn in the last assignment and (still) pass the class. [English]  
 (i) ‘John can [<sub>NegP</sub> **not** [turn in the last assignment and (still) pass the class]].  
 (ii) ‘John can [<sub>NegP</sub> **not** [turn in the last assignment]] and (still) pass the class.

It is well-known that this scope ambiguity in coordination only holds for long form negation in Korean.

- (16) a. V and [V-ci Neg]: Lower scope

*Swuni-ka swul-ul masi-ko [<sub>NegP</sub> tambay-lul piwue-ci an]-ess-ta.*  
 Swuni-NOM liquor-ACC drink-and cigarette-ACC smoke-CI L-Neg-PST-DECL  
 ‘Swuni drank alcohol, but didn’t smoke cigarettes.’  $\phi \wedge [\neg \psi]$

- b. [V and V-ci Neg] : Higher scope

*Swuni-ka [<sub>NegP</sub> swul-ul masi-ko tambay-lul piwue-ci an]-ess-ta.*  
 Swuni-NOM liquor-ACC drink-and cigarette-ACC smoke-CI L-Neg-PST-DECL  
 ‘Swuni didn’t drink alcohol and didn’t smoke cigarettes.  $\neg [\phi \wedge \psi]$  (Cho 1993)

As shown in (16) above, the scopal ambiguity in long form negation arises from the inherent dual structural interpretation between L-Neg type I and L-Neg type II. In the former interpretation with verbal suffix ‘ci’ (16a), negation scope is confined to the second VP. In the latter interpretation, the negation scopes over the first and the second VP (16b) because the focus clausal complementizer ‘ci’ has both VPs under its reach. The existence of both interpretations indicates a dual structure of long form negation.

Note also that there arises no such ambiguity in coordination construction with short form negation in (17). The invariably narrow scope of S-Neg has no alternative interpretation.

- (17) V and [Neg V]

*Swuni-ka swul-ul masi-ko tambay-lul [<sub>NegP</sub> an-piwue]-ss-ta.*

Swuni-NOM alcohol-ACC drink-and cigarette-ACC **S-Neg**-smoke-PST-DECL  
 ‘Swuni drank alcohol, but didn’t smoke cigarette.’

Furthermore, the coordination construction also demonstrates that NegP is lower than Tense Phrase (TP) in English and Korean. In contrast to ambiguous negation scope in two coordinated bare verbs in (18a), the tense-marked second verb *smashed* in (18b) exempts itself from the otherwise possible negated interpretation.

(18) a. John did **not** go home and smash windows here.

[<sub>NegP</sub> **not** [ go home and smash windows here ]] or,  
 [<sub>NegP</sub> **not** [ go home ]] and [smash windows here ]

b. John did [<sub>NegP</sub> **not** go home] and smashed windows here’ [English]

In the same manner, negation in (19) only scopes over the adjacent verb (the second one) when the first verb *masi-ess* is tense-inflected in Korean.

(19) *Swuni-ka swul-ul masi-ess-ko [<sub>NegP</sub> tambay-lul piwue-ci an]-essta.*

Swuni-NOM liquor-ACC **drink-PST**-and cigarette-ACC smoke-CI **L-Neg**-DECL  
 ‘Swuni drank alcohol, but didn’t smoke cigarette.’

Therefore, the structure with NegP lower than TP is also born out.

## 2.6. Test 6: Try to V- construction

The distinction between sentential negation (20) and constituent negation (21) in English<sup>3</sup> can also be found from Korean counterparts of L-Neg (20) and S-Neg (21). As expected, the narrow scope constituent negation is only observed in S-Neg.

(20) Bill didn’t try to laugh.

(21) Bill tried [**not** to laugh]. [English]

(22) *Bill-un wusulye-ko nolyekha-ci an-ha-ss-ta.*  
 Bill-TOP laugh-to try-CI **L-Neg**-do-PST-DECL  
 ‘Bill didn’t try to laugh.’

(23) *Bill-un an-wusulye-ko nolyekha-ss-ta.*  
 Bill-TOP **S-Neg**-laugh-to try-PST-DECL  
 ‘Bill tried [not to laugh].’

## 2.7. Test 7: *deliberately-test*

The scope of each negation type is further supported by application of the *deliberately-test* (Klima 1964; Payne 1985; McCawley 1988) to Korean negation.

- (24) a. *Swuni-ka koyucekulo Tom-ul an macwuchi-ess-ta.*  
 Swuni-NOM deliberately Tom-ACC **S-Neg** encounter-PST-DECL
- b. *Swuni-ka koyucekulo Tom-ul macwuchi-ci an-ss-ta.*  
 Swuni-NOM deliberately Tom-ACC encounter-CI **L-Neg-PST-DECL**
- (i) ‘Swuni deliberately did [not run into Tom].’, → **a/b**
- (ii) ‘It is [not [deliberate that Swuni ran into Tom]].’ → **b**

S-Neg (24a) only means that ‘Swuni avoided Tom on purpose’ (i), while L-Neg (24b) is ambiguous between (i) ‘Swuni avoided Tom on purpose’ and (ii) ‘Swuni encountered Tom but it was not on purpose’.

## 2.8. Test 8: *Tag-Questions*

Although Klima’s (1964) “negative appositive tag” test is inapplicable to Korean negation as it is, a slightly modified version of the tag question ‘*kuraysni?(did so?)*’ shows the scope differences between negation types. The tag-question preceded by a sentence with S-Neg (25a) only obtains the negated meaning (i) ‘Sue didn’t give John a gift’, whereas the one with L-Neg (25b) takes either a negated (i) ‘Sue didn’t give John a gift’ or a non-negated (ii) ‘Sue gave John a gift’ as its antecedent.

- (25) a. *Sue-ka John-ekey senmwul-ul an-cwun-keskatuntay, kuraysni?*  
 Sue-NOM John-DAT gift-ACC **S-Neg-give-seems,** **did so?**
- b. *Sue-ka John-ekey senmwul-ul cwu-ci-an-unkeskatuntay, kuraysni?*  
 Sue-NOM John-DAT gift-ACC give-CI-**L-Neg-seems,** **did so?**
- (i) ‘Sue didn’t seem to have given John a gift; did she not give him a gift?’ → **a/b**
- (ii) ‘Sue didn’t seem to have given John a gift; did she give him a gift?’ → **b**

## 2.9. *Summary*

In section 2, I have discussed eight diagnostics for distinguishing narrow and wide scope negation in Korean, which are highly applicable to other languages. The

consistent results of these tests serve crucial empirical evidence for the distinct structures that will be proposed in section 3.

### 3. Syntax of Negation in Korean

Base on the observations so far, I argue that a finer division of negation is required in order to correctly capture semantic scopal interpretations and numerous unresolved syntactic phenomena with respect to negation. To this end, three basic types of Korean negation will be characterized in terms of the interrelation between the syntactic structures and the semantic interpretations for the remainder of this paper. Furthermore, semantic property differences between negation types will also come into play to illustrate the logical contrast between narrow scope negation and wide scope negation.

#### 3.1. Short Form Negation (S-Neg: Narrow Scope Neg)

I claim that there are three types of negation in Korean: Short-Negation (S-Neg), Long-Negation type I (L-Neg I), and Long-Negation type II (L-Neg II). The first type is the S-Neg which is indeed a case of narrow scope negation excluding even the object outside the scope of negation and only negating the predicate itself.<sup>1</sup> This narrow-scope nature of S-Neg can be attributed to its inherent syntactic location.

A significant piece of evidence for this analysis is found in the clitic-like nature of S-Neg. As Han et al (2007) and others have argued, Neg-Cliticization analysis of S-Neg is supported by the adjacency condition between the negative element ‘an’ and the verb stem. As shown below, S-Neg and the verb should be adjacent. Neither the object in (26b) nor the adverb in (27b) can occur between S-Neg and the verb.

- (26) a. *Swuni-ka maykcwu-lul an masi-n-ta.* (S O Neg V)  
 Swuni-NOM beer-ACC Neg drink-PRES-DECL  
 ‘Swuni doesn’t drink beer.’
- b. \**Swuni-ka an maykcwu-lul masi-n-ta.* (\*S Neg O V)  
 Swuni-NOM Neg beer-ACC drink-PRES-DECL  
 ‘Swuni doesn’t drink beer.’

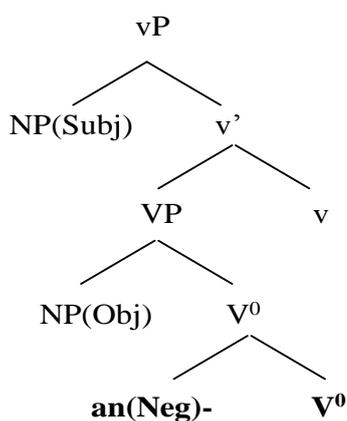

---

<sup>1</sup> Weak indefinite objects under S-Neg will be discussed in section 4.

- (27) a. *Swuni-ka maykcwu-lul cal an masi-n-ta.* (S O Adv Neg V)  
 Swuni-NOM beer-ACC well Neg drink-PRES-DECL  
 ‘Swuni doesn’t drink beer.’
- b. \**Swuni-ka maykcwu-lul an cal masi-n-ta.* (\*S O Neg Adv V)  
 Swuni-NOM beer-ACC Neg well drink-PRES-DECL  
 ‘Swuni doesn’t drink beer.’

Given this property of S-Neg cliticized to the following verb stem, its syntactic location becomes predictable as right adjoining to the verb stem. Furthermore, the eight diagnostics discussed in the previous section have shown the narrow scope property of S-Neg. Thus, I propose the structure of short negation as the following.

(28) Structure of S-Neg

- (29) *Swuni-ka maykcwu-lul an masi-ess-ta.*  
 Swuni-NOM beer-ACC S-Neg drink-PST-DECL  
 ‘Swuni did [not drink] beer.’

The structure (28) above illustrates a sentence with short form negation as in (29). Notice the lower scope of Neg. As a result of ‘an’(neg) being cliticized onto the verb, negation only scopes over the verb, and the subject and the object at higher locations are outside the scope of Neg. Assuming the isomorphism of syntactic structure and semantic interpretation, the sentence with S-Neg is naturally interpreted with strictly narrow scope such as *Swuni did [not drink] beer.*

### 3.2. Long Form Negation type I (L-NegI: Narrow Scope Neg)

In contrast with short form negation which takes only narrow scope, long form

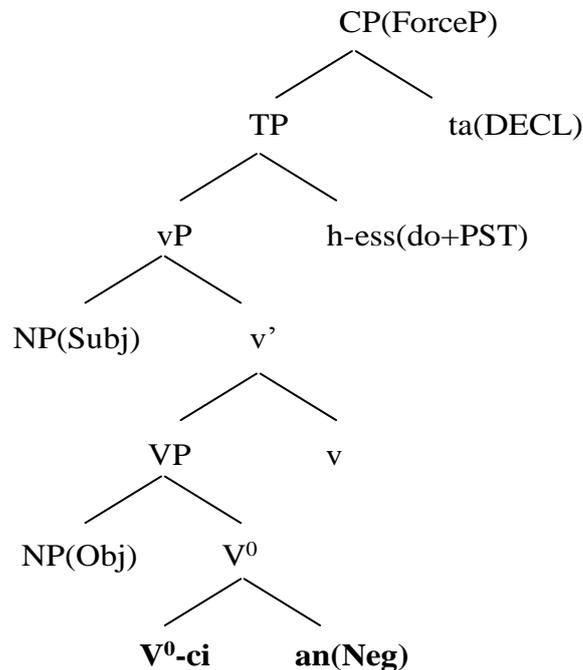

negation shows ambiguous behaviors between narrow and wide scope. According to this binary nature in scope, long form negation needs to be classified into two different categories: Long form Negation type I versus Long form Negation type II. The former is the one that takes narrower scope than a subject and an object within the clause (in the same fashion as Short form negation), whereas the latter takes wide scope.

This unusual division of L-Neg should be attributed to the dual nature of *ci*-marker preceding the negative element, which is analyzed as a simple verbal suffix in the former (taking narrow scope) and as a focus-clausal complement in the latter (taking wide scope). Given this, let me demonstrate the structure of L-Neg type I. In this form of negation, the *ci*-marker is a verbal suffix simply linking the preceding verb to the following negative element. The linear order and the hierarchical structure of sentence (32) for this type of negation are given in (30) and (31), respectively.

(30) Verbal Suffix -ci:

Subject    Object    [[Verb]-suffix(ci)    neg(an)]-do(ha)-Tense-DECL

(31) Structure of L-Neg type I

(32) *Swuni-ka    maykcwu-lul    masi-ci    an-ess-ta.*  
 Swuni-NOM    beer-ACC    drink-suffix    L-Neg-PST-DECL  
 ‘Swuni did [not drink] beer.’

Recall the strictly narrow scope of S-Neg presented in the preceding section.

Since the negative element ‘an’ of L-Neg I resides at the same height as S-Neg (i.e. adjacent to the verb stem) scoping only over the verb, the negative verbal complex ‘verb-ci(suffix) an(neg)’ is predicted to have a narrow scope interpretation as well. Therefore, L-Neg I should be included as another instance of narrow scope negation along with the case of S-Neg.

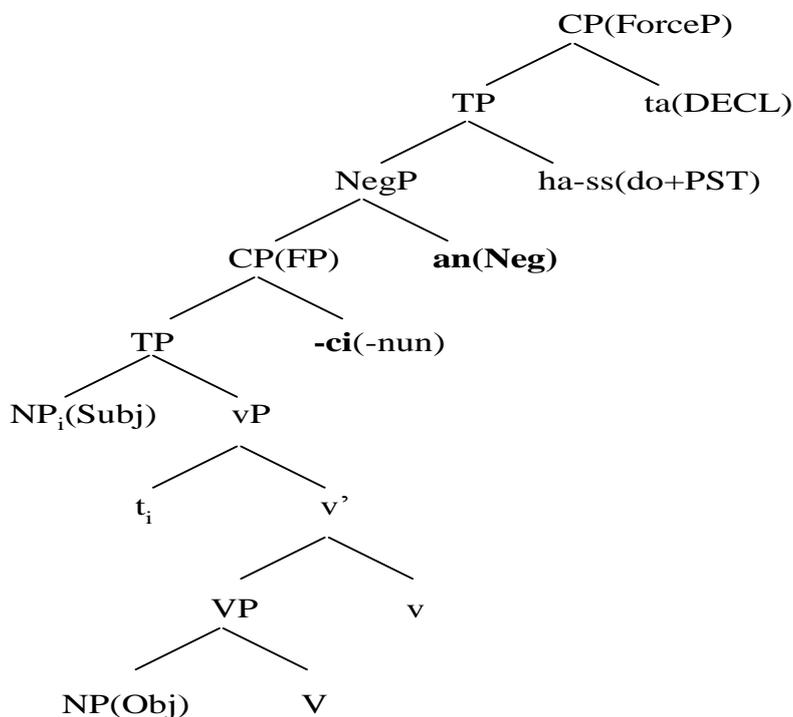

### 3.3. Long Form Negation type II (L-NegII: Wide Scope Neg)

Although L-Neg I can be interpreted with strictly narrow scope, L-Neg shows an ambiguous nature in terms of its interpretative scope. The same sentence given in (32) (in L-Neg I) above meaning *Swuni did [not-drink] beer* can also be interpreted with the widest scope: *It is not the case that Swuni drank beer* in (35). This wide scope negation will be dubbed as L-Neg type II in order to distinguish from the narrow-scope-taking L-Neg type I.

As pointed out already, the negation-preceding marker ‘ci’ seems to play a different role here, namely a focus clausal complementizer. Compare the linear order (33) and the hierarchical structure (34) of L-Neg II with the ones of L-Neg I in the preceding section.

- (33) (Focus) clausal complementizer/shell –ci  
 [[<sub>FocP</sub> Subject Object Verb]-COMP(ci) neg(an)]-do(ha)-Tense-DECL

(34) Structure of L-Neg type II

- (35) *Swuni-ka*      *maykcwu-lul*      *masi-ci(-nun)*      *an-ess-ta.*  
 Swuni-NOM      beer-ACC      drink-COMP(-Foc)      **L-Neg-PST-DECL**  
 ‘It is not the case that Swuni drank beer.’

In sharp contrast with L-Neg I (31), the above structure shows L-Neg II locating higher than the CP (/FP) and scoping over the whole clause including the subject, the object, and the verb. Despite the identical surface form of the two sentences, (32) and (35), the observed scope disparity of long form negation is unsurprising considering the fact that the seemingly identical marker ‘ci’ is endowed with inherently distinct grammatical roles.

The above structure (34), particularly where CP is treated as a focus phrase (FP), is further justified by the attachability of ‘nun’ at FP level because ‘nun’ is an explicit indicator of contrastive topic/focus phrase (C-M Lee 2003, 2005). Furthermore, the status of CP as a FP seems reasonable considering the general principle that a focused phrase always takes narrow scope. This type of negation can be characterized as a special focus phrase formation similar to the focus-cleft construction that creates the wide negation scope with ‘it is not the case that ...’ interpretation. As pointed out by Sells (2005), negation targets a focus phrase in Korean in the following data (36).

- (36)a. *John-i amwu kes-to ecey sa-ci-nun an-ess-ta.*  
 John-NOM n-thing yesterday buy-CI-Foc **L-Neg-PST-DECL**  
 b. Stress on John: unacceptable  
 c. Stress on ecey: ‘Whatever it was, it was [not yesterday] that John bought it.’  
 d. Stress on sa-ci: ‘Whatever it was, it was [not buying] it that John did yesterday.’

Considering the focus-targeting negation in English (Jackendoff 1972: 254) in the following (37), the inseparable nature of focus and negation seems universal.

- (37) Maxwell didn’t kill the judge with a silver hammer.  
 a. Maxwell didn’t . . . (i.e., someone else did)  
 b. He didn’t kill the judge . . . (i.e., he did something else to him)  
 c. He didn’t kill the judge . . . (i.e., he killed someone else)  
 d. He didn’t kill the judge with a silver hammer (but with something else)

Also, the argument that the focus on XP is marked by ‘nun’ in Korean is supported by Jackendoff (1969) and Büring (2003) note that similar effects are realized by stress in English, as illustrated in (38).

- (38) a. ALL \ the men didn’t go \ (all>neg)  
 b. ALL \ the men didn’t go / (neg>all) (Jackendoff 1969)

Furthermore, the focus phrase assumption is supported by the fact that an accusative case marker can be attached to ‘ci’ in (39).

- (39) *Swuni-ka maykcwu-lul masi-ci-lul an-ess-ta.*  
 Swuni-NOM beer-ACC drink-CI-ACC(Foc) L-Neg-PST-DECL  
 ‘It is not the case that Swuni drank beer.’

Observing this, Suh (1993) claims that this indicates the double clausal structure of long form negation in which the negated matrix verb assigns ACC case to the embedded clause. However, I argue that the ACC case here plays a dual role as a focus marker based on the following facts: first, ACC case here sounds more natural when it receives a phonological focus (*masi-ci-LUL*), and second, this double ACC case structure gives an emphatic effect to its recipient (‘*It is not DRINKING that Swuni did with the beer. She was just looking at it.*’)

Finally, this dual clausal structure assumption is unsurprising considering the acquisition fact that S-Neg is acquired much earlier (1.8-2 years old children) than L-Neg (3.5-4 years). Assuming only the structure for L-Neg type II, Kim (1991) argues that it is because a dual clausal structure is harder to acquire than a mono-clausal one. However, it seems equally plausible to attribute the acquisition difficulty in part to the structural and hence semantic ambiguity between L-Neg type I and type II.

#### **4. Conclusion**

Thus far, I have argued for the co-existence of narrow-scope negation (S-Neg and L-Neg I) and wide-scope negation (L-Neg II) in one language. It was shown that Korean has grammaticalized the two types of negation, narrow scope and wide scope negation, in its overt syntactic structures. Although negation is an extremely controversial issue in linguistic theory, the current paper significantly contributes to the clarification of negation scope by presenting a language which systematically distinguishes the scope by means of two different overt forms of negation. All the contrasts found in the results of the newly suggested diagnostics for narrow vs. wide scope negation followed from the proposal that Korean short form negation is narrow scope negation while long form negation is wide scope negation. As such, I have presented novel evidence that both narrow scope negation and wide scope negation are equally viable as inventories of natural language negation.

This opens the possibility of the same argument holding in other languages. Languages usually have their own strategy to mark different syntactic scope. For instance, English adopts additional strategies to mark narrow scope negation either by locating the negative *not* in different positions (e.g., She is able to [not breathe] for one minute) or by attaching an antonymous prefix (e.g, un-able, mis-match, dis-like). On the other hand, Japanese uses special forms such as ‘dewa nai’ (COMP+Topic Neg) to emphasize the wide scope negation property but lacks a way to express pure narrow scope negation as Korean S-Neg does. Further crosslinguistic investigation remains for future research.

#### **Note:**

<sup>1</sup>. The Korean data here are transcribed by Yale Romanization. The following abbreviations are used for the data: ACC: accusative; CI: ‘ci’-marker (verbal

suffix/focus marker); CL: classifier; COMP: complementizer; DAT: dative case; DECL: declarative sentence ending; L-Neg: long form negation; NOM: nominative case; PL: plural; PST: past tense; S-Neg: short form negation; TOP: topic marker.

<sup>2</sup> In Korean literature, the L-Neg in exclamatives was treated as factive use. Although, exclamatives show factive property as Portner & Zanuttini (2003) argues, the negation occurring in exclamatives and sentences with adversative predicates uniformly show expletive properties in Korean as well as many other languages.

<sup>3</sup> *Try*-type verb is usually analyzed as restructuring predicates (Cinque 1999), and Wurmbrand (1998) argues that *try*-type RPs involve semantic control (Chierchia 1982, 1984) without projecting an embedded PRO as seen in (ii).

(i) Bill<sub>j</sub> tried [PRO<sub>j</sub> talking to his boss].

(ii)\*Bill<sub>j</sub> tried today [PRO<sub>j</sub> talking to his boss tomorrow].

# Productivity and Constraint in Morphology and Lexicon

Weon-Don Jeong

Semyung University

wdjeong@yahoo.co.kr, wdj2000@semyung.ac.kr

## Abstract

This paper deals with the productivity and constraint which take place in morphology and the lexicon, and also explores the relationship between two modules. Many words or compounds are made by affixation and compounding. As a result of word formation processes, possible or actual forms appear in morphology and the lexicon. However, we need a kind of device to restrict a power of word formation. So many kinds of constraint and blocking play an important role in distinguishing grammatical or acceptable forms from ungrammatical or unacceptable ones. These grammatical or acceptable forms are stored in the lexicon.

**Keywords:** word formation, productivity, constraint, lexicon, blocking

## 1. Introduction

In this paper, I will examine the productivity and constraint which take place in morphology and the lexicon. I will also explore how new words produced by word formation processes are related to the lexicon.

Since affixes or lexemes can be put together with bases, a number of words or compounds appear as an output. This shows the productivity of word formation. However, while some affixes are easily attached to bases, others are not. The nominal suffix *-ness* makes more nouns than *-al* in English. Similarly, compared to *-kay*, the nominal suffixes *-i*, *-um*, *-ki* are productive because they make a lot of nouns in Korean.

When words are generated by word formation processes, some forms are grammatical or acceptable but others are ungrammatical or unacceptable. Aronoff (1976), Bauer (2001) and Plag (2003) suggest that they are divided into actual and possible (potential) words. For example, Plag (2003) mentions that *affordable*, *readable* and *manageable* are existing words whereas *cannibalizable* may not be found in English dictionary. We can find similar phenomena in Korean:

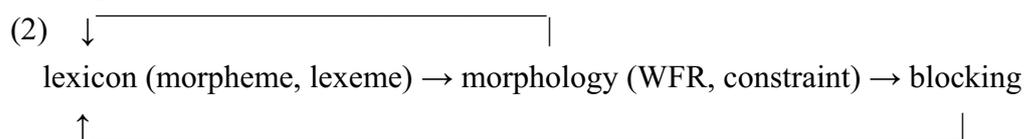

(1) a. kongchaki 'kicking a ball', kkanthongchaki 'kicking a tin'

b. ?kwusekchaki ‘kicking a corner’, cayuchaki ‘kicking freedom’

The examples in (1a) are good forms, but those in (1b) are somewhat strange words. In order to explain this difference, we have to ask what kinds of device affect the productivity of word formation. Furthermore, we need constraints or conditions to restrict the productivity of word formation. In Korean, since *chaki* can be attached to movable things, *kongchaki* and *kkangthongchaki* are well-formed words. However, *kwusekchaki* and *cayuchaki* occur as possible but strange words because *kwusek* and *cayu* are unmovable. This shows that there is a specific condition on word formation. We can have various kinds of constraint on word formation: morphological constraint, phonological constraint, semantic constraint, Binary Branching Hypothesis (Aronoff 1976, Scalise 1984), and Blocking (Aronoff 1976).

Blocking shows interesting phenomena as a filtering device. When we assume that the lexicon is a kind of storage, words made by word formation processes are put in the lexicon. So actual or possible words may be stored in the lexicon. However, some words cannot appear as lexical entry. For example, *guide* is found in English noun but we cannot find *guider*. Compared to words with –er, *guider* is possible but non-existent. According to Aronoff (1976), an existent form *guide* blocks a new form *guider*. He defines blocking as “the non-occurrence of one form due to the simple existence of another”. This means that blocking plays a major role in word formation.

The lexicon contains morphemes and lexemes, whereas word formation and constraint take place in morphology. The relationship between lexicon and morphology can be represented as follows:

The diagram in (2) shows a circular process. Morphemes or lexemes selected from the lexicon take part in word formation processes. In morphology, the output generated by word formation processes is restricted by constraint. The form which blocking filters out can enter the lexicon.

## 2. Productivity

Morphology is divided into inflection and word formation with respect to different properties (Plag 2003). Word formation includes affixation and compounding. This section deals with the productivity which takes place in affixation and

compounding.

## 2.1 Affixation

Affixation is formed by means of affixes. The affixation is composed of prefixation, suffixation, and infixation. But infixation rarely occurs in word formation. The affixation can be represented as follows: (prefix\*)-base-(suffix\*). This process can produce many English and Korean words.

- (3) a. im (Pref)-possible (A), beauty (N)-ful (Suf)  
un (Pref)-happy (A)-ness (Suf)  
de (Pref)-center (N)-al (Suf)-ize (Suf)-ion (Suf)  
b. tol (Pref)-pay (N) ‘wild pear’, teph (V)-kay (Suf) ‘cover’  
kay (Pref)-cwuk (V)-um (Suf) ‘useless death’  
keyulu (V)-m (Suf)-payngi (Suf) ‘idle person’

Unlike prefixation, suffixation can change a lexical category.

- (4) a. black-en (A → V)  
curious-ity (A → N)  
demonstrate-ion (V → N)  
b. sulki-lop(ta) ‘wisdom-Verb Suf’ ‘to be wise’ (N → V)  
kekceng-sulep(ta) ‘worry-Verb Suf’ ‘to be worried’ (N → V)  
salam-tap(ta) ‘man-Verb Suf’ ‘to be humane’ (N → V)

Certain nominal suffixes in Korean turn a verb into a noun (V → N). The suffixes make free or bound forms. Compared to (5a), the examples in (5a’) cannot be used independently, and rather they are always put together with other nouns.

- (5) a. mek-i ‘eat-Nom Suf’ ‘food’  
a’. kel-i ‘hang-Nom Suf’ ‘hanger’ (os kel-i ‘clothes-hanger’)  
cap-i ‘hold-Nom Suf’ ‘thing which someone holds’  
(son cap-i ‘knob, handle’)  
kkoc-i ‘be inserted-Nom Suf’ ‘thing in which something is inserted’  
(kkoch kkoc-i ‘flower arrangement’)  
b. cwuk-um ‘die-Nom Suf’ ‘death’, kkwu-m ‘dream-Nom Suf’ ‘dream’  
c. po-ki ‘see-Nom Suf’ ‘example’, tut-ki ‘hear-Nom Suf’ ‘hearing’

The suffixes -i, -(u)m, or -ki can be attached to a phrase.

