presents the responses in the 0 dB S/B ratio condition and the right panel presents the responses in the -4 dB S/B ratio condition.

As might be expected due to the increase in masking energy, the percentages of correct identifications were, overall, significantly lower (by 5%) in the -4 dB S/B condition than in the 0 dB S/B condition ( $F(1,18)=16.96$ ,  $p=.003$ ,  $\eta^2=.653$ ). There was also a significant main effect of position. The percentage of correct identifications of fricatives in the final position (92.6%) was significantly higher than the identification of fricatives in either initial (80.6%) or medial (derived) position (81.3%). The latter two positions did not differ significantly from one another.

There was an increase in the percentage of correct responses (5%) following training ( $F(1,9)=6.00$ ,  $p=.037$ ,  $\eta^2=.400$ ). However, the effect of training was strongest for final position in the -4 dB S/B condition (14%), producing a significant training-by-position interaction ( $F(2,18)=3.55$ ,  $p=.05$ ,  $\eta^2=.283$ ). None of the other interaction effects was statistically significant. These data continue to demonstrate that subjects had greater difficulty correctly producing and perceiving these fricatives in initial and medial (derived) positions. Conversely, their performance was significantly better when the fricative occurred in final position.

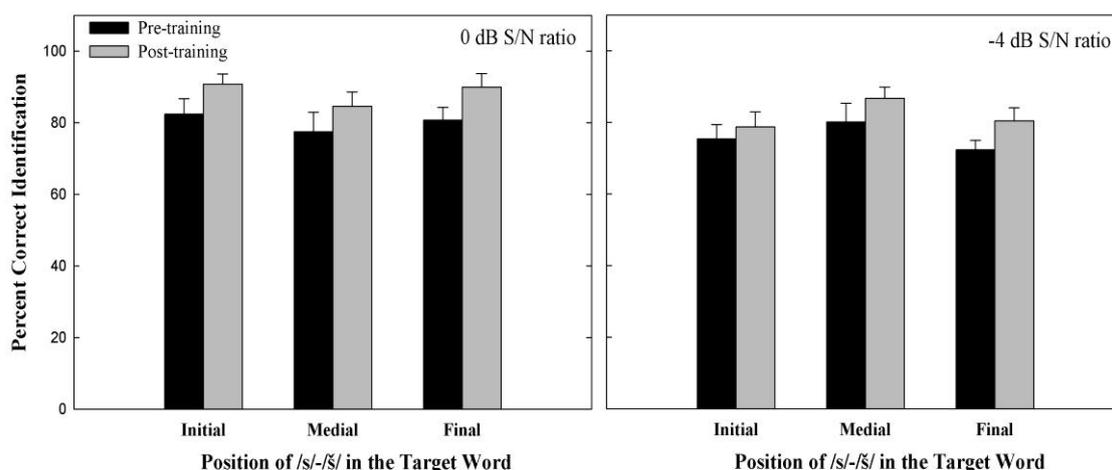

### 3.2.3. Identification in noise masker condition

The target-in-noise condition also presents a more challenging testing condition for the listener than does the no-masker condition. However, the noise masker is different acoustically from the babble masker. In the target-in-noise condition, the masker is Gaussian noise whose energy is spread across the spectrum (and not concentrated in the frequency range of human speech). The addition of “white noise” represents the introduction of energetic masking only (without any linguistic content whatsoever). The difference between the two maskers (babble and noise) almost certainly accounts for the different patterns we find in the perceptual responses.

Shown in Figure 4 are mean percent correct identifications of the fricatives in three different positions both before and after training. The left panel presents the responses in the 0 dB S/N and the right panel presents the responses in the -4 dB S/N ratio condition.

A three-way repeated-measures ANOVA of these data with the factors test time, position and S/N level revealed a significant effect of S/N level ( $F(1,9)=15.68$ ,  $p=.003$ ,  $\eta^2=.635$ ) and training ( $F(1,9)=10.01$ ,  $p=0.01$ ,  $\eta^2=.527$ ). Identification performance improved by 7% following training and was 5% better in the 0 dB than the -4 dB condition. However, for these data, the main effect of position was not significant.

Instead, there was a significant S/N level by position interaction ( $F(2,18)=20.46$ ,  $p<.001$ ,  $\eta^2=.695$ ) produced by the fact that the identifications of the fricatives in medial (derived) position were significantly better than expected in the -4dB condition. In fact, the mean percent correct identification of the fricatives in medial position was actually higher in the -4 dB condition (83.4%) than in the -0 dB condition (81.0%). It is important to examine each of these S/N conditions separately in order to understand better this unexpected outcome.

**Figure 4.** Mean correct identification of the /s/-/ʃ/ contrast in target-in-noise condition before and after training. Error bars indicate one standard error.

The pattern of responses in the 0 dB S/N condition matches many of the patterns that we found in the production data and in the perception results for the no-masker and target-in-babble conditions. Namely, the mean percent correct was lower in the medial (derived) condition (81%) than in either initial (86%) or final position (85%). This was true for data collected both before and after training.

The pattern of responses in the -4 dB S/N condition does not match earlier patterns in an important way. Although, as expected, the mean percent correct identifications for initial and final positions drop (by 9%) for both positions in the -4 dB S/N condition compared to the 0 dB S/N condition, mean percent correct identifications actually improve by 2% in the -4 dB S/N condition for medial (derived) position. The anomalous behavior in the -4 dB S/N condition can be explained, we believe, by more closely examining the acoustic characteristics of the target stimulus (/s/ and /ʃ/), the nature of the masker and the likely strategies used by the listeners in the identification tests.

Phonetically, both /s/ and /ʃ/ are voiceless, sibilant fricatives. Acoustically, these two fricatives differ primarily in terms of their spectral mean (/s/ has more energy in the higher frequencies than does /ʃ/). The babble masker will include spectral energies across the speech range (and the talkers in the background babble are producing the entire range of English speech sounds). The noise masker, on the other hand, is actually more like the fricatives themselves in that it represents acoustic noise. In the no-masker and babbling conditions we are assuming that listeners are making their decisions on the basis of a linguistic judgment (i.e. whether there is an /s/ or an /ʃ/ in the word). The lower performance of listeners in the medial (derived) position (even after training) matches their difficulties as speakers in producing these fricatives in the same derived context.

Although listeners are likely making decisions on a linguistic basis in the 0 dB S/N condition, one can explain the anomalous pattern of identifications by suggesting that, in the -4 dB S/N condition, the present listeners have adopted a non-linguistic strategy in making their identification decisions. In particular, they may have been listening to the nature of the noise and when they heard a higher-pitched noise embedded in the noise masker, they responded with /s/ and when they heard a lower-pitched speech noise, they responded with /ʃ/. Why would this occur for only the medial (derived) fricatives and not the initial and final fricatives? The answer is that the rms levels (a measure of mean amplitude) of the fricatives in the medial (derived) position are approximately 7 dB higher than the fricatives in either the initial or final position. Thus, the strategy will benefit listeners when the fricative is in medial position, but not when it is in initial or final position.

#### **4. Discussion**

This study examined the relationship between production and perception of English fricatives /s/ and /ʃ/ by native speakers of Korean along linguistic variables (morphological context and position in a word) and as a function of subject's training. The results indicate a close relationship between production and perception for the above factors in most of the testing conditions.

The production data indicated a positional asymmetry, which was manifested in significantly lower accuracy in initial position in a word for the basic environment and in medial position for the derived environment as compared to medial and final positions in the basic environment. Moreover, for the two positions in which the

accuracy was lower, the improvement with training was found only in the initial basic position and not in the derived. This indicates that the English fricatives in initial position in a morphologically basic word are difficult to produce by a Korean speaker, which is comparable with a difficulty encountered in a morphologically derived context. However, while the pronunciation in initial position improved with training, the production in the derived context remained essentially the same. Conversely, fricatives in the medial and final positions in a basic word were produced with greater accuracy, which was reflected in high number of correct classifications by a transcriber who was a native speaker of American English. The question arises whether the asymmetry in production is matched in the perception results from the same subjects.

Although we can compare the production and perception data only for selected positions in a morphologically basic word due to the lack of the medial position in the present design, we still find a correspondence between the lower performance in initial position in production and poorer identification in this position in perception. Furthermore, both the production and perception were significantly better in the final position in a word. As for the derived context, the production and perception results show again a close match in that the accuracy in both tasks was significantly lower. Finally, as was found for the production data, the improvement with training in perception was most evident in the word-initial position.

It needs to be pointed out that this close production-perception relationship was found only when the perception stimuli were delivered in the no-masker condition, i.e., when no distortion was introduced to the speech signal. When the target stimuli were presented in a multitalker babble, we found some variation in this pattern. In particular, although the identification was again highest in final position in a basic word, the improvement with training was also significant in this position. Unlike for the no-masker condition, no improvement was found in initial position when target stimuli were presented in a babble masker. However, listeners continued to show lower accuracy in initial and medial (derived) positions, which is consistent with the pattern observed for the no-masker condition.

Using noise as a masker introduced yet another type of variance to the general pattern found thus far in perception. Most importantly, there was no significant effect of word position, indicating no difference in the accuracy of identification of the fricatives across all positions and morphological contexts. Another discrepancy was found in the -4 dB condition, where the percentage of correct identifications significantly increased in medial (derived) position. This anomalous effect can be explained on the basis of differences in processing of a fricative sound in background noise as opposed to

background babble, as already discussed. Another discrepancy between the target-in-noise condition and the two other listening conditions lies in the significant improvement after training in all positions in a word, not only in selected positions (either initial or final). This improvement was observed in both 0 and -4 dB S/N conditions.

In summary, the present data support the existence of a production-perception link in the acquisition of segmental contrast in a second language. However, this relationship may not be manifested in all testing conditions and, especially in perception, listener behavior may depend on other than linguistic factors in processing the second language sound. We have observed a departure from the general pattern of a close match between production and perception when the fricatives were presented with background noise. This environmental factor “successfully” interfered with the linguistic processing of both fricatives so that the positional asymmetry found in other testing conditions was to a great extent lost in the target-in-noise condition. This result suggests that for some types of speech sounds, the acoustic content and distribution of spectral energy may contribute to increased confusion or to unexpected improvement in performance. This may happen when the listener is uncertain about the source of the noise, i.e., linguistic or environmental, when attending to a speech signal which itself contains a great portion of noise, such as fricatives and aspirated stops.

The lower accuracy in word-initial position, both in production and perception, was an unexpected finding in the present study. It has been widely accepted that word-initial position is the strongest and most salient, so that a consonant in this onset position tends to be acquired earlier than a consonant in the final position (or coda position in a CVC syllable structure). The syllable-initial position is often linked to early babbling, which is composed mostly of CV syllables (Locke, 1993). A consonant in the coda (and not in the onset) tends to be deleted or mispronounced in early child language (Smith & Stoel-Gammon, 1983; Vihman, 1996). Similarly, second language learners were shown to produce more errors in word final position than in word initial position (e.g., Flege & Davidian, 1984). The current results clearly depart from this established view.

However, a possible explanation of the present outcome may be linked to models of lexical access which emphasize the importance of word initial information for word recognition (e.g., Cole & Jakimik, 1980; Walley & Metsala, 1990, Vitevich, 2002). Accordingly, word initial information is essential for activating words in lexical processing, which stresses the importance of accurate production of initial consonants. It has been shown that errors in word initial position produced by second language

speakers are more detrimental to word intelligibility for native speakers of a language than errors in word final position (Bent et al., 2007). The present second language listeners had reduced ability to make a distinction between minimally contrastive words when the contrast was in word-initial position, indicating that the contrast between the two fricatives may not have been yet fully acquired. Consequently, they might not have developed lexical representations of English words which contrast /s/ and /ʃ/ word initially and their perceptual identification of this contrast was also poorer than in other positions in the morphologically basic word. This possibility must be tested in further experiments, however.

## **5. Conclusion**

This study investigated the ability of Korean L2 learners of English both to produce and perceive the contrast between /s/ and /ʃ/ in derived as well as basic environments. The results show a close relationship between production and perception for each position in the word. This was the case when listeners' perception was tested in no-masker listening condition. The perceptual responses did not always match the production pattern when the stimuli were presented in background babble or noise, which introduced considerable distortion to the signal. However, this outcome can be somewhat expected in the case of L2 learners.

Of particular interest here is the close production-perception relationship found for the contrast occurring across a morpheme boundary, i.e. in derived environments. This indicates that learners' perceptual response corresponds to their ability to produce the contrast in this difficult position. An unexpected finding of the study was that the current learners seemed to acquire the contrast in word-final position (in a syllable coda) before they acquired the contrast in the initial position (in a syllable onset). Although this matter warrants further investigation, it is noteworthy that this pattern was reflected again in both production and perception of the contrast, showing that these two systems are closely related.

Macau, China  
robts@umac.mo

## **Abstract**

This paper studies the didactic materials of Portuguese as a foreign language (PFL) and the building of textual competence. Our work is developed in the context of the Luso-Chinese schools – official schools in Macau. We consider that the classroom is a social situation constructed by a particular type of interaction. Therefore we adopt the theoretical approach of the Interactional Sociolinguistics. We assume that the discourse of the teacher in foreign language classes has to be viewed as didactic materials. Consequently, it needs to be planned, aiming the development of the textual competence. To undertake this study, we analyze the teacher's discourse, applying the ethnographic method of qualitative analysis, based on two concepts: textual cohesion and coherence.

**Key-words:** textual competence, didactic materials, Portuguese as a foreign language, discourse of the teacher, cohesion, coherence

## **1. Introduction**

### *1.1. A glimpse of the History of the Portuguese language in Macau*

Macau is a Special Administrative Region in China. In 1557, Portugal established the first settlement in Macau. Since then, the presence of the Portuguese language and culture and the cross-cultural contact with the Chinese community created an idiosyncratic environment. It is not our objective, in this paper, to explore the nature of this relation. For us, it is sufficient to understand that Portugal had the administrative power under this region and it is impossible to ignore its presence. Because of this cross-cultural relationship, the basis of the cultural and social organization is formed by three principal groups: the Chinese, the Portuguese and the Macanese (descendants of the miscegenation between Portuguese and Asian women).

Despite the presence of this European nation, the teaching and imparting of the Portuguese language has only recently become a central concern. Because of, but not limited to, this aspect, the Portuguese language could never be a widely used language in Macau. It was always employed in very particular contexts.

In 1999, the Portuguese government gave back the administration of Macau to China. Now Macau is known as a SAR (Special Administrative Region) in China and the government system will be maintained until 2049.

In the contemporary context, however, the status of the Portuguese language has changed within the past decade. Now more and more people, especially from mainland China, are interested in learning the Portuguese language. The major reason behind this change is not cultural but basically economical.

The government of Macau has a group of official schools called Luso-Chinese which offer kindergarten, primary and secondary levels. In all levels, from kindergarten 3 (preparation for the primary level) to the secondary level, the curriculum offers Portuguese language classes. Therefore, these schools can have an important role in the preparation of specialized professionals in the field of Portuguese language: teachers, translators and interpreters.

Our research context takes place within this context.

### *1.2. Teaching Portuguese language in Macau' context*

I have participated in various activities concerning the teaching of Portuguese in Macau, both as assessor and as well as coordinator.

Through that experience I was able to observe that the state of affairs regarding the teaching of Portuguese in Macau is rather complex. Apart from the sociocultural environment, one of the central points of this situation is the didactic materials in use.

Didactic materials may provide significant information on the practical teaching of foreign languages. It is fundamental for our paper to state here that we consider the discourse of the teacher, also, as didactic material – one of the most important.

Based on a set of pedagogical activities to which I had access, I noticed that the materials (including the teacher's discourse) do not reveal concern with the development of textual competence (oral or written). Textual competence is the ability to construct adequate texts to each particular social contexts in which interactants are. Without it, we cannot interact with competence in a language.

Therefore, the research will, consequently, deal with investigating the discourse of the teacher as didactic material in the development of textual competence of the students.

## **2. Theoretical base**

### *2.1. Interactional Sociolinguistics*

The theoretical basis of our research builds upon interactional sociolinguistics (Silva, 2004; Ribeiro e Garcez, 2002; Schiffrin, 1994; Tannen, 1984; Gumperz, 1982a/b; Goffman, 1967] 2002), which analyzes language in its use, as a living organism, within society.

Interactional Sociolinguistics has its roots in linguistics, in sociology and in anthropology. Therefore, in our study, language, society and culture are engaged.

Given the above, it is essential that the teacher be aware that, culturally, Portuguese has its specific features and uses, like any language. Thus it is essential to deeply immerse oneself into the culture that involves this language, in order to learn the language and interact in it appropriately.

This means that it is very important to show to students the social and cultural meanings of the language that they are learning. For example, the Portuguese word “desculpa” (sorry or excuse me) is applied in different situations and it is connected to learning politeness in various Lusophone cultures. Therefore, it is not only “a word” it is “a world” that the students are facing. In this way, it is not adequate to teach this and

other linguistic aspects out of a cultural and social context. The context informs us about the socio-cultural rules which determine the use of the language.

At the same time, the teacher cannot forget to take into consideration the culture of the students; in our case, the Chinese culture (Watkins & Biggs, 1999; Kelen, 2002): to teach is also a cross-cultural event.

By importing these perspectives to an educational context, what is sought, in the teaching and learning of a language, is the development of the communicative competence (Hymes, 1972), comprised of a set of knowledge.

Considering that language is interaction, then in teaching it is not feasible to merely focus on, for example, linguistic structural knowledge. It is necessary to be aware of the different knowledge that surrounds the interaction by language.

It is, thus, necessary to know the system of language – the grammar rules that differentiate it from other languages; one also needs to have a knowledge of the world, of the set of experiences that guide us in relation to what things are (or what we are told they are supposed to be), of how to act and how we expect the others to act towards us at every interaction; and further, we need to have the interactional knowledge which will help us to mold language appropriately to the interactional situations we may find ourselves in.

As part of the interactional knowledge, there is the *supra-structural knowledge*, which deals with textual genres (letters, poems, C.V., dialogues). Each interaction implies the use of a different genre of text (oral and written); the interaction will determine the most appropriate in order to achieve the desired effect (Koch, 2004 & 1994).

It should be noted that the interactional knowledge is an important contribution to the creation of didactic materials, as well as in the assessment process of the learners' productions. We believe that the discourse of the teacher needs to be carefully prepared under an interactional approach. The teacher who can have access and discuss this type of theories will, undoubtedly, be better prepared to build a more appropriate vision of language and of teaching. This will allow the educator to be able to interact qualitatively with his/ her students.

Based on the consideration of all of this knowledge, I will focus on the building of textual competence, studying the *supra-structural knowledge*.

## 2.2. What is a text?

First of all, it is necessary to understand two concepts: *text* and *discourse*.

Some discussions indicate that *text* is what we can call a *concrete linguistic object* with its limits. It is the “material manifestation of the discourse” (Verdonk, 2002:17), constructed by a number of words and sentences, structured according to general rules.

The discourse, on the other hand, is the language in use; texts are produced in singular contexts and, thus, can make sense. In this point of view, discourse is constructed through texts. The type and genre of texts are created according to various kinds of discourse that we must use in different concrete interactions. “The process of activation of a text by relating it to a context of use is what we call *discourse*” (Verdonk, 2002:18).

Here, however, we will consider that this separation of concepts is inadequate. Text as “material manifestation” actually does not exist. What exists are the real situations and the discourse that we produce in order to interact within society. Any linguistic element of this “concrete object” is chosen according to real necessities of communication, according to contexts. Thus, it does not seem adequate to separate the concepts.

Here we will use *text* and *discourse* synonymously. We will consider that they are organized through two principles: coherence and cohesion.

### 2.2.1. Cohesion

Cohesion can be classified into two types: referential and sequential. The first is related to textual elements that make references to other elements in a text. The second is related to linguistic processes that establish semantic and pragmatic connections among the sequences of a text (Koch, 1991).

Cohesion is related to the superficial organization of the sequences of the texts. However, it is not sufficient to give textuality to sequences of a language: the coherence is responsible for the textuality. The coherence transforms a single word into a text.

### 2.2.2. Coherence

Coherence can be studied in different perspectives. There is the intratextual coherence (semantic and syntactic); for example, the choices of words, the adjusted syntax organization. But there is, as well, a global coherence, that we will call pragmatic coherence. In our paper, we will observe the second type of coherence. Therefore, in order to undertake our objectives the context is the key. Koch (2004) says that “o recurso ao contexto é indispensável para a compreensão e, deste modo, para a construção da coerência textual”<sup>1</sup>.

The meaning of the texts is not basically inside that *concrete object*, the material manifestation of the discourse, but within discourse (text + context). It appears based on the interaction in written and oral situations. As Koch (ibidem) claims:

(...) o tratamento da linguagem, quer em termos de produção, quer de recepção, repousa visceralmente na **interação produtor - ouvinte/leitor**, que se manifesta por uma antecipação e coordenação recíprocas, em dado contexto, de conhecimentos e estratégias cognitivas.

Desta forma, a explicitude de um texto deve ser avaliada em termos da interação entre produtor e leitor/ouvinte tal como mediada pelo texto (Nystrand & Wiemelt, 1991)<sup>2</sup>.

That is why the context is fundamental for producing and understanding texts. We will discuss some of the aspects involved in the contextualization.

---

<sup>1</sup> “the context is indispensable for the understanding and, thus, the construction of the textual coherence.”

<sup>2</sup> (...) using/studying/approaching language, both in terms of production and reception is strongly connected to the interaction between producers and listeners/readers. This interaction shows us a reciprocal anticipation and coordination of knowledge and cognitive strategies. Thus, the explicitness of a text should be evaluated in terms of interaction between producers and listeners/readers as mediated by the text (Nystrand & Wiemelt, 1991).

### 3. Contextualizing our data

Our data comes from a video-recorded lesson of a 1st grade class in an official primary school in Macau. The interaction between teacher and students is our object of study. We will analyze an excerpt from the fifth class.

**Content of the class:** expressions of the Portuguese Language:

<b>In Portuguese</b>	<b>Literal translation in English</b>
Bom dia	Good day/ good morning
Boa tarde	Good afternoon
Boa noite	Good night/Good evening
Adeus	Good bye
Obrigado/a	Thank you
Desculpa	Sorry / excuse me
Posso entrar?	Can I come in?
Posso sair?	Can I leave?

#### **Interactants:**

- Students :
  - 22 Chinese students, around 06 years old, native speakers of Cantonese and Mandarin;
  - 01 Filipino student, around 06 years old, native speaker of Tagalog.
- Teacher:
  - 01 Chinese teacher of PFL, bilingual, native speaker of Cantonese.

#### **Didactic materials:**

- Pictures/Images;
- A puppet;
- Audio-Cassette.

In class – especially at the beginning of the academic year – the teacher uses both Portuguese and Chinese (Cantonese). In our data, when the teacher and students are speaking in Portuguese we have a regular transcription. When the teacher or students speak in Cantonese, the transcription (which is a translation from Cantonese) is made in ***bold and italic***.

The examples are indicated as follow:

- Class/page/line, for example: 05/01/30;
- ↑↓ - indicates that the excerpts are in sequence.

### 4. The discourse of the teacher

First, let us see the excerpt that we have chosen for our analysis.

#### *4.1. The excerpt*

**05/01/38-58 (class 05, page 01, lines 38 to 58)**

38.	Roberta	Sim! Olá! (a professora passa a falar através do fantoche, um porco)	Yes! Hello! (the teacher starts to speak through a puppet, a little pig)
39.	Alunos	Olá!	Hello!
40.	Roberta	Hoje eu vou apresentar algumas expressões.	Today, I am going to present some expressions.
41.	Roberta	<b><i>Vou ensinar algumas expressões!</i></b>	<b><i>I am going to present some expressions!</i></b>
42.	Roberta	<b><i>Ora!</i></b>	<b><i>Well.</i></b>
43.		(A Roberta coloca um desenho no quadro.)	(Roberta puts an image on the board.)
44.	Roberta	<b><i>Ora! Vocês sabem o que significa este desenho?</i></b>	<b><i>Well. Do you know what this image means?</i></b>

50.	Roberta	<i>Ora bem, vamos ouvir a terceira expressão.</i>	<i>Well, let us listen to the third expression.</i>

Considering that the language classroom is a space for interaction and also considering that for interactions we need to use texts, let us observe the organization of the discourse of the teacher. For the theoretical discussion of this excerpt, we will reflect upon what is necessary in order to produce texts through the concepts of cohesion and coherence.

#### 4.2. Aspects of cohesion

##### 4.2.1. Conjunction and enumeration

In a class, we should have two clear movements:

- the text of the teacher (that should generate the organization of the lesson and that should help to generate/stimulate the discourse of the students);
- and the text of the students (that should be constructed in the class in order to make them able to create texts and, thus, to interact in PFL).

These two movements are the base of the texts that teachers and students need to construct in the classroom interaction

As we could see in the above excerpt, the cohesion of the discourse of the teacher was constructed by the use of the coordinating conjunction “and” as well as enumerations.

- 05/02/10 – E agora, vamos ver. / And now, let’s see.
- 05/02/50 – Vamos ouvir a terceira expressão. / Let us listen to the third expression.

- 05/03/34 – E agora, o que é que eles estão a fazer? / And now, what are they doing?

The choice of the conjunction “and”, in addition to the “enumeration”, indicates that the discourse in construction aims to make a list of elements. As the teacher says, she wants “apresentar algumas expressões / present some expressions” (05/01/41). Therefore, we can see that the objective for the class is to teach a group of linguistics resources to the students.

A list is a genre of text. For example, when we go shopping, we prepare a list for the supermarket. Similarly, when we have many things to do at work, we can make a list of tasks etc. In these contexts, the lists are texts. Each element of the lists makes sense and is related to the others.

In the situation of that class, the list of expressions taught could be united in a text as well. However, here, those expressions are unrelated. The way they are shown indicates a complete independence between them. They do not have any kind of relation, nor are they applied in a real context of use. They do not contribute to the development of textual competence because there is no text.

The teacher’s discourse in this case is the text that she uses to organize the class: “Hoje, eu vou apresentar algumas expressões. /Today I am going to present some expressions”(1/41). She explains to the group what she intends to do: to teach some linguistic elements.

Supposedly, such discourse intends to give elements that are necessary for the students to learn and to apply in the creation and development of texts.

Nevertheless, the list of expressions is presented without any connection. They are independent elements. There is no cohesion among them.

#### 4.2.2. Repetition

In the teacher’s discourse, there is yet another important cohesive resource: the use of repetition.

This resource is extensively used by the teacher. She asks the students to repeat the list of expressions twice. It seems as though her repetition could help the students to understand the meaning and social contexts in which they could apply such expressions. This shows us about the beliefs of the teacher about what it means to teach a foreign language. However, repetition does not guarantee comprehension.

Here we can see a moment in which the students are trained to repeat.

After showing the 08 expressions, the teacher says:

- 05/06/12 Ora, vamos rever. / Well, Let us review.
- 0510/19 Primeiro, vamos rever, vamos rever. / First, Let us review, let us review.

Repetition is linked to memorization. Memorization can be a learning/teaching strategy, but it certainly is not the more adequate pedagogical resource in order to achieve social or cultural meanings in language interaction.

This resource also does not help the student to understand how to organize a text in Portuguese.

#### 4.2.3. Summary

To summarize, the discourse of the teacher is essentially fragmented. It has a type of cohesion that indicates that she will present a list. The teacher does not create a discourse in which the linguistic elements exist as active elements in real context of use. Each element is presented without any kind of significant linguistic link with the others.

The elements are not organized as a text. Therefore, there is no cohesion between them. As results, the students did not have contact with a text, thus they could not produce an oral discourse. They did not have the opportunity to start to construct their textual competence. As we can observe, a simple juxtaposition of sequences (expressions) does not guarantee textuality.

#### 4.3. Aspects of coherence

The text will be incoherent if the speaker/writer does not know how to adapt it to the situation. It is necessary to take into consideration the communicative intention, the objectives, the interactants, the socio-cultural rules, other elements of the situation, linguistic resources and so on (Koch, 1994).

The concept of coherence is not linked to linguistic forms (words, sentences, types/genre of texts... expressions.). It is linked to the process of interaction; it is linked to the concept of context.

Therefore, to present forms, or to present expressions, does not help in understanding texts. The meanings come from the relation between texts in contexts and interactants in concrete situations (real or fictitious).

In our data, when the teacher is presenting the expression “boa tarde / good afternoon”, she tries to contextualize the expression, using images and translations.

The image show us two students on a table, eating. Beside the table, there is a woman standing and looking at them. Above them, on the wall, we can see a clock: the time is 12:40.

Let us see what happened in the dialogue of the teacher with the students. She shows the image to the class.

#### 05/02/10-22

10.	Roberta	Ora bem! E agora? Vamos ver.	Very well! And now? Let us see.
11.	Aluno	(ruído) Fa/	(noises) Fa/
12.	Roberta	O que, o que é que eles estão a fazer?	What are they doing?
13.	Aluno	(ruído)	(noises)
14.	Roberta	Ah?	Ahn?
15.	Roberta	Estão a comer.	They are eating.
16.	Roberta	<b>O que significa esta expressão?</b>	<b>What does this expression mean?</b>
17.	Roberta	<b>Já aprendemos.</b>	<b>We have already learned.</b>
18.	Roberta	(??)	(??)
19.	Alunos	Professora	Teacher.
20.	Roberta	Professora?	Teacher?
21.	Alunos	Boa tarde.	Good afternoon.
22.	Roberta	Boa tarde.	Good afternoon.

The first thing that the students can identify, looking at the image, is the woman standing like a teacher.

Let us follow the rest of the dialogue.

05/02/23-39

23.	Roberta	Boa tarde?	Good afternoon?
24.	Roberta	Vamos ouvir!	Let us listen!
25.	Aluno	Bo-a tar-de.	Good – after – noon.
26.	Roberta	<i>Vamos ouvir está certo?</i>	<i>Let us listen and check if it is correct.</i>
27.	Aluno	Boa tarde	Good afternoon.
28.	Cassette	2.	2.
29.	Cassette	Boa tarde.	Good afternoon.
30.	Roberta	Bo-a tar-de!	Good – after – noon!
31.	Aluno	Ehhh! (fica animado porque está certo)	Yeah! (a student feels very happy with the positive answer)
32.	Roberta	<i>O que é significa “Boa tarde”?</i>	<i>What does “good afternoon” mean?</i>
33.	Aluno	<i>Almoço!</i>	<i>Lunch!</i>
34.	Roberta	<i>Almoço?</i>	<i>Lunch?</i>
35.	Aluno	<i>Boa tarde!</i>	<i>Good afternoon!</i>
36.	Roberta	Boa tarde! <i>Vamos ver:</i> boa/	Good afternoon! <i>Let us see:</i> good/
37.	Alunos	<i>Boa tarde!</i>	<i>Good afternoon!</i>
38.	Roberta	<i>Vamos ouvir se está certo.</i>	<i>Let us listen if it is correct.</i>
39.	Alunos	<i>Boa tarde!</i>	<i>Good afternoon!</i>

Theoretically, the use of pictures is a very ambiguous resource. It can make the students think that words and things have a cartesian relation. But we know that the meanings are social constructions.

However, pictures can be resources for contextualization of the language. Here, the picture shown does not help the students. The picture guides them to understand the meaning “lunch”.

The teacher asks “what does ‘good afternoon’ mean?”. But the correct answer does not appear. Actually, the expression does not have exactly a meaning, but a social function: to express politeness. Only in an appropriate context the students could understand that. The same thing happens with “good night” in another moment during the class; the students answer “to sleep”. The contextualization fails and the influence of the image, here, is fundamental for that.

However, there is a more serious consequence of the example “good afternoon”: there is no relation between the use of this expression in Portuguese and in Cantonese. In Portuguese we can use the expression in many situations when we meet someone (in the street, at home, at work...); in Cantonese, on the other hand, the expression is used only in formal contexts, like at work meetings, for example.

In this way, the literal translation (that the teacher uses very often) is an inadequate resource because the expressions have no social or cultural correspondence.

In summary, the attempt to contextualize made at least two mistakes:

- It gave a wrong cue to understand the basic meaning of the expression (“lunch” instead of “good afternoon”);
- It gave a wrong cue to understand the social and cultural use of the expression.

The instructor does not give useful contextual elements for the students to understand texts in PFL. However, the context (linguistic and extra-linguistic) is essential for understanding and, thus, for the construction of textual coherence.

Without context, her discourse cannot create a text with the students. She talks about the expressions instead of encouraging the students to use the expressions. It is

important to say that she is teaching children. One appropriate strategy is to allow children to experiment before constructing any knowledge.

#### 4.4. Conclusion

It appears that the class was organized by interactive principles. The elements that the teacher has chosen have explicit interactional characteristics. They are not, for example, a group of grammatical information. However, the way that they were presented did not show their interactional characteristic; they did not constitute a text.

The architecture of the class did not work. As we can see in this last excerpt, the students at the end of the class do not know how to apply one of the expressions taught. Instead of saying “Can I leave”, they say “Can I come in”.

05/13/41-49

41.	Roberta	<i>Ora! Todos estão saindo; então como se diz?</i>	<i>Well! Everybody is leaving; then what do we say?</i>
42.	Alunos	Posso entrar?	Can I come in?
43.	Roberta	Posso sair?	Can I leave?
44.	Alunos	Posso sair?	Can I leave?
45.	Alunos	Posso entrar?	Can I come in?
46.	Roberta	Po-ssó... ?	Can I... ?
47.	Alunos	En-trar	Come-in
48.	Roberta	Po-ssó... ?	Can I... ?
49.	Alunos	En-trar	Come-in

The teacher corrects the students, explaining in Cantonese the meaning of “come in”.

05/13/50-55

50.	Roberta	“entrar” é “ <i>entrar</i> ”	“to come in” is “ <i>to come in</i> ”
51.	Roberta	Po-ssó...?	Can I...?
52.	Alunos	Sa-ir?	Lea-ve?
53.	Roberta	Mais uma vez	One more time
54.	Roberta e alunos	Po-ssó sa-ir?	Can I leave?
55.	Roberta	Sim! Podem!	Yes! You can!

The students, therefore, choose the adequate expression. After this, the teacher asks them to repeat again (05/13/53 - “mais uma vez/ one more time”). Then, finally, they repeat the adjusted expression.

Finalizing, in these last examples, we could see that the students did not experience an interaction in Portuguese. They did not have contacts to any particular contexts of language. They were taught a list of expressions which do not make a text. They did know how to apply these expressions. They did not have a cultural experience because they, actually, did not have contact with the new language that they should have been learning.

The class was not organized with the aim to develop textual competence. The students did not participate in a real situation of communication. The type of interaction

was traditional in that the teacher only asks yes/no questions. These kinds of questions do not stimulate interaction because the students do not need to sustain a conversation.

In language classes, if we must learn to adapt texts to different situations, the class is not ultimately successful.

## 5. Final comments

We are in a moment in which the communicative perspective is one of the most debated. And we can see for example this influence in the class analyzed. The linguistic elements that the teacher chose seem to be according to the communicative approach: the expressions are applied for interactions and the title of the lesson is “social interaction”. However, the way that the expressions were presented does not show their interactional characteristic because they do not constitute a text.

They were presented exactly in a traditional way: lists of elements, analysis of the language instead of the usage, no contextualization, no concern about social, cultural aspects and so on.

It is important to say that the teacher is very dedicated to her job. She works hard trying to motivate her students. As she said in an interview, she was trying to use a communicative approach when she was preparing the class. However some beliefs about what to teach a language are making her take some decisions that are not according to a communicative approach.

In consequence:

- The teacher’s discourse is not constructed to generate and stimulate the discourse of the students.
- The language is presented in pieces that make no sense.
- There is no development of the textual competence.

The teacher’s discourse should be constructed as didactic material. It should help students learn how to choose and apply cohesion elements that construct the superficial organization of the text (not explaining, but making them use the language). It should also show how to adjust these elements in order to make coherent texts for each context in everyday life.

When I decided to study the process of teaching-learning of PFL, I was, at the beginning, interested in the progression of the students’ discourse. However, because of the methods applied in classroom, the students could not produce discourse in Portuguese.

Without an appropriate discourse of the teacher, students have many difficulties in learning and, thus, in achieving communicative competence. Therefore, depending on the conditions and on the methods adopted in classroom, it is impossible to undertake a study of the process of learning a foreign language.

As Fabrício (1999:06) claims,

a interação social pode ter um impacto decisivo (facilitador ou impedor) no processo de ensino/aprendizagem (Vygotsky,1978), apontando para a necessidade da investigação dos tipos de interação que são mais favoráveis à aprendizagem.<sup>3</sup>

---

<sup>3</sup> The social interaction can have a significant impact on the teaching/learning process, making it more or less easy

To investigate the interaction in classroom is fundamental. The quality of this interaction is one of the most important elements for the teaching-learning process. Especially, the contact with all types/genres of texts (oral and written) is the way to reach textual competence.