- (6) a. [makwu cap]<sub>VP</sub>-i ‘[randomly catch]-ing’  
b. [son-ul ssi]<sub>VP</sub>-um ‘[wash hands]-ing’  
c. [hakkyo-ey ka]<sub>VP</sub>-ki ‘[go to school]-ing’

Since *makwu* in (6a) is an adverb and it modifies the verb *cap-*, the structure makes a verb phrase. In (6b), since *ssis-* is a transitive verb and it needs an object *son*, the form corresponds to the verb phrase. The example in (6c) consists of a verb and a postpositional phrase. Compared to *-(u)m* or *-ki*, *-i* can very rarely be connected with a phrase. So it can be said that *-i* is less productive than *-(u)m* or *-ki*.

As in English, adverbs in Korean are derived by affixation, especially suffixation.

- (7) a. happy-ly, usual-ly  
 b. kath-i ‘be identical-Adv Suf’ ‘identically’  
 coyongha-i ‘be quiet-Adv Suf’ ‘quietly’  
 him-kkes ‘strength-Adv Suf’ ‘strongly’  
 cengseng-kkes ‘sincerity-Adv Suf’ ‘sincerely’  
 kkuth-nay ‘end-Adv Suf’ ‘finally’  
 kyewul-nay ‘winter-Adv Suf’ ‘throughout the winter’

While the adverbial suffix is connected with adjectives in English, the adverbial suffixes in Korean are attached to verbs and nouns. Interestingly, according to Korean grammarians, adverbs were formed from verb bases by zero derivation in Middle Korean. For example, *tel* ‘less’ is derived from *telta* ‘to subtract’. Similarly, nouns themselves can be used as adverbs in Modern Korean. For instance, such words as *cikum* ‘now’, *onul* ‘today’, and *nayil* ‘tomorrow’ appear in both forms.

## 2.2 Compounding

Compounds are combinations of words and words: N N, V N, V V, N V, Adv Adv, Prep Prep, Postp Postp. These forms are illustrated as  $X_1 X_2$ . The rightmost form  $X_2$  in  $X_1 X_2$  is a head because the properties of  $X_2$  determine those of the compound. In *blackbird*, for example, the head *bird* does affect a lexical category and other properties of compound.

Bauer (1983:30) classifies compounds into four groups in terms of modifier-head relationship: endocentric compound, exocentric (*bahuvrihi*) compound, appositional compound and copulative (*dvandva*) compound. For example, *beehive* and *armchair* belong to the endocentric compounds, where a beehive is a kind of hive and an armchair is a kind of chair. However, since the exocentric compounds *redskin* and *highbrow* is not a kind of skin or brow, we cannot find the head relationship. Bauer mentions *maidservant* as an example of appositional compound, because maidservant is a type of maid and also a type of servant. Finally, there is no clear head in the

copulative compound *Alsace-Lorraine*.

I suggest that the appositional compound corresponds to a sort of endocentric compound because maidservant is a kind of servant, which is a head. Bauer's division shows ambiguity because of dual criteria of hyponymy and the head relationship. According to him, the appositional compound *maidservant* is a hyponym of both maid and servant: a maidservant is a type of maid and also a type of servant. Here, it is not clear whether maidservant has one head or two heads. Considering that maidservant is a kind of servant, servant may be regarded as the head. So the appositional compound should belong to the endocentric compound in terms of the head relationship. If the appositional compound did not have the head relationship, it would have to correspond to the exocentric compound or the copulative compound. In addition, the exocentric compound cannot be treated as the pure compound but as a kind of idiom, because its meaning is totally changed. Thus, since the exocentric compound is turned into an idiom, it will be listed in the lexicon.

Unlike Bauer's classification, I divide compounds into two groups in terms of the modifier-head relationship: (a) If  $X_2$  in  $X_1X_2$  satisfies IS A Condition and  $X_2$  is a head,  $X_1X_2$  is a sub-compound. (b) If  $X_1$  and  $X_2$  in  $X_1X_2$  has a parallel relationship and  $X_2$  is not a head,  $X_1X_2$  is a co-compound. With respect to these conditions, we consider the compounds in Korean.

- (8) a. miyek (N) kwuk (N) 'seaweed soup', kwun (V) pam (N) 'roasted chestnut'  
b. pam (N) nac (N) 'day and night', son (N) pal (N) 'hand and foot'

Since the examples in (8a) are sub-compounds, they satisfy the *IS A Condition* proposed by Allen (1978). For example, *miyek kwuk* 'seaweed soup' is a kind of soup rather than seaweed and soup. But the condition is not observed in (8b), which are co-compounds, because they are usually composed of words with contrastive meanings.

Verb compounds in Korean have sub-compounds and co-compounds as well. They are composed of two verb bases.

- (9) a. ttwi-nolta 'run-play' 'to romp'  
may-talta 'hang-hang' 'to hang'  
kwut-seyta 'be hard-be strong' 'to be strong'  
b. o-kata 'come-go' 'to come and go'  
ye-tatta 'open-close' 'to open and close'  
olu-naylita 'rise-fall' 'to rise and fall'

Compared to noun compounds, it is difficult to tell whether the examples in (9a) are sub-compounds or co-compounds. We assume that they are sub-compounds because the right-hand forms determine the meaning of the compounds. For example, *cith-phwuluta*

means ‘to be deep blue’, not ‘to be deep and blue’. In contrast, the examples in (9b) are co-compounds. Since the examples consist of contrastive or opposite forms, they exhibit semantic compositionality and lack a single head. Thus, the right-hand forms cannot determine the meaning of compounds.

Adverbs are rarely formed by compounding: *com-te* ‘a little more’, *kot-palo* ‘very-straight’, and *kot-cal* ‘pretty-well’. It is not certain whether the examples are sub-compounds or co-compounds. But since their meaning is determined by the words on the right side, they may be sub-compounds.

Compounding usually takes place in content words because they are open category. So compounding rarely occurs in function words. However, compounding can appear in function words. In English, for example, *into* and *onto* may be the compounds of preposition.

We assume Korean postpositions in terms of the position, which means that the postpositions in Korean are usually placed after nouns. They are classified into inherent case markers (ICM), delimiters (DEL), and structural case markers (SCM). ICMs include *-eykey* (Goal), *-pwuthe* (Source), *-eyse* or *-ey* (Location), and so on; DELs include *-(n)un* (Topic), *-man* ‘only,’ *-to* ‘also,’ and so on; SCMs include *-ka/i* (Nominative), *-(l)ul* (Accusative), and *-uy* (Genitive). The postpositions in Korean may be generated by compounding: *eyse-man* ‘in (Loc)-only’ and *man-i* ‘only-Nom’. While the former consists of an ICM and a DEL, the latter is composed of a DEL and a SCM. Since these examples exhibit compositionality, *eyse-man-i* is possible, as in the following example:

- (10) ?Ku kapang-ul Waikiki-eyse-man-i sa-l swu issta.  
 the bag-Acc Waikiki-in-only-Nom buy-can  
 ‘(We) can buy the bag only in Waikiki.’

The example in (10) is not perfect, but it is acceptable. Thus, postpositional compounds consisting of three postpositions can be represented as ICM-DEL-SCM. Compound postpositions always follow the order. If this order is violated, then the compound postposition is ungrammatical. So the structure *\*man-eyse* or *\*eyse-i-man* is not allowed.

Compound postpositions may be co-compounds because they exhibit composite meaning. For example, meaning in *eyse-man* is a combination of *in (at)* and *only*, and *man-i* indicates the meaning *only-Nominative*. Thus, it is difficult to determine the head in compound postpositions.

Bauer (1983:212-213), who treats onomatopoeia forms as compounds, divides them into *rhyme-motivated compounds* and *ablaut-motivated compounds*. The rhyme

between two elements is the major factor in the rhyme-motivated compound: *hokey-pokey*, *roly-poly*, and *teeny-weeny*. This shows that sound is changed in word-initial, which means the sound change of onset position. In the latter, vowel change or alternation appears in the two elements: *flip-flop*, *tick-tock*, and *zig-zag*. Following Bauer, when we assume that a lot of onomatopoeic words or sound symbolisms in Korean are regarded as compounds, *wulkus-pwulkus* corresponds to the rhyme-motivated compound and *singswung-sayngswung* corresponds to the ablaut-motivated compound.

### 3. Constraint

In this section, we will explore various kinds of constraint on the productivity of word formation.

#### 3.1 Morphological Constraint

As many morphologists (Bauer 1983, Bauer 2001, Plag 2003) have pointed out, it is not usual to add English adverbial suffix *-ly* to adjectives which end in *-ly*. Although *-ly* formation is a productive process, the adjectives ending in *-ly* do not show this process: \**elderlily*, \**miserlily*, \**sisterlily*, and \**worldlily*.<sup>1</sup> Another productive suffix *-ee* can be added to intransitive and transitive verbs: *resignee* and *huggee*. But the suffix is attached mainly to the transitive verbs. Rarely, *-ee* forms such as *escapee* and *infiltratee* appear as formation with the intransitive verbs.

Zimmer (1964:15) points out the interesting examples: *unwell* vs. \**unill*, *unhappy* vs. \**unsad*, and *unoptimistic* vs. \**unpessimistic*. This means that negative prefixes are not used with adjectival stems that have negative value on evaluative scales such as good and bad.

The suffix *-ity* is added to [+latinate] words, and *-hood* is attached to [-latinate] words: *possible-ity* vs. *boy-hood*. Korean also needs constraint to explain ungrammatical or unacceptable word formation. For example, forms such as *olun-ccok* ‘right side’ vs. *oyun-ccok* ‘left side’ and *wu-chuk* ‘right side’ vs. *cwa-chuk* ‘left side’, which indicate the relationship of antonym, are good word formation. On the other hand, *olun-chuk* vs. *oyun-chuk* and *wu-ccok* vs. *cwa-ccok* are very ungrammatical and unacceptable structures. This difference is due to lexical features in words. While *olun-*,

---

<sup>1</sup> According to Bauer (1983), *friendly* and *sillily* are listed in the OED.

*oy-* and *-cok* are pure Korean forms, *cwa-*, *wu-* and *-chuk* Sino-Korean ones. The former have [+Kor] feature, and the latter [-Kor] feature. As in English, certain feature is required to explain the appropriateness of word formation.

Since the serial order of postpositions (ICM-DEL-SCM) is followed, the postpositions have a constraint on their combination. As S.-K. Kim (1989) points out, DELs do not freely cooccur with SCMs (DEL-SCM): (*man-i*, *man-ul*, *man-uy*) vs. (*\*to-ka*, *\*to-lul*, *\*to-uy*). The examples show that certain DELs connect with SCMs. This is confirmed in the following examples: (*kkaci-ka*, *kkaci-lul*, *kkaci-uy*), (*cocha-ka*, *cocha-lul*, *?cocha-uy*), and (*mata-ka*, *?mata-lul*, *mata-uy*). In the examples mentioned above, only *man*, *kkaci*, *cocha*, or *mata* can cooccur with the SCM.

At the same time, cooccurrence restrictions exist even within DELs. In other words, one DEL can cooccur with another DEL. When the DELs are divided into with respect to their position of appearance, we call them DEL<sub>1</sub> (*mace*, *cocha*, *kkaci*, *mata*, *ssik*, *man*) and DEL<sub>2</sub> (*(n)un*, *to*). While most DELs occur in the first position, only *(n)un* or *to* appears in the second position. The DEL *man* can also be put in the second position, but it can only combine with *kkaci* or *ssik* in the DEL<sub>1</sub> position: *ccaci-man* and *ssik-man*.

An interesting phenomenon turns up in the above cooccurrence restrictions. These restrictions specify the following order: DEL<sub>1</sub> {DEL<sub>2</sub> SCM}. This cooccurrence restrictions affect the order of DEL<sub>1</sub> and SCM, but also DEL<sub>1</sub> and DEL<sub>2</sub>. Since this is a mutually exclusive relation, DEL<sub>1</sub> must take either DEL<sub>2</sub> or SCM. For example, neither *\*kkaci-ka-to* nor *\*cocha-lul-un* exists in Korean.

### 3.2 Phonological Constraint

The velar consonant *k* is changed to *s* in certain word formation. As is well known, velar softening only occurs in words originate from Latin: electric [k] vs. electric-ity [s]. This phenomenon does not take place in words which are inherited from Anglo-Saxon.

Following Siegel (1972), Halle (1973) points out the phonological constraint on deadjectival verb formation, where a suffix *-en* is added to adjectives.

- (11) a. blacken, whiten, toughen, dampen, harden  
 b. \*dryen, \*dimmen, \*greenen, \*laxen  
 c. soften, fasten, moisten

The word formation in (11) must obey a phonological condition: (C) V (C[+son]) C[-son]]<sub>Adj</sub>. This constraint means that the forms are monosyllabic and end in an obstruent

which optionally may be preceded by a sonorant. The words in (11c) seem to violate the constraint because they have obstruent clusters. In order to solve this problem, if *t*-deletion rule applies after word formation, the derived form satisfies the phonological constraint: soft+en > *t*-deletion.

Deletion processes are shown in word formation. In adverb affixation, we can see the deletion of *l* in *kyewu-nay* (*kyewul-nay* → *kyewu-nay*): the *l* of *kyewul* is deleted before *n*. This phenomenon is also found in nominal or verbal compounding.

- (12) a. *mal-so* → *ma-so* ‘horse and cow’  
b. *mil-tatta* → *mi-tatta* ‘to push and close’

In (12), *l* is deleted before *s* or *t*. This *l*-deletion has a phonetic motivation. An alveolar consonant *l* is deleted before other alveolar consonants *n*, *s*, or *t*.

We can see the peculiar phenomena with respect to *l*-deletion:

- (13) a. *atul + nim* ‘son-Hon’ → *atunim*, *ttal + nim* ‘daughter-Hon’ → *ttanim*  
b. *pyel + nim* ‘star-Hon’ → *pyelnim*, *tal + nim* ‘moon-Hon’ → *talnim*

The examples in (13) show that although they have the same phonetic environment, *l*-deletion takes place in (13a) whereas it does not happen in (13b). This cannot be explained in a purely phonetic or phonological way. Since the same suffix *-nim* is attached to the nouns in (13), there is not a structural problem. In order to solve this trouble, we need to observe the different property between (13a) and (13b). While the former nouns have [+human] feature, the latter ones maintain the opposite feature [-human]. Instead of the phonological explanation, we should introduce semantic feature to handle the idiosyncrasy in (13).

### 3.3 Semantic Constraint

Bauer (1983:93) points out an interesting semantic constraint. In *blue-eyed*, *three-legged*, and *red-roofed*, the base must be inalienably possessed by the head noun that the adjective modifies. Thus, *\*two-carred man* or *\*a black-shoed lady* are not possible, since cars and shoes are possessed alienably.

Bauer (1983:94) mentions that there should not be any genus-species compounds like *\*humanman*, *\*animalhorse*, and *\*placemoor* where the determining element is implicit in the head element. Species-genus compounds are far more common: *cod fish*, *beech tree*, *puppy dog*, *palm tree*, and *boy child*. This shows not macro-micro but micro-macro relationship, and also implies that the modifier is a part or subset of the head. Korean compounds exhibit the same relationship as English ones: *namca-ai* ‘boy child’, *so-namwu* ‘pine tree’, and *yaca-namwu* ‘palm tree’.

The meaning in stratum 1 or level 1 affixes is more specific than that in stratum 2 or level 2 affixes: *-ity* (curiosity) vs. *-ness* (happiness). Aronoff (1976) claims that the more productive a process is, the more easily can its semantic effect be specified. This means that when affixes are used productively, they have a predictable meaning. In other words, productive affixes are more transparent in meaning if we assume that predictable meaning is related to meaning transparency. In Korean, the nominal suffix *-ki* shows more productivity than *-kay* in word formation: *tut-ki* ‘hearing’ vs. *teph-kay* ‘cover’. So *-ki* is more predictable than *-kay* in meaning of word formation.

Semantic transparency also affects the choice of causative suffix. While *-i*, *-hi*, *-ki*, and *-li* are causative and passive suffixes, *-wu*, *-kwu*, and *-chwu* are used only as causative suffixes. For the purpose of eliminating semantic opacity, single causative forms already formed seem to select one among *-wu*, *-kwu*, and *-chwu* rather than suffixes with both properties of causative and passive. Moreover, the addition of *-wu* is governed by a phonological condition, where *-wu* occurs with vowel-final bases, and *-kwu* and *-chwu* appear with consonant-final bases:

- (14) a. pi-ta ‘to be empty’ → pi-wu-ta  
       kkay-ta ‘to awake’ → kkay-wu-ta  
       say-ta ‘to dawn’ → say-wu-ta  
       b. sos-ta ‘to rise’ → sos-kwu-ta  
       tot-ta ‘to rise’ → tot-kwu-ta  
       c. nuc-ta ‘to be late’ → nuc-chwu-ta  
       nac-ta ‘to be low’ → nac-chwu-ta

This choice also exemplifies the movement of word formation towards increasing semantic transparency.

### 3.4 Binary Branching Hypothesis

The structure of word formation follows the Binary Branching Hypothesis proposed by Aronoff (1976) and Scalise (1984). This implies that it has a hierarchical structure: (a) [*kay* [*cwuk-um*]] ‘useless death’ (b) [[[*keyulu-m*] *payngi*] ‘idle person’. However, the Binary Branching Hypothesis permits ambiguity, as in the following example:

- (15) a. hes (Prefix)-pal (Noun)-cil (Suffix) ‘false-foot-doing’ ‘false kicking’  
       b. (i) [[hes-pal] cil]  
       (ii) [hes [pal-cil]]

The examples in (15) illustrate ambiguous binary branching. With respect to this

ambiguity, Scalise (1984:149-50) suggests that in Italian suffixation precedes prefixation. Such structure as [*kay* [*cwuk um*]] (\*[[*kay cwuk*] *um*]) ‘useless death’ confirms Scalise's suggestion. Moreover, although (15bi) and (15bii) are possible structures, the latter is preferred over the former. So it appears that suffixation applies before prefixation in Korean as well.

### 3.5 Blocking

In the lexicon, certain words can be formed, but others are not possible. For example, English noun *guide* is found but we cannot find *guider*. At the same time, *suere* does not exist in English because of the occurrence of *sewer*.

Clark & Clark (1979:800) claim that *spring* and *fall* are not used as verbs whereas *summer* and *winter* are used as verbs because of the prior existence of the homophonous irregular verbs *spring* and *fall*:

- (16) a. They summered/wintered in the country.  
 b. \*They springed/falled in the country.

This shows that regardless of meaning, homophony prevents word formation.

In order to explain possible but non-existent forms, Aronoff (1976:43) suggests blocking, and defines it as "the non-occurrence of one form due to the simple existence of another." As in English, blocking is often found in Korean. Verbal nouns, which are derived from verbs in Korean, are formed by verb base plus *-i*, *-(u)m*, or *-ki*. Consider the following examples:

(17) Verb	-i	-(u)m	-ki
a. mek-ta 'to eat'	mek-i	mek-um	mek-ki
pel-ta 'to earn'	pel-i	pel-um	pel-ki
b. wus-ta 'to laugh'	*	wus-um	wus-ki
ca-ta 'to sleep'	*	ca-m	ca-ki
c. po-ta 'to see'	*	po-m	po-ki
khu-ta 'to be big'	*	khu-m	khu-ki

The suffixes *-i*, *-(u)m*, or *-ki* can function as derivational suffixes which change verbs into nouns. In (17), the existence of forms with *-i* blocks other forms carrying *-(u)m* or *-ki*. While *mek-i* ‘food’ and *pel-i* ‘earning’ appear as nouns, *mek-um* or *mek-ki* ‘eating’ and *pel-um* or *pel-ki* ‘earning’ are still verbs.

On the other hand, it is possible that forms with *-(u)m* or *-ki* occur as nouns because of the non-existence of the forms with *-i*. This is confirmed in (17b) and (17c). In (17b), since *wus-um* ‘laughing’ and *ca-m* ‘sleep’ appear as nouns, *wus-ki* ‘laughing’

and *ca-ki* ‘sleeping’ remain verbs. In (17c), on the other hand, *po-ki* ‘example’ and *khu-ki* ‘size’ prevent *po-m* ‘seeing’ and *khu-m* ‘being big’ from becoming nouns. The examples in (17) illustrate that when the noun derived from a verb is already stored in the lexicon, it blocks the new noun.

Blocking is also found in forms with *-kelita* and *-hata*. Both suffixes can attach to onomatopoeic or mimetic words. The following examples present an interesting phenomenon:

(18) mimetic	-kelita	-hata	
pintwung	pintwung-kelita	*pintwung-hata	‘to be idle’
hetwung	hetwung-kelita	*hetwung-hata	‘to be hasty’
wungseng	wungseng-kelita	*wungseng-hata	‘to be noisy’
tetum	tetum-kelita	*tetum-hata	‘to grope’
esulleng	esulleng-kelita	*esulleng-hata	‘to hang around’

Using the symbol X for an onomatopoeic or mimetic word, the examples in (18) are represented as follows: [X / X-*kelita* / \*X-*hata*]. We can say that when X-*kelita* occurs in the lexicon, X-*hata* cannot be found. This fact can be described by blocking. Since X-*kelita* is already filled in the lexicon, there is no X-*hata*.

We consider blocking with respect to causative forms. As S.-Y. Bak (1982) points out, avoidance of meaning confusion is a factor in the formation of the double causative *-i-wu*. Since Korean is an agglutinating language, various kinds of inflectional suffixes can attach to the verb base. In contrast, only one derivational suffix can be added to the verb base: Verb Base-Causative and Verb Base-Passive. But the so-called double causative *-i-wu* is an exceptional and peculiar case. Consider the following examples:

- (19) a. *ca-ta* ‘to sleep’ → (\**ca-i-ta*) → *ca-i-wu-ta* → *cay-wu-ta*  
 b. *se-ta* ‘to stand’ → (\**se-i-ta*) → *se-i-wu-ta* → *sey-wu-ta*  
 c. *ttu-ta* ‘to float’ → (\**ttu-i-ta*) → *ttu-i-wu-ta* → *ttuy-wu-ta*  
 d. *cha-ta* ‘to be full’ → (\**cha-i-ta*) → *cha-i-wu-ta* → *chay-wu-ta*

Single causative forms without *-wu* may have sufficiently causative meaning. Nevertheless, these forms take double causatives by adding *-wu*. This phenomenon apparently results from an attempt to strengthen transparency of meaning. Single causative forms are identical with other verbs which already exist in the lexicon: *cayta* ‘to measure’, *seyta* ‘to count’, *ttuyta* ‘to appear’, and *chayta* ‘to snatch’. Since this coincidence causes confusion in meaning, blocking takes place in this case. In order to avoid semantic opacity, therefore, another causative suffix *-wu* is added to single causative forms.

#### 4. Morphology and Lexicon

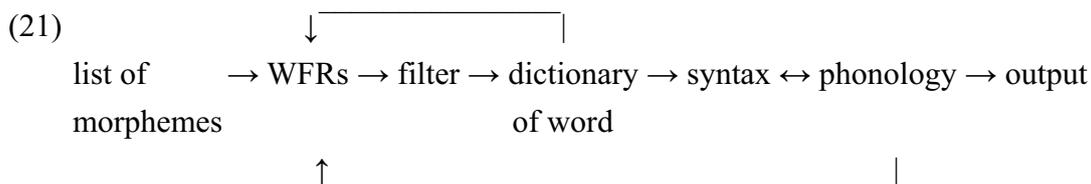

In this section, I will investigate the properties of morphology and the lexicon, and the relationship between morphology and the lexicon.

The lexicon, which may be called a dictionary of linguists, contains a list of morphemes and lexemes. In other words, the lexicon has been known as a storage where morphemes, affixes or words are included. Furthermore, since the lexicon has lawless properties (Williams & Di Sciullo 1987), idiosyncratic information of the morphological, phonological, syntactic and semantic components is stored in the lexicon. For example, Bauer (1983:190) mentions that there are three kinds of adjectives in English. The adjectives like *red* and *cold* are used either attributively or predicatively; those like *former* can only be used attributively; those like *afraid* can only be used predicatively.

- (20) a. The red house is on the hill.  
           The house on the hill is red.  
       b. The former president is in the audience.  
           \*The president in the audience is former.  
       c. \*The afraid man is at the bar.  
           The man at the bar is afraid.

Since it cannot be handled in syntax or semantics, this information has to be listed in the lexicon: red [+attributive, +predicative], former [+attributive, -predicative], and afraid [-attributive, +predicative].

Since Halle (1973), morphology has become an autonomous component where we investigate internal structure of words. Traditionally, morphology, which is recognized as word formation, has been handled in syntax and phonology. This means that there are no word formation rules in morphology, and that WFRs exist in other components. Syntacticians (Baker 1988, Lieber 1992) suggest that word formation can be dealt with in the syntactic component. Phonologists (Kiparsky 1982, Katamba 2005) argue that morphology is part of the lexicon. In contrast, Halle (1973) claims that morphology consists of three distinct components: a list of morpheme, rules of word formation, and a filter containing the idiosyncratic properties of words.

In (21), morphemes are input of WFRs. The forms derived WFRs are checked by filter, and then are listed in the dictionary. The listed forms or the phonological forms can be the input of WFRs. These three groups are summarized as follows:

- (22) a. lexicon (O), morphology (X) (→ syntax, phonology)
- b. lexicon (O), morphology (X) (part of the lexicon)
- c. lexicon (O), morphology (O) (autonomous, independent)

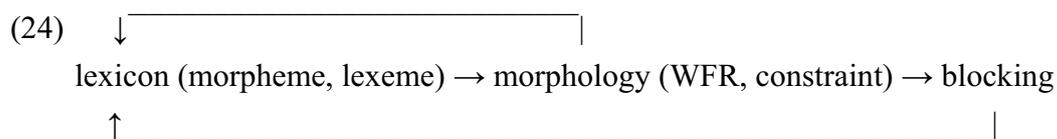

We assume that the lexicon is unproductive and irregular, whereas morphology is productive and regular. We may also say that potential or possible words are formed in morphology, and actual words appear in the lexicon. In (21), the list of morphemes and WFRs make potential words. Actual words are forms where potential words pass through the filter, and they are stored in the dictionary. So Halle (1973) mentions that morphology can be thought of as producing a long list of words; this list is designated by the term dictionary, which is similar to the notion listedness proposed by Williams & Di Sciullo (1987).

Katamba (2005:75) mentions an interesting example which shows the relationship between morphology and lexicon.

- (23) a. *yupp-ie* (= young urban professional people)
- b. *yuppi-fy*, *yuppie-dom*, *yup-ette*
- c. *buppie* (= black yuppie), *guppie* (= gay yuppie)
- d. *re-yuppification*, *de-yuppification*

The form *yuppie*, which corresponds to a kind of nonce word, is produced by an acronym *yupp* plus a suffix *-ie* meaning affection. The words in (23b) express a verbal form, a nominal form and a diminutive form, respectively. The words in (23c) are a kind of blending with respect to word formation. The words in (23d) exhibit affixation where prefixes and suffixes are added to the base *yuppie*. The acronym *yuppie* was a potential or possible word, but now it appears as lexical entry in a dictionary, which means that *yuppie* becomes an actual word by institutionalization. This process is summarized as follows: potential or possible word (morphology) → (institutionalization) → actual word (lexicon). On the other hand, the forms in (23b), (23c) and (23d) are recognized as potential or possible words. So they cannot be stored in the lexicon.

Unlike Halle and Katamba, I schematize the relationship between lexicon and morphology as follows:

The schema in (24) shows a circular process. Morphemes or lexemes in the lexicon can

be involved in WFRs. The possible or potential words derived by WFRs are restricted by constraints. The words which constraints are applied to may be acceptable or unacceptable forms. Since acceptable words become actual words, they can be stored in the lexicon. Unacceptable words go to the next stage, and they have to pass through blocking which is various kinds of filter. The forms which succeed in passing through blocking may be stored in the lexicon.

## 5. Conclusion

In this paper, I have dealt with the productivity of word formation and various kinds of constraints on word formation. A large number of words or compounds are made by affixation and compounding. As a result of word formation processes, possible or actual forms appear in morphology and the lexicon. This shows the productivity of word formation. However, we need a kind of device to restrict a power of word formation. So many kinds of constraint and blocking play an important role in distinguishing grammatical or acceptable forms from ungrammatical or unacceptable ones. These grammatical or acceptable forms are stored in the lexicon.

# **Japanese women's language: Ideological constructs and changing gender roles**

**Barry Kavanagh**

Aomori University of Health and Welfare

b\_kavanagh@auhw.ac.jp

## **Abstract**

The Japanese Language has been characterized as being highly gendered with distinct male and female speech registers (Shibamoto 1985). These differences manifest themselves within self reference, addressee terminology, honorifics, pitch ranges and sentence final particles. However there seems to be an emerging pattern that suggests that women, in particular young women are abandoning 'traditional' Japanese women's language in favour of more masculine forms. (Okamoto & Sato 1992)

This synchronic study looks at two generations comprising of two sets of women from the rural north of Japan in an investigation to examine whether Japanese women's language use is in fact changing.

**Keywords :** Japanese women's language, Ideology, gender roles

## **Introduction**

Japanese women's language as a subject has been well represented and commented upon by both Japanese and non-Japanese scholars (Shibamoto, 1985, 1987, Okamoto 1995, Matsumoto, 1996, Reynolds, 1990). The general consensus within the metapragmatic discourse on how women should talk suggests that in contrast to men's language (*dansei-go*) Japanese women's language ( *joseego*) should adhere to being polite, gentle, softly spoken and non-assertive. Self reference (personal pronouns), honorifics, pitch ranges, address terminology, and sentence final particles have all been discussed as having these feminine traits and usage (Reynolds, 1985, Shibamoto, 1985).

Nevertheless are the cultural and scholarly representations of Japanese women's language reflective of the linguistic practices of contemporary Japanese women? Is Japanese women's language in a period of transition paralleling the change in gender roles or could it be suggested that 'feminine language' simply an ideological construct that does not in fact exist or find itself widespread in practice? (Sunaoshi 2004,

Okamoto & Sato 1992)

Technical terms such as *josego* and *onna kotoba* (women's language) argues Endo (2008) are used by linguists which carry with them a history of being forced on women in attempts to define their normative language since the Meiji period (1868-1912) So what is Japanese women's language and how strong is the relationship between *onna-rashii* ('feminine') language and the broad variety of language used by the Japanese woman of today?

The Japanese woman is defined as being elegant, polite, soft-spoken, non-aggressive and submissive and her language use and linguistic choices should therefore be reflections of this. Jordan (1990) states however that this is a stereotypical image of a weaker sex, of a woman who knows her place and is careful in demonstrating it. A throwback perhaps to days gone past to what Iwao (1993:1) calls "The Kimono-clad bamboo parasol-toting, bowing female walking three paces behind her husband".

Iwao (ibid:265) however suggests the traditional female has now become one of several breeds and that "The profound changes now taking place among Japanese women represent no less than a quiet revolution".

Kawashima (1995:271) states that "Japanese women have come a long way from the times when being a 'good wife and a wise mother' (*ryosai kenbo*) described her role in the family and society" With the growth in the number of roles for women and the independent economic status that they have acquired (Iwao1993; Lebra 1986; Fanselow & Kameda 1994; Jordan 1990) could this lead us to the assumption that these women's linguistic choices are also changing? Reynolds (1990) suggests that although contemporary women have a new found status, women's language still remains a representation that refers to the speaking practices of women in the past and recognizing this conflict is imperative if we are to understand the changing status of Japanese women and the change in Japanese women's speech. Such change has been given media attention which has highlighted the *midareta nihongo* or corrupt Japanese used by contemporary women as not being reflective of 'traditional Japanese women's language'. It has been labeled merely a vulgar, dirty and even tasteless use of the language with scholars such as Okamoto & Sato (1992) finding that young women are using less feminine forms and adapting a more masculine use of the language. This study attempted to determine if the same is true in the case of rural Japan, through an examination of Japanese women's discourse and their linguistic choices with particular reference to sentence final particles.

### *Final particles*

Inoue (2004) states the case that typical feminine sentence ending particles such as *da wa* and *wa yo* did not come to represent femininity as a result of being innately indexicalized as female exclusive. She argues that other sociolcultural and political phenomena are at work here.

At the beginning of the 20th century, Women's language was something that was read and not heard for the majority of the population. The late Meji period saw the consolidation of Japan's modern nation-state and the emergence of industrial capitalism. This period was also extremely influential in the creation of Japanese Women's roles. Based on Confucianism the notion of *ryoosai Kenbo*, *good wife, wise mother*, was introduced to compulsory education programmes. Such institutions emphasized homemaking, modesty, obedience to one's father and husband, chastity and high morality. Linguistically, writing and speech became standardized (*gembun ichi*) based on the elite of Tokyo. The rise of Women's language can be found in this linguistic modernization process. Inoue (1994:325) confirms this when she says "The construction and dissemination of women's language is closely linked to the construction and dissemination of the doctrine of 'good wife and wise mother' and to the larger political project of the conciliation of the nation-state".

By the early 20<sup>th</sup> century sentences endings such as *dawa* and *noyo* were increasingly assigned to female dialogue in novels, especially in *katei shoosetsu* or domestic novel which acted as learning aids for women on how to be a good wife and mother. This argument suggests that female education in the pre war years produced and ingrained gender differences with Sugimoto (1997) maintaining that from 1890 –1912 of the Meji period every effort was extended in order to make women more feminine.

#### *Masculine and Feminine Sentence Final Particles (SFP)*

*A full table categorizing SFPs and references can be found in Appendix A*

Maynard (1997) states that these 'interactional particles' express the speakers attitude and judgment toward the message and the addressee. McGloin (1990) suggests that these SFP's can create or maintain an interpersonal immediacy but these particles as has been discussed are sensitive to the gender of the speaker. The following sections will try to illustrate the bulk of these particles in practice.

### *Masculine particles*

The literature illustrates sentence endings as the predominant markers of gendered language in Japan. McGloin (1990) Streehan (2004) and Reynolds (1985) indicate that Japanese men use sentence final particles that index authority, aggression and masculinity as exemplified in the particles *ze* and *zo* and which are never used by women. Smith (1992) calls this men's linguistic privilege. But McGloin (1990) does argue that in monologues as does Hasegawa (2005) such particles are permitted to be used.

*Zo* is one of the more imposing of the masculine SFPs as it creates the impression of insistence, authority, aggressiveness and a status higher than your addressee. For example, father to children, a male teacher to his students.

McGloin (1990) asks the question why are *zo* / *ze* / *na* / *and sa* common in male speech with limited access to females with the response from Reynolds (1985) being that there exists a relationship with the assertive particle use and power within society. The more assertive particles are therefore reserved for men or those with greater power and authority (boys would not be encouraged to use such particles when speaking to their fathers) and that as women are regarded as the weaker sex they are taught to use those particles with weaker assertion. For example, '*Yo*' has been analyzed to express the speaker's insistence and emphasis on the information and is considered mildly masculine although as McGloin (ibid) admits is soft enough to be used by women and by inferiors to a superior making it a more neutral particle.

### *Feminine particles*

As illustrated in Appendix A feminine particles can fall into the mildly feminine or strongly feminine category. '*Wa*' is commonly attributed to women's speech. It is used by women when addressing both intimates and acquaintances but can also be attributed to men in the Osaka region of Japan to express surprise and admiration. *Wa* with a rising intonation gives it a distinct classy feminine edge. Ide and Yoshida (1999) speak of the dual nature of the particle. Ide (1992) as in Ide and Yoshida (ibid) suggests that the softening function of *wa*, an effect of the negative politeness strategy (Brown and Levinson 1987), enables the creation of relaxation as it functions as a non-impositional particle with respect for the addressee. This leads to an atmosphere of sharing which is an effect of the positive polite strategy.

Ide and Yoshida (1999) suggest that the speaker who frequently uses *wa*, *wa yo* or

*wa ne* index their identity as female while those who use *zo* or *na* as SFP's index their identity as male. This would suggest a conscious choice can be made, however such a choice has social implications. Sasaki (2003) suggests that a man using feminine forms is giving the impression he wants to be feminine. A woman who uses masculine forms gives the impression she wants to be one of the boys (Reynolds 1990).

McGloin (1990) reveals that 'wa' and 'no' are used as tools that function as softeners of women's speech because of the effect of uncertainty created by them. *no* however may be more neutral in questions but when used in declarative sentences is considered feminine. Below are some cultural representations of 'wa' and 'no'.

### **Cultural representations of WA わ and NA NO なの**

#### **Female version**

あした友だちの結婚式なの  
*ashita tomodachi no kekkon shiki na no*  
Tomorrow is my friend's wedding

#### **Male version**

結婚式なんだ  
*kekkon shiki nan da*  
Tomorrow is my friend's wedding  
(From *Mangajin's Basic Japanese through Comics Ashizawa (1998)*)

#### **At school**

数学のテスト、何点取ったの？  
*Suugaku no testo, nan ten totta no?*  
What did you get on the Math test?

100点よ。あのテストは朝飯前だったわ  
*100 ten yo. Ano testo ha asameshimae data wa.*  
100%. That test was a piece of cake.

あなたにとってはね。。。  
*Anata ni totte wa ne...*  
For you, maybe...

(From *Nova city, An English conversational school magazine (2005) Various authors*)

Okamoto however (1997) as cited in Ide and Yoshida (1999) found that women

tend not to use the above particle *wa* instead opting for masculine particles in informal situations. Her informants commented on a lack of assertiveness in feminine SFPs and that such particles create a distance between the speakers so they are not likely to use them in conversations with close friends. They opted to choose particles such as *yo* preferred by men which emphasize intimacy toward the addressee because of its directness. She explains that the use of masculine SFPs such as *zo* reinforces solidarity among close friends.

Having provided a discussion of the two gendered forms of SFPs use it can be concluded that that we have the blunt, the aggressive and the forceful (masculine) juxtaposed with the gentle, the soft and the hesitant (female).

Matsumoto(2004b:255) however suggests that these divisions of masculine and feminine linguistic behavior can be misleading giving the "...impression that Japanese women and men speak differently at all times, as if they were originally from two different tribes with two different languages". While It has been noted that traditionally the male female dichotomy is a strongly embedded one within Japanese culture it appears that language forms especially amongst the young are changing.

## **Empirical Evidence**

Ozaki (1999) found that the use of feminine forms (SFPs) was extremely frequent in women aged fifty and over, but that women in their twenties hardly used them at all. Sasaki (2003) suggests that feminine forms peaked with *dankai no sedai* (post war baby boomer generation) and has since gradually decreased with the possibility that the forms may disappear in the future. Perhaps a more linguistically neutral future. Sasaki (ibid) does state however that more women are using masculine linguistic forms, not the strongly masculine forms, but that 80% of young women in their twenties are using forms that were previously thought of as purely masculine.

Sasaki (ibid) does not hold an optimistic future with regard to the longevity of the female linguistic form and suggests that if the use of feminine forms continues to decrease at the present rate, it is a possibility that they will become obsolete except in the world of literature, cinema and song.

Mizokami (2003) found that college women use expressions typically reserved for men concluding that they may not be tied to the idea of women's language than older women. Informants in her study of whether women are in fact politer than men revealed that TV dramas and novels exaggerate linguistic differences between the sexes

hinting at it being an ideological construct rather than a reality. Although her informants were aware of the sex distinctions of speech they suggested that context played a significant part in what sentence endings and expressions are used. Mizokami (2003:122) therefore sums up by stating that "... there is in fact no absolute difference between men's and women's language, rather the boundary between men's and women's language is re-marked according to the context at all times". She suggests that feminine language has not been so deeply internalized by the younger generation. Her study however looked at college students but as this investigation examines slightly older women, what happens to their language use as they enter their 20's and join the workforce. Do they as Eckert and McConnell-Ginet (2003) state grow into the language?

Okamoto and Sato (1992) in their study of 14 middle class Japanese women found that younger women from the 27-34 age group used 'feminine' forms 24% of the time compared with women in the 45-57 age bracket who used them 50% of the time. The youngest group (18-23) used them 14% of the time. Eckert and McConnell-Ginet (2003:187) state that "While it is unclear whether this represents change in usage through time or in the lifetime of the speakers, it certainly shows that at least nowadays feminine forms are not favored by younger speakers". Reasons to why are numerous. Matsumoto (2002) has argued that younger women have not used such forms in comparison to their elders because of the fact that they have not learned the 'delicacies of choice' and because the 'nature of their social relations is not as yet hierarchically complex'

Another probable reason could be that social change has decreased the need for such forms as women enter the marketplace and demand greater equality. This may be reinforced with the situation of women growing up with different expectations and dynamics among their peers (Eckert and McConnell-Ginet 2003) Reynolds (1985) however suggests that the phenomenon of women using masculine forms occurs with younger women conversing amongst themselves. She also states that expectations with regard to expected linguistic behavior of the sexes is so ingrained that as soon as younger Japanese women either enter the workplace or get married she modifies her speech to conform to social expectations. This point of view would suggest that such findings have no significant effect on the overall status of women or women's use of language in the foreseeable future.

Matsumoto (2002:339) points out that the categories of feminine and masculine can be problematic and suggests that the recent studies that have disputed the dichotomy between men's and women's language illustrate "... that the relationship between

linguistic expressions and the gender of the speaker is only probabilistic at most, rather than a strict correspondence” Furthering this point Ochs (1993) suggests that indexing gender is not simply a process of matching linguistic forms to a speakers sex but instead it should be realized that speakers draw from a menu of stereotypical forms to enact social identities. These identities can be seen to be changing and the linguistic forms chosen from this menu is also changing, but are women, particularly young women, choosing from the feminine menu, the neutral or masculine menu in terms of the sentence final particles they use?

Is femininity therefore something that you grow into as implied by Eckert and McConnell-Ginet (2003) and as you age consequently select from the feminine particle menu or is the fact that young Japanese using less feminine or deferential language (as illustrated in sentence endings) a reflection of social and linguistic change? Eckert and McConnel-Ginet (2003:329) do not see current behavioral changes as a process of women becoming masculine, but admit that social and linguistic change has taken place. They argue that it may be a sign that girls are making a claim for authority as their male peers do. They suggest

The linguistic changes are not something that have simply washed over the younger generation: they are the result of girls finding ways of constructing kinds of selves that were not available to earlier generations. They are the result of social and linguistic strategies. In other words, this linguistic change is part of identity work of finding ways of being in the world of creating new meanings for themselves. Young Japanese women who use stronger forms may be seen by some as speaking like men, and their motives may be attributed to their trying to be more ‘like’ men.....perhaps she is affirming her right to be assertive

### **The Informants**

It must be stressed that this study is not intended to reflect the population as a whole, rather it is intended to shed light on the linguistic practices of two generations of women who residing in rural Japan, taking into account how gender can interact with

other social variables, such as class and occupation. It differs from other studies on this subject (Mizokami, 2003; Okamoto & Sato, 1992, Okamoto,1995) in that it looks only at women from rural agricultural working class backgrounds in contrast to studies which focus on middle class women from the Tokyo area.

The majority of informants used were my own acquaintances. Others were introduced by friends, particularly those over 50. A total of 30 informants were interviewed. 15 of these women were between the ages of 21 and 29, with an average age of 25. The older group was comprised of 15 women between 50 and 63, with an average age of 53. The average age difference between the two groups made it possible to compare across distinctly different generations. All informants were born and raised in the rural areas of Akita and Aomori.

Of the fifteen older informants 13 were homemakers, two of whom held part-time jobs; the remaining two held full-time jobs. All but two were married, and all came from a rural agricultural ‘working class’ background. Most had worked in farming or agricultural related companies. None of the older group had lived abroad, though many had taken brief holidays overseas. Four of the informants, however, are friends with local foreigners and are very interested in foreign culture. The younger group was comprised of ten single women (eight of whom were working full-time), four married homemakers, and one married working professional. Occupational backgrounds were quite varied; none work in the agricultural industry. Compared to their older peers, the younger women are more ‘international’ Eight of the younger informants have been abroad to various extents, speak English, and socialize within foreigners on a regular basis.

The informants have been categorized as in the following examples:

**OJF1 (Older Japanese female 1)**

**YJF1 (Younger Japanese female 1)**

## **Methods**

By means of discourse elicitation tasks, informants spoken discourse was recorded and assessed for the number of masculine and feminine forms used. This was followed by a semi-structured group interview in which informant perceptions and opinions of language and gender were discussed.

The discourse elicitation tasks presented the informants with a series of statements for discussion. The tasks were broken down into two categories, the first of which asked informants to choose between a set of opposing pairs such as coffee or tea and to give reasons for their choices. This was followed by the second task which asked informants to comment upon statements or hypothetical questions such as ‘What would you do if...?’ These tasks were designed to get as much recorded discourse as possible with the time given which usually stretched to an hour. Feminine and masculine sentence final particles uttered by the informants during these informal conversations were counted.

After the recordings were transcribed, a total of 100 sentences were taken from the same point of the interview (from the discourse elicitation tasks). The same point usually meant when the author determined when the informants were comfortable with the interview which was usually about 5 to 10 minutes into the interview session. The number of strongly/slightly masculine particles and strongly/slightly feminine particles as well as neutral ones were counted and totaled as a percentage (See Appendix A for the SFPs and their forms).

Upon completion of the discourse elicitation tasks the session concluded with informants being asked a series of open ended questions in an informal interview that specifically attempted to investigate the question Is Japanese Women’s language in transition and if so why?

## **Results**

The table below illustrates the collective findings of the two groups from the discourse elicitation tasks and shows variation in the speech practices of the two generations with the younger group being less feminine and more masculine than the older group in the use of sentence final particles.

## Use of gendered sentence final forms for the two group

**Table 1.**

	<b>Final forms used by young group (20-29)</b>	<b>Final forms used by older group (50-63)</b>
<b>Strongly masculine forms</b>	45 items. (3%)	36 items. (2%)
<b>Slightly masculine forms</b>	265 items. (18%)	159 items (11%)
<b>Neutral</b>	1111 items. (74%)	1120 items (75%)
<b>Slightly feminine forms</b>	65 items (4%)	135 items. (9%)
<b>Strongly feminine forms</b>	14 items. (1%)	50 items. (3%)
<b>Totals</b>	1500	1500

### *The older generation*

In contrast to the studies of Okamoto and Sato (1992) the older generation here is radically different to the middle / upper class professional women of Tokyo in which they found that in females aged 45-57 strongly feminine SFPs were used 28% of the time and slightly feminine 50% of the time which lies in stark contrast to these working class homemakers from an agricultural background. (3% strongly feminine and 9% slightly feminine)

A number of reasons can be perhaps given here as to why the older generation are electing not to use feminine language and favoring a neutral, unisex one. (75% of utterances). Unlike other studies such as Okamoto and Sato (1992) this study focused on rural working class women with agricultural rural backgrounds. These rural backgrounds exclude them from the assertion that Japanese women's language hails from the perspective of highly educated women who are living in or aspiring to be associated with Tokyo. Sunaoshi (2004) argues that for women outside this category or who live in regional Japan as seen here, Japanese women's language plays a different role, if any at all. An example she gives is that "...women who live in regional Japan and who are in working-class occupations may not use features of 'Japanese women's language', not because they are unable to master them but because features of 'Japanese women's language' are simply not in their language repertoire" (2004:188)

The older women interviewed here formed part of a small yet close agricultural community, where perhaps the necessity to use women's language is not requisite when compared to the urban middle class equivalent. Perhaps then the notion of a feminine language is an ideologically construct not reflected in reality can be supported here, at least not for the rural homemaker. Sunaoshi (2004:200) argues "Indeed, the use of

“Japanese women’s language” is itself a regional phenomenon; “Japanese women’s language” is the ideal shared by women of a certain socioeconomic background who reside in Tokyo or aspire to Tokyo values, including language use”. The findings here would seem to support this.

### *The younger generation*

As reflected in the data here the younger generations use of their language appears to be abandoning feminine use of the language and adopting a more neutral stance similar to that of the older generation with the masculine uses of the language stemming largely from the ‘slightly masculine category’. The evidence here shows that among the young, speaking styles and sentence final particles that were once thought of as the domain of men, in the case here slightly masculine particles, are now in use by these women. There were over 100 more slightly masculine forms used with the younger generation than the older group with only an additional 10 in the strongly masculine category. Nevertheless results were not overwhelmingly different in their percentage form (18%) in comparison to 11% for the older group.

It can be argued however that these women have incorporated them into their daily conversations almost unconsciously allowing as suggested by Matsumoto (2004b) “some of the expressions considered “feminine” to fall into disuse (208)”. The data would certainly seem to support this notion. With the younger generation registering 4% and 1% for slightly feminine and strongly feminine forms respectively. In comparable studies Okamoto and Sato (1992) found that with the same age group of 18-23 year old women and 27-34 year olds their feminine utterances totaled 14% and 24% respectively. Again however it must be emphasized that the women in their study came from different socio-economical environments to the women here.

### **The Interview**

The interview initially asked informants to describe the younger generations language use and to explain the changes and reasons if any in their spoken discourse. A comparison was also asked of the informants to explain the differences in language use with the two generations of women here. Below are some of the views and opinions that the groups expressed.

### *Language use and changing gender roles*

Both generations agreed that it is the older generation who employ more feminine language use and that it is the young who are masterminding a trend that is moving away from what is considered Japanese women's language with their spoken discourse employing more masculine forms.

YJF14 suggests that the use of women's language creates a distance between the speaker and the addressee and does not cement a rapport between speakers. Maynard (1989:30) states "... frequent insertion of particles encourages rapport between the conversation partners and achieves a closer monitoring of the partners feelings". These particles of rapport are *sa / ne / no / kana / yo na / and ze*. The strongly masculine *Sa* (18 items) and *na* (27 items) was seen to be used by the young group with the strongly masculine *na* (29 items) favored more than the alternative softer and feminine *ne* by the older group. *Kana* was favored more by the younger group with the feminine alternative *kashira* only spoken by 4 older informants. The younger informants spoke of 'having a good time' with the language and that in intimate close relationships with same sex friends masculine usage of the language enabled this (See table below for when women elect to chose masculine language). This parallels Okamoto & Sato (1992) who found that the use of strongly masculine forms seem to be a highly conscious decision. Okamoto (1995:315) states "Their employment therefore functions to increase the expressiveness of an utterance, making the conversation between peers more interesting and spirited"

#### **When do you use masculine language?**

	<b>Older group</b>	<b>Younger group</b>
When angry	66%	24%
Do not use	23%	0%
Speaking with close friends	7%	57%
When doing sports	0%	10%
Other	4%	9%

YJF3 pointed out that the older generation have not changed the way they speak since they were young and that the encouragement of that generation on the young to use feminine forms is something she as well as other young people do not agree with. For this reason particles like *da wa* are fading out amongst the young. (Evident in the

fact that the use of *da wa* was not used once in the spoken recorded discourse among the young group). YJF7 suggests that young women do not worry about how they speak anymore. (perhaps the stigma and taboo is disappearing) YJF7 (aged 29) also points out that if a young woman were to use the language of women in their 50's then their peers would find it strange and that for her personally to speak '*kirei na kotoba*' beautifully is a little embarrassing. YJF8 is adamant that women have become stronger and that this is reflected in a more assertive language use which has been termed '*ranbo*' or rough by observers.

OJF14 whose language use was recorded as 84% neutral and 10% strongly masculine suggested that the borders between masculine and feminine language use is becoming blurred as perhaps shown in her own discourse.

OJF11 pointed out that language use is a growing process, perhaps as Eckert and McConnell-Ginet (2003) suggest it is something that you grow into. The informant suggested "We have experience compared to the younger generation so naturally we can use women's language"

YJF2 the youngest informant at 21 agreed that young women's language use is *hidoi* (awful, terrible). She suggested that before women reach the age of 50 that somehow their speech style changes in an unconscious process and that women in their 20's who go through changes such as employment, marriage and motherhood also witness their language change too.

Some informants however claimed that even though young Japanese women's language is perceived to be changing they in fact did not adhere to the change. YJF15 states that when she hears the 'rough' language of the young she feels disappointed and distances herself from such use as it is not reflected in the way she speaks. She continued that the language is changing as exemplified in the young abbreviating their Japanese and creating their own vocabulary.

The young point to a genderless language in the future and suggest that changing social roles of women are primarily the cause of this. The older generation may disagree but the evidence here certainly seems to suggest that very fact.

The younger generation suggested that social pressure on young women in particular to use feminine language is not strong, nor widespread, but that cultural representations of the feminine language as seen through Japanese TV drama's tend to exaggerate these forms and are not representative of all Japanese women. The younger informants believe there is a relationship between place of birth and language use. A woman from Tokyo is more prone to use feminine language than a woman from Akita or Aomori which would support the notion that Japanese women's language is a Tokyo

centric phenomena.

## **Conclusion**

This paper has tried to highlight the change in contemporary women's speech in an synchronic study with two generations. The data suggests the younger generation are adopting more masculine forms in their spoken discourse and are moving away from traditional Japanese women's language discourse.

A change in gender roles and new social identities are given to account for these trends in younger women's spoken discourse. However what this research has also attempted to SHOW is that these synchronic variations in Japanese women's language have challenged the concept that Japanese women's spoken discourse constitutes a discrete, homogeneous category.

Research on Japanese language and gender has tended to uphold the stereotypical *yamanote* speech of Tokyo women as the true sound of Japanese femininity.

Nevertheless the term 'Japanese women's language as suggested by Okamoto (1995) is a culturally and ideologically constructed, class-based norm that is too static and monolithic to account for the varied speech styles of Japanese women. The speech styles documented within this research are perhaps testament to this.

With the younger generation it can be argued that their language use is in a period of transition with the adoption of more masculine and neutral forms with the severe depletion of feminine forms within their spoken discourse. The data also indicates synchronic variation among the generations that can possibly raise questions for future investigation. Is this change temporary? Will the younger women bloom linguistically into a more feminine use of the language as they age? A diachronic study would be needed to answer these questions nevertheless based on the results of the older women's discourse here and within this region this may not be the case.

## Appendix A

### Masculine and Feminine Sentence Final Particles

The observations below are based on the literature of (Okamoto1995. Okamoto & Sato, 1992 .Maynard, 1997. Ide & Yoshida,1999. McGloin, 1990. Smith,1992. Shibamoto, 1985. Reynolds, 1990. Matsumoto, 2004 . Makino, 1989).

Strongly masculine	Slightly masculine	neutral	Slightly feminine	Strongly feminine
		‘No’ used in interrogatives	‘No’ after a noun or na adjective	‘no’ after a noun or na adjective* in a statement
	‘da’ after nouns and na adjectives*	Nouns alone		‘wa’ proceeded by da or the past version datta
	Auxiliary ‘da’ followed by yo, ne or yone			‘wa’ proceeded by da / data and followed by ne, yo or yone.
	Auxiliary ‘n da’			‘wa’ proceeded by da / data and followed by

				ne, yo or yone.
	Auxiliary 'n da' followed by yo, ne or yo ne			
	Auxiliary 'daro(o) for expressing probability/ seeking confirmation/ agreement		Auxiliary 'desho(o)' for expressing probability / confirmation / seeking agreement	
	'Kana' Attached at the end of sentences meaning 'I wonder...'			'kashira' I wonder
Ze for strong assertion	Yo after a plain form of a verb or I adjective *			'yo' (with a high sustained intonation) after a noun or na adjective*

Strongly masculine	Slightly masculine	neutral	Slightly feminine	Strongly feminine
Zo for strong assertion (considered stronger than ze )		Plain form of verb or I adjective* for assertion		Wa (with rising intonation) for mild emphasis and its variants (wane ,wa yo ne)
'na' for eliciting agreement		Particle yo followed by ne for seeking agreement or confirmation	Ne after a noun or adjective	No followed by ne or yo ne for seeking confirmation or agreement
'ka yo' for expressing defiance / criticism				
The negative command 'na'				
	-oo ka? Used for an invitation or offer			
Strong imperative Yamero! Stop it!		Imperative Yamete Stop it		

	Sa. When used following verbs and adjectives	Sa. Used by both men and women. Feminine version may have the longer saa sound which acts like a colloquial filler		
	Jan Male equivalent and contraction of 'ja nai'? Considered neutral by some. Used to seek agreement with mild assertion		Ja nai? Like the particle 'ne' used to seek agreement with mild assertion considered neutral by some	

\*na adjective, an adjective that takes na to modify a noun. An \*I adjective ends in I.