## Abstract

This article presents a lexical database of Dutch, called Cornetto, that is interconnected with corresponding English synsets and a formal ontology. The Cornetto database is based on two existing electronic dictionaries - the Referentie Bestand Nederlands and the Dutch wordnet. The former holds Dutch FrameNet-like information and the latter is structured as the English wordnet. Three different collections are maintained for lexical units, synsets and ontology terms. The database interlinks these collections and clarifies the relations. We describe the work processes, the design and the implementation of new tools. The tools are based on the DEB platform as special dictionary clients for the DEBVisDic wordnet editor and browser. Finally, we discuss the complex relations between the synsets and the ontology.

**Keywords:** Wordnet, Synsets, Lexical Units, Ontologies, databases, editors.

## 1. Introduction

Lexical data and knowledge resources have rapidly developed in recent years both in complexity and size. The maintenance and development of such resources require powerful database systems with specific demands. In this paper, we present an extension of the DEBVisDic environment (Horák et al. 2006) for the development of a lexical semantic database system for Dutch that is built in the Cornetto project. The system holds 3 different types of databases that are traditionally studied from different paradigms: lexical units from a lexicological tradition, synsets within the wordnet framework and an ontology from a formal point of view. Each of these databases represents a different view on meaning. The database system is specifically designed to

create relations between these databases and to allow edit the information in each. It represents a complex editing environment but also a research tool to study the relations between languages, as defined in a lexicon and wordnet, and knowledge, as defined in an ontology.

The paper is further structured as follows. In the Section 2, we will describe the Cornetto project in terms of the design of the database structure and the major editing actions. The Section 3 introduces the DEB platform and the new features that have been introduced for the Cornetto project. Next, we describe the specific client interface for viewing and editing the data in section 4. Finally, we discuss the relation between the lexicon and the ontology in section 5.

## **2. The Cornetto Project**

Cornetto is a two-year Stevin project (STE05039) in which a lexical semantic database was built, that combines Wordnet with FrameNet-like information (Fillmore et al. 2004) for Dutch. The combination of the two lexical resources resulted in a much richer relational database that may improve natural language processing (NLP) technologies, such as word sense-disambiguation, and language-generation systems. In addition to merging the Wordnet and FrameNet-like information, the database was also mapped to a formal ontology to provide a more solid semantic backbone.

The database was filled with data from the Dutch Wordnet (Vossen 1998) and the Referentie Bestand Nederlands (Maks, Martin and Meerseman 1999). The Dutch Wordnet (DWN) is similar to the Princeton Wordnet for English, and the Referentie Bestand (RBN) includes frame-like information as in FrameNet plus additional information on the combinatoric behaviour of words in a particular meaning.

An important aspect of combining the resources is the alignment of the semantic structures. In the case of RBN these are lexical units (LUs, Cruse 1986) and in the case of DWN these are synsets (Fellbaum 1998). Various heuristics have been developed to do an automatic alignment. Following automatic alignment of RBN and DWN, this initial version of the Cornetto database has been extended both automatically and manually. The resulting data structure was stored in a database that keeps separate collections for lexical units (mainly derived from RBN), synsets (derived from DWN) and a formal ontology (SUMO/MILO, Niles and Pease 2003) plus extensions. These 3 semantic resources represent different view points and layers of linguistic and conceptual information. The alignment of the view points was stored in a separate

mapping table. The database was set up so that the formal semantic definition of meaning can be tightened for lexical units and synsets by exploiting the semantic framework of the ontology. At the same time, we wanted to maintain the flexibility to have a wide coverage for a complete lexicon and encode additional linguistic information. The resulting resource is available in the form of an XML database, and can be licensed for free for research. The Cornetto database provides a unique combination of semantic, formal semantic and combinatoric information.

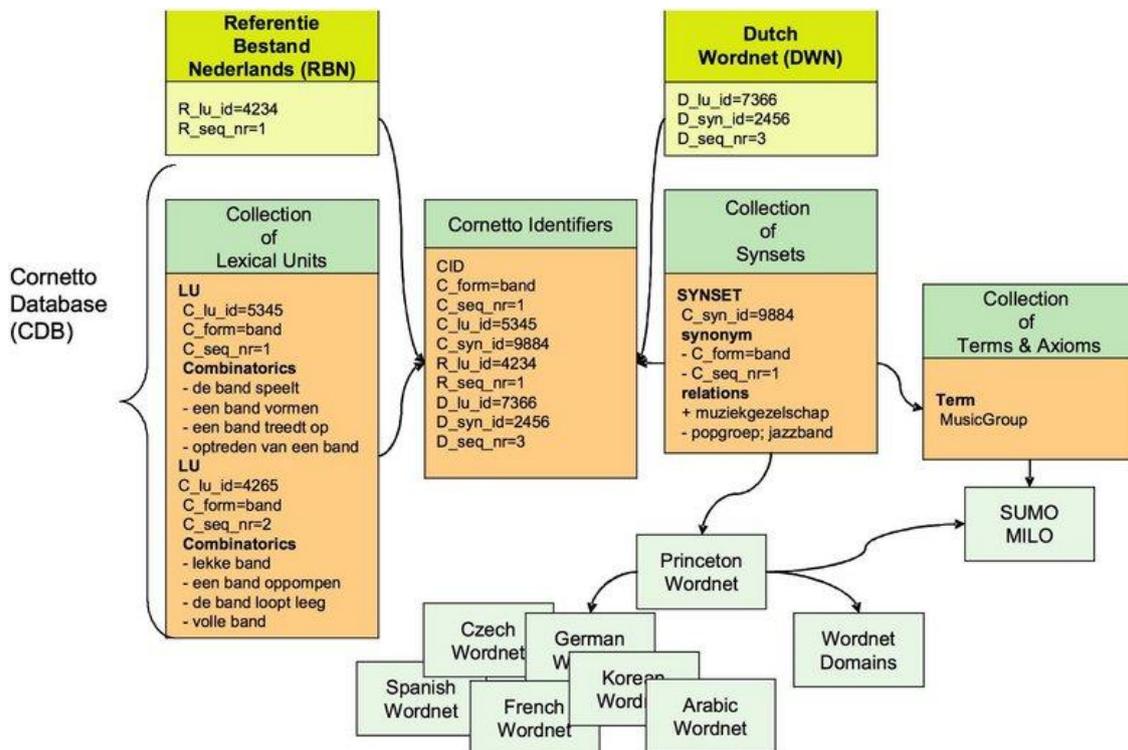

### *2.1. Architecture of the Database*

The Cornetto database (CDB) consists of 3 main data collections:

1. Collection of Lexical Units, mainly derived from the RBN
2. Collection of Synsets, mainly derived from DWN
3. Collection of Terms and axioms, mainly derived from SUMO and MILO

The Lexical Units are word senses in the lexical semantic tradition. They contain all the necessary linguistic knowledge that is needed to properly use the word in a language. The Synsets are concepts (as defined by Miller et al 1991) in a relational model of meaning. Synsets are mainly conceptual units strictly related to the lexicalization pattern of a language. Concepts are defined by lexical semantic relations. For Cornetto, the semantic relations from EuroWordNet are taken as a starting point (Vossen 1998).

Outside the lexicon, an ontology provides a third layer of meaning. The Terms in the ontology represent the distinct types in a formal representation of knowledge. Terms can be combined in a knowledge representation language to form expressions of axioms. In principle, meaning is defined in the ontology independently of language but according to the principles of logic. In Cornetto, the ontology represents an independent anchoring of the relational meaning in Wordnet. The ontology is a formal framework that can be used to constrain and validate the implicit semantic statements of the lexical semantic structures, both the lexical units and the synsets. In addition, the ontology provides a mapping of a vocabulary to a formal representation that can be used to develop semantic web applications. In addition to the 3 data collections, a separate table of so-called Cornetto Identifiers (CIDs) is provided. These identifiers contain the relations between the lexical units and the synsets in the CDB but also to the original word senses and synsets in the RBN and DWN.

**Figure 1: Data collections in the Cornetto database.**

The Figure 1 shows an overview of the different data structures and their relations. The different data can be divided into 3 layers of resources, from top to bottom:

1. The RBN and DWN (at the top): the original databases from which the data are derived;
2. The Cornetto database (CDB): the ultimate database built;
3. External resources: any other resource to which the CDB is linked, such as the Princeton Wordnet, wordnets through the Global Wordnet Association, Wordnet domains, ontologies, corpora, etc.

The center of the CDB is formed by the table of CIDs. The CIDs tie together the separate collections of LUs and Synsets but also represent the pointers to the word meaning and synsets in the original databases: RBN and DWN and their mapping relation.

The LUs will contain semantic frame representation. The frame elements may have co-indexes with Synsets from the wordnet and/or with Terms from the ontology. This means that any semantic constraints in the frame representation can directly be related to the semantics in the other collections. Any explicit semantic relation that is

expressed through a frame structure in a LU can also be represented as a conceptual semantic relation between Synsets in the Wordnet database.

The Synsets in the wordnet are represented as a collection of synonyms, where each synonym is directly related to a specific LU. The conceptual relations between Synsets are backed-up by a mapping to the ontology. This can be in the form of an equivalence relation or a subsumption relation to a Term or an expression in a knowledge representation language. Finally, a separate equivalence relation is provided to one or more synsets in the Princeton Wordnet.

The construction of the database was divided in 4 steps:

1. Automatic alignment of the word meanings of the two resources
2. Import of the result of the alignment into the database
3. Import of the SUMO ontology and WordNet domains to the synsets of the Dutch wordnet
4. Manual revision of the lexical units, the synsets and the ontological mapping

In the next paragraphs, we will discuss these steps briefly.

## 2.2. *Aligning Word Meanings*

To create the initial database, the word meanings in the Referentie Bestand Nederlands (RBN) and the Dutch part of EuroWordNet (DWN) have been automatically aligned. The word *koffie* (coffee) for example has 2 word meanings in RBN (*drink* and *beans*) and 4 word meanings in DWN (*drink*, *bush*, *powder* and *beans*). When we try to automatically align these meanings, we can get a complete match, no match or a partial match between these meanings. This may result in 4, 5, or 6 distinct meanings in the Cornetto database depending on the degree of matching across these meanings. Note that this alignment is different from aligning WordNet synsets because RBN is not structured in synsets. We can for example not use the overlap of synonyms because RBN has no synonyms. For measuring the match, we used all the semantic information that was available in both resources: e.g. definitions and domain labels. The alignment of the word meanings is discussed in detail in Vossen et al. (2008a and 2008b). As a result of the alignment, a new list of lexical units and synsets is generated. All the relevant data for these lexical units and synsets are copied from the RBN and DWN, respectively.

### *2.3. Importing External Data*

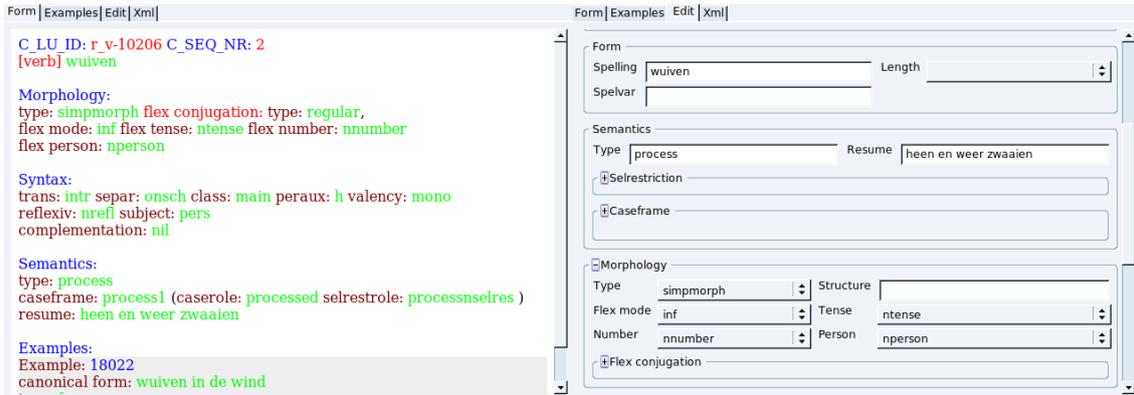

DWN was linked to WordNet1.5. WordNet domains are mapped to WordNet1.6 and SUMO was mapped at that time to WordNet2.0. In order to apply the information from SUMO and WordNet domains to the synsets, we needed to exploit the mapping tables between the different versions of Wordnet. We used the tables that have been developed for the MEANING project (Daude et al. 2003). For each equivalence relation to WordNet1.5, in DWN we consulted a table to find the corresponding WordNet1.6 and WordNet2.0 synsets, and via these we copied the mapped domains and SUMO terms to the Dutch synsets. In the end, the Dutch synsets were mapped to WordNet2.0 and contained imported mappings to both SUMO and WordNet domains. The structure for the Dutch synsets thus consists of:

1. a list of synonyms;
2. a list of language internal relations;
3. a list of equivalence relations to WordNet2.0;
4. a list of domains, taken from WordNet domains;
5. a list of SUMO mappings, taken from the WordNet2.0 SUMO mapping

The structure of the lexical units is fully based in the information in the RBN. The specific structure differs for each part of speech. At the highest level it contains:

1. orthographic form
2. morphology
3. syntax
4. semantics
5. pragmatics
6. examples

A snapshot of this information is given in Figure 2 below, which is a screen dump of the Cornetto client that gives access to the lexical unit data.

**Figure 2: Cornetto Lexical Units, showing the preview and editing form**

#### 2.4. Manual Editing

The aligned data was further manually edited through various cycles of editing. For this purpose, special editing clients have been developed. We will discuss the editing clients in more detail below. The editing process itself consisted of a number of steps, where we focused on different types of information. In the first cycle, we manually verified the alignment of word-meanings. For this purpose, selections of words and word meanings were made. This selection involved the following criteria:

1. Frequent nouns and verbs
2. Words with many meanings
3. Lexical units with a mapping to a synset with a low score
4. Lexical units without a mapping with a synset
5. Synsets with many (low-scoring) equivalence relations to WordNet2.0

During this work, we typically carried out the following actions:

1. Confirm or delete a mapping
2. Create another mapping
3. Split a single lexical unit in two lexical units
4. Merge two lexical units into one
5. Add lexical units or delete lexical units
6. Split a synset unit in two synsets
7. Merge two synsets into one

8. Add synsets or delete synsets
9. Add or delete synonyms to synsets
10. Select a proper WordNet2.0 equivalent
11. Revise the SUMO mapping
12. Revise the WordNet domain mapping

At the end of actions 1-9, we got a new and revised list of senses and mappings to synsets, representing new sense and synset structure of the Cornetto database. Table 1 gives an overview of the final database. For more details on the final database, see Vossen et al. (2008c).

	ALL	NOUNS	VERBS	ADJECTIVES	ADVERBS	NEW SYNSETS/ LEXICAL UNITS
<b>Synsets</b>	70,434	52,888	9,053	7,703	220	570
<b>Lexical Units</b>	118,466	85,278	17,363	15,731	73	21
<b>Lemmas (form+pos)</b>	91,991	70,556	9,055	12,307	73	n.a.
<b>Synonyms in synsets</b>	102,572	74,893	14,091	12,899	84	605
<b>CID records</b>	103,668	75,812	14,093	13,089	484	190
<b>Synonym per synset</b>	1.46	1.42	1.56	1.67	0.38	1.06
<b>Senses per lemma</b>	1.29	1.21	1.92	1.28	1.00	n.a.

**Table 1: Overview data for the Cornetto repositories**

The second phase of the editing involved the relation of the synsets to the ontology (actions 10-12), which will be discussed in more detail in section 5.

### 3. The DEB Platform

The Dictionary Editor and Browser platform (Horák et al 2006) offers a development framework for any dictionary writing system application that needs to store the dictionary entries in the XML format structures. The most important property of the system is *client-server* nature of all DEB applications. This provides the ability of distributed authoring teams to work fluently on one common data source. The actual development of applications within the DEB platform can be divided into the server part (the server side functionality) and the client part (graphical interfaces with only basic functionality). The server part is built from small parts, called *servlets*, which allow a

modular composition of all services. The client applications communicate with servlets using the standard HTTP web protocol.

For the server data storage the current database backend is provided by the Berkeley DB XML (DBXML), which is an open source native XML database providing XPath and XQuery access into a set of document containers.

The user interface, that forms the most important part of a client application, usually consists of a set of flexible forms that dynamically cooperate with the server parts. According to this requirement, DEB has adopted the concepts of the Mozilla Development Platform (Feldt 2007). Firefox Web browser is one of the many applications created using this platform. The Mozilla Cross Platform Engine provides a clear separation between application logic and definition, presentation and language-specific texts.

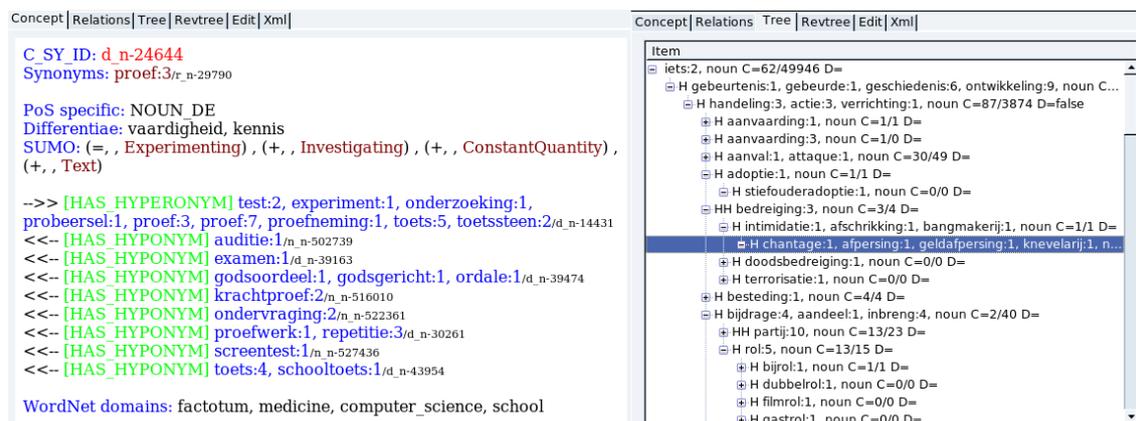

Figure 3: Cornetto Synsets window, showing a preview and a hyperonymy tree

### 3.1. New DEB Features for the Cornetto Project

During the Cornetto project the nature of the Cornetto database structure has imposed the need of several features that were not present in the (still developing) DEB platform. The main new functionalities include:

1. **entry locking** for concurrent editing. Editing of entries by distant users was already possible in DEB, however, the exclusivity in writing to the same dictionary item was not controlled by the server. The new functions offer the entry locking per user (called from the client application e.g. when entering the edit form). The list of all server locks is presented in the DEB administration interface, allowing the handling of the locks either manually or automatically on special events (logout, timeout, loading

new entry, etc.).