- These sentences are found only in informal speech where gender differences are distinct
- Uchida (1983) found that men used 'Jan' which is considered neutral by Okamoto (1995)
- Kana is considered neutral by Okamoto (1995) but masculine by the majority of sources (Ide & Yoshida, 1999. Makino, 1989. Uchida, 1983)
- For the purpose of this study the particles as illustrated in the table were assessed

# **The Influence of Gender on the Prosody of Buenos Aires Spanish**

**Claudia Enbe and Yishai Tobin**

Department of Foreign Literatures and Linguistics  
Ben-Gurion University of the Negev  
P.O. Box 653 (84 105) Be'er Sheva Israel  
claudiaenbe@hotmail.com / yishai@bgu.ac.il

## **Abstract**

The classic research on Spanish prosody ignored the sociolinguistic variables of gender and age. However, we found variation in the prosodic patterns of Buenos Aires Spanish according to these variables.

The population of our study includes 132 native speakers of BAS (66 males /66 females) divided equally in three age groups (5-8, 18-50 and 51-78). The corpus contains declarative; wh-questions and exclamatory sentences.

Our results indicate that: (1) there was an inverse proportion between the difficulty of the sentence and the range of prosodic variation among speakers, (2) females of all ages consistently prefer marked prosodic forms; (3) adult males have more random intonation patterns (4) younger adults of both genders show the most prosodic variation according to sentence type.

**Keywords:** prosody, Buenos Aires Spanish, gender, age.

## **1. Introduction**

The classic research on Spanish intonation (both Peninsular and Latin American) overlooked the sociolinguistic variables of gender and age (e.g. Navarro Tomás 1944/1974, Quilis 1993, Beckman et al 2002). Modern studies of Buenos Aires Spanish (BAS) prosody have also ignored these variables (e.g. Sosa 1999, Toledo 2000, Colantoni and Gurlekian 2002, 2004, Gurlekian et al. 2004, Barjam 2004). In our previous research, based on a limited number of speakers and sentences, we found variation in BAS prosodic patterns for these variables (Enbe et al. 2006, Enbe and Tobin 2007, 2008). Therefore, the goal of the present study was to compare and contrast the prosodic patterns of BAS in different sentence types according to gender and age analyzing a more extended population using a larger corpus of sentences. Our new results support and even further strenghten our original findings. The results were analyzed and explained according to: (1) the defintion that language is a symbolic tool whose structure is shaped both by its communication function and by the characteristics of its users (Tobin 1990, 1993, 1994) and (2) the principle that language represents a compromise in the struggle to achieve maximum communication through minimal effort (Diver, 1979, 1995; Davis 1984/1987; Tobin, 1997) associated with the Theory of Phonology as Human Behavior.

## 2. Experimental design

### 2.1. Participants

The participants for this study were 132 native speakers of BAS divided into 3 age groups: a) children (5-8 years); b) adults (18-50 years) and c) adults (51-78 years), with 22 males/ 22 females per group. The subjects were native, monolingual, middle-class speakers of BAS living in the Buenos Aires area. They had been diagnosed with normal hearing and have no physiological disorders of the vocal folds or of the vocal tract. Adolescents (9-17) were not included in our study because of hormonal changes affecting fundamental frequency (F0).

### 2.2. Speech material

The corpus was composed of the following seven sentences:

- (a) Declarative sentences: *El agua hierve.* ('The water is boiling.') (S-V), *El agua y el aire dan la vida.* ('Water and air give life.') ((S1+S2)-V-O); (b) Wh-questions: *¿Dónde vive el nene?* ('Where does the boy live?'), *¿Cómo era el avión?* ('How was the airplane?') and *¿Quién era el amigo?* ('Who was the friend?') (Wh-word—V—S); (c) Exclamatory sentences: *¡Gol!* ('Goal!') (Noun) and *¡Viva!* 'Hooray!' (V).

The sentences contained only voiced consonants and vowels in order to obtain an uninterrupted fundamental frequency contour. The target sentences were examined and verified by a board of eight experts (four speech pathologists, two linguists and two language teachers) who listened to the sentences and classified the utterances as typical BAS declarative, wh-question and exclamatory sentences.

### 2.3 Procedure

The current study is part of a larger research project (Enbe 2003, Enbe et al. 2004, Enbe and Tobin 2006, 2007, 2008) which initially investigated the prosodic patterns of typical versus atypical speech in BAS. Therefore, we employed sentences with a controlled prosodic pattern and similar content words using a repetition task to enable us to compare and contrast the utterances among speakers. We are aware that in sociolinguistic studies as close an approximation to spontaneous speech is preferred, and that the repetition task may present additional problems for the sociolinguistic aspects of our study from the point of view of context, pragmatics and the priming effect, among others factors, and must be taken with caution. However, being that the sociophonetic variables of gender and age in prosody in general and in BAS in particular have not been adequately researched previously, we view this study as a limited first step and would suggest a different elicitation methodology or methodologies for future sociolinguistic studies of prosody.

Moreover, we found that the use of a repetition task has advantages over the other elicitation tasks previously used in intonation studies (e.g. reading aloud, spontaneous speech) because of the following two reasons: a) the study includes children who do not necessarily read or do not read fluently and b) the speakers of atypical speech included in the original project restricted the kind of elicitation tasks because spontaneous speech and reading aloud were not suitable for speakers with speech disorders. We also avoided the use of other elicitation tasks such as picture naming, word identification, word production, and fragment completion frequently employed in the clinic because these tasks are also related to complex cerebral activity that not suitable for the atypical population of our original study.

The target sentences of our study were recorded by the first author, a native speaker of BAS who is also a speech language pathologist. The speaker was requested to produce each utterance using his/her own “natural” (or habitual) prosodic patterns for each of the specific grammatical sentence (declarative, interrogative or exclamatory). The utterances were recorded in a partially-isolated acoustic room, using AKG acoustics D50S dynamic vocal microphone on a Mini-disc Sony MZ-R37. Waveforms were digitalized and stored on a hard disc with a quantization rate 16 bits using a sampling frequency of 44 kHz. Acoustic analysis was performed with the “Anagraf” speech program (Gurlekian 1997/2004) and each utterance was labeled according to the principles of AM-Theory (Pierrehumbert 1980), following the guidelines of ToBI (Beckman and Ayers 1993/1997) within “ToBI-A” (a wide ToBI system proposed for Argentinian Spanish; Gurlekian et al. 2001, 2004). The results were interpreted within the framework of the theory of Phonology as Human Behavior (PHB) which attempts to explain linguistic phenomena in general and phonological and prosodic features, in particular, according to the axiom of “maximum communication with minimum effort.”

### 3. Results

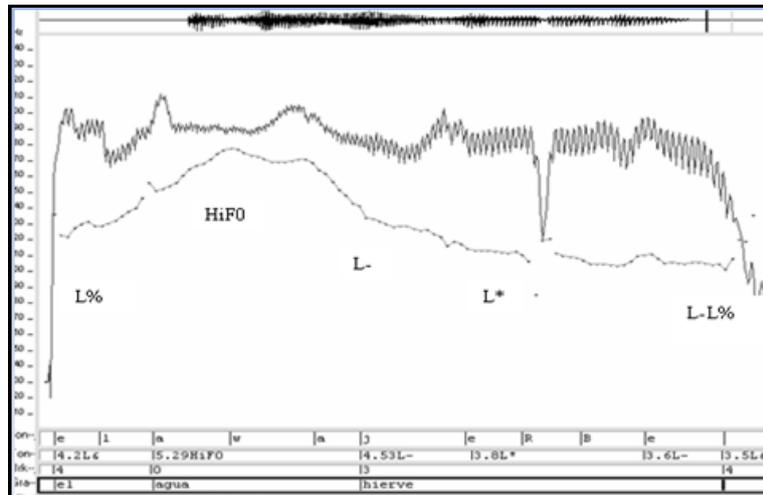

#### 3.1. Declarative sentences

##### 3.1.1. Simple declarative sentences (S-V)

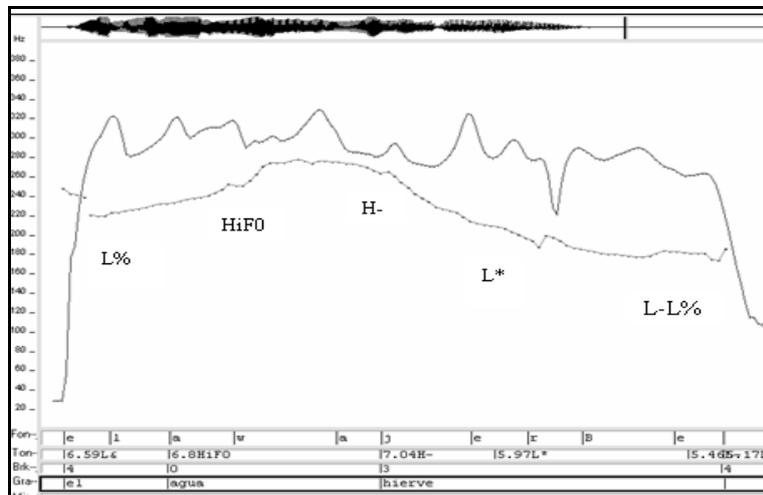

The results obtained based on 132 simple declarative sentences (S-V) show that the majority of speakers produce patterns similar to both classic Spanish patterns: the unmarked Type-1 (1a) and the marked Type-2 (1b) originally established by Navarro Tomás (1944/1974).

- (1)                    *El Agua HIERve*  
                          the water boils  
                          ‘The water is boiling.’

In (1) the sentence *El agua hierve* is uttered according to the classic unmarked and marked patterns Type-1 (1a) and Type-2 (1b) illustrated in figures 1 and 2 respectively.

**Figure 1:** Prosodic pattern Type-1 of the sentence *El agua hierve* ('The water is boiling.') uttered by a man aged 19.

**Figure 2:** Prosodic pattern Type-2 of the sentence *El agua hierve* ('The water is boiling.') uttered by a woman aged 21.

In both examples, the speakers divide the sentence into two melodic groups by a tonal change. Both BAS patterns have the highest tone of the sentence on the subject and a falling prosodic contour in the predicate. In the unmarked Type-1 pattern, however, the falling contour already starts at the subject of the sentence

and continues to fall in the predicate until the end of the sentence, thus requiring minor effort to produce the prosodic contrasts (see figure 1). The marked Type-2 pattern, however, requires more effort by maintaining the rising prosodic contour longer over the entire subject, followed by a shorter falling prosodic contour only in the predicate until the end of the sentence, thus producing a clearer contrast between both parts of the sentence (see figure 2).

The prosodic pattern distribution according to gender for S-V declarative sentences shows that half of the females prefer the marked classic contour pattern Type-2 (50%) over other non-classical patterns (29%) and the unmarked classic pattern Type-1 (21%). Males prefer other non-classical patterns (45%) over unmarked Type-1 (30%) or marked Type-2 (25%) classical patterns (see table 1).

**Table 1.** Pattern distribution in BAS S-V declarative sentences according to gender.

<b>Declarative sentences with simple subject (S-V)</b>						
	<b>Type-1</b>		<b>Type-2</b>		<b>Other patterns</b>	
	Tokens	%	Tokens	%	Tokens	%
<b>Males</b>	20	30%	16	25%	30	45%
<b>Females</b>	14	21%	33	50%	19	29%

Therefore, table 1 clearly shows that in the simple S-V declarative sentence, females prefer the marked classic pattern Type-2 while males randomly produce non-classical patterns more than both classic patterns unmarked Type-1 and marked Type-2. Children of both genders (45% of males and 52% of females) follow adult female speakers by favoring the marked classical Type-2 pattern.

### 3.1.2. Declarative sentences with compound subject ((S1+S2)-V-O)

Our results for declarative sentences with a compound subject ((S1+S2)-V-O) based on the sentence *El agua y el aire dan la vida* ('Water and air give life.') show that both males and females randomly prefer three different non-classical patterns uniquely found in BAS. We called them the unmarked BAS-Type0 (2a), and the marked BAS-TypeA (2b) and BAS-TypeB (2c) patterns, respectively.

- (2) El Agua y el Aire DAN la Vida  
the water and the air give the life  
'Water and air give life.'

In the three unique BAS patterns mentioned above, the subject consistently has two high pitch accents but we found different prosodic variations in the predicate. In general, BAS speakers prefer to place the highest pitch accent of the sentence

Analyzing the results in this more complex declarative sentence (S1+S2)-V-O, differences in gender seem to be neutralized because both males and females randomly prefer the three unique BAS patterns (see table 2).

**Table 2.** Pattern distribution in BAS declarative sentences with compound subject according to gender.

Declarative sentences with compound subject								
	BAS Type0		BAS TypeA		BAS TypeB		Other patterns	
	Tokens	%	Tokens	%	Tokens	%	Tokens	%
<b>Males</b>	14	21%	21	32%	18	27%	13	20%
<b>Females</b>	21	32%	13	20%	21	32%	11	16%

However, as we can see in the following table 3, we found prosodic variations according to age:

- a) Girls (5-8) and older females (51-78) prefer the marked pattern BAS-TypeB. The majority of younger females (18-50) produce the most basic and unmarked pattern BAS-Type0.
- b) Males of all ages randomly prefer the three BAS pattern types. However, the majority of younger males prefer the marked pattern BAS-TypeA.

**Table 3:** BAS distribution of declarative sentences with compound subject according to gender and age.

Declarative sentences with compound subject									
Participants		BAS-Type0		BAS-TypeA		BAS-TypeB		Other patterns	
		Tokens	%	Tokens	%	Tokens	%	Tokens	%
<b>Males</b>	<b>5-8</b>	7	32%	4	18%	8	36%	3	14%
	<b>18-50</b>	4	18%	14	64%	3	14%	1	5%
	<b>51-78</b>	3	14%	3	14%	7	32%	9	41%
<b>Females</b>	<b>5-8</b>	5	23%	2	9%	9	41%	6	27%
	<b>18-50</b>	15	68%	4	18%	3	14%	0	0%
	<b>51-78</b>	1	5%	7	32%	9	41%	5	23%

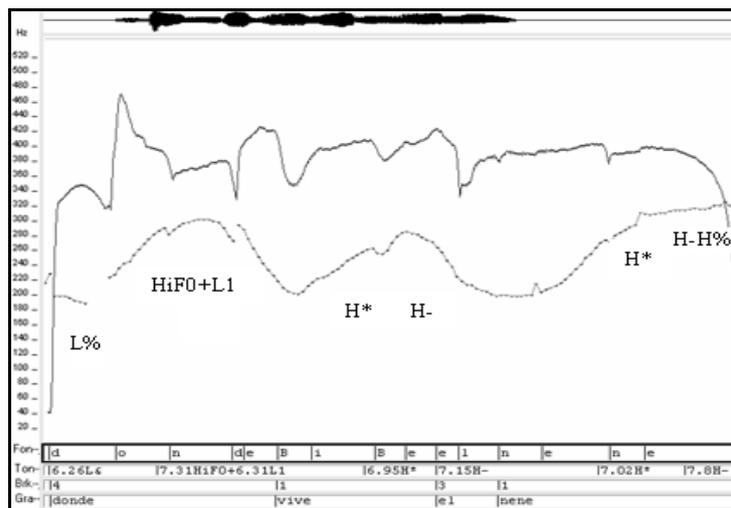

In summary, unlike the simple S-V declarative sentences of BAS which conserve the classic Spanish patterns unmarked Type-1 and marked Type2, the more complex (S1+S2)-V-O declarative sentences with compound subjects were produced by all speakers with unique Buenos Aires *porteño* intonational patterns: (a) unmarked BAS-Type0, (b) marked BAS-TypeA and marked BAS-TypeB or (c) other non classical patterns. Younger adult speakers of both genders (18-50) show more prosodic variation than the other age-groups. Children follow the prosodic pattern preferences of older female speakers (51-78).

### 3.2. Wh-questions

The BAS data are based on the following three simple wh-questions which have similar grammatical and syntactic structure (Wh-word-V-S): a) *¿Dónde vive el nene?* ('Where does the boy live?'), b) *¿Cómo era el avión?* ('How was the airplane?') and c) *¿Quién era el amigo?* ('Who was the friend?').

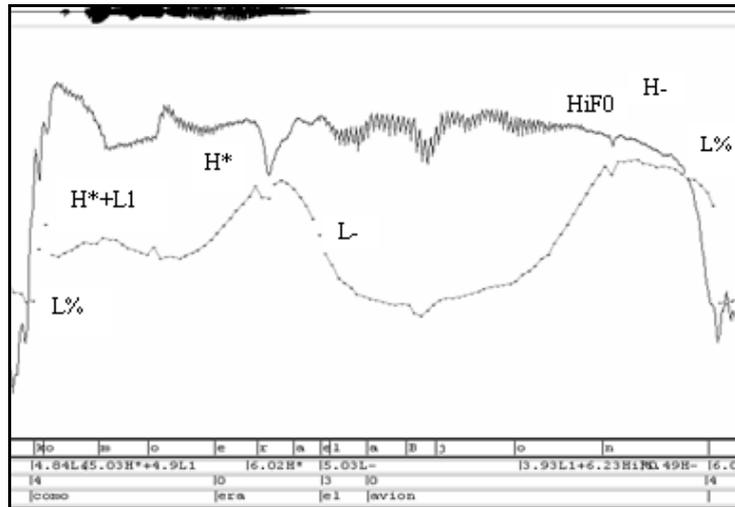

The analysis of the 396 BAS wh-questions shows that speakers have similar pitch accent preferences according to gender: the majority of speakers of both genders place high pitch accents on the wh-word (95% of males and 94% of females), in the verb (78% of both males and females) and in the noun subject (90% of males and 91% of females) (see examples 3a-3c and figures 5-7 respectively).

- (3) a.                   ¿DONde   Vive    el   NEne?  
                           where   lives   the   boy  
                           'Where does the boy live?'

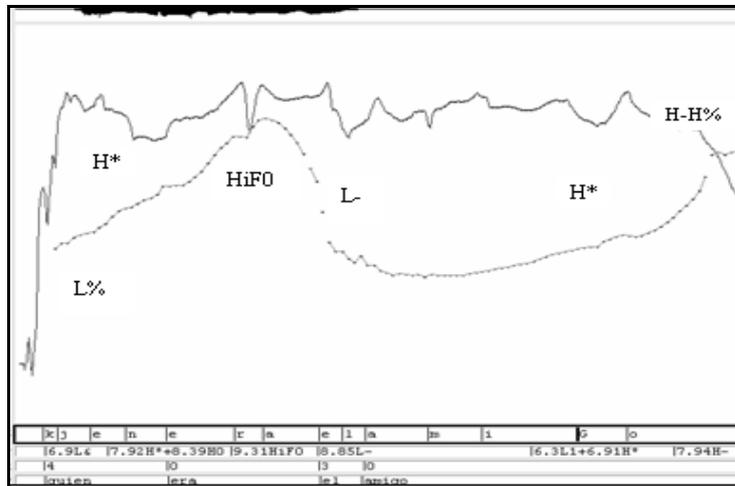

**Figure 5.** *¿Dónde vive el nene?* ('Where does the boy live?') uttered by a woman aged 27.

- b.                   ¿COMo   Era   el   aVION?  
                           how    was   the   airplane  
                           'How was the airplane?'

**Figure 6.** ¿Cómo era el avión ? ('How was the airplane ??') uttered by a man aged 63.

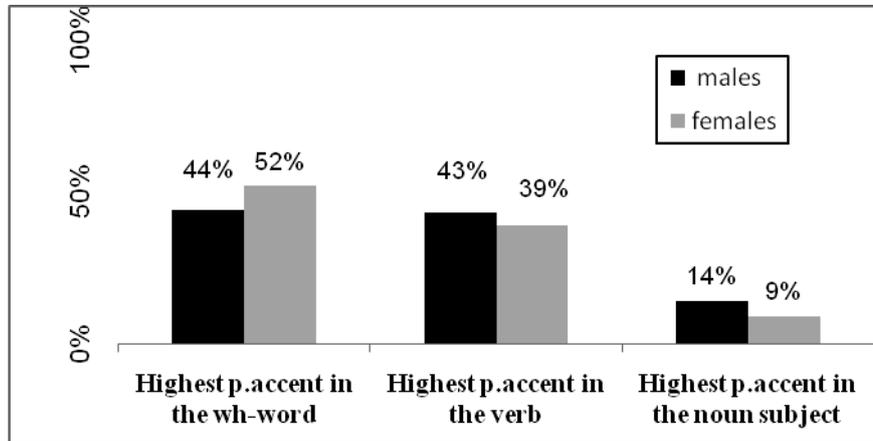

- c.                   ¿QUIEN Era el aMIgo?  
                           who was the friend  
                           'Who was the friend?'

**Figure 7.** ¿Quién era el amigo? ('Who was the friend?') uttered by a woman aged 68.

However, only 44% of males and 52% of females of BAS follow the classic prosodic model of wh-questions by having the highest pitch accent of the sentence in the wh-word. We also found -- that unlike the classic prosodic pattern -- 43% of males and 39% of females of BAS produce the highest pitch

accent of the sentence in the verb while 14% of males and 9% of females produce the highest pitch accent in the noun subject (see figure 8).

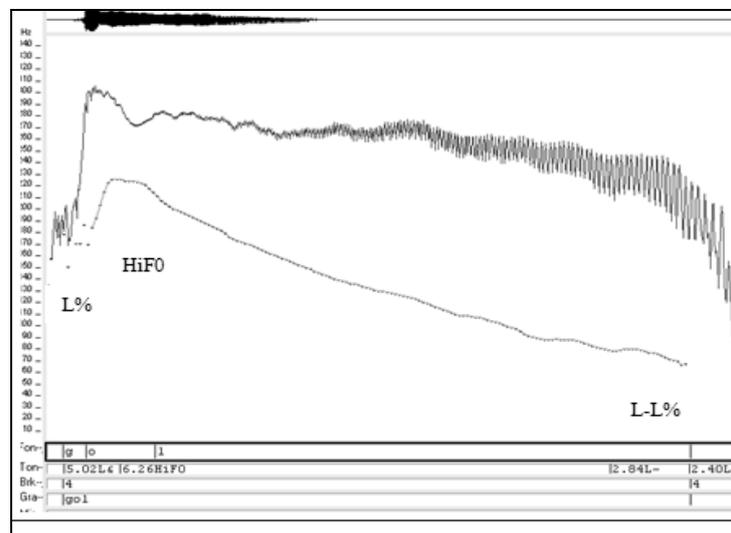

**Figure 8:** Highest pitch accent distribution in BAS wh-questions according to gender.

Moreover, we found prosodic variation in the terminal contour of the final position of BAS wh-questions according to gender: (a) 62% of females and 41% of males prefer the classic marked ‘polite’ rising terminal contour; (b) 45% of males and 30% of females prefer the classic marked ‘emphatic’ rising-falling terminal contour; (c) only 14% of males and 8% of females end the sentence with the classic ‘unmarked’ falling prosodic contour which is commonly used by the vast majority of Spanish dialects in wh-questions. We also found that children of both genders follow adult females in the preference for marked rising terminal patterns.

In conclusion, BAS speakers of both genders have similar preferences for high pitch accents throughout the wh-questions (Wh-word-V-S). The majority of BAS speakers of both genders prefer marked terminal contours (‘rising’ or ‘rising-falling’ patterns) over the classic falling terminal contour attested to in the literature on Spanish prosody (e.g. Alcoba & Murillo, 1998; Barjam, 2004; Canellada & Madsen, 1987; Navarro Tomás, 1921, 1944/1974; Quilis, 1993, Sosa 2003). However we do have gender differences in BAS wh-questions in the terminal contour: females and children prefer a marked rising contour pattern more than males. Finally, younger adults of both genders (18-50) have the most prosodic variation in BAS wh-questions by placing the highest pitch accent of the sentence in the verb and not in the wh-word, and by using the unmarked falling terminal contour rather than the marked ‘polite’ rising or ‘emphatic’ rising-falling terminal contours used by children and older adults.

### 3.3. Exclamatory sentences

Based on two familiar and popular exclamatory sentences used in BAS *¡Gol!* ('Goal!') and *¡Viva!* 'Hooray!' the analysis of 264 exclamatory sentences shows minimal contour pattern variations between both genders. The vast majority of BAS speakers produce the classic unmarked falling exclamatory pattern described in the research of classical Spanish prosody. In figure 9, the sentence *¡Gol!* is uttered by an older man aged 62. The prosodic pattern has the highest pitch accent of the sentence in the stressed syllable of the content word followed by the classic falling terminal contour.

**Figure 9:** Exclamatory sentence *¡Gol!* uttered by a man aged 62.

The results of BAS exclamatory sentences show that 99% of males and 100% of females produce the highest pitch accent of the sentence in the stressed syllable of the content word. The vast majority of speakers of both genders produce the classic falling terminal contour. Only 10% of speakers of both genders produce a marked falling-rising terminal contour which was not described in the Spanish classic research of Navarro Tomás (1944/1974). This variation is found mostly in children. In summary, the data of BAS exclamatory sentences - which are only one word utterances but require more effort to produce prosodic contrasts - show minimal prosodic variation according to gender and age.

#### 4. Conclusions

The analysis of 924 sentences of BAS (declarative, wh-questions and exclamatory) indicates that: (1) females of all ages consistently prefer marked prosodic forms for all sentence types; (2) children tend to follow adult female speakers' preference for marked prosodic forms; (3) adult males have more random intonation patterns and (4) younger adults of both genders (18-50) show the most prosodic variation for the more complex sentence types.

Furthermore, we found an inverse proportion between the complexity of the sentence and the range of prosodic variation between the speakers according to gender. First, in the most simple unmarked S-V declarative sentences, the differences between females and males were the greatest. Secondly, in the more complex declarative sentences with a compound subject and in marked exclamatory sentences, we found only minimal differences between males and females. Finally, in the most difficult, complex and highly marked wh-questions, gender differences were neutralized for pitch accents but we still found gender differences in the use of terminal contours.

All of the sentence types for BAS speakers exemplify the fundamental axiom of the theory of Phonology as Human Behavior (PHB) (Diver, 1979, 1995; Davis 1984/1987; Tobin, 1990, 1993, 1994, 1997) that language represents a struggle to achieve maximum communication with minimal effort. In the easiest S-V declarative sentences, which require the least effort to produce prosodic contrasts, we found the greatest prosodic variation between males and females. This may be because less effort was being invested in creating clear-cut communicative oppositions so more effort could be allotted to other issues such as speaker identity and gender. In the more complex (S1+S2)-V-O declarative sentences, exclamatory sentences and wh- questions, which require more effort to produce the prosodic contrasts, less variation was found for gender. The reason may be that for more complex sentences the speakers have to invest more effort in order to achieve the fundamental and basic communication oppositions. Thus, their efforts are directed and primarily focused on achieving maximum communication and therefore differences in gender are neutralized.

Regarding the interaction between gender and language in general, our research in BAS prosody provides further evidence found for different aspects of language in sociolinguistic studies of Western societies. These studies show that women favor marked forms that are considered to be more “conservative”, “polite”, “correct” and “prestigious” (Labov 1990; Foley 1997; Cameron 2000; Silva-Corvalán 2001; Chesire 2002; Tobin 2002; Moreno Fernández 2005). In addition, speakers of both genders use unique local prosodic patterns found only in the Buenos Aires *porteño* dialect in complex declarative sentences with compound subjects and in marked wh-questions patterns. These unique local patterns may signal a common social identity and can be added to other well-known segmental markers indicating the *porteño* BAS identity.

# Social Status and Intimacy in the Characters of Shakespeare

*V.K. JAIN*

MEENA JAIN

Govt. Girls' P.G. College, Khandwa, India

vinayprof@yahoo.com

## Abstract

**Thee** is generally used in Shakespeare by a master to a servant. Being the appropriate address to a servant, it is used in confidential and good-humoured utterances. **You** was received by a master. Hindi **tu** and **aap** express roughly the same social meanings as English **thou/thee** and **you** used to express respectively.

The pronouns **thou, thee** and **you** have been reduced to **you** whereas in Hindi we still have all the three pronouns – **aap, tum** and **tu**. It reveals that our society has not yet reached the unidimensional solidarity semantics toward which the present European pronominal usage seems to be moving.

## Introduction

"Farewell to **you** ; and **you** ; and **you**, Volumnius,  
Farewell to **thee**, too, Strato".

(**Julius Caesar**. V.5.33)

The difference between **thee** and **you** is well illustrated by the farewell address of Brutus to his schoolfellow Volumnius and his servant Strato. **Thou/thee** is generally used in Shakespeare by a master to a servant. Being the appropriate address to a servant, it is used in confidential and good-humoured utterances. During Elizabethan age, pronoun **you** and **ye** were considered as honorific pronoun used to address to a single person in reverence and polite distance and pronoun **thou** and **thee** were nonhonorific- used by a superior to his inferior.

Pronouns are linguistic reflections of human relationships. “They indicate systematically a person's social status in terms of class, age, sex, education and so on. Their use also seems to be geared to a complex of attitudes, sentiments, and traditions and reveals a deeper cognitive and emotional aspect of the interlocutor's personality. Pronouns serve not merely as a bridge between the individuals but also as a kind of “Emotional capital” which can be invested and manipulated in order to achieve a specific result. The differential usage of pronouns has been institutionalized as a means of defining and affirming both the identity and the status of the speaker and the person addressed. In fact, a good deal of information regarding the social structure and psychological make-up of the addressing dyad can be inferred from an examination of these verbal art forms in their two indispensable and interrelated dimensions- linguistic and sociological. **Friedrich’s** work on the pronouns of nineteenth century Russian literature has led “to the inference of a relational system of positional slots in the status system and of other culturally specific categories” (1966:252). The study of linguistic etiquette in Java in **Clifford Geertz** (1960) also shows that honorific usage is built on a natural base and is correlated with the stratification of society. **Evans Pritchard** (1964:221), writing on the modes of address in Nuer, an African language, also testifies to the fact that, “names and titles of address.....symbolize a man’s social position in relation to the people around him”. **Samuel Martin’s** (1964) insightful article on speech levels in Japan and Korea also proves it.

**Brown and Gilman** (1960:253) who studied the use of *tu* and *vous* among the Parsian students at university in Boston affirm that "a man's consistent pronoun style gives away his class status and his political views". They also maintain that "society is now changing rapidly and, consistent with that change, the norms of pronouns usage are also changing". Some other linguists have identified Brown and Gilman’s ‘power’ and ‘solidarity’ dimensions as formality and informality (**Beidelmen**, 1963; **Pride**, 1971; and politeness levels (**Martin**, 1964), confidence and respect (**Moles**, 1973), and ‘socially remote’, ‘socially close’.

A sociolinguistic description of pronouns will describe not only the forms that occur but also how their choice is affected by the contexts in which they occur. In normal usage a speaker may use one pronoun for a person, but in his use of non-normal pronoun he

encodes some additional information he wants to convey in that particular context. The two dimensional analysis of **Brown** and **Gilman** in terms of 'power' and 'solidarity' is valuable for the study of the pronominal usage of marginalized characters of Shakespeare with a view to determine and analyze their normal and contextual meaning. It is in this framework that we have studied the pronouns used in English (**thou, thee ye, you**) and compared it with Hindi pronouns (**'tu', 'tum'** and **'aap'**) with a view to determine and analyze their normal and contextual meanings. Let us discuss the formal features of pronouns and their usage in different contexts.

". In a *Common School Grammar of English Language*, **Simon Kerl** (1866) tries to explain personal pronouns very carefully:

When objects are near to us, or already known by having been mentioned, we do not always use their names, but certain little words instead of the names. If I say, "William promised Mary that William would lend Mary William's grammar, that Mary might study the grammar," you can easily see that the sentence is clumsy and disagreeable, because I have repeated the words William, Mary, and grammar ..... The easiest way in which you can generally distinguish a pronoun from a noun is to consider whether the word denotes an object, without being itself the name of the object.

Kerl's description of personal pronouns omits important aspects of the behaviour of pronouns. In deep structure, pronouns are treated as a special class of noun. In modern English we have only one second person pronoun, **You**, used both as singular and plural, whereas in Hindi we have pronouns **tu, tum** and **aap**. The Hindi pronominal system makes a distinction between honorific, non-honorific and general uses, but English does not make such distinctions.

The development of the English pronouns can be divided into three periods:

Old English	:	449 - 1150
Middle English	:	1150 - 1500
Modern English	:	1500 - Present time.

In Old English personal pronouns not only had distinctive forms for gender, person and case but also preserved the dual number:

### Old English Second Person Pronouns

	Singular	Dual	Plural
N.	þu	git	ge
A.	þe	inc	eow
G	þin	incer	eower
D.	þe	inc	eow

In Middle English, it was still possible to express the idea of number in personal pronouns. As the singular of the second person pronoun **thou** was used as subject and **thee** as dative and accusative object, while in the plural **ye** served as subject and **you** as dative and accusative object. These grammatical functions **ye** and **you** were widely observed until the middle of the sixteenth century, and survived in the Biblical language. In the fourteenth century, however, the form **you** - with reference to one or more - sometimes replaced **ye** in the usual intercourse and later, during the sixteenth century, became more common than **ye**. In the Biblical language **ye** was uniformly employed as nominative and **you** as dative and accusative, as can be seen in the present version of the king James' version of the Bible.

### English - *thou, thee* and *you* Vs. Hindi - '*tu*', '*tum*', and '*aap*'

Like Hindi, **Aap**, **tum** and **tu** Shakespearean English has second person singular (**thou/thee**) and plural (**ve/you**) pronouns. But in the thirteen century, under the influence of French, the plural form became a mark of politeness in general and was used in speaking to an equal as well as to a superior. The new polite form of addressing one person by the plural **ye** and **you** did not at once displace the older usage of employing **thou** and **thee**.

#### 1. Pronouns in English :

## 1.1 Thou

**Thou** is the nominative singular second person pronoun derived from old English **þu** (cf. Old Teutonic **þu**, Latin **tu**, and Sanskrit **twam**). The paradigms of **thou** in modern English are as follows:

	<b>Singular</b>	<b>Plural</b>
Nom.	thou	ye, you
Dat./Acc	thee	you
Poss. (absol.)	thine	yours
(adj.)	thy	your

**Thou** and its transforms, **thee**, **thine** and **thy**, were in Old English (OE) used in ordinary speech; in Middle English they were gradually superseded by the plural forms, **ye**, **you**, **your** and **yours**, in addressing a superior, and (later) an equal, but were long retained in addressing an inferior. **Thou** is also used in addressing God or Christ, in homiletic language and in poetry, apostrophe, and elevated prose. **Thou** was also used in familiar intercourse, and **you** was employed as a polite form in formal relations. In Peacock's *Donet* (about A.D.449) the father throughout the book, addresses his son by **thou** and **thee**, while the son out of deference uses **ye** and **you** to his father. Similarly, in Hindi the father addresses his son by **tu** and **tum** while the son out of deference uses **aap**. Some British dialects of the South and South midland still distinguish between **thou** or **thee** used in intimate relation and **you** or **ye** employed in polite language in more formal intercourse. In eighteenth century, Richardson in his *Pamela* Lady Davers uses **thou** to her brother in moments of strong emotions and employs **thou** to Pamela in moments of anger and tenderness.

**Thou** in Shakespeare's time was, not unlike **du** in German, the pronoun of: (i) affection towards friends; (ii) good-humoured superiority to servants; and (iii) contempt or anger to strangers. It has, however, already fallen into disuse, though it is seen occasionally in a higher poetic style and in the language of solemn prayer.

In *Two Gentlemen of Verona*, Valentine and Proteus in the first twenty lines of earnest dialogue use nothing but **thou**. But as soon as they begin to jest, "thou art" is found too seriously ponderous and we have, "**you** are over boots in love" (I.i.25) while

the lighter **thee** is not discarded in "it boots thee not" (I.i.28). So in the word-fencing **you** and **your** are preferred, but an affectionate farewell brings them back again to **thou**.

**Thou** is generally used in Shakespeare by a master to a servant. Being the appropriate address to a servant, it is used in confidential and good-humoured utterances. The master, however, finding fault, may often resort to the unfamiliar **you**, (To the newly-engaged servant, Julia says: "I'll do what I can", Proteus blandly replies: "I hope **thou** wilt. (To Launce) How now, **you** whoreson peasant, where have **you** been these days loitering?")

**Two Gentlemen of Verona.** iv.4.48.

During the Elizabethan period, **thou** towards strangers who were not inferiors was an insult, "If **thou thouest** him some thrice, it shall not be amiss" (**Twelfth Night.** III.ii.48) is the advice given to Sir Andrew Aguecheek when he is on the point of writing a challenge. In present times, however, the pronoun **thou** is reserved for prayers and naive poetry, which was the form of familiar address to a single person in the past.

### 1.2 Thee

**Thee** is the accusative and dative singular second person pronoun, which was derived from: (i) OE accusative **dec, deh.** later **de** (cf. Latin **te**); (ii) OE dative **de, þe.** **Thee** is also used as nominative instead of **thou**. The Elizabethans reduced **thou** to **thee**.

"Hear **thee**, Gratiano !" (**The Merchant of Venice.** II.ii.189)

We have gone further and rejected it altogether.

### 1.3 Ye

**Ye** is the nominative plural (singular) second person pronoun, which was derived from OE **Ze** (cf. O. Teutonic **jus, juz**; Skt. **yuyam**). In ordinary use it is replaced by **you**. The first uses of **ye** as a reverential singular occurred in the thirteenth century (Kennedy, A.G. 1915) and seem to have been copied from the French nobility. When **you** displaced it as the ordinary nominative, it came to be used as objective singular and plural.

As the nominative or vocative plural of **thou**, OE **ye** was used in addressing a number of persons. In Middle English **ye** was used, instead of **thou**, in addressing a single person in order to show respect or deference. It was also used instead of **you** as objective singular or plural in 1449 (cf.OED).

The use of **ye** is found in the Bible but was disregarded by Elizabethan authors by whom it seems to have been generally used in questions, entreaties and rhetorical appeals. Ben Jonson said: "The second person plural is for reverence sake to some singular thing". He quotes from Gower:

"O good father dear,  
Why make **ye** this heavy cheer?"

A similar use is found in Shakespeare:

"Therein, **ye** gods, **you** make the weak most strong".

(Julius Caesar. III.i.91)

#### 1.4 You

**You** is an objective (nominative), plural (singular), second person pronoun, which was derived from OE accusative and dative plural **eow**. Originally restricted to accusative and dative plural uses, **you** gradually replaced **ye** as nominative plural in 14th - 15th centuries and also by extension of the deferential plural came into general use for **thou** and **thee**. **You** is now, in ordinary use, the second person pronoun for any number and case.

The singular **you** is used in addressing a person (or thing) in reverence and polite distance. In Modern English **you** serves both as singular and plural. For example:

- 1) **You** did it yourselves (Plural)
- 2) **You** did it yourself. (Singular)

The use of **you** to refer to a single person seems to be related to the royal use of **we**. Since kings saw fit to refer to themselves in the plural with **we**, it seemed only proper to address them in the plural with **you**. This usage was then extended to other royal people, to people who were noble but not royal, to people who were rich though not noble, and so on until eventually everyone was addressed as **you**, and **thou** went out of use. In some

parts of the United States a new plural, **you-all**, has been introduced. In these areas, **you** by itself may be thought of as a singular form.

(At last) in the thirteenth century, under the influence of French, the plural form became a mark of politeness in general and was used in speaking to an equal as well as to a superior. In the Standard English prose of the eighteenth century, **thou** and **thee** were entirely replaced by **you**, so that the form of polite address became general in the common intercourse.

## 2. Pronouns in Hindi :

### 2.1 Tu

Skt. **tvaya** > Prakrit **tuam** > Apbhransha **tuham** > Hindi **tu**.

Thus the nominative singular **tu**, of the second person, has arisen from the skt. Nominative singular, **tvaya**. Hindi **tu** expresses the same connotation as English **thou** used to express. The declension of **tu** and **thou** are as follows:

	<b>Tu</b>	<b>Thou</b>
N.	tu	thou
Ac.	tujhe/tujhko	thee, to thee
D.	tujhko/tujhe	thee, to thee
Ag.	tune	by thee
Ab.	tujhse	from thee
G.	tera	thy, thine
L.	tujh men/par	in/on thee

In Hindi **tu** is at once a pronoun of intimacy and insult. These meanings of **tu** are determined by the social distance. Where the distance is zero, it is expressive of intimacy used by a superior to an inferior, it shows distance and, therefore, authority but given by an inferior to his superior, it shows contempt for the addressee. Its use in the first two cases is normal and so is the meaning but the use in the last case is deliberate.

Children use it obligatorily for each other. Parents normally teach their children not to use pronoun **tu** for each other. Quite a few children reported that they did

not say or did not like to say **tu**, but it just slipped out of the mouth. An attitude of shame and self-hatred connected with **tu** makes it an 'undesirable' pronoun. But interestingly enough, men did not concede using it whereas women and children frankly said that they used it in spite of their dislike for it. In the case of the father **tu** is strictly prohibited, though the mother may receive **tu**. The status of the son and the daughter gets elevated after marriage. The son/daughter who got a mere **tu** from the father begin to receive **tum** or **aap** after they are married. Such a change or an elevation in status becomes evident when a person gets **tu** along with **tum**. Such a usage of **tu** and **tum** for the same person is subject to a context sensitive social distance.

The husband and the wife use **tu** to show anger or break off the bond. But in the case of young spouse it may also indicate deep love. This variety of **tu** is quite often used in Hindi film songs. Like English **thou**, Hindi **tu** is also used to address God in prayer.

The use of **tu** for superiors like parents, teachers, boss, etc., is one of the few prohibited usages of Hindi. Probably on account of the connotation of disrespect and insult associated with it, **tu** has become one of the most stigmatized words in the Hindi language.

The stigma attached to **tu** is a result of its probable use in asymmetrical relationship. When used by a superior to his inferior, it usually co-varies with **tum** or with polite intonation which makes it less authoritarian in general. The assumption behind the use of exclusive **tu** by the superior for the inferior (e.g. master-servant) or even among equals (e.g. friends) misled **Kellogg** (1876) into assigning it a meaning of insult or contempt. This resulted from a failure to see co-variation of pronouns.

## 2.2 Tum

**Tum** is derived from the Sanskrit pronoun **tvam** : Skt. **tvam** > Prakrit **tumha** > Apbhransha **tumhai** > Hindi **tum**. **Tum** is the most common form of the nominative plural of the second person, which has arisen from skt. Nominative singular **tvam**. Hindi **tum** is like English plural pronoun **you**. The declensions of **tum** and **you** are as follows:

	<b>Tum</b>	<b>You</b>
N.	tum	you
Ac.	tumhen/tumko	you
D.	tumko	you, to you
Ag.	tumne	by you
Ab.	tumse	from you, with you
G.	tumhaaraa (-re, -ri)	your, yours
L.	tummen or par	in or on you

**Tum** takes naturally the second person plural form in the verb : **Tum kahaan se aae ho ?** (Whence have you<sub>T</sub> come from ?) **Tum yahaan baitho** (you<sub>T</sub> sit here).

The plural pronoun **tum** is used for the singular whenever it is intended to express respect but the respect indicated by **tum** always lacks the formality and high respect of **aap**. The longer forms (**tum** and **aap**) are considered more respectful in Hindi than the shorter (**tu**). In order to avoid ambiguity, an additional lexical item **log** ('people') is used after the pronominal **tum** and **aap** to denote plurality (Vajpei, 196:237, ; Guru, 1962:96). Thus in a plural sense, instead of the forms given in the paradigms, in Hindi we preferably have :

N. : **tum log** (you<sub>T</sub> people), Ac. : tum logon ko (to you<sub>T</sub> people) Ac. : **tum logon ko** (of you<sub>T</sub> people). G.: **tum logon ka** (of you<sub>T</sub> people).

**Tum** is used when contacts are frequent, but the relationship demands some respect for the addressee or elegance on the part of the speaker. It is the most heavily used of all the second person pronouns in Hindi and is used in a greater number of social relationships and contexts than the other pronouns. It can be used in most relationships, if not all, without risking markedness of meaning.

The contexts in which **tum** is marked are less than those of **tu** and **aap**. It can be said that marked usage of an alternate is in inverse proportion to its normal usage. The greater the contexts of normal usage, the less the contexts of marked usage and vice versa. **Tum** tends to co-vary either both **tu** and **aap** in unmarked contexts. As a result, it loses its markedness in frequency as well as in intensity. That may be one reason why it

is the most favoured of all pronouns. The relationships where **tum** is marked are parents-children, brother and sister, school friends and master-servant.

### 2.3 Aap :

**Aap** has descended from Skt. **aatman** :, **aatman** > Prakrit **appo** > Hindi **aap** (Vajpei 1966 : 255).

It is an 'honorific' pronoun used instead of **tu** or **tum** whenever it is intended to show respect to the person addressed. Like **tum**, **aap** is also a plural pronoun used for singular to express more respect. Its declensions are given below:

	<b>Aap</b>	<b>You</b>
N.	aap	you
Ac.	aap ko	you
D.	apne ko	to you
Ag.	aapne	by you
Ab.	aapse	from you, with you
G.	apna (-ne, -ni)	your, yours
L.	aap/apne mein, par	in/on you

The plural forms of **aap** are the same as the singular, with the exception of the genitive **aapas ka** (of themselves), and the locative **aapas mei** (among themselves). In other cases when more than one person is addressed, the plural is denoted by affixing the word **log**.

The genitive **apnaa** sometimes assumes the plural termination **apnon** and is then used as a noun, in the sense of 'one's own people'. It is sometimes used elliptically in the singular, when the reference is clear as in **usne apne ko maaraa** (He stroked his own child/body, etc.).

We have one more type of **aap** in Hindi which is honorific and which behaves as the third person pronoun in its behaviour and form; e.g.

**Dr. Hari Singh Gour Sagar Vishwavidyalaya Ke Pratham Vice-Chancellor the. Aap bare Kushaagrabuddhi the.**

(Dr. Hari Singh Gour was the first Vice-Chancellor of Sagar University. He<sub>A</sub> was very intelligent).

In this context whether **aap** indicates more respect than **ve** may be a controversial question, but **aap** can be more impressive when it is used in the presence of the addressee and will certainly indicate more respect. In this special context the person addressed by **aap** may not be among the audience, though he may be listening to our statement:

Bhaaiyon ! hamaare aaj ke mukhya atithi shikshaa mantriji hain. Aapko apne bi:ch paakar ham sabhi dhanya hain.

(Brothers! the chief guest of today is the Education Minister. We feel honoured to find him<sub>A</sub> among us.)

According to **Kellogg** (1876:277), in such cases "where **aap** is used for the person spoken of, when that person is present (so that reference will be evident), it is better to use, instead of **aap**, the proper title of the person addressed, as, **saahib, pandit, laalaa**, etc."

**Scholberg** (1955:67), explains the use of the honorific **aap** as follows:

**Aap** is used honorifically for third person when it is indicated by a wave of the hand, or a nod of the head or by the context, to whom reference is made. For instance, referring to a speaker or some person known to the listeners, one may say, **aapne such kahaa** (He spoke the truth); **aap bahut dayaalu manushya hain** (He is very merciful man).

Among all the pronouns, **aap** shows maximum social distance between the speakers and the addressee. It is a pronoun of high respect and, whenever such respect is due to the addressee, **aap** is used for him. **Aap** is also used in the marked contexts. In public context inferiors within a family use it for superiors to show elegance or politeness towards the addressee. **Aap** is mostly used in ceremonial and social dyadic relationships.

**Brown and Ford** (1961:377), while analyzing the address system in American English, have suggested that "it is to be expected in a society whose values are more strongly linked to achieved personal attributes than to ascribed attributes... that occupation would prevail over age in the determination of deference". In the traditional Yiddish community, however, where values are at least as strongly linked to ascribed personal attributes such

as age, family history, learning, inherited wealth, etc., age prevails over occupation in the determination of deference (Slobin, 1963).

The process of personal interaction in a given society and its pronominal usage and address forms indicate differences of dominance, intimacy of distance, equality or differential status of the addresser and the addressee. The nature of the relationship between linguistic structures and social and cultural patterns is a central issue in sociolinguistics. Palkornkul's (1957:27) study of the Thai pronominal system has revealed that "A choice of a pronominal variant is not made arbitrarily. On the contrary, there are systematic variant rules to guide and govern the speaker's choice". Paul Friedrich's (1972:273) work on the Russian pronoun also points the same fact. His announced purpose is to demonstrate "how speech usage is determined by cultural principles" by positing a new set of semantic categories. Friedrich has supplemented Brown and Gilman's (1960) two dimensional (i.e. Power and Solidarity) analyses with an additional eight-fold system of his own, comprising topic of discourse, contexts of the speech event, age, generation, sex, kinship status, direct spoken, and group membership. Relative jural and political authority and emotional solidarity are also features of Friedrich's system. He asserts that the ten discrimination and their patterns of combinations account for nearly all the variability in his corpus.

## Conclusion

Thus Hindi **tu** and **aap** express roughly the same social meanings as English **thou** and **you** used to express respectively. Like Hindi pronouns, Old English and Middle English used to make the distinctions between honorific (ye, you) and non-honorific (thou, thee), general and specific uses of pronouns. A pronoun of intimacy is observed among friends, family, colleague of same age group and other familiar persons etc. People of higher status use lower pronoun to the people of lower status as to younger children or subordinate. Modern English does not make such distinctions and uses you in singular as well as in plural contexts. The pronouns **thou**, **thee** and **you** have been reduced to **you** whereas in Hindi we still have all the three pronouns – **aap**, **tum** and **tu**. It reveals that

our society has not yet reached the unidimensional solidarity semantics toward which the present European pronominal usage seems to be moving.

The semantic system of modern English is quite different from that of the Elizabethan English, so much so that we can no longer even follow the shifts which take place in the personal relationship of Celia and Rosalind in *As You Like It*, indicated by their sensitive switching between **thou** and **you** (Mc Intosh, 1963).

# **Implications of a study on L2 interlanguage phonology for the learning of L2 pronunciation: The phonological variants of the syllable initial /n-/ in L2 English produced by Cantonese speakers in Hong Kong<sup>1</sup>**

**Cecilia Yuet Hung Chan**

City University of Hong Kong,  
Tat Chee Avenue, Hong Kong  
ctcyhc@cityu.edu.hk

## **Abstract**

This research investigated the interlanguage phonology in English produced by Cantonese speakers, focusing on the phonological variants of the syllable initial /n-/. The study adopted Labov's (1972) and Tarone's (1983, 1988) research methodology. Six oral tasks were designed for collecting data from Hong Kong students. Results show that six [n-] variants were produced, and the new variant [l-] most frequently appeared. In this paper, the reasons for the frequent production of the variant of [l-], and the effects of L2 proficiency, phonological environment and contextual style on the shift from /n-/ to /l-/ are closely examined. The implications of the findings of this study for the learning of L2 pronunciation are discussed.

**Keywords:** interlanguage phonology, phonological variant, phonological environment, L2 pronunciation

## **1. Introduction**

Previous studies based on incidental observations or small-scale experiments on Hong Kong students indicate that substitution of /n-/ by /l-/ appears in Hong Kong English (Bolton and Kwok 1990, Chan 2000, Hung 2000, 2002, Au 2002). This study closely examined the phonological variants of the syllable-initial /n-/ produced by Hong Kong students of three different levels of English proficiency (elementary, intermediate, intermediate to post-intermediate). The factors which might lead to phonological variation of /n-/ in L2 English of Hong Kong students, including L2 proficiency, phonological environment and stylistic variation, were investigated.

## **2. Research background**

### *2.1. Previous studies on phonological variation of initial /n-/ in Hong Kong English*

The phonological feature of the merging of the initial /n-/ with /l-/ in English by Hong Kong students was described in a small number of publications (Bolton and Kwok 1990, Chan 2000, Hung 2000, 2002, Au 2002 ). Bolton & Kwok (1990) and Chan (2000) described the phonological variation of /n-/ and /l-/ based on a small quantity of incidental observation data. This phonological variation was more closely investigated in Hung (2000, 2002) and Au (2002). The data in these studies were collected from the reading of wordlists and controlled presentations by university students. Hung (2000, 2002) pointed out that the two initials, /n-/ and /l-/, were used interchangeably by students due to the influence of their mother tongue, Cantonese, in which /n-/ and /l-/ are merged. In Au's (2002) study, the phenomenon of the loss of /n-/ in a number of lexical items demonstrated that Hong Kong students have difficulty in producing the onset /n-/ in English. Au (2002) also suggested that the replacement of /n-/ by /l-/ in English is influenced by the non-distinction of /n-/ and /l-/ in Cantonese.

All the above studies claimed that mother tongue interference plays a significant role in the variation of /n-/ and /l-/ in L2 English of Hong Kong students. Unlike previous studies which mainly focused on university students, this study investigated the phonological variation of /n-/ in L2 English produced by primary school, secondary school and university students of elementary, intermediate and intermediate to post-intermediate level of English respectively. The involvement of these three student groups gives us a clearer picture of the phonological variation of /n-/ in Hong Kong English.

### *2.2. A multi-factor approach to L2 studies on interlanguage variability*

The multi-factor approach aimed to identify a number of factors that induce variability in learners language (Ellis 1994). These factors include: linguistic context, L2 proficiency of learners, speech style and situational context etc. VARBRUL computerised procedures are used to examine the effect and interaction of the factors on L2 variation (Young 1988, 1991, Preston 1989, and Adamson and Regan 1991). Adopting a multi-factor approach, this study analysed the phonological variation of /n-/ in L2 English of Cantonese speakers. The factors of L2 proficiency, phonological environment and contextual style on the phonological variation of /n-/, which have

received little attention in previous studies, were closely examined.

### **3. Aims of the study**

This study aimed to investigate phonological variation of the syllable initial /n-/ in L2 English of Cantonese speakers in Hong Kong. The following research questions were investigated:

- (a) What are the variants of /n-/ in L2 English produced by Cantonese speakers?
- (b) To what extent does the phonological variation of /n-/ in English correlate with the English proficiency of Cantonese speakers?
- (c) Do different variation patterns of the merging of /n-/ with /l-/ appear in different contextual styles?
- (d) To what extent does the merging of /n-/ with /l-/ vary in different phonological environments?

### **4. Research Methods**

#### *4.1. Participants*

This study involved elementary, intermediate and intermediate to post-intermediate English learners from primary school, secondary school and university in Hong Kong respectively. There were 14 participants in the elementary group, 14 in the intermediate group and 16 in the intermediate to post-intermediate group. Elementary learners were aged 10-12, intermediate learners 16-18 and intermediate to post-intermediate learners 20-23. There were equal numbers of females and males in each proficiency group. All participants were native Cantonese speakers who started to learn English as a second language in primary school. They participated in the study on a voluntary basis.

#### *4.2. Elicitation Tasks*

Adopting Labov's (1972) and Tarone's (1983, 1988) research methodology, this study designed six oral tasks of different styles for collecting data. These six tasks varied in terms of speech styles which require different amount of attention to speech, ranging from the most casual style (Task (a)) to the most careful style (Task (f)).

These six oral tasks were:

- (a) Conversation in pairs
- (b) Informal interview
- (c) Passage reading
- (d) Word reading
- (e) Minimal pair reading
- (f) Minimal pair repetition

(a) Conversation in pairs

Two students in the same subject group formed a pair. All of them knew each other.

Ten questions were given to them. They took turns to ask questions and give responses to their partner's answers. They were allowed to talk about something else they were interested in. Each pair was given 20 minutes for conversation.

Examples of questions:

- (1) What do you eat for lunch and for dinner?
- (2) Does your mother let you go out with friends at night? Why/Why not?
- (3) Do you wear new clothes at Chinese New Year? Why / why not?

(b) Informal interview

Each subject was interviewed by the investigator or a research assistant in a casual way. Ten questions were asked by the investigator. Each interview lasted about 20 minutes.

Examples of questions:

- (1) Do you have an English name? Would you like your friends to call you by your Chinese name or your English name?
- (2) Which language do you like more? Chinese or English?
- (3) What time do you wake up in the morning? Do you work late at night?

(c) Passage Reading

A passage in simple English of about 200 words was designed. About 40 words in the passage had a syllable initial /n-/. Students read the passage at their own pace.