2. *link display preview caching*. According to the database design that (correctly) handles all references with entity IDs, each operation, like structure entry preview or edit form display, runs possibly huge numbers (tens or hundreds) of extra database queries displaying text representations instead of the entity ID numbers. The drawback of this compact database model is in slowing down the query response time to seconds for one entry. To overcome this increase of the number of link queries, we have introduced the concept of *preview caching*. With this mechanism the server computes all kinds of previews in the time of saving a modified entry in special entry variables (either XML subtags or XML metadata). In the time of constructing the preview or edit form, the linked textual representations are taken from the preview caches instead of running extra queries to obtain the computed values.

3. *edit form functionalities* The lexicographic experts within the Cornetto project have suggested several new user interface functions that are profitable for other DEB-based projects like collapsing of parts of the edit form, entry merging and splitting functions or new kinds of automatic inter-dictionary queries, so called AutoLookUps.

All this added functionalities are directly applicable in any DEB application like DEBVisDic or DEBDict.

#### **4. The New DEBVisDic Clients**

Since one of the basic parts of the Cornetto database is the Dutch WordNet, we have decided to use DEBVisDic as the core for Cornetto client software. We have developed four new modules, described in more details below. All the databases are linked together and also to external resources (Princeton English WordNet and SUMO ontology), thus every possible user action had to be very carefully analyzed and described.

During the several months of active development and extensive communication between Brno and Amsterdam, a lot of new features emerged in both server and client and many of these innovations were also introduced into the DEBVisDic software. This way, each user of this WordNet editor benefits from Cornetto project.

The user interface is the same as for all the DEBVisDic modules (see Figures 2 and 3): upper part of the window is occupied by the query input line and the query result list and the lower part contains several tabs with different views of the selected entry.

Searching for entries supports several query types -- a basic one is to search for a word or its part, the result list may be limited by adding an exact sense number. For more complex queries users may search for any value of any XML element or attribute, even with a value taken from other dictionaries (the latter is used mainly by the software itself for automatic lookup queries).

The tabs in the lower part of the window are defined per dictionary type, but each dictionary contains at least a preview of an entry and a display of the entry XML structure. The entry preview is generated using XSLT templates, so it is very flexible and offers plenty of possibilities for entry representation.

#### *4.1. Cornetto Lexical Units*

The Cornetto foundation is formed by Lexical Units, so let us describe their client package first. Each entry contains complex information about morphology, syntax, semantics and pragmatics, and also lots of examples with complex substructures. Thus one of the important tasks was to design a preview to display everything needed by the lexicographers without the necessity to scroll a lot. The examples were moved to separate tab and only their short resume stayed on the main preview tab.

Lexical units also contain semantic information from RBN that cannot be published freely because of licensing issues. Thus DEBVisDic here needs to differentiate the preview content based on the actual user's access rights.

The same ergonomic problem had to be resolved in the edit form. The whole form is divided to smaller groups of related fields (e.g. morphology) and it is possible to hide or display each group separately. By default, only the most important parts are displayed and the rest is hidden (see Figure 2).

Another new feature developed for Cornetto is the option to split the edited entry. Basically, this function copies all content of edited entry to a new one. This way, users may easily create two lexical units that differ only in some selected details.

Because of the links between all the data collections, every change in lexical units has to be propagated to Cornetto Synsets and Identifiers. For example, when deleting a lexical unit, the corresponding synonym has to be deleted from the synset dictionary.

#### *4.2. Cornetto Synsets*

Synsets are even more complex than lexical units, because they contain lots of

links to different sources -- links to lexical units, relations to other synsets, equivalence links to Princeton English WordNet, and links to the ontology.

Again, designing the user-friendly preview containing all the information was very important. Even here, we had to split the preview to two tabs: the first with the synonyms, domains, ontology, definition and short representation of internal relations, and the second with full information on each relation (both internal and external to English Wordnet). Each link in the preview is clickable and displays the selected entry in the corresponding dictionary window (for example, clicking on a synonym opens a lexical unit preview in the lexical unit window).

The synset window offers also a tree view representing a hypernym/hyponym tree. Since the hypero/hyponymic hierarchy in Wordnet forms not a simple tree but a directed graph, another tab provides the reversed tree displaying links in the opposite direction (this concept was introduced in the VisDic Wordnet editor). The tree view also contains information about each subtree's significance -- like the number of direct hyponyms or the number of all the descendant synsets (see Figure 3).

The synset edit form looks similar to the form in the lexical units window, with less important parts hidden by default. When adding or editing links, users may use the same queries as in dictionaries to find the right entry.

#### *4.3. Cornetto Identifiers*

The lexical units and synsets are linked together using the Cornetto Identifiers (CID). For each lexical unit, the automatic aligning software produced several mappings to different synsets (with different score values). At the very beginning, the most probable one was marked as the “selected” mapping.

In the course of work, users have several ways for confirming the automatic choice, choosing from other offered mapping, or creating an entirely new link. For example, a user can remove the incorrect synonym from a synset and the corresponding mapping will be marked as unselected in CID. Another option is to select one of the alternate mappings in the Cornetto Identifiers edit form. Of course, this action leads to an automatic update of synonyms.

The most convenient way to confirm or create links is to use ***Map current LU to current Synset*** function. This action can be run from any Cornetto client package, either by a keyboard shortcut or by clicking on the button. All the required changes are checked and carried out on the server, so the client software does not need to worry about the actual actions necessary to link the lexical unit and the synset.

## 5. Cornetto Ontology

### 5.1. Ontological principles

The ontology is seen as an independent anchoring of concepts to some formal representation that can be used for reasoning. Within the ontology, Terms are defined as disjoint Types, organized in a Type hierarchy where:

1. a Type represents a class of entities that share the same essential properties;
2. Instances of a Type belong to only a single Type: => disjoint (you cannot be both a *cat* and a *dog*);

Terms can further be combined in a knowledge representation language to form expressions of axioms, e.g. the Knowledge Interchange Format (KIF, Genesereth and Fikes 1992), based on first order predicate calculus and primitive elements. Following the OntoClean method (Guarino and Welty 2002a, 2002b), identity criteria can be used to determine the set of disjoint Types. These identity criteria determine the essential properties of entities that are instances of these concepts:

1. **Rigidity**: to what extent are properties of an entity true in all or most worlds? E.g., a *man* is always a *person* but may bear a Role like *student* only temporarily. Thus *manhood* is a rigid property while *studenthood* is non-rigid.
2. **Essence**: which properties of entities are essential? For example, *shape* is an essential property of *vase* but not an essential property of the clay it is made of.
3. **Unicity**: which entities represent a whole and which entities are parts of these wholes? An *ocean* or *river* represents a whole but the *water* it contains does not.

The identity criteria are based on certain fundamental requirements. These include that the ontology is descriptive and reflects human cognition, perception, cultural imprints and social conventions (Masolo et al 2003). The work of Guarino and Welty (Guarino and Welty 2002a, 2002b) demonstrated that the WordNet hierarchy, when viewed as an ontology, can be improved and reduced. For example, roles such as agents of processes are often non-rigid. They do not represent disjunct types in the ontology and complicate the hierarchy. As an example, consider the hyponyms of *dog* in WordNet, which include both types (races) like *poodle*, *Newfoundland*, and *German shepherd*, but also roles like *lapdog*, *watchdog* and *herding dog*.

"Germanshepherdhood" is a rigid property, and a German shepherd will never be a Newfoundland or a poodle. But German shepherds may be herding dogs. The ontology would only list the *rigid* types of dogs (dog races): Canine => PoodleDog; NewfoundlandDog; GermanShepherdDog, etc.

The lexicon of a language then may contain words that are simply names for these types and other words that do not represent new types but represent roles (and other conceptualizations of types). From this basic starting point, we can derive two types of mappings from synsets to the ontology (Fellbaum and Vossen 2007, Vossen and Fellbaum fc.):

1. Synsets represent disjunct types of concepts, where they are defined as:
  - 1.1. names of Terms;
  - 1.2. subclasses of Terms, in case the equivalent class is not provided by the ontology
2. Synsets represent non-rigid conceptualizations, which are defined through a KIF expression;

For example, English *poodle*, Dutch *poedel* and Japanese *pudoru* are simple names for the ontology type: => (instance x PoodleDog). On the other hand, English *watchdog*, the Dutch word *waakhond* and the Japanese word *banken* should be related through a KIF expression that does not involve new ontological types:

(and (instance, ?C, Canine), (instance, ?G Guarding) (role, ?C, ?G) )

where we assume that *Guarding* is defined as a process in the ontology as well. The fact that the same expression can be used for all the three words indicates equivalence across the three languages.

The naming relation thus corresponds more or less with the way SUMO is currently mapped to the Princeton Wordnet, using equivalence and subsumption relations. The KIF expressions for non-rigid mappings are more similar to the axioms found in SUMO, except that one of the variables in the axioms correlates with the denotation of the synset that is being defined. In the case of the above example, the variable “?C” thus correlates with the possible referents of expressions with the syntactic head of the nouns *watchdog*, *waakhond* and *banken* in the different languages.

In a similar way, we can use the notions of Essence and Unicity to determine which concepts are justifiably included in the type hierarchy and which ones are dependent on such types. If a language has a word to denote a lump of clay (e.g. in

Dutch *kleibrok* denotes an irregularly shaped chunk of clay), this word will not be represented by a type in the ontology because the concept it expresses does not satisfy the Essence criterion. Similarly, a Dutch word *rivierwater* (river water) is not represented by a type in the ontology as it does not satisfy Unicity; such words are dependent on other valid types through a more complex semantic relation.

## 5.2. *Ontological implementation in Cornetto*

The ontology mappings in Cornetto are currently restricted to triplets consisting of the relation name, a first argument and a second argument. It is thus not possible to represent complex KIF expressions as is done in the axioms of SUMO. However, by assuming default values for the KIF syntax, we can generate expressions that come close to these. The default operator of the triplets is AND, and we assume default existential quantification of any of the variables, specified as a value of the arguments. Furthermore, we follow the convention to use a zero symbol as the variable that corresponds to the denotation of the synset being defined and any other integer for other denotations. Finally, we use the symbol  $\langle = \rangle$  for full equivalence (bidirectional subsumption). In the case of partial subsumption, we use the symbol  $\Rightarrow$ , meaning that the KIF expression is more general than the meaning of the synset. If no symbol is specified, we assume an exhaustive definition by the KIF expression. The symbol  $\langle = \rangle$  applies by default.

The following simplified expression can then be found in the Cornetto database for the above non-rigid synset of *waakhond* (watchdog): (instance, 0, Canine) (instance, 1, Guarding) (role, 0, 1). This should then be read as follows:

*The expression exhaustively defines the synset ( $\langle = \rangle$ ), AND there exists an instance 0 of the type Canine (instance, 0, Canine), AND any referent of an expression with the synset waakhond as the head is also an instance of the type Canine (the special status of the zero variable), AND there exists an instance of the type Guarding (instance, 1, Guarding), AND the entity 0 has a role relation with the entity (role, 0, 1).*

For names of types, we use the following expressions in Cornetto:

Hond ( $=$ , 0, Canine); the synset *hond* is a Dutch name for the rigid type Canine

Bokser ( $+$ , 0, Canine); the synset *bokser* is a Dutch name for a rigid concept which is a subclass of the type Canine

Naming relations are mostly imported from the SUMO mappings to the English Wordnet through the equivalence relation of the Dutch synset to the English synset. In the case of *bokser*, the mapping is manually added because it is dog race that is not in the English Wordnet and not in SUMO. Possibly, SUMO could be extended with this Type.

Another case of mixed hyponyms are words for *water*. In the Dutch wordnet there are over 40 words that can be used to refer to water in specific circumstances or with specific attributes. Water is in SUMO a CompoundSubstance just as other molecules. We can thus expect that the synset of *water* in Dutch matches directly to Water in SUMO, just as *zand* matches to Sand. However, *water* has 3 major meanings in the Dutch wordnet: water as liquid, water as a chemical element and a water area, while there are only two concepts in SUMO: Water as the CompoundSubstance and a WaterArea. In SUMO there is no concept for water in its liquid form, even though this is the most common concept for most people. Most of the hyponyms of *water* in the Dutch Wordnet are linked to the liquid. To properly map them to the ontology, we thus first must map water as a liquid. This can be done by assigning the Attribute Liquid to the concept of Water as a CompoundSubstance. A SUMO axiom for this is: (and (exists ?L ?W)(instance, ?W, Water),(instance, ?L Liquid) (attribute, ?L, ?W)). In the Cornetto database, this complex KIF expression is represented by the simpler relation triplets: (instance, 0, Water) (instance, 1, Liquid) (attribute, 1, 0).

The hyponyms of water in the Dutch Wordnet can further be divided into 3 groups:

1. Water used for a purpose, e.g. *theewater* (for making tea), *scheerwater* (for shaving).
2. Water occurring somewhere or originating from e.g. *putwater* (in a well), *slootwater* (in a ditch).
3. Being the result of a process, e.g. *pompwater* (being pumped away), *smeltwater*, *dooiwater* (melting snow and ice), *afvalwater* (waste water).

These concepts can be related to the ontology using the following expressions:

***theewater*** (tea water):

(instance, 0, Water) (instance, 1, Tea)(instance, 2, Making)(hasPurpose, 1, 0)(resource, 0, 2)(result, 1, 2)

***putwater*** (water in a well):

(instance, 0, Water)(instance, 1, MineOrWell)(located, 1, 0)  
*slootwater* (in a ditch):

(instance, 0, Water)(instance, 1, StaticWaterArea)(part, 0, 1)

Through the complex mappings of non-rigid synsets to the ontology, the latter can remain compact and strict. Note that the distinction between Rigid and non-Rigid does not down-grade the relevance or value of the non-rigid concepts. To the contrary, the non-rigid concepts are often more common and relevant in many situations. In the Cornetto database, we want to make the distinction between the ontology and the lexicon clearer. This means that rigid properties are defined in the ontology and non-rigid properties in the lexicon. The value of their semantics is however equal and can formally be used by combining the ontology and the lexicon.

### 5.3. *Ontology progress*

The work on the ontology was mainly carried out manually. The mappings of the synsets to SUMO/MILO are primarily imported through the equivalence relation to the English wordnet. We used the SUMO-Wordnet mapping provided on: <http://www.ontologyportal.org/>, dated on April 2006. If there is more than one equivalence mapping with English wordnet, this may result in many-to-one mappings from SUMO to the synset. The mappings have been manually revised traversing the Dutch wordnet hierarchy top-down, giving priority to the most essential synsets. Furthermore, we revised synsets with a large number of equivalence relations or low-scoring equivalence relations. Finally, we clarified the synset-type relations for some sets of co-hyponyms as shown above for water. Single triplets with the relation ‘+’ are still most frequent, i.e. a subsumption to a SUMO concept without a statement about rigidity. We hope to make more explicit mappings in a future extension of the database.

## 6. Conclusions

In the paper, we have described the Cornetto project workflow using the new lexicographic tools developed for this project. We have presented how a combination of automatic scored strategies with the human lexicographic work can be used for merging large databases of previous dictionaries to obtain a new qualitative language resource with complex morphological, syntactic and semantic information. The presented project

tools are, however, not a single purpose programs but they fit in the general framework of the Dictionary Editor and Browser (DEB) platform used for developing other publicly available language data tools.

## 7. Acknowledgments

The Cornetto project is funded by the Nederlandse Taalunie and STEVIN. This work has also partly been supported by the Ministry of Education of the Czech Republic within the Center of basic research LC536 and in the Czech National Research Programme II project 2C06009.

## Abstract

Semantic symbols are essential components of Chinese characters. ShuoWenJieZi (Xyu Shen 121), the oldest dictionary of Chinese, is organized according to the radical forms as semantic symbols.. In this research, we use the semantic symbols representing four Artifact Domains in ShuoWenJieZi , “皿 (min3, ‘basin/container’)", “耒(lei3, ‘plow/a farm tool’)", “刀(dao1, ‘knife/weapon’)" and “网 (wang3, ‘net’)" as our research objects. In this study ,two interesting finding are discovered. First, the primary meanings of characters that shared the same radical symbol are indeed conceptually dependent on the basic concept of that radical. Second, although the four radical of artifacts have similar conceptual extensions, the capabilities of generating new characters, of each individual radical are rather different.

**Keywords:** Ontology; HanZi ; Semantic Lexicon

## 1. Introduction

Chinese radical (*yi4fu2*, ideographs ;semantic symbols) system offers a unique opportunity for systematic and comprehensive comparison between formal and linguistic ontologies. Previous studies adopt either WordNet-based representation.(Wong et al 2002)(Hsieh 2005) or SUMO-based mapping (Chou 2005). Among these studies, Chou and Huang (2007) suggests that the family of Chinese

characters sharing the same radical can be linked to a basic concept by Qualia relations. This approach has great implications of accounts for radicals as linguistically conventionalized ontology. In this paper, we take this approach further and try to account for each radical group as domain ontology headed by one basic concept. In particular, we examine in details 4 radicals of artifacts: 皿 (min3, basin/container), 耒 (lei3, plow/a farm tool), 刀(dao1, knife/weapon) and 网 (wang3, net).

## 2. Theory

The two important theoretical problems that we would like to resolve are: First, If and how the conceptual extensions encoded by these radicals of artifacts differ from those by natural objects? Second, If the design features of these artifacts play a role in their possible conceptual extensions? By answering these two problems, we aim to elaborate on how shared experience and cognitive salience affects the formation of linguistic ontology.