Part of the English passage:

...Nancy only liked eating, not studying! Her mother gave her money to buy lunch at school every day. She spent all the money buying snacks, like chocolates, nuts and ice-cream. She never bought proper meals....

(d) Word reading

In the English wordlist, there were 53 words. The initial /n-/ was in the 1st, 2nd, 3rd or 4th syllable of the word. For example:

- (1) number, nation (18 words with an initial /n-/ in the first syllable)
- (2) morning, penny (13 words with an initial /n-/ in the second syllable)
- (3) questioning, cleverness (13 words with an initial n-/ in the third syllable)
- (4) unhappiness, examination (4 words with an initial /n-/ in the fourth syllable)

These 53 words could be divided into two groups: one group of 9 words with /n-/ followed by nasal coda, and another group of 42 words with /n-/ followed by non-nasal coda.

There were three words in which /n/ was in a consonant cluster: snake, snack and snow.

(e) Minimal pair reading

There were 22 minimal pairs. In each minimal pair, one word had an initial /n-/ and one had an initial /l-/.

There were 5 pairs of words with /n-/ and /l-/ followed by nasal coda. Examples:

- (1) nine/ line
- (2) name/ lame
- (3) net/ let
- (4) no/ low

There were four pairs of words in which /n/ or /l/ was in a consonant cluster.

- (1) snow- slow
- (2) snack - slack

(f) Minimal pair repetition

The minimal pair list for Task (e) was used. Informants listened to the model pronunciation of each minimal pair and then read it aloud.

#### 4.3. Administration procedure

Each informant completed all the tasks in one day. All informants did the six task types in the following sequence:

- (a) Conversation in pairs
- (b) Informal interview
- (c) Passage reading
- (d) Word reading
- (e) Minimal pair reading
- (f) Minimal pair repetition

Tasks (a) and (b) were conducted first to collect natural data, because tasks (c) to (f) give increasing clues to participants to pay attention to the pronunciation of /n-/.

All tasks done by the students were recorded by a professional MD in a sound-proofed phonetic lab.

#### *4.4. Methods of data transcription and analysis*

The data were transcribed by ear by four trained research assistants and then randomly checked by the investigator and a phonetician. Spectrographic analyses were done when the acoustic properties of /n-/ and /l-/ produced by the students were difficult to identify. In a few cases, the initial /n-/ or /l-/ was not clearly pronounced. Those data were not included in the analysis.

VARBRUL computerised procedure was used to analyse the effect of each independent variable on the phonological variation of /n-/ in L2 English produced by Cantonese speakers.

## **5. Results**

### *5.1. The variants of [n-] in the oral production*

The following [n-] variants appeared in the English production of Cantonese speakers:

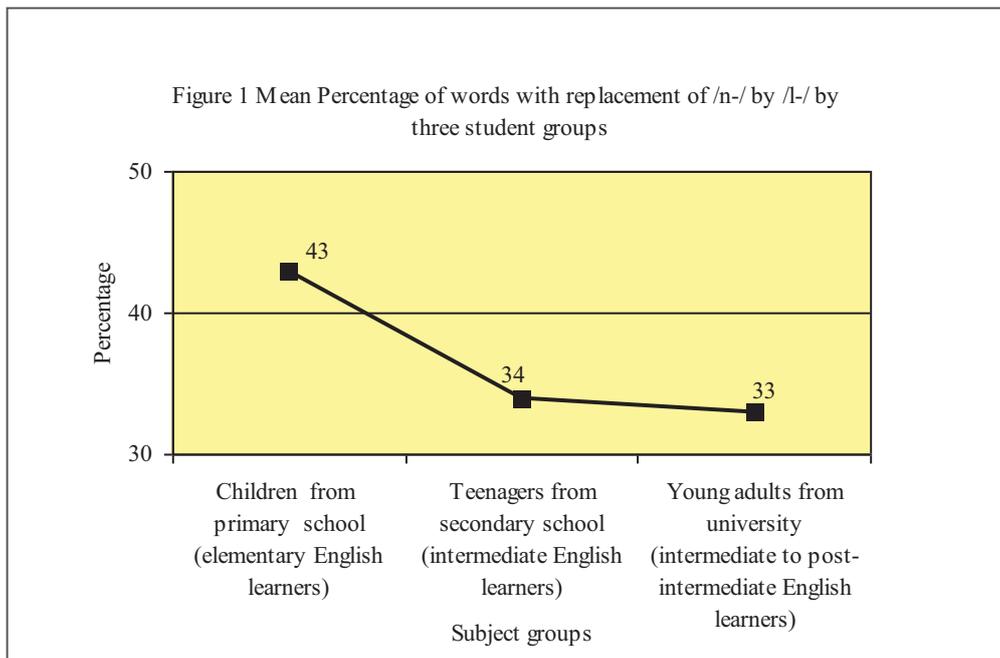

- (a) [l] : substitution of [n] by [l-];
- (b) nasalized [l];
- (c) [j] : [n] weakened to a glide;
- (d) Ø: deletion of [n] sound;
- (e) [n] pronounced as a [n-l] sequence;
- (f) [n<sup>d</sup>] : oral release in the [n] sound,

Among these six [n-] variants, the first variant [l], which substituted [n], most frequently appeared (96% of the [n-] variants). As argued in the L2 studies reviewed in Section 2.1, the shift from /n-/ to /l-/ in English by Cantonese speakers is due to L1 phonological transfer. Previous studies indicated the loss of initial /n-/ and the replacement of /n-/ by /l-/ in Hong Kong Cantonese (Hashimoto-Yue 1972, Yeung 1980, Bauer 1982, 1997, Bourgerie 1990, Zee 1999, Ho 2004).

## 5.2 . Replacement of /n-/ by /l-/

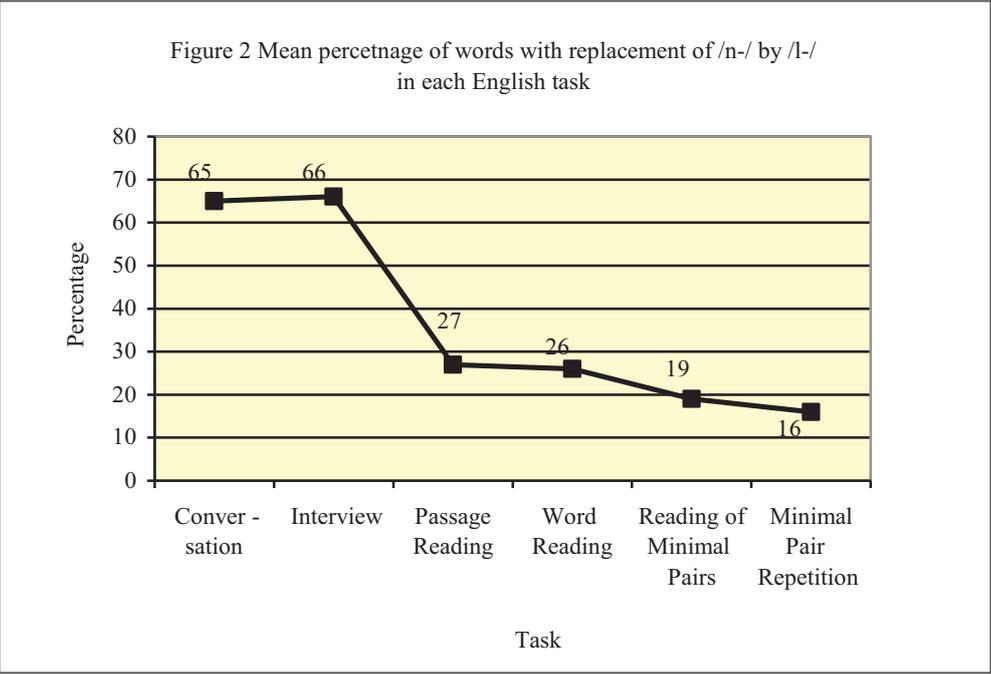

### 5.2.1. By three proficiency groups

Figure 1 shows that the replacement of /n-/ by /l-/ by elementary English learners from primary school was more than that by the intermediate and post-intermediate learners from secondary school and university respectively.

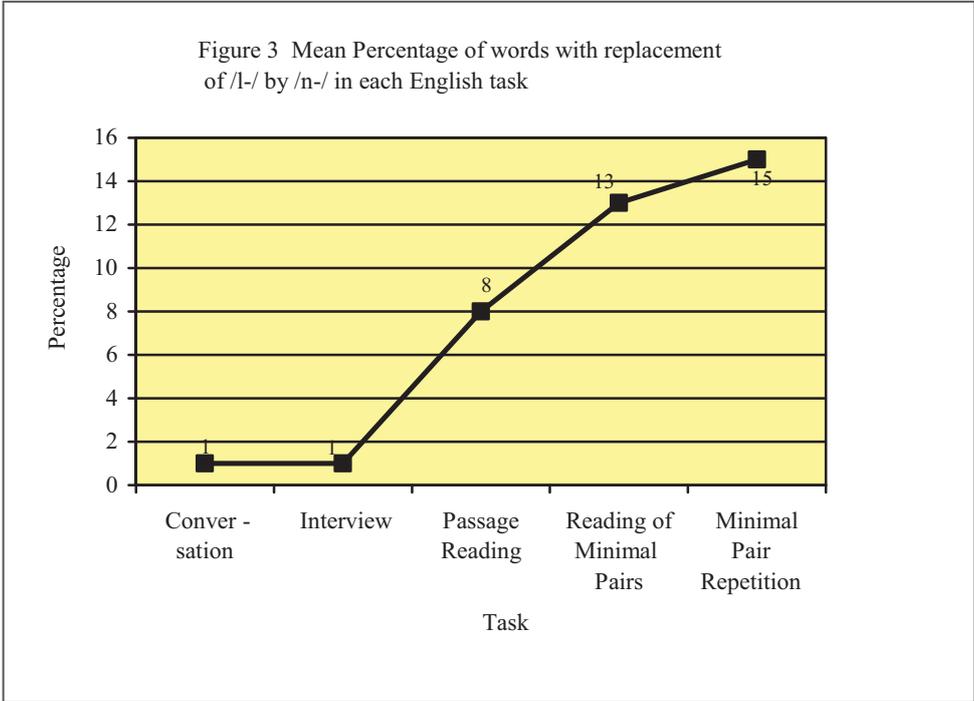

### 5.2.2. In different contextual styles

Figure 2 indicates that the highest percentage of /n-/ words (about 60%) replaced by /l-/ was shown in the two casual spontaneous oral tasks (i.e. conversation and interview tasks), the percentage decreased sharply in the passage reading task, and then decreased gradually in the other three oral tasks.

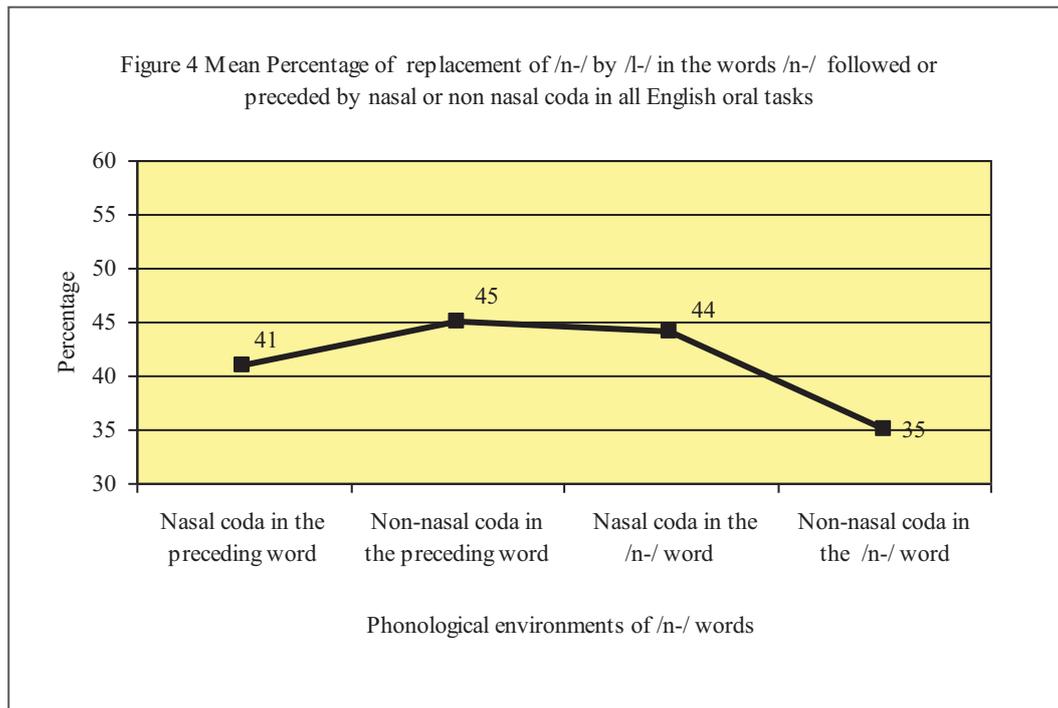

In addition, hypercorrection occurred in the reading tasks. As shown in Figure 3, the replacement of /l-/ by /n-/ clearly appeared in the passage reading task and the two minimal reading tasks.

### 5.2.3. In different phonological environments

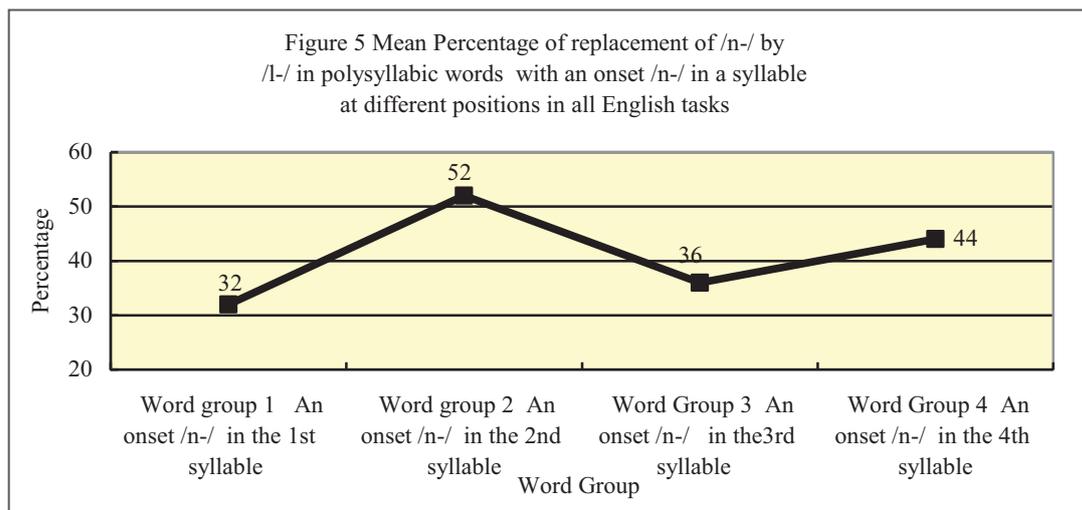

In the oral tasks, the words with /n-/ was followed by nasal or non nasal coda, or preceded by a syllable with nasal or non-nasal coda.

We predicted that, due to assimilation, when the /n-/ is preceded or followed by nasal coda, it is less likely for the speakers to substitute /l-/ for /n-/. The results shown in Figure 4 are not completely in line with our prediction.

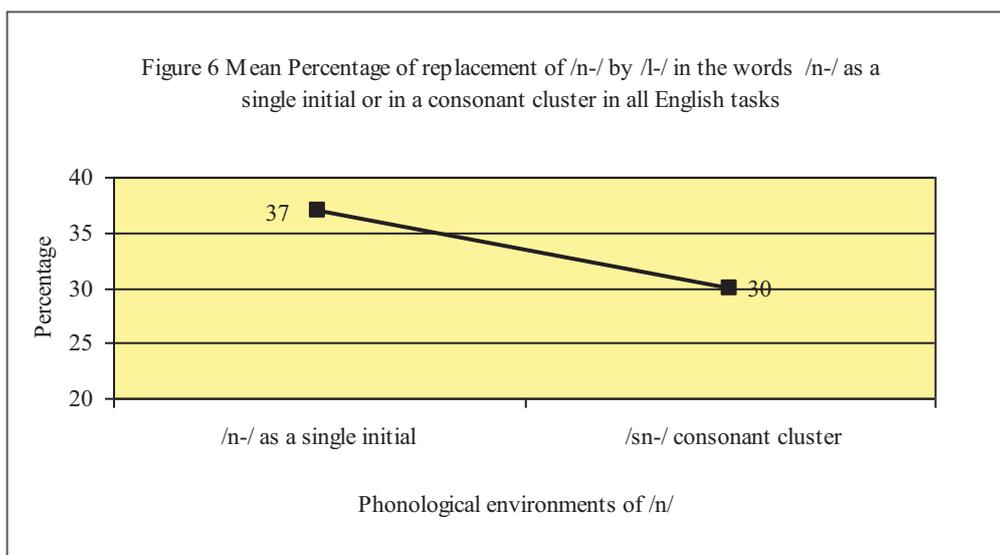

We also speculated that if /n-/ is in a syllable in an earlier position of a polysyllabic word, the replacement of /n-/ by /l-/ will be less likely to appear. This is because speakers normally pay more attention to the pronunciation of the syllable in an earlier position.

Results given in Figure 5 partly support this speculation. The pronunciation of /n-/ was most accurate in the first syllable. But the pronunciation of initial /n-/ in the third syllable and fourth syllables of polysyllabic words was more accurate than that in the second syllable of polysyllabic words.

We further predicted that if /n/ is in a consonant cluster, not as a single initial, it will be more likely to be replaced by /l-. This is because consonant clusters are less easy to pronounce than a single consonant. Results given in Figure 6 seem to support our prediction. But this independent variable was not selected in the Variable Rule Analysis, which will be presented later.

#### 5.2.5. Comparison of the effects of L2 proficiency, contextual style and phonological environment on the phonological variation of /n-/

The results of Variable Rule Analysis in Table 1 show that contextual styles had the strongest effect on the phonological variation of /n-/ (0.546). The effect of L2 proficiency was moderate (0.143). As for phonological environment, the effect of single phonological variable ranged from very minimal to moderate (0.005-0.14). The onset

/n-/ in a syllable at different positions had a moderate effect (0.282), which was the strongest phonological environment factor. The consonant type (single consonant/consonant cluster) was not selected for analysis.

Table 1 Variable Rule Analysis of substitution of /n-/ by /l-/ by all participants (9844 tokens)

Factor Groups and Factors		n→l	
		Means	Probability
<b>Learners' English Proficiency</b>			
Young adults from university (intermediate to post-intermediate English learners)	3581(36%)	33%	0.455

## 6. Discussion

### 6.1 Why does /l-/ substitute /n-/ in the L2 English of Cantonese speakers?

We argue that “ease of articulation” may initiate the replacement of /n-/ by /l-/ in L1 Cantonese, and that the phonological variation in L1 is transferred to L2 English.

As given in the literature of sound change and variation, it was argued that

phonological systems are organised such that they are easy to produce. There are inevitable tendencies of phonological change because of ease of articulation, which is castigated as “laziness” (Aitchson 2001, Silverman 2006). Phonetically, /n/ and /l/ are both alveolar, but /n-/ is a nasal sound. When the /n-/ sound is produced, the soft palate is lowered, which opens a passageway into the nasal cavity and air continually escapes through the nose. Compared with the /n/ sound, the /l/ sound is therefore relatively easier to produce as lowering the soft palate is not involved. Therefore, as shown in our study, it is very rare for students to substitute /n-/ for /l-/ in spontaneous speech in English.

### *6.2. Why does English proficiency play a role in the substitution of /n-/ by /l-/ in L2 English?*

Word pronunciation training receives attention at early stages of English learning in Hong Kong. More advanced English learners have more exposure to spoken English and therefore L1 phonological transfer in terms of the replacement of /n-/ by /l-/ is not very persistent. We conducted a follow-up interview with students and it was found that Hong Kong students aimed at accurate pronunciation in English. Students’ positive learning attitudes towards English may help them improve their L2 pronunciation.

### *6.3. Why does the extent of replacement of /n-/ by /l-/ vary with different contextual style?*

Regardless of English proficiency, our students’ accuracy of pronunciation of /n-/ is affected by the variation of task types. The task types differed in terms of contextual styles and vary with the amount of attention students’ paid to pronunciation, and with the degree of their phonological awareness of making a distinction between /n-/ and /l-. Learners’ attention to pronunciation and phonological awareness of making a distinction between /n-/ and /l-/ was least in spontaneous casual production (i.e. conversation and interviews), and most in the minimal reading tasks. Therefore, the replacement of /n-/ by /l-/ was most in two casual speech productions, but least in the minimal reading tasks of the most careful style. The highest degree of phonological awareness of making a distinction between /n-/ and /l-/ causes hypercorrection (i.e. replacement of /l-/ by /n-/) in the careful minimal reading tasks.

In contrast with the two casual conversational tasks, the passage or word reading task of careful and formal style does not require participants’ attention to the speech

content, but only to pronunciation, and therefore the replacement of /n-/ by /l-/ decreased.

*6.4. Why do most of the phonological environments of /n-/ included in our study play weak roles in the substitution of /n-/ by /l-/?*

We argue that it is not the phonological environment itself which affects the phonological variation of /n-/. It is a speaker's attention paid to pronunciation that makes a difference.

Therefore, only the factor group of syllable position played a relatively more important role in the replacement of /n-/ by /l-/. When /n-/ is in the first syllable of a polysyllabic word, not in the 2nd, 3rd or 4th position, the /n-/ is least likely to be replaced by /l-/. This is because speakers normally pay more attention to the pronunciation of the first syllable than to the syllable in a later position of a polysyllabic word.

## **7. Implications**

The findings of this study shed light on teaching English pronunciation to Cantonese speakers. We suggest that the perception and production of /n-/ should be one of the teaching focuses in English lessons for Hong Kong students. They should be taught to feel and observe the phonetic features of /n-/, which are similar to or different from those of /l-/:

We propose that: (1) variation of styles should be paid attention to in the training of L2 pronunciation; and (2) the Consciousness Raising approach (Sharwood Smith 1981, Rutherford & Sharwood Smith 1988, Schmidt 1990, 1995), which was originally adopted for learning L2 grammar, could be used to raise Cantonese speakers' phonological awareness between /n-/ and /l-/ in English. The most careful styles of minimal pair reading and repetition can be used for raising learners' phonological awareness. The word reading task can arouse learners' attention to /n-/ which is in a syllable at a later position of a polysyllabic word.

## 8. Conclusion

This study shows that among six phonological variants of [n-], [l-] is the most dominant. The substitution of /n-/ by /l-/ in English by Cantonese speakers is caused by L1 phonological transfer and initiated for phonetic reasons. Different variation patterns of the merging of /n-/ with /l-/ appear in different contextual styles. The variation of contextual styles plays the most important role in the phonological variation in focus. The substitution of /n-/ by /l-/ in English does not significantly vary in most of the phonological environments of /n-/ included in this study. The phonological factor is not important in the sound variation in focus.

It is suggested that the teaching of L2 pronunciation aims at arousing learners' attention to pronunciation with different speech styles, raising learners' phonological awareness and linking learners' sound production with perception.

## Notes

1. Research supported by CityU SRG Grant (7001657) and CERG Grant (CityU 1438/05H). The whole research investigated the merging of /n-/ with //l-/ in Hong Kong Cantonese, Putonghua and English. This paper only reported the results regarding Hong Kong English.

# E-tailing English Language Teaching

Jamie Shinhee Lee

## Abstract

This study examines e-tailing practices commonly observed in the English language teaching (ELT) industry in South Korea. The findings of the study indicate that technology, economy, and native speakerhood (Nayar 1994 and Gupta 1999) are overarching themes in the ELT marketing materials in cyberspace. In providing instructions and services for student-initiated learning activities, the majority of the ELT institutes in this study depend on technologies such as live video streaming, podcasts, audio files, voice recognition/pronunciation correction software, daily English text messages, and e-dictionaries. The topic of economy is articulated in conjunction with various complimentary services and cost-effective programs. This study argues that the South Korean ELT industry's heavy reliance on e-tailing is a direct response to accommodate techno-savvy and Internet oriented consumers.

**Keywords:** ELT business, e-tailing, English education, private language institute (*hakwon*), South Korea

## 1. Introduction

As technology evolves, the way we live our lives changes as well. These days many consider life without the Internet to be inconvenient, if not impossible. The Internet is an integral part of modern day business transaction, including vending and purchasing products. In this paper, I address one of the "hottest" commodities in contemporary South Korea, that is, English and how it is marketed in cyberspace. Although English is not what you would call a typical commercial product, its consumer appeal is quite irresistible worldwide, South Korea being no exception. Some might perceive English as a luxurious designer label that many wish to possess but few can afford. Perhaps this used to be the case, but English is now considered to be a necessity item rather than a luxurious rarity in South Korea. Lee (2007) observes that English is now recognized as essential linguistic capital for academic and professional advancement in South Korea. Considering the widely acknowledged importance of English in South Korea, I argue that English language programs and courses are among the most popular and essential products and services Koreans purchase and consume.

Whang (2000) reports that approximately 3000 language schools exist in Korea and the business is growing. Prospective employees have shifted their job search preparation focus from the Test of English for International Communication (TOEIC) to interview and business negotiation skills (Lee 2008). It is quite common that Korean working

professionals take a course at a language institute called *hakwon* to improve their English. According to a report on SBS TV, most one to one English speaking classes at *hakwon* maintain a 90% enrollment rate and 68% of working professionals take some courses to further their education after work. In particular, those in their 20s and 30s show a 20% increase in their endeavor to improve themselves, and 45% of the surveyed report that they study more than three hours a day (SBS TV May 19, 2003). Yook (2007) characterizes this type of unusual passion for improving English as “the national zeal” and “a sign of sheer madness.” Jeong (2004:40) goes so far as to say that “[c]urrently, it is no exaggeration to say that the Korean peninsula is overwhelmed by a zest for English. The whole country seems to be in the grip of ‘English fever’, and many factors, internal and external, have added fuel to the flames.” In accounting for the driving force behind this heightened interest in English, Lee (2008) argues that discourse such as “segeywha” or “global Korea” pushes speaking English to be all the more desirable qualification in contemporary Korea and the globalization ideology is often incorporated into various cyber-texts promoting English and English education.

There is no shortage of research on English language acquisition or English language teaching (ELT) in South Korea. However, marketing and retailing—the essential components of ELT—particularly in private education, have been mostly neglected. ELT is a booming business with private language institutes aggressively marketing their programs to secure more students through various channels. Among the marketing channels these institutes use, the Internet plays a prominent role as their programs, instructors, and services are often advertised there. Since these programs are marketed directly for an individual learner, the term *retailing* is more suitable than *wholesale*. Retailing is defined as “a business that sells products and/or services to consumers for their personal or family use and encompasses “the interface of retailers with both vendors and consumers, as well as other topics that impact retailers” (*Journal of Retailing* accessed 7 June, 2008 from <http://www3.babson.edu>).

In this paper, I opt for the term *e-tailing* to focus on retailing ELT in cyberspace. According to *Free Encyclopedia of Ecommerce*, electronic retailing (e-tailing) is defined as “the practice of selling goods and services over an electronic medium like the Internet” (accessed 10 July, 2008 from <http://ecommerce.hostip.info/pages/423/E-Tailing.html>). *Wikipedia* notes that there are two types of e-tailers: *pure plays* and *bricks and clicks*, the former using “the Internet as its primary means of retailing (e.g., Dell and Amazon.com) and the latter using “the Internet to push its good or service but also has the traditional physical storefront available to customers (accessed 11 October, 2008 from <http://en.wikipedia.org/wiki/E-tailer>). South Korean ELT institutes are bricks and clicks; they do have brick-and-mortar operations, but at the same time the Internet serves as a business growing tool for marketing programs, offering and improving services, and recruiting and managing customers, that is, English learners.

Marketing of products and services is often facilitated and can become successful through effective advertising. Advertising, as a discourse of persuasion, aims to convince potential consumers to purchase a product presented. According to Hermerén, (1999:4), advertising is “an activity which normally involves language, the purpose of which is to sell a product or service” and the main purpose of advertizing is “to make the listener, viewer or

reader adopt a certain viewpoint and/or act in a certain way” (p.5). Similarly, Stern (1996:62) views advertising text as “any media artifact designed to persuade consumers and generated, composed, recorded, and analyzed by sponsorial agents and/or researchers.”