### 2.1 *Qualia Structure*

Our theoretical foundation is Pustejovsky's *Qualia Structure*(Pustejovsky, 1995), and the original analysis of 'ShuoWenJieZi'(Xu 121). In *ShuoWenJieZi*, all Chinese characters are classified as derived from 540 radicals. In this study, we assume that these radicals each represent a basic concept and that all derivative characters are conceptually dependent on that basic concept. Our study aims at accounting for the exact nature of these conceptual dependencies. Combined with previous work, we suggest that conceptual extensions from the basic concept encoded by a radical can be classified into seven main types: formal, constitutive, telic, participant, participating, descriptive

(state/manner) and agentive.

## *2.2 The Semantic Symbol Ontology*

The Semantic Symbol Ontology is a system expressing the relations of Hanzi and its meaning cluster. This ontology system extended the basic structure constructed, (Chou, 2005), which maps the meanings of 540 radicals in *ShuoWenJieZi* with IEEE SUMO. We use the results from analyzing derivative concepts to express the Semantic Ontology for each radical. Our current working interface allows easy query of existing database as well as recording of new entries.

### *2.2.1 Radical Search*

There are two searching methods for the semantic symbol ontology:

#### (i) Search on SUMO concepts classification

Choose certain SUMO concept, then this concept and its lower SUMO concept will show up on the interface.

#### (ii) Search on the radical word forms

Key in the radical word form, and users can get the data of that radical directly.

Figure1:Radical search in semantic ontology system

### 2.2.2 The classification of Hanzi semantic symbols

Based on the definition in *ShuoWenJieZi*, our structure classifies the relationship between deriving meaning cluster and the basic concept of a radical. We use Pustejovsky's *Quilia Structure* as base and observe the analysis on the definitions in *ShuoWenJieZi*, and then classify the deriving concepts of Hanzi radicals into 7 categories, expanded from the original four qualia aspects of Formal, Constitutive, Agentive, and Telic:

- (i) Formal: This category can be further divided into 5 small categories: “sense,” “characteristic,” “proper names,” and “atypical.” The “sense” categories can be further divided into 5 small categories: “vision,” “hearing,” “smelling,” and “taste.”
- (ii) Constitutive: This category can be further divided into 3 small categories: “part,” “member,” and “group.”
- (iii) Telic: Concepts related to function or usage.

(iv) Participant: Words are classified into this category when the definition in *ShuoWenJieZi* mentions the participant involved.

(v) Participating: According to different events, concepts are divided into 6 small categories: “action,” “state,” “purpose,” “function,” “tool,” and “others.”

(vi) Descriptive: This category can be further divided into two categories: “active” and “state.”

(vii) Agentive: The relationship between the radical and its meaning cluster coming from production or giving birth are classified in to agentive.

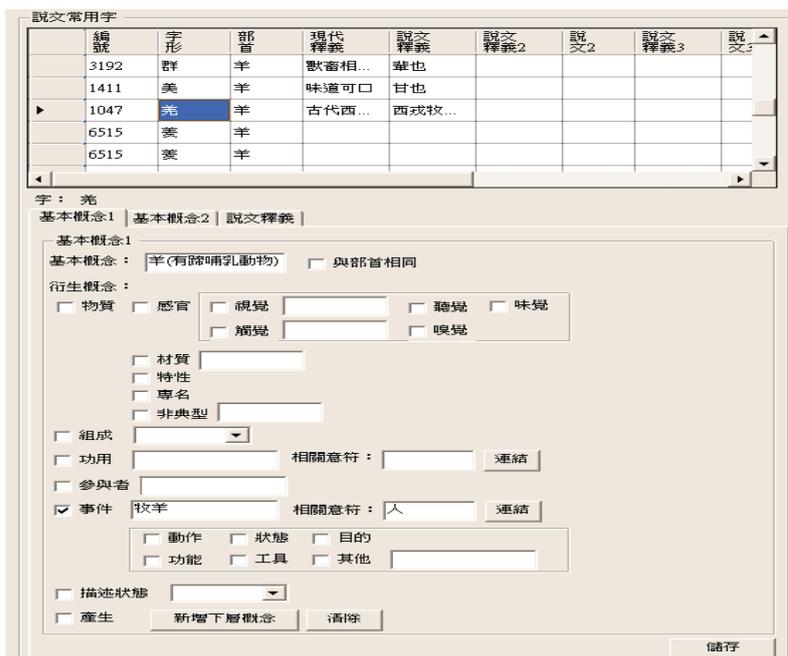

Figure2: The classification of Hanzi semantic symbols

### 2.2.3. The link of related semantic symbol

Under “telic” and “participating,” we add a column for “related semantic symbol” to

show and link the related deriving concepts. For example, the character “羌”is explained as “西戎羊種人也.”(the person whoe herds sheep in Xiyu) and involves two basic concepts that are represented in the character: bovid and human sincethe Chinese character form of “羌,” contains bothe “羊”(bovid) and“人” (human). Our ontology system links “羌”with its related semantic symbol “人” to offer cross-referencing in order to build a more realistic ontology of the conceptual convention.

### **3. Domain Ontologies of Four Artifact domains as Conventionalized by radicals**

According to our analysis, we observe that the basic concept of four radicals of Artifacts is:皿 (min3, ‘container’), 耒(lei3, ‘a farm tool’), 刀(dao1, ‘1.knife,2.weapon’) and 网 (wang3, 1.catching/fishing, 2.net ).

The following figures is The Qualia Structure on derivative concepts of 皿,耒,刀 and 网.

#### *3.1 The Quilia structure on Derivative Concepts of Four Artifact domains*

##### *3.1.1 皿(min3) Basic concept : container*

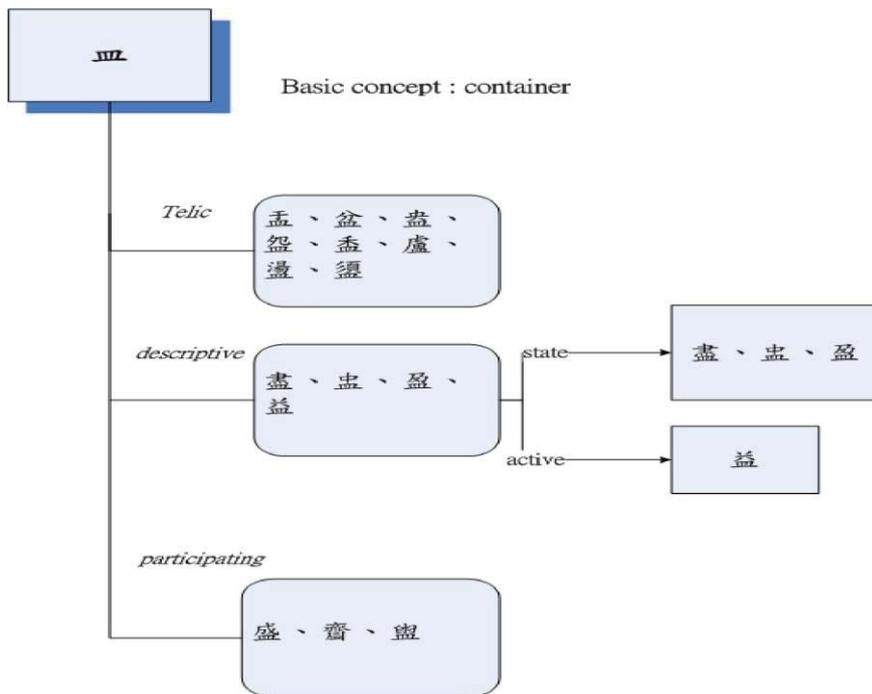

Figure3: The Quilia structure on Derivative Concepts of 皿.

### 3.1.2 耒(lěi3) Basic concept :a farm tool

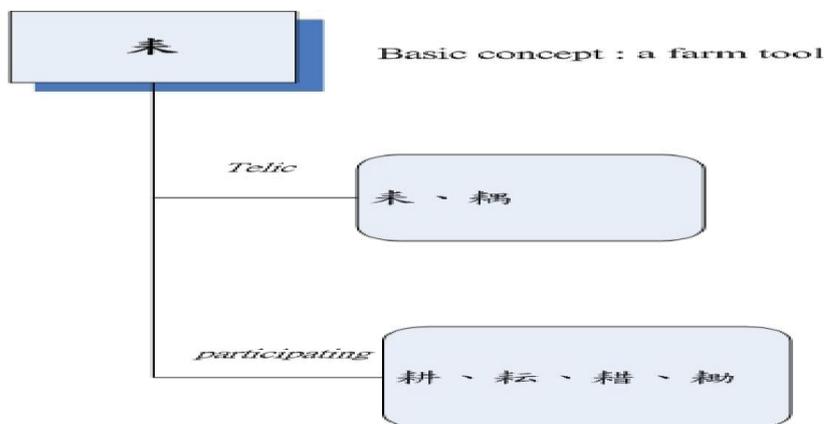

Figure4: The Quilia structure on Derivative Concepts of 耒

### 3.1.3 刀(dāo1) Basic concept : 1.knife 2.weapon

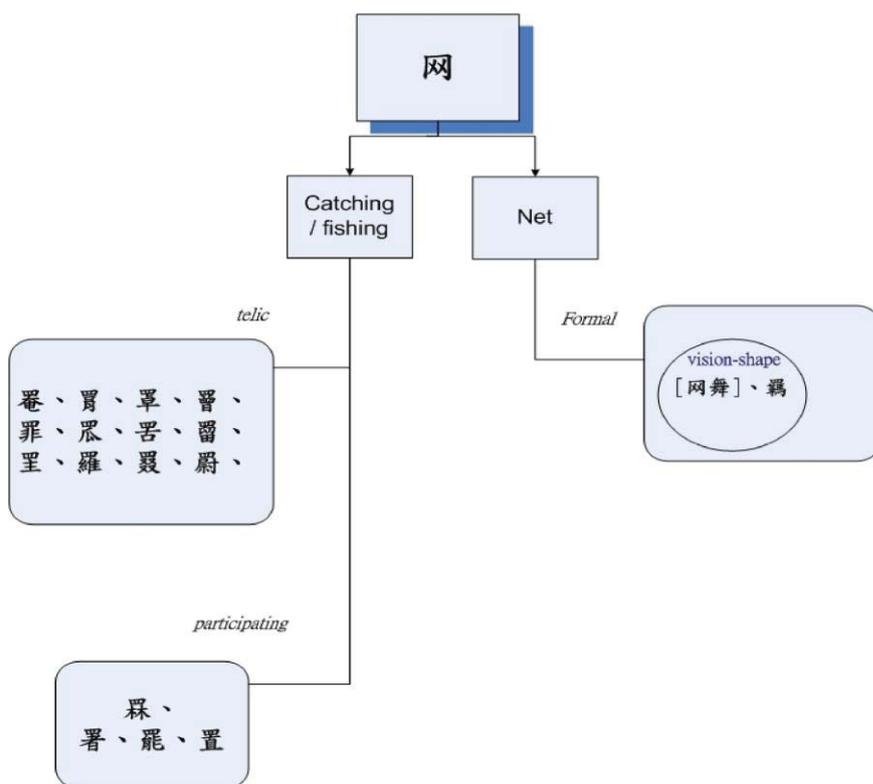

Figure6: The Quilia structure on Derivative Concepts of 网

### 3.2 Findings

Two interesting findings are discovered in this study. First, the primary meanings of characters that shared the same radical symbol are indeed conceptually dependent on the basic concept of that radical. For instance, the basic concept of radical 网(wang3) listed in ShuoWenJieZi is “a tool made from string for fishing”, which covers two key meanings on “weaving a net” and “catching/fishing”. Characters with the radical 网(wang3) are generated based on these two key meanings, such as 罗(luo2) is a tool to catch bird; 网舞(wu3) refers to a latticed window that looks like a reticulation. Second,

although the four radical of artifacts have similar conceptual extensions, the capabilities of generating new characters, of each individual radical are rather different. These preliminary findings have the following theoretical implications:

### *3.2.1 Dimensions of conceptual extensions*

The conceptual relations between these four radicals of artifacts and their derivative characters are all centered on telic, participating and descriptive. This differs from the those of derivative characters and radicals of natural object “艸”, where formal, constitutive and telic relations are the main foci (chou 2006). Artifacts are designed with a specific functionality, so most of the modes of conceptual extensions between characters and artifact radicals belong to telic relations. In addition, the concept of an artifact can best be understood by how it is used, hence a character often denotes a typical event in which the artifact is a main participant. For example, “耕(geng1)” is from the radical symbol “耒”(‘plow /a farm tool’) and refers to the activity of farming; “刑” (xing2) is from the radical symbol “刀”(‘knife/weapon’) and means inflicting punishment. Figure7 shows the result of comparison schematically.

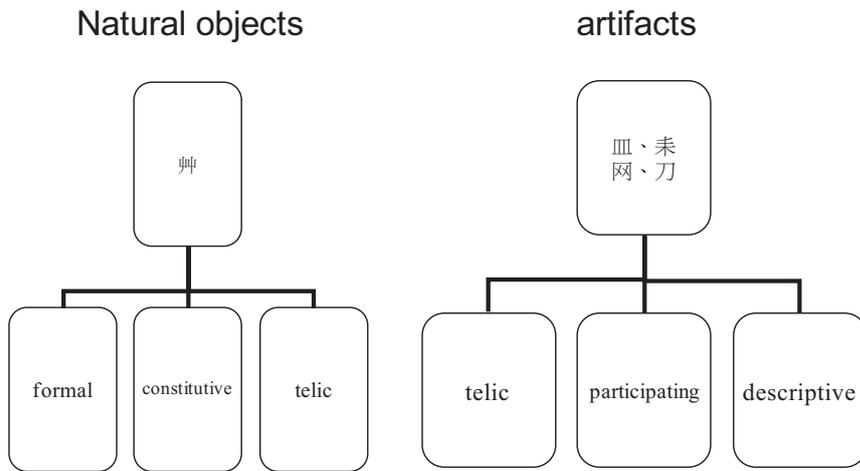

Figure7:comparison of Natural objects & artifacts

### 3.2.2 Semantic coverage and generative power

Our proposed modes of conceptual extension capture the generative nature of radical creativity. However, The generation scopes of the four chosen radicals of artifacts are quite different. Our account involves two possible perspectives:(1) generalized vs. specific functions, and (2) imitation vs. invention.

(1) “皿” (‘basin/container’, with 28 derived characters) and “耒” (‘plow /a farm tool’, 8 characters) have very different generative power: We note that their designedfunction types are different. “耒” is a kind of farming tool, so its event function is task-oriented and socially defined. Therefore, the generative power of “耒” is more restricted. On the contrary, “皿”, as a container, is a basic tool with generic purpose, so its capability of generating new characters is less restricted.

(2) It is also possible that an artifact that is a human imitation of natural object or function is conceptually more versatile, and can serve as the base of conceptual extensions similar to a natural object. A human invention with functional components, however, is directly restricted by its intended function and limited in conceptual extensions. In both cases, however, eventive conceptual extension occurs frequently based on the event associated with the function of that artifact. This hypothesis may also explain why only certain artifacts are considered as basic words.

#### **4. Conclusion**

In sum, our study supports the null hypothesis that all derived characters are conceptually dependent on the basic concept. We also revealed the specific contrasts between conceptual extensions from artifacts and from natural objects. We further discovered that even dependencies on artifact concepts can vary according to the design features of the artifact concept. The result of our analysis will be formally represented as ontologies in OWL format.

# **Ontological representation of event structure across languages: the case of psych verbs**

**Evguenia Malaia**

Purdue University  
500 Oval Drive, West Lafayette, IN 47906  
emalaya@purdue.edu

## **Abstract**

The paper addresses the problem of cross-linguistically valid ontological representation of predicates from different languages. Using a complicated linguistic problem of psych verb classification as an example, we demonstrate an efficient solution to cohesive representation of psych verb classes in English and Finnish within event structure framework. The proposed classification takes into account verbal semantics (agentivity, causality, etc.), morphology, possible alternation of syntactic frames, and argument structure. We further argue that such event-based approach to predicate representation is cognitively based, and can be adapted for any linguistically-oriented applied ontology system.

**Keywords:** ontology, event structure, psych verbs

## **1. Introduction.**

Ontological knowledge representation used for Natural Language Processing (NLP) aims to approach the results of human language processing. As such it needs to either model the human cognitive capacity used for a linguistic representation of the world, or model the results of it. The quest for cognitive constraints on possible human ontologies, and the reflection of those ontologies in language is formulated by Shalley and Zaefferer (2006), who define the focus of ontolinguistics in “relating linguistic to non-linguistic phenomena with a focus on decompositional structures and the network of connections”.

We propose that a human cognitive representation of the world plays a major role not only in providing ‘encyclopedic information’ to the lexicon, or conceptual selectional restrictions to syntactic structures, but also in encoding the minimal structures – events – represented in natural languages (see O’Bryan 2003, Folli, R. and Harley, H., 2006, Wilbur, R. 2007). In this work, we connect recent developments from linguistic theory and behavioral psycholinguistics to the problem of cognitive approaches to ontological representation of events for Natural Language Processing.

We specifically address a widely known linguistic problem of Subject/Object alternation in psych verb predicates (such as Jake fears bears/Bears frighten Jake), and use event structure to account for the assignment of the Subject or Object syntactic role to semantic Experiencer arguments of such predicates. We show that the class of psych

predicates is cognitively homogenous across languages (in that psych verbs do not allow for an internal event Initiator), and that the alternations in the surface syntactic structures can be predicted from the language-specific event-structure configurations (see Ramchand 2008, Pustejovsky 1991). We demonstrate that event structure can be coded at the ontological level, and applies across different lexical items, as well as cross-linguistically. We further argue that the application of event structure to ontological representation, as demonstrated in the specific domain of psych verbs, shows applicability of such an approach to developing cognitively-based ontologies for Natural Language Processing.

Shalley and Zaefferer (2006) distinguish the two main questions of ontolinguistic research: 1) how the ontological status of a concept restricts the ways it can be coded in the world's languages, and 2) which concepts figure in everyday ontologies of humans, and how they are structured. The present work seeks to address both questions, as they are applied to the domain of verbs of psychological state, or psych verbs.

## 2. Psych verb classes: definition and models.

Psych verbs are an interesting group of predicates from the event-structure perspective. Cognitively, psych verbs are united by the feature of having an Experiencer, but not an Agent. The same feature considered from the event-structural perspective means that psych verbs consistently lack the argument role associated with the Initiator of the event. Nonetheless some psych verbs license Subjects. The Experiencer may surface as Subject (1), Direct Object (which in some language may be marked with Accusative case (2)), or Indirect Object, which may bear Dative or other cases (3).

(1) Jake fears bears.

(2) Bears worry Jake.

(3) Bears appeal to Jake.

This phenomenon has long been of interest to linguists (Belletti & Rizzi 1988, Grimshaw 1990; Jackendoff 1990; Dowty 1991). Treatments of syntactic properties of psych verbs using a thematic hierarchy simply assign verbs to several different classes based on their Case grids. Then, the obvious question arises: can these verb classes be derived from something deeper that is invariant cross-linguistically, and rooted in human cognitive representations?

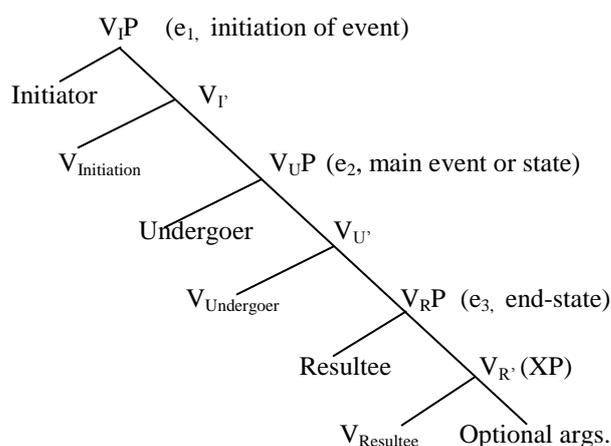

We would like to demonstrate that syntactic properties of psych verbs cross-linguistically can be explained by variations in their event structure patterns, which themselves can be deduced from the factorial typology of event structures. We show specific results (syntactic role assignments) of event structure interactions with argument structure. We do not go into details of the mechanism that links particular argument structures to syntactic roles of subject and object here, because the representation of this mechanism will depend on the NLP system in use, and also because we expect some cross-linguistic variability in terms of subject/object assignment (e.g. there is a rule for required subjects in English, but no such rule in Catalan or Russian). The present analysis simply aims at revealing consistent patterns of event structure in psych verbs, taking English and Finnish as examples of languages with partially overlapping psych verb typologies, and demonstrating convergent results

of syntactic role assignment according to event structure and semantic patterns. As a result of this analysis, we can relate decomposed structures of psych verb meanings in the two languages, and demonstrate the possibility of constructing a cognitively-based NLP system, that can interact with varying lexical and syntactic patterns across languages.

### 3. Modelling event structure.

We use the model of event structure proposed by Ramchand (2003), as the one that has adopted the most from psycholinguistic (e.g. O’Byran 2004) and neurolinguistic (Metzinger and Gallese, 2006) research. This model, while formal in its representation, structurally incorporates the features that have been demonstrated to be salient for human processing of language and perception: causality, orientation of actions towards goals (posited as telicity), distinction among semantic Agents, Experiencers, and Themes of the predicate, and close interaction between decomposed semantics of verbs and argument structure. We adopt the following ‘full’ First Phase Syntax event structure tree as a basis for our modeling (Figure 1), adapted from Ramchand 2008.

**Figure 1. Full model of possible event structure tree.**

This structure shares several assumptions with ontological descriptions used for NLP, namely:

- Lexico-syntactic information is available at word-level;
- This information is internally structured and systematic across predicates (i.e. affecting more than just Subject/Object alternation).

The arboreal model for event structure is a conventional representation; the same information about event structure can be encoded for systems that make no use of syntactic trees, or do not have a syntactic representation level altogether (see Malaia, 2006 for examples).

Linguistic conventions surrounding the phenomenon of Subject/Object Experiencer alternation include the following: 1) In psych verbs, the Initiator role cannot be filled by an independent argument; 2) Verbs with “similar” semantics in different languages can fall into different pattern categories with respect to their event

structure (i.e. the main cognitive restriction is the event structure itself); 3) In languages with rich overt morphology (Finnish, Russian), affixation is an available method of modifying the event structure of the root morpheme of the psych verb.

Finally, in the event structural approach, each phase is related to the previous one by causal relations: i.e. Initiation is the cause of the main event, and the main event causes the Resultant State. One of the corollaries to this system has immediate importance for analyzing Finnish psych verbs: if the Initiator and Undergoer roles in event structure are filled by different individuals (lexical items), the event is interpreted as causative (i.e. the action taken by one actor has a causing effect onto another); if Initiator and Undergoer are co-indexed to one lexical item (i.e. entity initiating the event is the same entity that is affected by it), the event is agentive, but not causative.

### 3.1. *Finnish psych verbs*

#### 3.1.1. *Finnish verbal morphology.*

There are several morphological features of Finnish that require special attention. First, Finnish allows morphological derivation of Object Experiencer verbs from Subject Experiencer verbs by adding the suffix –TTA- “causative”. Following Belletti & Rizzi’s (1988) typology, Nelson (2003) identifies Subject Experiencer verbs as Class 1, and observes that derived Object Experiencer verbs can be divided into two classes: Class 2 derived from inchoative roots, and Class 3 stative, which do not allow agentive readings and display unaccusative features (Nelson 2003, 194).

Another morpheme participating in formation of Finnish psych predicates is the inchoative –stU. Pylkkänen (2000) notes that verbs with this morpheme are nonstative, and the interpretation of their object is more complex than that of –TTA- verbs: namely, when stacked with –TTA- (i.e. *raivo-stu-tta* ‘cause to become furious’), the verb allows either an Accusative or Partitive Experiencer Object (which correspond to complete and incomplete telic readings, and presence of the Resultant Phrase in event structure). A verb with only an inchoative suffix (e.g. *raivo-stu* ‘become furious’) has an Experiencer Subject in Nominative case - the suffix contributes the Resultative Phrase to the structure of the verb.

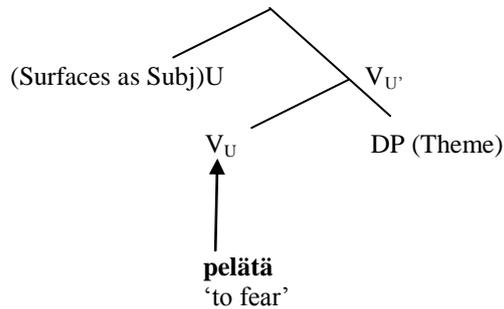

Nelson (2003) attempts to explain why it is impossible in normal discourse to get Accusative case with Class 3 (causative, stative) psych verbs. We address a larger issue of cross-linguistic typology of psych verbs, by way of re-considering the classes of Finnish psych verbs with respect to their event structure, especially since Finnish overt morphology allows the language to form one event structure from another by deriving new types from the two basic ones.

#### 3.1.2. *Four classes of Finnish psych predicates.*

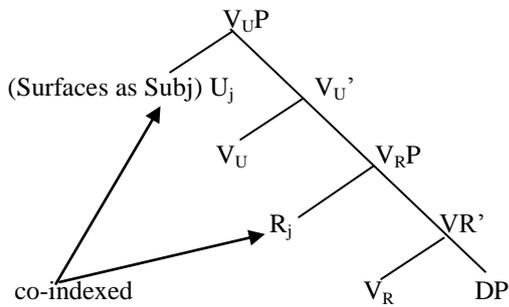

We build event structure representations of each of the four classes of psych verbs and describe each class in detail, followed by an event-structure tree, and some discussion of possible bearing that such a structure can have on the sentence-level syntactic behavior of the verbs. Within Class 1 there are two basic Subject Experiencer roots: a transitive one (Class 1a; Figure 2) and an intransitive one (Class 1b; Figure 3).

In both of these subclasses the Undergoer, the highest argument role, surfaces as Subject.

**Figure 2. Event structure of Class 1a intransitive stative Finnish Subject Experiencer verbs.**

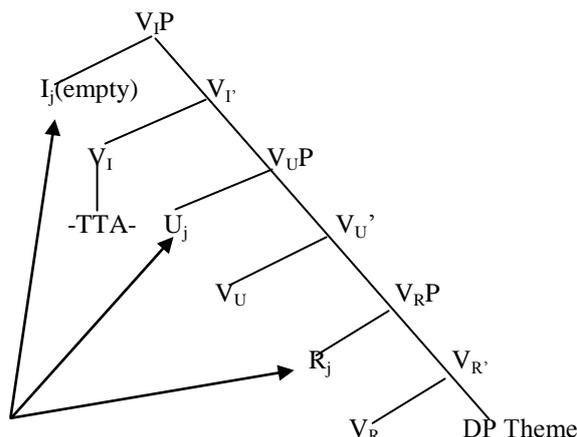

**Figure 3. Event structure of Class 1b inchoative Finnish Subject Experiencer predicates, with inchoative –stU- and Resultant Phrase.**

The suffix –TTA- introduces the Initiator phase into the event structure when added to Class 1 verbs. For psych verbs, however, no independent Initiator argument is possible. Thus, instead of allowing a new argument to be introduced, the new Initiator slot must be co-indexed with an available lexical item, which already fills the Undergoer slot. The resulting reading is agentive. Semantically, it can also be interpreted as “causing self to become...” Class 2, derived from Class 1b by addition of -TTA, has the event structure in Figure 4.

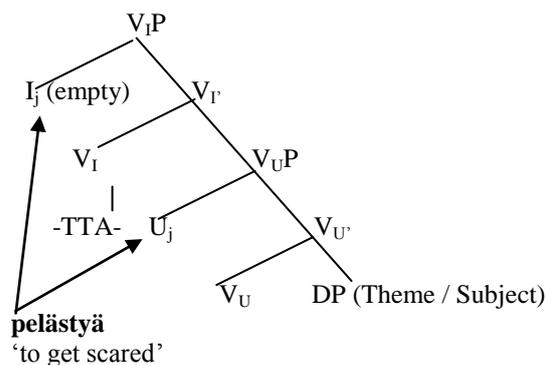

**Figure 4. Event structure of Class 2 of Finnish psych verbs derived from Class 1b with –TTA**

This class demonstrates that the co-indexing of argument roles does not allow the (I)-U-R lexical item to surface as the subject. In regard to case marking, these verbs exhibit the following traits: 1) Impersonal passivization is preferable with the use of Accusative case (note that the Undergoer/Resultee is the affected entity, projecting Accusative case); 2) The Experiencer allows both Accusative and Partitive case.<sup>1</sup>

Class 3 Finnish psych predicates are derived from Class 1a with –TTA and are thus ‘causative’ and stative; their event structure tree is presented in Figure 5.

**Figure 5. Event structure of Class 3 Finnish psych predicates, derived from Class 1a with -TTA.**

This system of event-structure pattern derivation does not preclude Class 1a predicates from being converted to Class 1b (in a manner similar to English optional

<sup>1</sup> The co-indexing of the existing argument with an argument that is newly introduced by overt morphology is not the only way to explain the peculiar distribution of syntactic roles in psych verbs. An alternative explanation would involve a mechanism for the empty Initiator slot to ‘block’ the Undergoer argument from the syntactic position of a subject. Our reasons for adopting the co-indexing explanation are both semantic and syntactic. First, although an Undergoer that follows an empty Initiator slot is precluded from surfacing in the subject role, the theme (from the RP), is not – and it is located low enough on the tree as to not constitute a compulsory argument. Thus, from the syntactic standpoint, co-indexing is a more plausible explanation for this phenomenon, as compared to simple ‘blocking’ mechanism. Secondly, in Finnish, as well as in Russian (see Ramchand 2003), the morphology responsible for the introduction of the Initiator phase into the event structure is interpreted semantically as “causative” and “reflexive”, which strongly points to semantic correlation between the Undergoer and the Initiator roles. The most obvious way to solve this discrepancy at the syntax-semantics interface is to allow an Undergoer-linked lexical item to co-index to an empty Initiator role, and vice versa.

transitivity alternation). On the contrary, given their similarity of argument structure (with a single required argument), this is a likely possibility. Indeed, a single psych root (such as *pelä-/pelo-* ‘fear’ or *nolo-* ‘embarrassed’) can be associated with 4 predicates, corresponding to those is Figures 2-5 (or Classes 1a, 1b, 2, and 3).<sup>2</sup>

All psych verb event structures employed in Finnish are summarized in Table 1 (we use the equals “=” sign to show that the argument positions in event structure are co-indexed to the same lexical item in the particular pattern).

**Table 1. Typology of Finnish psych verbs.**

Event structure\argument structure		I not co-indexed w/U	I co-indexed w/U
<b>Telic (RP present)</b>	U = R	Class 1b	Class 2 (derived)
<b>Atelic</b>		Class 1a	Class 3 (derived)

### 3.2. English psych verbs.

We use Levin’s work on English verb classes (1993) to present specific classes of English psych verbs, and to describe how they can be classified, and their behavior explained, using event-structural approach. We demonstrate the patterns of event structure that are possible in English psych verbs, then compare and contrast them with corresponding structures in Finnish.

Levin singles out 4 categories of psych verbs in English - two transitives and two intransitives; as in Finnish, the difference in argument role assignment and in surface syntactic roles can be exhaustively explained by alternations in event structure; the four classes in both languages, however, are not completely overlapping.<sup>3</sup>

#### 3.2.1. “Amuse” verbs.

Example: *The clown amused the children.* Levin (1993, p.189) notes that this class has the following properties: 1) The argument with the thematic role of

<sup>2</sup> Nelson notes that the same ‘causative’ suffix –TTA – can be applied more generally to verbs other than psych verbs. Under our analysis, the prediction is that this suffix would introduce an Initiator argument. Without the cognitive restriction of psych verbs that prohibits an explicit Agent, the Initiator argument should be filled overtly – as, indeed, it is (the resulting structure is recursive, with two Agent arguments, of which only the topmost surfaces as subject). Unfortunately, we can not include the analysis of –TTA- in non-psych verbs for consideration of space.

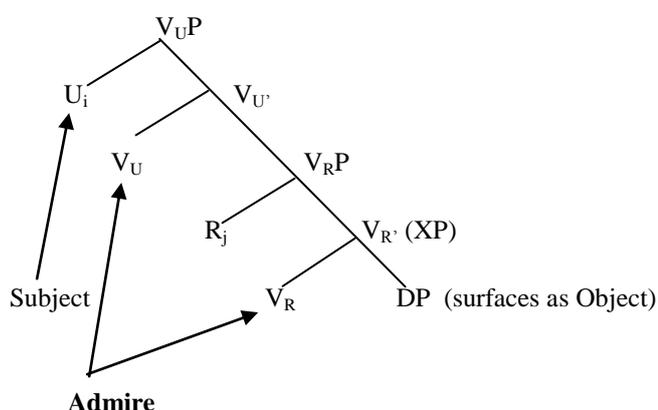

<sup>3</sup> Semantically, the ‘absence of causer’ and the motivation for the use of argument co-indexing in English is somewhat less apparent than in Finnish. However, if we take the ‘amuse’ verb class, and consider an animate vs. inanimate ‘causer’, such as “The book amused the children” and “The clown amused the children”, we have to conclude that while the sentences behave syntactically the same way, semantically only the animate subject can possibly be the Agent. This leads to conclusion that actually neither of the subjects is the semantic Agent – they are both Instruments, promoted to the syntactic role of the subject.

Levin (1993) identifies these verbs as having the following properties: 1) the Experiencer (our Undergoer) surfaces as the subject; 2) no middle alternation is possible with this class (e.g. “*I admire paintings*”, but not “*Paintings admire easily*” in the sense that it’s easy to admire them.<sup>5</sup>

The properties of this class can be explained using the tree illustrated in Figure 7, as follows: 1) The highest, independent argument U surfaces as the subject; 2) Middle alternation is impossible, since U and R are not co-indexed to the same argument; 3) While a resultant reading is possible with this group of verbs (“*I love him to death*”, “*she likes it to pieces*”), and would, indeed, be predicted by the fact that a  $V_{RP}$  is present, this resultant reading is not as easily acquired as for the *Amuse* group. For the resultant readings here it has to be clear that the Undergoer (surfaced as a subject) is not the holder of the resultant state: the Resultee is. This could explain a lower incidence of use of verbs of this group in resultative constructions.

**Figure 7. Event structure of Admire-class verbs in English.**

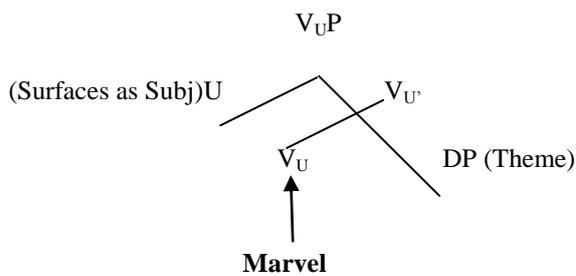

### 3.2.3. “Marvel” verbs.

These verbs, as identified in Levin (1993), behave in the following manner: 1) while the verbs are intransitive, the Experiencer (Undergoer) argument surfaces as a subject; 2) if used transitively, these verbs pattern with the “admire” verb class. Figure 8 represents the event structure of this verb class – the minimal one among English psych verbs. (Note that Finnish class 1a is the exact counterpart of the English “marvel” verb class, while Finnish Class 1b does not have an English counterpart.)

**Figure 8. Event structure of Marvel-class verbs in English.**

<sup>5</sup> We are not using and interpreting the full range of verb class diagnostics given in Levin; for example, Derived Nominal, Sentential Components, and Extrapolation of Sentential Components are out of the picture for the time being. The reasons are two-fold: first, we mainly want to present a clear case for cross-linguistic comparison of psych verbs, and second, we feel that work remains to be done on connecting these diagnostics to the event structure model, and that has to be the subject of a separate investigation.

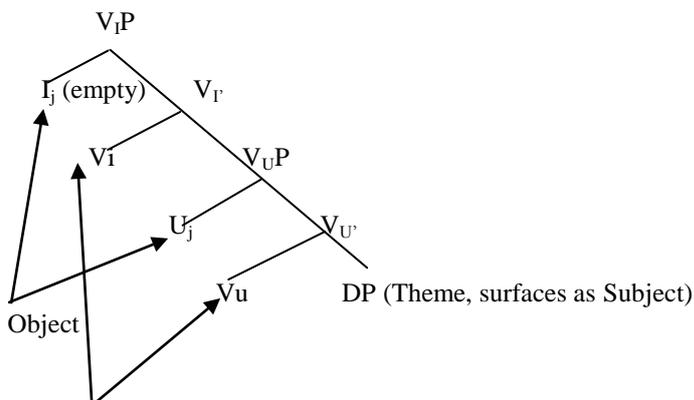

The behavior of this class can be interpreted as follows: 1) The highest-ranking argument (U) surfaces as a subject; 2) Optional transitivity (patterning with “amuse” verbs) includes a simple extension of the tree to include a Resultant Phrase.

With regard to verb class alternations in English, we propose that if a certain ‘pattern of utilization’ of event structure is already available, a lexical item can switch between the patterns to which it conforms (cf. use of overt morphology in Finnish to accomplish the same goal). As an example of this phenomenon in English psych verbs, consider optional transitive alternation of verb “to worry”, an atelic predicate of ‘marvel’-type, and its extension into an ‘amuse’-type telic/resultative predicate<sup>6</sup>: *I worried over the outcome of my exam/ The exam worried me (silly)*.<sup>6</sup>

### 3.2.4. “Appeal” verbs.

These verbs are distinguished by the following characteristics: 1) in these intransitive verbs, the Stimulus argument surfaces as the subject of the sentence; 2) the (required) Experiencer (or Undergoer) surfaces in a PP or DP (in Dative case); 3) no passive alternation is possible for these verbs.<sup>7</sup> Figure 9 presents illustrated the structure of this verb class.

**Figure 9. Event structure of Appeal-class verbs in English.**

<sup>6</sup> This mechanism accounts not only for verb class alternations in psych verbs, but for optional transitivity in general. How can one lexical item exhibit behavior diagnostics of two distinct verb classes? We suggest that once certain event structure patterns are available in a given language, lexical items (verbs) can be re-interpreted as potentially conforming to several of them. From the cognitive standpoint, there is a logic of event structure preservation in reinterpreting “marvel” verbs as “amuse” verbs: namely, the Undergoer remains the single required argument. From the “marvel” event structure, a verb can simply extend into V<sub>I</sub>P and V<sub>R</sub>P, keeping argument structure intact, and be re-interpreted (and behave) like an “amuse”-group verb.

<sup>7</sup> They also resist modification by temporal adverbials. The issue merits separate investigation; we mention it here as corroborative evidence for separating ‘appeal’ verbs into a natural class.

## **Appeal**

The properties of this class can be explained as follows: 1) Like in Finnish, the co-indexed argument roles do not allow the (I)-U lexical item to surface as the subject in the presence of ANY other arguments (and the “instrumental” DP gets the subject position); 2) Causative alternation with spec- $V_1$  is empty AND co-indexed; 3) Passive alternation is impossible, because it would involve promotion of the Undergoer to the subject position, which a co-indexed I-argument slot would not allow.

The overall typology of English psych verbs is presented in table 2.

**Table 2. Typology English psych verbs.**

Event structure\argument structure		I ≠ U	I = U
Telic (RP present)	U ≠ R	“Admire”	
	U = R		“Amuse”
Atelic (no R present)		“Marvel” English	“Appeal” English

#### 4. Event structure of psych verbs across languages: factorial typology and its ontological salience.

In the previous sections we have demonstrated that the event structure patterns realized for psych verbs in English and Finnish include both telic and atelic verbs in which the roles of I, U and R can be co-indexed to produce a factorial typology in Table 3.

**Table 3. Factorial typology of Finnish and English psych verbs.**

Event structure\argument structure		I not co-indexed w/U (Experiencer Subject)	I co-indexed w/U (Experiencer Object)
Telic (RP present)	U ≠ R	“Admire” English	
	U = R	1b Finnish	2 Finnish, “Amuse” English
Atelic		1a Finnish, “Marvel” English	3 Finnish, “Appeal” English

The co-indexing of argument roles has the following effect on syntactic role realization: an argument co-indexed with an empty argument role (spec-V<sub>P</sub>-slot in psych verbs) does not surface as a subject. Thus, an event structure breakdown of psych verbs explains the language-internal dichotomy of Subject and Object Experiencers, and makes valid cross-linguistic predictions for the realization of syntactic roles. Thus, the event-structural approach emerges as a cognitively-based tool for solving problems at the semantics-syntax interface, including syntactic role and case assignment. It also explains verb frame alternations within a language, and makes valid predictions as to

cross-linguistic syntactic behavior of verbs conforming to specific event-structure patterns.<sup>8</sup>

The problem of capturing complete and exhaustive verbal meanings cross-linguistically has been a problem for many ontologies (see Shalley and Zaefferer 2006, for review). The main advantage of the event-structural approach to capturing predicate meaning in an ontology lies in its ability to represent minimal units of meaning for verbs (not just psych verbs, but other verb groups as well – see Malaia, 2005, for examples) of different languages in a single ontology. That ontology can then be linked to lexical items in ways that capture the specifics of their meaning relevant to a verb's semantics, syntactic combinability, and argument structure. The event-structural approach to the ontological representation of verbs that we offer is cognitively motivated, and independently confirmed by psycholinguistic (e.g. O'Bryan 2004). It is also supported by corroborative evidence from research in theoretical linguistics for both spoken (e.g. van Hout 2000, Ramchand 2003) and signed languages (e.g. Wilbur, 2007).

## **Abstract**

This paper presents a semantic account of argument selection of nominals in terms of ontological relations formally represented in the model of Generative Lexicon (Pustejovsky 1995). I argue that argument-taking nominals are either “relational” or “thematic”, depending on how the denotation of the head noun is determined with reference to the ontological relations encoded in its lexical semantic representation. Based on an analysis of semantic interpretation of nominals within the GL framework, I claim that the arguments related with an Agentive qualia role can be syntactically realized under the eventive interpretation of the head noun whereas those related with a Telic qualia role are syntactically inert. The nominals whose denotation has only indirect relevance to an event interpretation select arguments on the basis of ontological relations encoded in their Constitutive roles in qualia structure.

**Keywords:** argument selection, agentive noun, qualia, ontology, Generative Lexicon.

## **1. Introduction**

Verbs are a prototypical argument-taking category. They need to select proper arguments because the event denoted by a verb is represented in terms of semantic or thematic roles that the arguments of the verb (namely, the set of individual event participants) bear in relation with each other. Thus, the argument selection of verbs is in substantial sense a linguistic manifestation of eventiveness. Is this the case in other argument-taking categories? Obviously nouns are an argument-taking category, but the expression of eventiveness is not so much self-evident as that of verbs because they denote individuals as well as events. Then, do they select arguments in a manner substantially different from verbs? If so, how is the eventiveness concerned with the syntactic or lexical realization of semantic relations associated with arguments of nouns?

In this paper I would like to explore a semantic account of argument selection of nouns in terms of ontological relations formally represented in the model of Generative Lexicon (Pustejovsky 1995). I argue that argument-taking nominals are either “relational” or “thematic”, depending on how the denotation of the head noun is determined with reference to ontological relations encoded in lexical structure. In the next section, with a brief review of two different approaches to the eventiveness in nominals, I will show that the notion of eventiveness has correlations with the distinction in the interpretation of nouns and the selection of arguments. Then, we will see that eventiveness of agentive nominals is not morphologically marked in English but in Japanese eventive and noneventive agentive nominals are differentiated morphologically. In sections 3 and 4, I will show that the arguments associated with the Telic qualia role are not syntactically realized as the complements to the noun but those of the Agentive qualia role are syntactically realized under the eventive interpretation of the head noun. In section 5, a closer look at complex agentive nominals in Japanese reveals that a third type of nouns should be identified in relation with eventiveness. Two pieces of evidence are given to show that this type of agentive nouns is more like event nouns than stage-level nominals.

## 2. Eventive Interpretation

Rappaport Hovav and Levin (1992) propose an analysis of *-er* nominals in terms of the distinction between event and non-event nominals. According to their analysis, the two types are characterized as follows:

(1) a. Event *-er* nominals:

- typically receive an agentive interpretation (*driver, walker, baker*).
- inherit the complement structure of the base verb.
- presuppose that the entity expressed by the nominal have actually participated in the event denoted by the base verb.

b. Non-event *-er* nominals:

- receive a variety of interpretation, including an instrument interpretation (*dryer, grinder, printer*).
- do not inherit complement structure.
- do not presuppose that the event has occurred.

What is important in their analysis is the correlation between the presence of complement structure and the event interpretation of nouns. Compare the nouns in the *-er* form in (2a) and (2b). In (2a) the head noun selects the argument of the base verb as its syntactic complement while in (2b) the complement noun is missing, or in a compound form, it appears as a word-internal noun:

- (2) a. a grinder of imported coffees  
b. a grinder, a coffee grinder

Rappaport Hovav and Levin note that there is a difference in the denotation of the nominals in (2a) and (2b). The nominal in (2a) denotes a person who has actually been engaged in the action of grinding coffee and thus presupposes that an event of grinding has occurred. This is what they call an event interpretation. In contrast, a grinder on the instrumental interpretation in (2b) may properly denote a machine designed for grinding something even if it has never been used in an actual situation. The instrumental interpretation is not eventive because it does not presuppose that the event has occurred. The contrast in (2) shows that the event interpretation of an agentive noun has a correlation with the presence of complement structure. In (2a), the argument of the verb from which grinder is derived is syntactically realized as the complement to the noun. In (2b), the argument is absent in the simple noun, or it is expressed word-internally in a compounding form.

The event/non-event distinction is also embedded in Pustejovsky's (1995) and Busa's (1996) analyses of nominals in the Generative Lexicon framework. Pustejovsky proposes that the distinction between individual-level predicates (e.g. *Firemen are intelligent.*) and stage-level predicates (e.g. *Firemen are available.*) can be extended to the distinction in nominals. For example, *violinist* and *pedestrian* are different in this respect. The former may refer to a person who is not engaged in the activity of playing the violin at the time of reference. The noun is thus not eventive because we need not assume a particular situation that determines the proper denotation of the noun. In contrast, the noun *pedestrian* is eventive, i.e. a stage-level nominal, because it properly denotes an entity only if the entity is identified as being involved in the walking event. The difference in eventiveness shows up in the contrasts in (3) and (4)(Busa 1996).

- (3) a. Watch out, there is a pedestrian on the crosswalk!  
b. Watch out, there is a violinist on the crosswalk!

- (4) a. a frequent passenger/customer  
 b. ?a frequent violinist/teacher/doctor

The sentence in (3a) implies that the person referred to as a pedestrian is walking on the crosswalk at the time of the utterance whereas the sentence in (3b) lacks this implication. The examples in (4) show that stage-level nouns can collocate with temporal adjectives such as *frequent* whereas individual-level nouns cannot. Stage-level nouns have an implication for an event-related interpretation of the noun but individual-level nouns lack such an implication, or they only indirectly invoke an event.

In the GL model of lexical semantics, the two interpretations are associated with different qualia relations in lexical representation. According to Pustejovsky, the event interpretation of stage-level nominals follows from the Agentive role of the noun, while the non-event interpretation of individual-level nominals is associated with the Telic role of the noun. This leads to the following representations of qualia structure.

- (5) a. violinist  
 Qualia = FORMAL = x  
 TELIC = play (e, x, y: violin)  
 ...  
 b. pedestrian  
 Qualia = FORMAL = x  
 AGENTIVE = walk (e, x)  
 ...

Notice that in Pustejovsky's account of agentive nominals the correlation between the eventiveness of nominals and the presence of complements is not put into question—a matter on which Rappaport Hovav and Levin have put particular focus.

Given those two approaches to the semantics of nominals, two questions arise as to the eventive interpretation of nominals in relation with the selection of arguments. The first question is if there are any empirical differences between the two analyses of eventiveness in nominals. The second one is how the eventive interpretation of nouns is correlated with the presence of complement structure and the interpretation of the noun?

Pustejovsky's and Busa's arguments for the individual/stage-level distinction are not particularly confined to agentive nouns in *-er* form; however, it should be noted that the distinction can be applied to a single lexical item, resulting in a polysemous

interpretation of the agentive nominal. For example, *driver* can be interpreted either as a individual-level or stage-level noun. A person may be referred to as a driver if his or her job is operating a vehicle, or if he or she has actually been engaged in the activity of driving. The former is an individual-level (noneventive) reading and the latter is a stage-level (eventive) reading. In light of this distinction, compare the examples in (6):

- (6) a. Police have arrested the driver of a double-decker coach that overturned on a motorway slip-road near London's Heathrow Airport.  
b. Police officers pulled over the stolen car and arrested the driver.

In (6a), *driver* has an individual-level reading whereas in (6b) driver is most likely to be understood as a stage-level noun.

The eventiveness distinction explicitly shows up if the two types of nouns are modified by distinct types of modifiers. In (7a), with a temporal modifier the agentive noun has a stage-level interpretation, while in (7b), with a property modifier it allows an individual-level interpretation.

- (7) a. an occasional driver  
b. a talented driver

As shown in (6) and (7), English does not have any morphological markers to differentiate the two types of nominals, but Japanese has distinct affixes for the individual-level and stage-level nominals, as noted in Kageyama (2002). Japanese has the derivational morphemes, *shu* and *sha*<sup>1</sup>, which are affixed to verbs (or more precisely verbal nouns) to derive agentive nominals. The two affixes roughly correspond to the individual and stage level distinction of nominals. Take a look at the following examples in which the two affixes are attached to the verbal noun *untēn* 'to drive'

- (8) a. *untēn-shu* (DRIVE-*shu*) 'driver'  
b. *untēn-sha* (DRIVE-*sha*) 'driver'

---

<sup>1</sup> *Shu* and *sha* are Sino-Japanese morphemes, which literally mean 'hand' and 'person' respectively. One of the anonymous reviewers has pointed out to me that the same distinction may hold in languages that share the etymologically related morphemes, Japanese, Korean and Chinese. This point is beyond the scope of the present paper.

*Unten-shu* normally refers to a professional driver, while *untensha* simply means a person who drives a car. So, *driver* in (6a) would be translated as *untenshu*, and *driver* in (6b), *untensha*.

The polysemic interpretation of individual nouns in English can be represented in lexical semantic structure, associated with different qualia of a single lexical item. *Driver* has the following lexical representation<sup>2</sup>:

- (9) driver  
Qualia = FORMAL = x  
TELIC = drive (e, x, y: vehicle)  
AGENTIVE = drive (e, x, y: vehicle)

Given that the activity of driving is specified for the value of the telic role and the agentive role, the polysemic nature of the agentive noun may be attributed to the multiple encoding of the eventiveness in the lexical semantic representation.

On the other hand, in Japanese, the individual-level and stage-level distinction is made by the morphologically distinct affixes. Thus, the interpretation of *untenshu* (DRIVE-shu) is associated with the value in the Telic quale and that of *untensha* (DRIVE-sha) is associated with the value of the Agentive quale:

- (10) a. *untenshu* (DRIVE-shu) ‘driver’  
Qualia = TELIC = drive (e, x, y)  
b. *untensha* (DRIVE-sha) ‘driver’  
Qualia = AGENTIVE = drive (e, x, y)

Agentive nominals affixed with *sha* from a large class of agentive nominals in the lexicon of Japanese; however, the *shu/sha* distinction of complex nominals does not completely correspond to the eventiveness distinction. There are some irregularities between the form and meaning of agentive nominals. For example, in each pair of examples (11) through (13), (a) has an individual-level (telic) interpretation while (b) has a stage-level (agentive) interpretation. The distinction is morphologically marked as such pairings as *shu/sha*, *ka/sha*, *ko/te*.

---

<sup>2</sup> We put aside here the question of how instrumental interpretations of *driver* (a computer program or a golf club) should be represented in qualia structure. We will return to this question shortly.

- (11) a. unten-shu (DRIVE-shu) ‘driver’  
 b. unten-sha (DRIVE-sha) ‘driver’
- (12) a. ensoo-ka (PERFORM-ka) ‘performer’  
 b. ensoo-sha (PERFORM-sha) ‘performer’
- (13) a. odori-ko (DANCE-ko) ‘dancer’  
 b. odori-te (DANCE-te) ‘dancer’

Obviously, a more detailed analysis of agentive morphemes is needed. But these morphological irregularities show at least that the distinction between the Telic and Agentive interpretations are not established by means of derivational rules<sup>3</sup>.

In short, Rappaport Hovav and Levin’s distinction between event and non-event –*er* nominals does not tell anything about the regular polysemy of agentive –*er* nominals in English. We can account for the regular polysemy in terms of Pustejovsky’s stage-level and individual-level distinction in agentive nominals. This would answer the first research question addressed in the previous section. In the next section, we will turn to the second research question and discuss how the presence of complement structure in a nominal is correlated with the eventiveness of nominals.

### 3. Argument selection and nominal types

*Novelist* in (14a) is an individual-level nominal. It does not take a complement. But *author* and *writer* are stage-level nominals, licensing a complement as shown in (14b).

- (14) a. \*the novelist of this best-seller  
 (Individual-level noun)
- b. the author/writer of children’s books  
 (Stage-level nouns)

---

<sup>3</sup> *Sha* may attach to the non-verbal nominal base as in *gengogaku-sha* (LINGUISTICS-sha, ‘linguist’), *tetsu-gaku-sha* (PHILOSOPHY-sha, ‘philosopher’), or it may form lexicalized nouns such as *isha* (doctor), *gakusha* (scholar), *kisha* (journalist), *ninja* (ninja) and so on. Notice that in those cases –*sha* affixes to non-verbal elements and the resulting noun form has an individual-level interpretation. But there are some exceptions : *sakusha* (author), *haisha* (loser), *kanja* (patient) are formed in this way but they have a stage-level interpretation.

Under the GL account of eventiveness in nominals, we propose that stage-level nominals license the inheritance of arguments from the Agentive role, and the arguments are syntactically realized as the complement to the head noun, but individual-level nominals do not license the inheritance of arguments from the Telic role.

(15) a. novelist

Qualia = FORMAL = x

TELIC = write (e, x, y)

b. author/writer

Qualia = FORMAL = x

AGENTIVE = write (e, x, y)

The same observation holds for the stage and individual-level nominals in Japanese. -*Shu* agentive nominals and -*sha* agentive nominals differ in the inheritance of complement structure from the base verb. In (16a), *torakku-no* ‘of a truck’ is not a complement but a restrictive modifier of the head noun because, as (16b) shows, it can be incorporated in a compound form of the noun (cf. (2b)).

(16) a. torakku-no unten-shu (Individual-level)

truck-GEN driver

‘the driver of a truck’

b. torakku unten-shu

truck driver

‘the truck-driver’

In contrast, the stage-level nominal in (17a) does license a complement. And the complement NP cannot be incorporated in the compound form.

(17) a. zikosha-no unten-sha (Stage-level)

crashed-car-GEN driver

‘the driver of the crashed car’

b. \*zikosha unten-sha

crashed-car-GEN driver

‘\*the crashed-car driver’

Thus, the arguments of the Agentive role may be realized as syntactic complements but

those of the Telic role cannot.