In this study, I focus on e-tailing, one of the most recent advertising/marketing strategies commonly used by the South Korea ELT business and discuss how the speech act of persuasion is carried out by English language institutes in cyberspace.

## **2. Data**

The data were collected in August 2007 from the *Yahoo Korea* website, which provides one of the most popular Korean Internet search engines. I conducted a key word search using the phrase 영어학원 (*yenge hakwen* ‘English language institute’) and examined the first 20 items on the list. The English language institutes discussed in this study were not selected because of their importance or reputation. Rather, my goal was to simulate a search as closely as possible to an actual situation in which Korean learners of English may find themselves when they do not have a specific language institute in mind but engage in a general Internet search to find an English program suitable for their needs. I visited each of these 20 randomly selected English language institutes’ websites and examined their main homepages in terms of what is highlighted visually and emphasized linguistically regarding their programs and institutes. Rhetorical strategies and predominant themes exploited in the marketing materials available on these websites are classified first into categories by emphasis, and tokens of each category are subsequently tallied up to investigate a frequency factor.

## **3. Results and Discussion**

A textual analysis of the e-tailing materials of these 20 ELT institutes reveals seven predominant discourse strategies. The results are summarized in Table 1. The strategy categories are presented in descending order of frequency, that is, how many times it is mentioned in the data, and an example of each strategy category is provided to illustrate what a representative text is like. A more detailed discussion of different e-tailing texts will be presented subsequently.

Most e-tailing texts in this study resort to more than one advertising strategy; in fact, no language institutes in the data use only one type of e-tailing text. Technology-driven instructional methods and complimentary services and/or materials are commonly mentioned across different ELT institutes websites. In addition to technology, the concept of cost-effectiveness is often articulated in advertising. For instance, the majority of the institutes emphasize that their programs are reasonably priced, considering the amount of instruction and attention given to individual students and the many kinds of free services and materials available for enrolled students.

Table1. Categories and Frequency of ELT e-tailing strategies

	Frequency Times mentioned	Example
Technology-driven instructional methods	23	“Voice recognition software”
Complimentary services/ materials	22	“Free English text service”
Native speaker instructor	15	“Native speaker 100% authentic English”
Sensitive to individual needs	13	“One to one tailored consulting”
Time and cost effective	12	“60,000 won (less than \$60) per month 30% discount for three consecutive enrolled courses”
Emphasis on experience	6	“Everyday <i>okam cheyhem</i> ” (‘five sensory experience’ meaning ‘experiential learning’)
Convenience (flexible time/location)	4	“ <i>Call study</i> for busy working professionals” (‘instruction offered over the phone’)

### 3.1 Technology

The orientation to technology in ELT e-tailing is evident in a plethora of services and perks enrolled students are entitled to. Technology-dependant tendencies exist both in teaching and learning practices. Podcasts of sample lectures, Video-on-Demand showing streaming videos, and audio-files are mainly advertised for the teaching component. For the learning component, a variety of self-study or student-initiated learning maintenance tools such as daily English text service, e-dictionary, voice-recognition and pronunciation correction software, podcast and MP3 downloads of lectures are highlighted. These services are provided so that students can review the material and initiate their own learning in their free time. Thus, technology is closely tied to convenience as well.

The term *high-tech* appears fairly frequently on these websites. For instance, several websites feature an English pronunciation assessment software program as their “pride and joy” and provide detailed instructions as to how to use this program. One ELT institute’s e-tailing text indicates that two modes are available for enrolled students to take advantage of: *thought unit* and *role play*. Students are warned that if they score 50 or below, they cannot pass a test, which normally consists of 9-10 sentences. According to a picture on this website, when the “speaker bar” is blinking on a computer screen, students are supposed to talk into a microphone. To help students avoid failing the test, this ELT provides some practical tips for students to consider to improve their score on the institute’s English pronunciation evaluation test, which is presented in Excerpt (1).

- (1) GnB English Software 를 사용해서 최적의 영어 발음 인식을 높이는 방법은 **정확한 발음 (미국식 발음)**, 정확한 말하기 시점, 좋은 마이크, 좋은 컴퓨터도 중요하겠지만 가장 중요한 건 바로 여러분의 자신감입니다.

GnB English Software-lul sayonghayse choycekuy yenge palum insiklyul-ul Nophinun pangpepun **cenghwakhan palum (mikwuksik palum)**, cenghwakhan malhaki sicem, cohun mic, cohun computer-to chwungyo hakeyssciman kacang chwungyo hanken palo yelepwnunuy casinkamipnita.

‘The best way to improve your score using our GnB English pronunciation recognition software is to have **accurate pronunciation (American Accent)**, perfect timing, a good quality microphone and computer. But the most important thing is to have confidence.’

Excerpt (1) enumerates what the institute believes to be important components in successful use of this software, including accurate pronunciation, perfect timing, a good quality microphone and computer, and confidence. The “accurate pronunciation” is explicitly equated with “an American accent” in parenthesis, which is literally translated into “the US style” pronunciation. Although the main point of this text is to help the students see the value of confidence in learning English, the valorization of native speaker pronunciation, particularly American English, is hard to overlook. What is implied in the text is that speaking English with a Korean accent is something students should avoid if they want to score high enough to pass the test.

Technology is factored into advertising instructors as well. Some institutes feature video clips of teachers in which instructors briefly introduce themselves, mentioning their name and where they are from, and invite potential students to join the language institutes they work for. Their welcoming messages frequently include instructors’ excitement about the program and/or the possibility of working together with whoever views a video-clip.

As several interactive telecommunication technologies have become available, offering a course in a traditional classroom setting is no longer the only way to teach English. Live video streaming and simultaneous video conferencing enable teachers to teach from anywhere in the world. In other words, English teachers instructing Korean students do not necessarily have to reside in Korea. As it turns out, some ELT institutes employ teachers who currently live outside Korea somewhere in an English speaking country. Technology allows them to upload videos of “self introduction” and lessons. Thus, being present in the same physical and temporal space is no longer required in English teaching. This indicates that ELT is going global without distinctive borders, resulting in an increasing sense of interconnectivity around the world.

The notion of “staying connected” is relevant not only to teacher-student interaction but also peer interaction. The concept of “English community” in cyberspace is a case in point. Several English communities are created and managed via chatting with and blogging to peers around the world using English. For instance, the ELT institute called *Bilingual Korea Shall E* maintains “E Space” (<http://espace.shalle.com>) to provide opportunities for members and visitors to communicate with *yenge chinkwu* (‘friend via the English language) dubbed e-friends, *e-* dubiously indicating perhaps both English and electronic. I would argue that this is an Internet generation version of pen pals. Visitors are asked to post their biographical notes (e.g., gender, English proficiency level, age) and preferred time to be connected (e.g., available time). E-friends meet at the “Talk station,” which has the following ad: “Speak English with friends. More friends better English.” To demonstrate what kind of verbal interaction is normally exchanged at the talk station, I introduce two e-friends’ texts below. These are verbatim texts with all typographical and syntactic deviations intact.

- (2) hello..! this s Cris! thanks for visiting my Minishall. we dont know anything each other but i believe we wanna enjoy ourselves through english ! so just do it~
- (3) ~! This is sun mi. I really can't speak english well.. ㅏ.ㅏ  
But I want to speak english well. let's try~ Why don't you speak with me? \*^^\*

Excerpts (2) and (3) contain several features of computer mediated communication (CMC) or *Netspeak* (Crystal 2001), including colloquialisms and informal language use (Baron 2003), no or minimum capitalization (e.g., *english, i*), omission of punctuation marks (e.g., *dont*), and emoticons (e.g., \*^^\*, ㅏ.ㅏ). Even with a few “non-native” English features such as the omission of a preposition (e.g., *know anything each other*), the message in excerpt (2) is not obscure: friendship can develop though speaking English and speaking English can be enjoyable when you do it with friends.

Excerpt (3) unequivocally demonstrates that the participant is not satisfied with her current proficiency level, has a strong desire to improve English, and believes that speaking English with others can facilitate the process. Her invitation to peers suggests that she views staying connected with those who speak English as a collaborative partnership in improving English. It is noteworthy that the participant recognizes her limited English with the emotion indicating depression or discouragement (i.e. ㅏ.ㅏ), which demonstrates that learning English can often be a daunting task to learners such as herself emotionally as well as intellectually. When she invites “e-friends” to join her, she uses the emoticon conveying shyness or bashfulness (i.e. \*^^\*). Although these two emoticons are very common in Korean CMC and not readily found in Western CMC, the concept of e-friend is not limited to Koreans. In fact, Koreans who do not speak English might experience difficulties in becoming e-friends. As long as one can and is willing to communicate in English, anyone can join as an e-friend regardless of nationality. They do not have to be fluent in English or native speakers of English. This rather non-discriminatory nature of membership seems to work because your e-friend is your equal not your teacher; he or she does not formally teach you English but can help you improve English through friendship. However, this kind of flexibility is not available when there is a clear role to play as a teacher or a student because the student-teacher relationship often entails asymmetrical power dynamics and each has certain expectations about the other’s responsibilities—the teacher, as an expert, provides instructions and the student relies on the teacher’s expertise.

### 3.2 Native speakerdom

According to Gupta (1999), native speakerdom in ELT is generally limited to a high prestige Standard English using person from one of the traditionally English as a Native Language (ENL) countries. Similarly, Nayar (1994) notes that “in the native-nonnative paradigm there is no doubt or dispute about who owns English. The native speakers own it,

but are willing to transfer controlled possession and award guided right of use to the non-native speakers, but may be forever unwilling to cede even a share of the ownership.”

Many e-tailing texts in this study show native speaker favoritism, which is the one and only recurring rhetoric related to instructors and linguistically manifested under the title “wenemin” (‘native speaker’). 75% of the surveyed institutes explicitly mention *wenemin* teaching staff in their marketing material, and among these only one institute opts for the English word *native* which is orthographically presented in Korean, 네이티브, the rest using the Korean equivalent, 원어민(*wenemin*). The discourse about *wenemin* is prevalent not only in language institutes’ hiring practice but also in students’ instructor preference. It can be argued that ELT institutes, as vendors, simply try to provide what consumers demand. The need for hiring native speakers is often fueled by the desire to learn “original” English or “authentic” English. In Excerpt (4), this particular institute advertises its program as a tool to help students learn to speak “real English,” which is understood as native-like fluency. What is implicit in the text is that English taught by non-natives is “fake,” and this institute provides no such teaching.

- (4) **100% cincca yenge** sengkong haseyyo. (<http://www.jungchul.com/>)  
‘(I hope) you will succeed in (speaking) **100% authentic (real) English.**’

Telephone English is marketed for busy students with a full-time job, who find it challenging to attend an English class on a regular basis. It is an appealing method of learning because (1) financially it is less burdensome (2) it is much more flexible in terms of location and time (3) it is not as strenuous as regular one hour in-class English lessons since it is normally 10 minutes and (4) it can be done more frequently. A text from the website of a phone English specialized institute called *Oxphone Yenge* shows another illustrative example of native speaker favoritism. Even the name of their program contains a hindclipping of a prestigious British university *Oxford*.

- (5) 원어민과 매일매일 직접 전화를 통해 다양한 상황극과 교재를 이용하여 영어로대화하는 학습 방법 입니다. 영어학습에서 가장 중요한 것은 영어사용을 일상화하는 것이며 영어를 원어민으로 배우는 것입니다. 이런 방법을통하지 않고는 제대로된 영어학습의 효과를 거두기 어렵습니다.수많은 방법과 엄청난 금전과 시간을 투자하고도 우리 주위에는영어로 부터 고통받는 많은 사람들이 있습니다.옥스포드 허브 영어에서는 이러한 단점을 개선하여 원어민과의직접대화 방식으로 여러분을 새로운 영어 학습의 장으로 초대합니다.

**Wenemin**-kwa mayil mayil cikcep cenhwa-lul thonghay tayangan sanghwangkuk-kwa kyocay-lul iyonghaye yenge-lo tayhwanun haksup pangpep ipnita. Yengehaksup-eyse kacang cwungyohan kesun yengesayong-ul ilsanghwanun kesimye yenge-lul **wenemin**-ulo paywunun kesipnita. Ilen pangpep-

ul thonghaci anhkonun ceytaylorloyn yengehaksup-uy hyokwa-lul ketwuki elyepsupnita. Swumanhun pangpep-kwa emchengnan kumcen-kwa sikan-ul thwucahakoto wuli cwuwieynun yenge-lo pwuthe kothongpatnun manhun salam-tul-i issupnita. Oxford Herb yenge-eysenun ilehan tancem-ul kaysenhaye **wenemin-**kwaury cikcep tayhwa pangsik-ulo yelepwn-ul saylowun yenge haksupuy cang-ulo chotayhapnita.

‘Our program is designed to help you practice communication in English by utilizing a variety of role plays and materials and by enabling you to talk to a **native speaker** on the phone on a daily basis. The most important thing in learning English is to use it in a daily conversation and to learn it from a **native speaker**. Without this it is difficult to achieve a desirable outcome in learning English. Even with numerous methods and significant investment of time and money, we witness many suffer from English. Oxford Herb English has dealt with these limitations and created a new space to directly communicate with a **native speaker**. You are all invited and come and join us.’

Excerpt (5) points out a predicament many learners are faced with—not being able to use English on a daily basis through a conversation with a native speaker. It states that learning English from a native speaker is a necessary process to fix previous ineffective English learning.

The “obsession” with native speaker teachers sometimes leads to ethnocentric, misguided recruitment practices which perpetuate the view that all “white” instructors are native speakers and therefore they do not have an accent. Tsuda’s (1992:32) observation about “an emotional attachment to and obsessive infatuation with Western, primarily American culture; elevation of ‘the native speaker’ and the ‘Caucasian race’ to a status of ‘cultural superiority’ in Japan’s *eikaiwa* seems to be quite salient in Korea as well. My personal encounters with some of the English instructors working in Korea confirm that some of them indeed have benefited from this hiring practice, enabling them to work as “native speaker” instructors despite the fact that they are originally from Francophone Canada or an Eastern European country, English their second language. What they have in common is their “foreigner look.”

One website features video clips called “messages to the students” showcasing non-local teachers including a Korean American and a Latino whose self introduction indicates that she resides in Florida but originally is from Argentina. The Korean American teacher does not have “an accent,” whereas the Argentinean teacher does. Physical attributes seem to play an important role in teacher recruitment. If the instructor is of East Asian descent, he or she needs to speak “perfect” English, but instructors with western features are not necessarily subject to the same standards. Thus, the native speaker rhetoric poses different often conflicting forms of discrimination against Asian teachers, going beyond just English proficiency.

The *wenemin* rhetoric is often reinforced by a visual aid as in Figure 1. At least this institute attempts to convey that its teaching staff are diverse in terms of gender and race. However, the most prominent is an attractive Caucasian female and the least memorable an Asian male, whose image is blurred and fades into the background. It is not clear whether the Asian male is Korean or not, since nowhere in the text or the picture is this information made specific. The native speaker preference is not driven solely by the desire to be exposed to “perfect English,” as some e-tailing texts of several ELT institutes seem to claim. It is also triggered by physical trait-based ethnocentrism that those looking different from Koreans speak “correct” English and those looking like Koreans speak “incorrect” English.

Figure 1. Picture of teaching staff (<http://www.global-academy.co.kr>)

The majority of the e-tailing texts feature the term *wenemin* but other qualification criteria are not mentioned at all. In other words, as long as the potential employee satisfies the most important requirement of being a native speaker, lack of other qualifications will not prevent the job candidate from getting hired as an English teacher. This type of minimum requirement is not applicable to eligible Korean teachers since they need to fulfill other requirements such as a few years of teaching experience, a teaching certificate, a Master’s degree from an accredited university in an English speaking country, and so forth. Excerpt (6) below is the only exception in the data, advertising native speaker teaching staff who have extra credentials other than just being native speakers.

(6) **Wenemincwung palum cohko phyocwune kwusa** kangsa cakyekcung  
(<http://www.native79.com>)

‘Among **native speakers**, those **speaking Standard English with good pronunciation** and a teaching certificate.’

Unlike some other marketing texts about native speakers, this excerpt puts some emphasis on a teaching certificate and equates Standard English with “good pronunciation” and suggests that not all native speakers have good pronunciation or are speakers of Standard

English. This website boasts its rigorous instructor selection process and stresses how this company differs from others who indiscreetly and carelessly hire people simply because they are native speakers of English.

The preferential treatment of native speaker instructors is also shown in terms of financial compensation and student-teacher ratio. For instance, excerpt (7) states that this institute offers “one to one tailored” English courses, but if it is with a Filipino instructor, it will be a private lesson but if it is with a teacher from America, England, or Canada, it will have to be in a group discussion format along with three other classmates. Thus, there is a clear difference in terms of the level of individual attention a student will be given. Although it is a positive development to have instructors both from the *Inner Circle* and *Outer Circle* (Kachru 1998), the Outer Circle teachers are not treated equally as those in the Inner Circle. Teachers from the *Expanding Circle*, especially Koreans, are not favored as conversation instructors.

- (7) One to one English 1:1 맞춤과정 (필리핀 선생과 온라인 교재), 1:4 그룹회화(미국/영국/캐나다선생과의토론방식) (<http://www.otoe.co.kr>)

One to one English 1:1 macchwumkwaceng (Philippine sensayng-kwa online kyocay), 1:4 group hoyhwa (Mikwuk/Yengkwuk/Canada sensayng-kwaury tholonpangsik).

‘One to one English 1:1 customized class (online material with a Filipino teacher), 1:4 group conversation (discussion with American/British/Canadian teachers.’

### 3.3 Experiential learning: Learning by doing

Experience is another buzz word in ELT marketing. An ambitious idea of creating an experience-oriented English immersion learning environment, *English Village*, has already produced three campuses in Gyeonggi and many mini campuses all over Seoul (Lee 2008). As the motto “creating global Koreans” indicates, these villages are attempts to bring the world to Korea and enable ordinary Korean citizens to experience travelling outside Korea. The Paju Campus I visited features a mock town that is similar to a village in the US or England (Lee 2007). Thus, *global* does not mean any place in the world but a place in which English is spoken. All the street signs in the English Village are in English and the medium of instruction and means of communication are supposed to be English as well.

Similar to English Villages, several private ELT institutes also stress the importance of “experience” in learning. The emphasis on experience is a reaction to traditional textbook-based English teaching in the classroom which is often criticized for being ineffective in producing fluent English speakers. What is referred to as experience is to get to do things and take care of daily business in English. Excerpt (8) argues that their program is a more convenient version of the English Village because students do not live in

the Village but can commute from home. The e-tailing text of this institute makes its purpose explicit as follows:

- (8) UN English 글로벌 영어인재를 양성하기 위한 “통학형 영어마을”  
대한민국의 30 후를 이끌어 나갈 글로벌 인재 양성을 위하여 설립된  
신개념 통학형 마을 Everyday 오감체험 영어.

UN English global yenge incay-lul yangsenghaki wihan “thonghakhyeng  
yengemaul” tayhanminkwukuy 30hwu-lul ikkule nakal global incay yangseng-ul  
wihaye seliptoy sinkaynyem thonghakhyeng maul Everday okam **cheyhem yenge.**

‘UN English is a new concept based commute enabling English Village with the  
aim of nurturing global English human resources who will lead Korea in 30  
years. Everyday five sensory **experiential English.**’

They claim that the institute has approximately 5000 “experiential educational spaces” and they are normally upgraded twice a year. The website also states that the United Nations Future Forum and Life University sponsor their institute. Although a world organization such as the United Nations has nothing to do with the institute, the mere linguistic association and what the UN represents can easily evoke a sense of authority or global good will which can enhance the legitimacy of the institute’s claim and program. A comparative allusion to the English Village is used positively to stress this institute’s experience-oriented teaching methods and facilities and sincere desire to realize a truly authentic overseas ESL environment, which is articulated in Excerpt (9). Furthermore, it is argued that the institute is not simply an amusement park, which resonates with some of the negative criticisms English Villages are subject to.

- (9) 단순놀이동산이 아닌 해외현지와 같은 진정한 ESL 환경 구현.

Tanswunnoli tongsan-i annin hayoyhyenci-wa kathun **cincenghan ESL  
hwankyeng kwuhyen.**

‘It is not a mere amusement park. It is a **true ESL environment** emulating  
overseas.’

The majority of the ELT e-tailing texts in this study reinforce one of the most powerful language ideologies in circulation in Korea, that is, English is necessary, if not indispensable, for social advancement and global competitiveness. The text below is a prime example of that idea.

- (10) 지앤비영어전문교육(주)은 그동안의 GnB 영어전문학원이라는 결과에  
만족하지 않고 대학생들과 일반 성인들을 위한 최첨단의 효과적인

영어교육프로그램도 개발·완료하여 “이 땅의 모든 사람들이 영어가 되는 그날까지” 최선의 노력을 경주하여 21C 영어교육을 선도하는 **세계적인 영어교육전문회사**로 성장하려고 합니다. 영어 의사소통 능력을 원하는 세상의 모든 사람들에게는 영어라는 언어가 더 이상 **장애물이 아닌 개인의 경쟁력**이 될 수 있도록.

GnB yenge cenmwunkyoyuk (inc)-un kutonganuy GnB yengehakwenilanun kyelkwaey mancokhaci anhko tayhaksayng-tul-kwa ilpan sengintulul wihan choychemtanuy hyokwacekin yenge kyoyuk program-to kaypal·wanlyohaye “ittanguy motun salam-tul-uy yenge-ka toynun kunalkkaci” choysenuy nolyek-ul kyengcwuhaye 21C yengekyoyuk-ul sentohanun **seykyeycekin yengekyoyuk cenmwunhoysa**-lo sengcanghalyeko hapnita. Yenge uysasothong nunglyek-ul wenhanun seysanguy motun salam-tul-eykey-nun yengelanun ene-ka te isang **cangaymwul-i anin kayinuy kyengcaynglyek-i toyl swu isstolok.**

‘GnB is no longer content with the reputation simply as an institute specializing in the English language. We will continue to develop and run high-tech, effective English programs for college students and adults until “English is possible for everyone on this soil” (i.e. every Korean can speak English). We aim to grow to be **a leading English language teaching institute in the world** so that English may **not be an obstacle but a competitive force** for those who want to communicate in English.

This institute does not view Korea as the only market. Its vision is to become a leading ELT institute “in the world” not just in Korea. This is an indication that the ELT industry is a business subject to the pressure of improving competitiveness in the global economy just like any other business. It is not immune to the “Global Korea” campaign, which is aggressively promoted in many domains of contemporary South Korea.

#### **4. Conclusion**

The findings of the study indicate that technology, economy, and native speaker preference are overarching themes in ELT marketing materials in cyberspace. Interactive telecommunication technologies are involved both in teaching and learning. Most ELT institutes make instructions available through live video streaming, podcasts, or audio files. Students can also actively manage their own learning maintenance activities by utilizing pronunciation correction software, daily English text message to their cell phones, and e-dictionaries and by downloading audio files and video podcasts of lectures they have already completed or missed.

The discourse of economy is often articulated in relation to time, cost, and complimentary services. The majority of ELT e-tailing texts mention reasonable tuitions, relatively short duration of a semester, and a variety of free services enrolled students can benefit from. Most ELT institutes claim to be willing to work hard to be sensitive to each student's needs by providing one to one tailored or customized teaching and flexible times and locations for instruction so that students may decide when and where to take a course.

Subtexts idolizing native speakers and emphasizing experiential learning are common. Almost all of the ELT institutes in the data advertise their *wenemin* ('native speaker') teaching staff as a main "selling" point and often highlight the importance of learning English from native speakers and argue how that is directly related to speaking so-called authentic English.

This study argues that the ELT industry in South Korea relies heavily on computer mediated communication for providing English instructions and retailing English language programs in response to changing needs of techno-savvy and Internet oriented learner consumers.

## **Abstract**

Maki et al (2003) developed the Minimal English Test (MET), which is a five-minute ESL test. The Maki Group has investigated whether the MET really measures ESL proficiency, in terms of its validity and reliability since the development of the MET. In this paper, we show that the MET, more or less, measures the same ESL proficiency as other widely used ESL tests, and the scores on the MET are moderately reliable. Therefore, the MET can be used as a useful ESL test in ESL research as well as ESL class.

**Keywords:** Minimal English Test, proficiency, reliability, validity.

## **1. Introduction**

Maki et al (2003) developed the Minimal English Test (MET), which is a five-minute English as a Second Language (ESL) test which requires the test taker to fill a correct English word with 4 letters or fewer into each of the 72 blank spaces of the given sentences, written on one piece of A4 paper, while listening to the CD on which the sentences are recorded. The MET is based on Lessons 1 and 2 of the textbook for college freshmen, written by Kawana and Walker (2002), and the CD that accompanies it. The contents of the textbook are essays on the modern society of the United States. The sentences on the CD last about five minutes at a speed of 125 words per minute.

---

\* An earlier version of this paper was presented at the 18th International Congress of Linguists held at Korea University on July 24, 2008. We would like to thank the audience at the meeting, as well as Jessica Dunton, Fumikazu Niinuma, and Shigeki Taguchi, for their helpful comments. All errors are our own.

The Maki Group has investigated whether the MET really measures ESL proficiency or not since the development of the MET, by seeing the correlations between the scores on the MET and the scores on other widely used ESL tests. This paper examines whether the scores on the MET are reliable or not in two ways: the Guttman split-half estimate and the Spearman Brown equivalent forms estimate. We found that the scores on the MET show statistically significant relatively high correlations with the scores on other widely used ESL tests, whose correlation coefficients are around .7. Therefore, it can be said that the MET is a valid ESL test. Furthermore, the reliability coefficients of the MET were around .9, and thus, moderate as an ESL test, in terms of the interpretation of the reliability coefficient by Lado (1961). Therefore, it can be said that the MET is a reliable ESL test. Hence, the MET is a valid and reliable ESL test. These results indicate that it might be possible to measure ESL proficiency within a short period of time, and that the MET can be used as a useful ESL test in ESL research as well as ESL class.

The organization of this paper is as follows. Section 2 introduces the MET. Sections 3 and 4 discuss the validity and reliability of the MET, respectively. Finally, Section 5 concludes this paper.

## 2. The Minimal English Test

The MET is a simple test which requires the test taker to fill a correct English word with 4 letters or fewer into each of the 72 blank spaces of the given sentences written on one piece of A4 paper, while listening to the CD which produces the sentences. The MET is based on Lessons 1 and 2 of the textbook for college freshmen by Kawana and Walker (2002) and the CD that accompanies it. The contents of the textbook are essays on the modern society of the United States. The CD lasts about 5 minutes at a speed of 125 words per minute. The MET is shown below.

### *The Minimal English Test (MET)*

Please fill an English word with 4 letters or fewer into each blank spot, while listening to the CD.

1. The majority of people have at least one pet at (     ) time in their (     ).
2. Sometimes the relationship between a pet (     ) or cat and its owner is (     ) close
3. that (     ) begin to resemble (     ) other in their appearance and behavior.
4. On the other (     ), owners of unusual pets (     ) as tigers or snakes

5. sometimes ( ) to protect themselves ( ) their own pets.
6. Thirty years ( ) the idea of an inanimate ( ) first arose.
7. This was the pet ( ), which became a craze ( ) the United States and
8. spread ( ) other countries as ( ).
9. People ( ) large sums of money for ordinary rocks and assigned ( ) names.
10. They tied a leash around the rock and pulled ( ) down the street just ( ) a dog.
11. The rock owners ( ) talked ( ) their pet rocks.
12. Now ( ) we have entered the computer age, ( ) have virtual pets.
13. The Japanese Tamagotchi---( ) imaginary chicken ( )---
14. ( ) the precursor of ( ) virtual pets.
15. Now there ( ) an ever-increasing number of such virtual ( )
16. which mostly young people are adopting ( ) their ( ).
17. And ( ) your virtual pet ( ),
18. you ( ) reserve a permanent resting place ( ) the Internet in a virtual pet cemetery.
  