Rappaport Hovav and Levin (1992: 131) point out that if a complement is expressed within a noun phrase, the head noun can only refer to a person, not an instrument. For example, a wiper of the windshield in (18a) refers to a person that wipes the windshield. In contrast, a wiper for the windshield in (18b) refers to an instrument. The only difference is that the windshield is marked with the preposition *for*, which, according to them, is used in the sense of “intended for”.

- (18) a. a wiper of the windshield  
b. a wiper for the windshield

Evidently, the *for* phrase is not a complement but a modifier of the head. It can be incorporated in the compound form of the nominal as in a windshield wiper. We will discuss more about the instrument nominals in the following section.

As for the complement selection and eventive interpretation of nominals, Barker and Dowty (1993) make a relevant proposal. They propose that “Nominal” proto-roles govern the argument-selection of nominals in a parallel fashion that “Verbal” proto-roles govern the argument-selection of verbal predicates. Verbal proto-roles consist of Proto-Agent and Proto-Patient (Dowty 1991) and nominal proto-roles are Proto-Part and Proto-Whole. One of the hypotheses that they present in their work is that if a noun denotes an event, the verbal proto-roles are relevant, but for those nominals whose denotation merely indirectly refers to an event, only nominal proto-roles are relevant (Barker and Dowty 1993: 60). In the spirit of their analysis, I would like to claim that the syntactic presence of the complement within a nominal has crucial relevance to an eventive interpretation, i.e. a stage-level interpretation, of the nominal.

#### **4. The instrument interpretation of *-er* nominals**

The class of instrumental *-er* nominals is one of the largest subclasses of *-er* nominals (*printer, dryer, grinder, heater, computer, etc.*). To see how an *-er* nominal is interpreted as an instrument, consider *printer*, for example. We assume that an instrument is a value specified for the Telic qualia relation of the verb in the Extended Qualia Structure (Busa et al. 2001). The idea underlying this is that in the activity of printing, an instrument is an indispensable part for carrying out the action.

(18) print

Qualia = AGENTIVE = print (e, x, y)

TELIC = create (e, x, y: printed matter)

Assume further that the Telic role of the base verb is mapped onto the Telic role of the derived noun. Consequently, we have the following representation:

(19) printer

Argument Structure = AG1 = R(z)

Qualia = FORMAL = z

AGENTIVE = print (e, x, y)

TELIC = create (e, x, y: printed matter)

It is the Telic relation of means/instrument that brings about the instrumental interpretation of the noun.

Note that *-er* nominals on the instrumental interpretation systematically do not inherit the complement of the base verbs. This fact suggests that the instrumental *-er* nominal is an individual-level noun. With respect to this point, Roeper (1987: 294) makes an interesting observation. In (20), the nominals with syntactic complements have an agentive reading (that an human being is involved), whereas in (21) each compound form has either an agentive or instrumental reading.

(20) a. a trimmer of trees

b. a cutter of hedges

(21) a. a tree-trimmer

b. a hedge-cutter

This phenomenon yields to the same explanation given in the previous section. If an *-er* noun on the instrumental interpretation is an individual level nominal, then it does not inherit the complement structure of the verb from which the nominal derives. Thus, in short, arguments that are associated with the Telic qualia relations are not syntactically realized as the complement to the noun but arguments of the Agentive quale are realized syntactically under the eventive interpretation of the head noun<sup>4</sup>.

---

<sup>4</sup> Lieber (2004) notes a few examples of *-er* nominal which are derived from a nominal base, e.g. *freighter*, *Londoner*. They are problematic for an analysis based on verbal argument structure. But our

## 5. Event-related nominals and event nouns

We have so far distinguished two types of agentive nominals in terms of eventiveness. Kageyama (2002) claims that stage-level nominals may be divided further into two types. Evidence in support of this claim comes from the existential construction illustrated below. The stage-level nominals in (22a) can appear as the subject of the verb of existence *aru*, whereas those in (22b) cannot. Call the former class of nouns event-related nominals.

- (22) a. *sanka-sha/ riyoo-sha/ mokugeki-sha ga aru.*  
participant/ user /witness –NOM aru.  
b. *\*unten-sha/ \*ensoo-sha –ga aru.*  
driver / performer –NOM aru.

In order to understand how the nominals in (22a) are interpreted in the existential construction, we need to give a brief explanation of the verb of existence in Japanese. In Japanese, the verb of existence has different forms depending on the animacy of the subject. *Iru* is used with an animate subject and *aru* is used with an inanimate subject.

- (23) a. *nakaniwa-ni gakuseitai-ga iru/\*aru.*  
patio-LOC students-NOM iru/aru.  
'There are some students in the patio.'  
b. *teeburu-no ue-ni hon-ga aru.*  
table-LOC book-NOM aru  
'There is a book on the table.'

(23a) shows that *aru* cannot be used with the animate subject *gakuseitai* ('students'). Because of this animacy condition on the selection of verb form, the *aru* form is used when the subject is a so-called 'event noun'. In (24) the event nouns MEETING and ACCIDENT cooccur with the verb *aru*.

- (24) a. *3ji-ni kaigi-ga aru.*  
at 3 o'clock meeting-NOM aru  
'The meeting is at 3 o'clock.'

---

analysis can be extended to incorporate those cases in terms of qualia structure of the nominal bases.

- b. kinoo koosaten-de jiko-ga atta.  
 yesterday intersection-LOC accident-NOM aru-PAST  
 ‘An accident occurred at the intersection yesterday.’

Keeping in mind the usage of the verb described above, let us now see what happens if an event-related nominal occurs with *iru* or *aru*. Because event-related agentive nominals in (22a) are animate, they can cooccur with the *iru* form of the verb. Thus, we have the *iru* form for event-related agentive nominals as illustrated in (25a), along with the *aru* verb in (25b) (cf. (22a)).

- (25) a. toshokan-ni riyoo-sha-ga ita.  
 In the library users-NOM iru-PAST  
 ‘There are some users in the library.’  
 b. toshokan-ni riyoo-sha-ga atta.  
 In the library users-NOM aru-PAST  
 ‘There was an event that people use the library.’

The sentences in (25a) and (25b) are subtly different in meaning. (25a) simply conveys the meaning that some users are in the library, but (25b) means that an event takes place at the time of reference. Thus, with the verb *aru*, event-related nominals are interpreted in a similar fashion as the event nouns in (24).

In addition to the eventive interpretation that event-related agentive nominals have in the *aru* verb construction, they behave like event nouns in another respect. Recall that stage-level nominals can express their arguments as the complement to the head noun. Event-related nominals can express adjuncts as well as complements from the verb they are based on. USERS in (22) can have an argument (THE LIBRARY) and an adjunct (IN WHEELCHAIRS).

- (26) Event-related nominals  
 a. toshokan-no riyoo-sha  
 library-GEN users  
 ‘the users of the library’  
 b. kurumaisu-de-no toshokan-no riyoo-sha  
 wheelchairs-GEN library-GEN users  
 ‘the users of the library in wheelchairs’

Similarly, event nouns license both arguments and adjuncts. CONSOLIDATION (27a) is an argument and in IN THE MEETING ROOM (27b) is an adjunct.

(27) Event nouns

- a. gappeimondai-no      giron  
consolidation-GEN    discussion  
'the discussion of consolidation'
- b. kaigisitu-de-no          giron  
meeting room-LOC-GEN discussion  
'the discussion in the meeting room'

Event-related nominals and event nouns syntactically license adjuncts specifying for time, location and means within the noun phrase. But stage-level nominals do not license adjuncts at all. See the examples in (28).

(28) Stage-level nominals

- a. zikosha-no          unten-sha  
crashed-car-GEN driver  
'the driver of the crashed car'
- b. \*koosoku-dooro-de-no zikosha-no          unten-sha  
freeway-LOC-GEN    crashed-car-GEN driver  
'the driver of the crashed car on the freeway'

Thus, event-related nominals are more like event nouns than stage-level nominals. In other words, event-related nominals are more 'verbal' than other stage-level nominals.

## 6. Conclusion

In this paper, I have shown that the notion of eventiveness in nominals has correlations with the interpretation of nominals and the syntactic realization of arguments and adjuncts. We have seen that eventiveness of agent nominals is not morphologically marked in English but in Japanese eventive and noneventive agent nominals are differentiated morphologically. Within the GL framework, I have argued that the qualia relations in Telic are not syntactically realized as the complement to the noun but those of Agentive are realized syntactically under the eventive interpretation of

the head noun. A closer look at complex agentive nominals in Japanese reveals that the third type of nouns should be identified in relation with eventiveness. Two pieces of evidence are given to show that this type of agentive nouns is more like event nouns than stage-level nominals.

# Endangered Mongolian Dialects in the North-western China \*

## Abstract

Though Mongolian is regarded as one of China's regional dominant languages, some dialects of it, especially outside Inner Mongolia, face danger of disappearing in the next several decades, used in limited social domains. Endangerment of some subdialects of the Oirat dialect and Khalkha dialect distributed over the north-western China is a case in point. Emergence of such endangerment is mainly caused by the following reasons: a) sparse population; b) Urbanization and immigration; c) Educational reasons; d) other reasons such as religious reasons, language attitude and intermarriage.

**Keywords:** Endangerment, Mongolian, Oirat Dialect, North-western China.

As is known to all, China is a multi-ethnic country with abundant language resources. According to statistics by Chinese scholars, more than 120 languages are being used in today's China although there are only 56 nationalities in the country. Of those languages, most are included in the Sino-Tibetan and the Altaic groups while some are typologically belong to the Indo-European and Austro-Asiatic families.

At the same time, China is also a country facing endangerment of some languages and dialects. Scholars say that half of the languages in China are gradually declining in social function, and some 20 of them are in danger of disappearing in the next several decades. Currently included in the list of severely endangered languages are: Manchu, Tatar, Orchun (Elunchun), She, Hezhe, Xiandao, Tujia, Melao, and some other ethnic languages in the southern China.

In early 1990s, the language endangerment had been popularly paid attention by international scholars. Although there were some different points of view on the

---

\* This paper is one of the staged achievements of the project *An Atlas of Mongolian Language in the Western China* (06XYY018) sponsored by the National Philosophy and Social Sciences Fund.

language endangerment, Chinese linguists responded actively by attaching importance to the issue since mid 1990s. As a result, some research projects on endangered languages have been conducted, and field works on some endangered languages and dialects have been done in succession. For instance, the Institute for Ethnology and Anthropology, Chinese Academy of Social Sciences completed China's part of *The World Languages Report* by UNESCO, and some works on China's endangered languages were published.

According to the *Language Vitality and Endangerment* (2003: 7-8) by UNESCO Ad Hoc Expert Group on Endangered Languages, the language endangerment can be ranked into 7 degrees: (1) safe; (2) stable yet threatened; (3) unsafe; (5) definitely endangered; (6) severely endangered; (7) critically endangered. Although the degree classifications are approved by most Chinese scholars, other criteria for language vitality and different classifications of endangerment degrees were suggested. For instance, some scholars made a proposal that the languages in China may be classified into three groups: dominant, vulnerable, and endangered.

In any case, many factors show that Mongolian should be listed in the safe or dominant group together with Chinese, Tibetan, Uighur, Kazakh, Korean, and some other languages in the southern China. Why can Mongolian be regarded as a safe or dominant language? Reasons are as follows:

1. Among the Mongols in China, some 70% are native Mongolian speakers, which means the absolute number of the Mongolian speakers is at least more than 4,000,000. (According to the census in 2000, the total population of Mongolian nationality in China has reached 5,810,000.)

2. Written Mongolian is used not only in Inner Mongolia Autonomous Region but also in other 7 provinces (autonomous region), including Xinjiang, Qinghai, Gansu, Heilongjiang, Jilin, Liaoning, and a small part of Hebei province.

3. Both written and spoken Mongolian are used in kindergartens, schools, and colleges. In other words, younger generations can receive education in their mother tongue at all levels, and teaching materials are considerably complete.

4. The Mongolian language is actively used in everyday media. Inner Mongolian Satellite TV broadcasting covers all over the country and the Mongolian radio broadcasting stations extend everywhere especially in Inner Mongolia. According to the latest statistics, close to 60 newspapers, and magazines are published in Mongolian. In Inner Mongolia, Xinjiang, Beijing, and Liaoning, there are 10 publishing houses which publish Mongolian books.

5. Protective regulations and measures are adopted; language policies are

favourable for Mongolian. For example, rules for Mongolian language use have been enforced in Inner Mongolia and Fuxin Mongolian Autonomous County, Liaoning Province.

At the same time, however, some indications also show that Mongolian is not such safe or dominant. For example:

1. Pupils at schools teaching in Mongolian have been reducing year by year since 1990s, resulting in that many primary and middle schools have closed down.

2. Although Mongolian has the legal status of the first official language in Inner Mongolia as well as in other autonomous prefectures and counties of Mongolian nationality, its actual use in administration etc. is very limited.

3. Because of the strong influence from other dominant languages such as Chinese, not only bilingualism has been more popular, but also creolization is becoming increasingly serious even in Inner Mongolia.

4. Although Mongols' language attitudes towards their own language are usually not negative in most areas, some have less positive attitudes towards it. What is more, some view their own language as a hindrance to economic mobility and integration into mainstream society. For the reason, more children are sent to schools where all of classes are taught in Chinese.

Considering the factors mentioned above, some suggest that Mongolian should be put into the unsafe or vulnerable group in spite of its official status and relatively wider use at present.

Surveys carried out outside Inner Mongolia Autonomous Region indicate that the Mongolian language is in a more unfavourable situation. Endangerment of some Mongolian dialects or subdialects over the north-western China (Xinjiang, Qinghai, Gansu) is a case in point. Apart from Khkha dialect distributed over Gansu province and Xinjiang Uighur Autonomous Region, all Mongolian subdialects in this region belong to Oirat dialect, which is classified as a separate Mongolic language by western scholars. Up to early 1990s, Oirat dialect was more stable than those in the eastern part of China. However, endangerment of the dialects is today deeply concerned by people and experts, who are engaged in research on Mongolian.

Severely endangered Mongolian dialects and subdialects in the north-western China are as follows:

1. In Xinjiang Uighur Autonomous Region:

- (a) Uriyangkhai subdialect in Altai City, Qinghe County, Fuyun County, Bu'erjin County;

- (b) Xinjiang Chakhar subdialect in Emin County, Tuoli County, and Tacheng

City;

(c) Jakhacin subdialect in Wusu City;

(d) Ölet subdialects in Yili Prefecture;

(e) Khalkha dialect in Balikun County.

2. In Qinghai Province: Khoshut subdialect in Haiyan County, Qilian County, Mengyuan County, Henan County, and Gonghe County;

3. In Gansu Province: Khalkha dialect in Sunan County.

Besides the above, some other subdialects such as Torghut subdialect in Hebukesair County and Chakhar subdialect in Bo'ertala are also at risk even though the Mongolian speakers inhabit in compact communities.

Scholars say that some Chinese dialects are on a path toward extinction due to the popularisation of Mandarin Chinese. Contrary to this, all of those endangered Mongolian dialects or subdialects in the north-western China are actually not under the threat from the standard Mongolian or local dominant Mongolian dialects but mainly under the threat from Chinese. Mongols in this region are bilingual or multilingual; however, Chinese has become their first preference for education and social communications. Especially in towns, the social position of Mongolian has been weakened, with the result that it has become a family language or a communicative language for elderly people.

On the other hand, some of the dialects or subdialects have been extremely influenced by other local dominant languages such as Tibetan and Kazakh, and will be replaced by the languages in the near future. For example, most Mongols in Henan County of Qinghai Province have become Tibetan speakers while only a small number of elderly people there still speak Mongolian. Similarly, younger Uriyangkhai Mongols in Qinghe County of Xinjiang Uighur Autonomous Region have also lost their own language, and Kazakh has become their adults' first language instead of Mongolian.

Occurrence of such endangerment is mainly caused by the following reasons:

1. Sparse population. As it is known to all of us, Mongols in the north-western China account for the absolute minority within the total population. For example, some 160,000 Mongols in Xinjiang are distributed over many counties or towns, one with the largest Mongolian population (ca. 27,000) of which is Hejing County of Bayinguoleng Mongolian Autonomous Prefecture. As for other counties or towns, amounts of the Mongolian speakers vary from several hundreds to some 15,000. Without doubt, the sparse population is an important cause led to the endangerment of Mongolian dialects in the north-western China, as a small speech community is always much more vulnerable than larger one. Moreover, Mongols in this region are usually surrounded by

people who speak a dominant language other than Mongolian.

**Mongolian population in chief prefectures and cities (2000)**

provinces (region)	prefectures (cities)	amounts	percentages (%)
Xinjiang	Bayinguoileng	43,544	4.1
	Bo'ertala	23,927	5.6
	Yili	26,624	1.3
	Aletai	5,486	1.0
	Tacheng	29,759	3.3
	Changji	6,062	0.4
	Hami	1,970	0.4
	Urumqi	7,252	0.3
	Kelamayi	1,842	0.6
Qinghai	Haixi	24,020	7.2
	Haibei	13,087	5.1
	Hainan	2,637	0.7
	Huangnan	29,071	14
	Xining	10,709	0.6
Gansu	Jiuquan	4,958	0.5
	Zhangye	916	0.07
	Lanzhou	2,802	0.09

2. Urbanization and migration. For ecological and economic reasons, many rural people in China have moved to towns or cities in recent years, and the migrants include many Mongols including those from western China. Surveys indicate that urban Mongols in Urumqi, Bole, Ku'erle, Yili, Jiuquan, Zhangye, Lanzhou, Xining, and Delingha have doubled in the last ten years. For example, more than 70 Mongolian households from Hebukesai'er County bought houses in Urumqi in 2007 alone although the adult members of them were still working in the county.

When the Mongols are in the countryside, everything is certainly more favourable to learning and safeguarding their mother tongue. After they move to towns or cities, situations will be entirely different: (1) Mongols will become the absolute minority within the total population; (2) the Mongolian language and culture will lose their original social basis and more beneficial environments; (3) most of Mongolian children have to study in Chinese schools.

3. Educational reasons. As mentioned above, Written Mongolian is also officially used among the Mongols in the north-western China. At the same time, Mongols in Xinjiang have their own dialectal writing system named *Todo üsüg* "clear script", which was created in 1648 by Zaya Pandida