19. Sports are big business. Whereas Babe Ruth, the ( ) famous athlete of ( ) day,
20. was well-known ( ) earning as ( ) as the President of the United States, the average
21. salary ( ) today's professional baseball players is ( ) times that of the President.
22. ( ) a handful of sports superstars earn 100 times ( ) through their contracts
23. ( ) manufacturers of clothing, ( ), and sports equipment.
24. But every generation produces ( ) or two legendary athletes ( ) rewrite
25. the record books, and whose ability and achievements ( ) remembered ( ) generations.
26. ( ) the current generation Tiger Woods and Michael Jordan are two ( ) legendary
27. figures, ( ) of whom ( ) achieved almost mythical status.
28. The ( ) that a large number of professional athletes ( ) huge incomes
29. has ( ) to increased competition throughout ( ) sports world.
30. Parents ( ) their children to sports training camps ( ) an early age.
31. Such ( ) typically practice three to ( ) hours a day,
32. ( ) weekend ( ) during their school vacations
33. in order ( ) better their chances of eventually obtaining ( ) well-paid position
34. on a professional ( ) when they grow ( ).
35. As for the ( ) young aspirants who do ( ) succeed,
36. one wonders if they ( ) regret having ( ) their childhood.

The test taker is verbally given the following 3 instructions in advance: (1) Fill an English word with 4 letters or fewer into blank spaces, while listening to the CD; (2) The CD lasts about 5 minutes; and (3) There is about a three-second interval between Line 18 and Line 19.

### **3. Validity of the MET**

The Maki Group, since the development of the MET in 2003, has investigated whether the scores on the MET had statistically significant correlations with the scores on two other tests: (1) the Center Test (English Part) (CT) from 2002 to 2007, which is the common Japanese university entrance examination (The University Entrance Examination Center (2007)), and (2) the Paul Nation Vocabulary Test (PNVT) (Nation (2001)), which is a widely used test in ESL research. They discovered statistically significant correlations between the scores on the MET and the scores on the CT 2002 ( $r=.68$  and  $n=154$ ) (Maki et al (2003)), the CT 2003 ( $r=.72$  and  $n=629$ ) (Maki et al (2004)), the CT 2004 ( $r=.72$  and  $n=657$ ) (Maki et al (2005)), the CT 2005 ( $r=.60$  and  $n=611$ ) (Maki, Kasai, Goto, Morita, von Fragstein, Yumoto, Ochi, Oku, and Date (2006)), the CT 2006 ( $r=.62$  and  $n=611$ ) (Maki, Kasai, Goto, Ito, Miyamoto, and Oku (2007)), the CT 2007 ( $r=.67$  and  $n=851$ ) (Maki et al (2008)), and the PNVT ( $r=.81$  and  $n=159$ ) (Kasai et al (2005)). The subjects were all Japanese university freshmen. These results suggest that the MET measures more or less the same sort of ESL proficiency as the CT and the PNVT do. Furthermore, the Maki Group has investigated whether the MET can efficiently be used to measure ESL proficiency of other populations. They have investigated whether there are statistically significant correlations between the scores on the MET and the scores on (1) Shinken-Examination (English Part) in 2005 (SE), by the second grade high school students, which is a mock examination for the Japanese university entrance examinations (Maki, Morita, Ichihara, Furukawa, Kasai, and Goto (2007)), (2) the College Scholastic Achievement Test (English Part) 2005 (CSAT) by Korean university freshmen, which is the common Korean university entrance examination (The Korea Institute of Curriculum & Evaluation (KICE) (2007)) (Maki, Kasai, Goto, Lee, Lee, and Kim (2006)), and (3) the PNVT by Chinese university freshmen in 2005 (Maki, Bai, Kasai, Goto, and Hashimoto (2007)). They found statistically significant correlations between the scores on the MET and the scores on the SE ( $r=.63$  and  $n=135$ ), the CSAT ( $r=.61$  and  $n=155$ ), and the PNVT ( $r=.70$  and  $n=549$ ). Therefore, the MET seems to measure ESL proficiency of not only Japanese

university freshmen, but also Japanese second grade high school students, Korean university freshmen, and Chinese university freshmen. Evidence from a series of research by the Maki Group suggests that the MET seems to be able to measure the same ESL proficiency as the other four widely used ESL tests to some degree. Therefore, it can be said that the MET is a valid ESL test.

#### 4. Reliability of the MET

In order to use the MET as a tool to measure ESL proficiency, the MET must be a reliable ESL test. In this study, we examined the reliability coefficients of the MET in two ways: (1) the Guttman split half estimate (Guttman (1945)), and (2) the Spearman-Brown equivalent forms estimate (Spearman (1910) and Brown (1910)). First, we examined the results of the MET obtained in 2006 in terms of the Guttman split-half estimate. The data was collected from freshmen at four universities in Japan. The Guttman split-half reliability coefficient of the MET was .88 ( $s^2_{h1}=35.5$ ,  $s^2_{h2}=29.4$ ,  $s^2_{h1+h2}=116$ , and  $n=693$ ). Also, the estimate of the standard error of measurement (SEM) of the MET was 3.66 ( $s_x=10.8$ ,  $r_{xx}=.88$ , and  $n=693$ ). Therefore, the 68 percent confidence interval for an observed score of X was  $X \pm 3.66$  out of 72.<sup>1</sup> Second, we examined the results of the MET obtained in 2005 and 2006 in terms of the Spearman-Brown equivalent forms estimate, using other 7 versions of the MET. The subjects were all Gifu University freshmen, and about half of the entire data samples were collected in

---

<sup>1</sup> Bachman (2004, 173) provides an explicit explanation of the confidence interval. He states the following:

“The three most commonly used probabilities for confidence intervals are .68, .95, and .99. We choose the appropriate level of probability depending on how confident we want to be in our estimate we want to be in our estimate of the test taker’s ‘true scores.’ In high-stakes situations, ..., we would choose the .99 probability level, .... On the other hand, for low-stakes situations, where we may be willing to accept a lower degree of confidence, we might choose the .68 probability, which means that we would be 68 percent certain that the test taker’s ‘true score’ is within the confidence interval.

(68 per cent confidence interval)  $CI_{.68} = X \pm 1.00 \text{ SEM}$

(90 per cent confidence interval)  $CI_{.90} = X \pm 1.96 \text{ SEM}$

(95 per cent confidence interval)  $CI_{.95} = X \pm 2.58 \text{ SEM}$ ”

2005, and the other half were collected in 2006. The reliability coefficients were around .9, as shown in Table 1, which is moderate for an ESL test.

*Table 1: Reliability Coefficients for MET 2 to MET 8*

	MET2	MET3	MET4	MET5	MET6	MET7	MET8
Reliability Coefficient	.895	.841	.886	.918	.896	.888	.864
Standard Error of Measurement (68%)	3.19	3.91	3.20	2.73	3.09	3.22	3.51
Observations	134	124	126	127	126	120	129

Therefore, it can be said that the MET is a reliable ESL test.

## 5. Conclusion

Through a series of research by the Maki Group since 2003, it has become clear that the MET is a valid and reliable test, and measures, more or less, the same ESL proficiency as four other widely used ESL tests, in spite of the fact that it takes only five minutes to administer it. Therefore, the MET could be a very practical and useful tool to predict one's scores of those widely used ESL tests, and could also function as a placement test for ESL learners. Furthermore, with the MET, researchers are able to conduct ESL research projects more easily.

## Abstract

An important question in the L2 acquisition of phonemic distinctions is whether learners have to perceive contrasts before they can successfully produce them. In this paper, data on both the perception and production of the English /s/-/ʃ/ contrast were elicited from native speakers of Korean, a language in which [s] and [ʃ] are allophones of the same phoneme. General principles of phonology predict that, in acquiring this contrast, Korean learners will suppress the application of the allophonic rule relating these sounds across a morpheme boundary only if they can prevent the rule from applying within morphemes. This study examines these predictions in both production and perception of the /s/-/ʃ/ contrast as a function of learner's training.

**Keywords:** production, perception, interlanguage grammar, second language, fricatives, Korean.

## 1. Introduction

This paper reports data from a pilot project that is part of an ongoing study investigating the acquisition of phonemic contrasts in second language acquisition. The focus of the research is the second-language (L2) acquisition of a target-language (TL) contrast between two phonemes where the native language (NL) contains the sounds in question as allophones of the same phoneme. The task of the L2 learner in this case is to acquire the contrast by suppressing the application of the NL allophonic

rule in the pronunciation of the TL words.

For the purposes of this study, we are interested in the acquisition of the contrast in two phonological contexts, in production as well as perception. The two general phonological contexts, or environments, are termed *morphologically basic* and *morphologically derived*, and refer to the morphological structure of representations that would trigger the application of the NL allophonic rule. Morphologically basic (henceforth, basic) environments are mono-morphemic words containing the appropriate segments for the application of the allophonic rule. For our purposes morphologically basic environments can be further subdivided into three phonological contexts: word-initial position before a vowel, word-medial position between vowels, and word-final position following a vowel. Morphologically derived environments (henceforth, derived) refer to words containing a representation to which the allophonic rule would apply, but the segments in question are separated by a morpheme boundary.

General principles of phonology predict that learners will be able to acquire a contrast in some positions before they can acquire the contrast in other positions. In basic environments, learners should acquire a contrast in word-initial and word-medial positions before they acquire the contrast in word-final position. This is because word-initial and word-medial positions are both syllable-onsets and word-final position is a syllable coda. Contrasts in onsets have been shown to be acquired before contrasts in codas.

General principles of phonology also make predictions about the acquisition of contrasts involving the learner having to split two NL allophones into separate TL phonemes by virtue of suppressing the application of the allophonic rule. The prediction is that learners will be able to suppress the application of the allophonic rule across a morpheme boundary only if they are also able to prevent the rule from applying within morphemes. In other words, a learner will acquire the contrast in derived environments only if that learner has acquired the contrast in basic environments. These general principles have always been formulated, and to date, have always been tested, on only production data. The purpose of this study is test whether these principles hold also for perception data.

The remainder of this paper is structured as follows. The next two sub-sections present the context for this study in terms of the connection between a learner's perception and production of a contrast, as well as the relationship between acquisition and phonological context. Section 2 outlines the methodology for eliciting the production and perception data, and Section 3 reports the results, which are, in turn, interpreted and discussed in the following section. The last section concludes the

paper.

### *1.1. The production-perception relationship*

One of the overarching questions in the L2 acquisition of phonemic distinctions is whether learners have to perceive contrasts before they can successfully produce them. Although it would seem to be intuitively clear that a learner must perceive any given contrast before being able to implement it in production, the literature in fact attests all four logical possibilities.

Two of these possibilities are straightforward and require little or no elaboration. There are numerous documented examples of learners who can neither perceive nor produce a TL contrast, as well as instances in which L2 learners can both perceive and produce TL contrasts (e.g., Bion, Escudero, Rauber and Baptista 2006, and others). The other two logical possibilities are not as straightforward, and therefore require discussion.

Flege's (1995) Speech Learning Model (SLM) is predicated on the notion of "equivalence classification", in which an L2 learner sets up categories for TL phonemes on the basis of that learner's perception of the segments in question. Flege (1999) examined correlations between perception and production in results from selected studies on L2 consonants and vowels (Flege, Bohn & Jang, 1997; Flege, MacKay and Meador, 1999), and found that L2 segmental production and perception are generally correlated, although factors such as age limits or methodological differences among the variables investigated by different researchers may weaken the correlation. Thus, the results from a number of studies support the claim that L2 learners perceive contrasts before they can successfully produce them.

The fourth logical possibility has also been documented. Sheldon and Strange (1982) reported that L2 learners' production of certain contrasts can exceed their ability to perceive that contrast. The authors tested native speakers of Japanese learning English on their ability to perceive and produce the distinction between /r/ and /l/, a contrast lacking in Japanese. Specifically, it was found that native speakers of English, when listening to recordings of the subjects' productions of minimal pairs containing /r/ and /l/, could successfully distinguish /r/ from /l/ better than the subjects could distinguish this contrast in their own productions.

Given the conclusion that all four logically-possible combinations of learning to perceive and produce a contrast have been attested, we turn our attention to the phonological environment in which the contrast is acquired.

## 1.2. *The relationship between acquisition and phonological environment*

Within the context of the above-referenced work on the relationship between the production and perception of phonemic distinctions by L2 learners, we investigated the ability of Korean L2 learners of English both to produce and perceive the contrast between /s/ and /ʃ/ in derived as well as basic environments. This contrast was chosen because the phonemic status of these two segments is different in Korean than it is in English. In Korean [s] and [ʃ] are in complementary distribution, with [ʃ] occurring only before high front vowels, [s] elsewhere.

General principles of phonology predict that learners will be able to acquire a contrast in some positions before they can acquire the contrast in other positions. In basic environments, learners should acquire a contrast in word-initial and word-medial positions before they acquire the contrast in word-final position, because word-initial and word-medial positions are both syllable-onsets and word-final position is a syllable coda. Contrasts in onsets are acquired before contrasts in codas, in both first and second language acquisition (Eckman and Iverson 1994; Goldsmith 1990).

General principles of phonology also make predictions about the acquisition of contrasts involving the learner having to split two NL allophones into separate TL phonemes by virtue of suppressing the application of the allophonic rule. The prediction is that learners will be able to suppress the application of the allophonic rule across a morpheme boundary only if they are also able to prevent the rule from applying within morphemes (Eckman, Elreyes and Iverson 2003). In other words, a learner will acquire the contrast in derived environments only if that learner has acquired the contrast in basic environments.

To be more specific, at the beginning stages of acquisition the learner's IL grammar lacks the contrast altogether and the transferred NL rule will apply "across the board" in both basic and derived environments. This causes words such as *sip* and *ship* as well as *messing* and *meshing* to be pronounced homophonously. As the learner begins to acquire the contrast in question, the two segments become part of the IL lexicon, and the principles in question restrict the rule to apply only in derived contexts, causing the learner to distinguish the pronunciation of *sip* and *ship*, but to continue to pronounce *messing* and *meshing* homophonously. The last stage would be one in which the contrast has become acquired to the point where the rule is suppressed altogether.

As pointed out above, these general principles have always been formulated on, and to date, have always been tested on, only production data. The purpose of this study is to test whether these principles hold also for perception data.

## 2. Methods

### 2.1. Study participants

Ten native speakers of Korean served as participants of the study. All were students at the City University of Incheon, Korea, ranging in age from 19-25 years. All participants learned English in a formal school setting (for 8-10 years) and none of them had any direct informal experience with English, neither by means of a personal native-English-speaking tutor or travel to an English-speaking country. They were enrolled in various majors at the University but none of them included English, linguistics, or other language-related studies. The English teachers of the participants in their elementary, middle, and high school years were also native speakers of Korean. While in the college, however, they were enrolled in a conversation course taught by native English speakers.

### 2.2. Stimulus materials

Two sets of stimuli were used in the study, one pertaining to the production of the target sounds and one to their perception. These two sets were used twice to collect subjects' responses at two points in time: (1) as a pretest, at the beginning of the study before each subject entered the training phase, and (2) as a posttest, after the training had been completed.

#### 2.2.1. Production stimuli

A set of 60 target words and 30 fillers were selected. All words were existing lexical items in English. Each target word contained /s/ or /ʃ/ in three different positions in a morphologically basic word: initial (e.g., *sip/ship*), medial (e.g., *lesson/ocean*) and final (e.g., *pass/crash*) and in one additional position (medial, at the juncture with another morpheme) in morphologically derived words such as *passing/brushing* or *messy/bushy*. In the word-initial position, /s/ or /ʃ/ occurred before a high front vowel which was also the case for the derived words, in which it was followed by the suffix *-ing* or *-y*. No high front vowel followed /s/ or /ʃ/ in either the medial or final position in the basic word. A complete list of the target words used in the production task can be found in Appendix A.

#### 2.2.2. Perception stimuli

Stimuli for the perceptual testing consisted of naturally produced single words

recorded by a male native speaker of American English. The words were existing lexical items in English. Only minimal pairs were used in which /s/ or /ʃ/ occurred in initial and final positions in basic words and in medial position followed by the suffix *-ing* or *-y*, e.g., *seep/sheep*, *plus/plush*, *classing/clashing*. The stimulus set consisted of 72 items (4 stimuli x 2 contrastive segments x 3 positions in a word x 3 repetitions). Appendix B lists all words used in the perception task.

### 2.3. Experimental procedures

Several custom programs were written in MATLAB for the purposes of the present study. First, a program controlling the recordings in the production task displayed on a computer screen a set of pictures, clues, and commands such as “Wait” or “Speak” designed to guide the subject and the experimenter in order to elicit the word in question. If a word could not be elicited through the picture display or written clues that followed, a verbal model was played and the subject repeated the word. The stimuli were presented in a random order. They were recorded directly into a hard disc drive at the sampling rate of 44.1 kHz. The subject spoke into a head-mounted microphone at a distance of 1 inch from the lips.

Another MATLAB program controlled the perception experiment. In this task, a single-interval two-alternative forced choice (2AFC) identification procedure was used with the two response choices, /s/ and /ʃ/, displayed on the computer monitor. After hearing the stimulus word, the subject indicated with the press of a mouse button whether the word contained an /s/ or an /ʃ/. The stimuli were presented in a random order over Sennheizer HD600 headphones at a comfortable listening level (~70 dB HL). Each subject was tested individually. First, the stimuli were presented in a no-masker condition so that no signal degradation was introduced to mask the signal. To make the perception task more demanding, the stimuli were then presented in multitalker babble and in masking white noise at two different levels of sound-to-babble (S/B) sound-to-noise (S/N) ratios: 0 dB, and -4 dB.

The testing took place in Incheon, Korea, in a quiet room near the University. All experiments were completed over two days. In the first day, each subject completed a production and a perception task to elicit the pre-training data. Next, the subject was trained on the production of the /s/-/ʃ/ contrast. This was done through a series of training steps which were developed as a part of a training phase whose implementation was guided by a separate MATLAB program. Only nonsense words were used in the training phase. The training was administered to the subject in a way somewhat similar

to the production task, using appropriate pictures and verbal models which were repeated and learned by the subject.

In the second day of testing, the same production and perception tasks were conducted to elicit subjects' production and perception responses to the /s/ - /š/ contrast. These tasks were administered as post-training tests to assess the effects of learning.

#### *2.4. Data analysis*

The production data were first transcribed by a native speaker of American English. All transcriptions were completed at The Ohio State University. The transcription process was fully automated using a custom MATLAB program that displayed the following choices on the computer monitor: "strong palatal," "weak palatal," "non-palatal" and "other, with comments." The data were transcribed in terms of degree of palatalization rather than categorically, i.e., as an instance of an /s/ or an /š/, because in some instances, it was difficult to determine for a native speaker of American English which fricative was produced. Degree of palatalization was easier to detect and therefore it was considered a more reliable measure of the difference between /s/ and /š/. After hearing each word, the transcriber selected an appropriate box on the computer screen to register her choice.

In analyzing the production results, we determined the percentage of correct productions for each fricative. The production of /s/ was considered correct if it was transcribed as "non-palatal" while the production of /š/ was considered correct if it was transcribed as either a "strong palatal" or a "weak palatal."

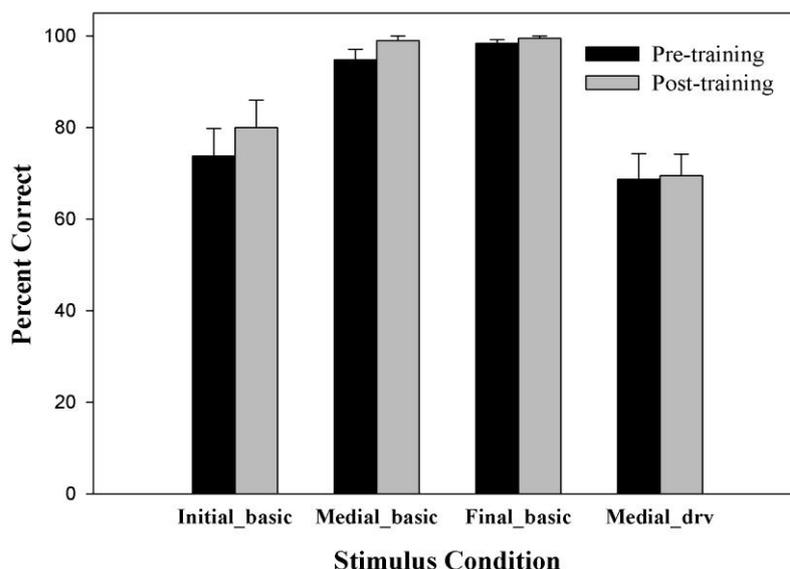

The perception results were analyzed in terms of overall percent correct score for both segments, i.e. an /s/ and an /š/. The total percent score provides information regarding the listener's ability to make a perceptual distinction between the two fricatives. As for the production data, we examined the perception responses for each position in the word.

### **3. Results**

#### *3.1. Results of production tests*

Shown in Figure 1 are the overall mean percent correct scores for productions in the pre-training and post-training tests. The data are displayed as a function of

morphological context (basic and derived) and position in a word (initial, medial and final).

**Figure 1.** Mean correct productions of the /s/-/ʃ/ contrast before and after training. Error bars indicate one standard error.

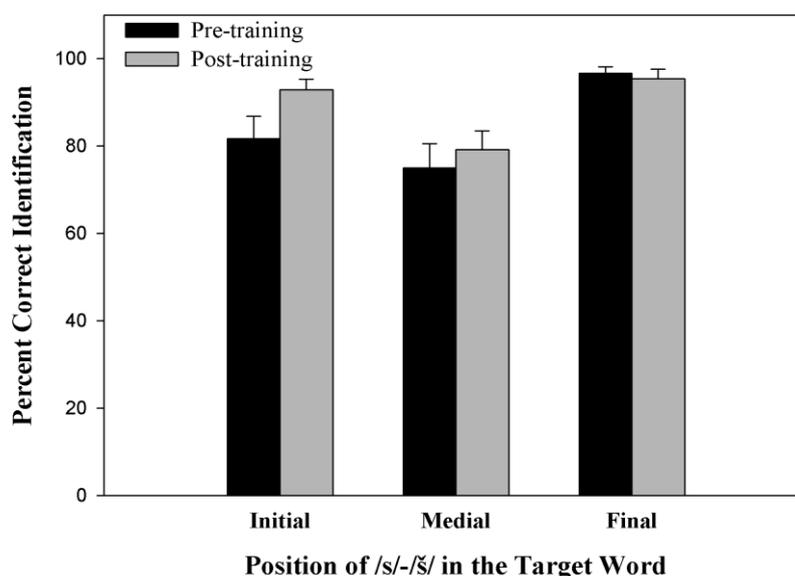

The production data were first analyzed using a two-way repeated measures ANOVA with the factors stimulus condition (initial\_basic, medial\_basic, final\_basic and medial\_derived) and test time (pre-training and post-training). The results showed a significant effect of stimulus condition ( $F(3,27)=20.65$ ,  $p<.001$ ,  $\eta^2=.696$ ), indicating that the percentages of correct productions in the medial and final basic contexts were significantly higher than in either the initial basic or medial derived conditions. The main effect of training on speakers' production just failed to reach significance ( $F(1,9)=4.88$ ,  $p=0.54$ ,  $\eta^2=.352$ ), primarily because there was very little improvement in either the final basic or medial derived positions. There was no significant stimulus condition by test time interaction.

Looking at only the basic contexts using a two-way repeated measures ANOVA with the factors position (initial, medial and final) and test time we find a significant effect of training ( $F(1,9)=9.89$ ,  $p=.012$ ,  $\eta^2=.523$ ), with the greatest improvement found in the production of /s/ and /ʃ/ in initial position. There was a significant main effect of position as well ( $F(2,27)=14.18$ ,  $p<.001$ ,  $\eta^2=.612$ ). The percentage of correct productions was significantly lower in initial position than in either medial or final position.

Of particular interest in the current study is the effect of the occurrence of the fricative in a derived vs. basic word. A two-way repeated measures ANOVA with the factors morphological context (basic medial and derived) and test time of the production data in medial position only showed a significant effect of morphological context ( $F(1,9)=52.51$ ,  $p<.001$ ,  $\eta^2=.854$ ) but no significant overall training effect or morphological context by training interaction. Matched-pairs t-tests showed that speakers did have a higher percentage of correct productions following training for the basic condition ( $t(9)=2.44$ ,  $p=.037$ ) but not for the derived condition ( $t(9)=.192$ , n.s.).

### 3.2. Results of perception tests

Each set of identification tests (in the no-masker, the babble, and the noise condition) was analyzed using the appropriate repeated-measures ANOVAs with the factors position and test time, with the additional factors babble-to-noise or signal-to-noise ratio in the later two conditions. Note that all tokens in which the target fricative occurred in medial position were derived words and the remaining tokens were basic words.

**Figure 2.** Mean correct identification of the /s-ʃ/ contrast in no-masker condition before and after training. Error bars indicate one standard error.

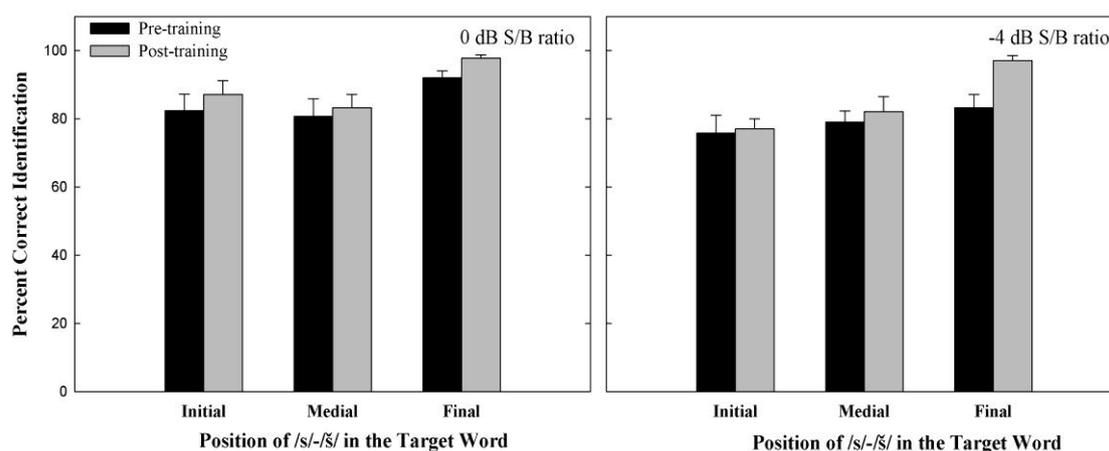

#### 3.2.1. Identification in no-masker condition

The no-masker identification task represents the perceptual condition that makes the least demands on the perceptual system and should show the best listener

performance. Shown in Figure 2 are the mean percent correct identifications of the fricatives in three different positions both before and after training. There was a significant effect of position ( $F(2,18)=17.9$ ,  $p<.001$ ,  $\eta^2=.666$ ), indicating that listeners had the lowest percentage of correct identifications in medial (derived) position (77%). There was also a main effect of test time ( $F(1,9)=6.18$ ,  $p=.035$ ,  $\eta^2=.407$ ). Overall, subjects improved in their identification of /s/ and /ʃ/ following training by an average of 5%. However, this must be evaluated in light of the significant test time by position interaction ( $F(2,18)=4.73$ ,  $p=.022$ ,  $\eta^2=.345$ ). Matched-pairs t-tests showed that listeners improved significantly after training only in initial position ( $t(9)=3.42$ ,  $p=.008$ ). There was no significant improvement in final position ( $t(9)=0.61$ , n.s.), but this was likely because listeners were already close to ceiling performance (over 95% correct) before training. Again, as in the production tasks, the performance was poorer in the medial (derived) position compared to the positions in the basic environment.

### 3.2.2. Identification in babble masker condition

The target-in-babble condition represents a more challenging testing condition for the listener than does the no-masker condition as it adds a masker. In particular, since babbling is a combination of different talkers producing speech (or speech-like) sounds, babbling may introduce both energetic masking (i.e., “noise” at speech frequencies) and informational masking (linguistic content).

**Figure 3.** Mean correct identification of the /s/-/ʃ/ contrast in target-in-babble condition before and after training. Error bars indicate one standard error.

Shown in Figure 3 are mean percent correct identifications of the fricatives in three different positions in the word both before and after training. The left panel
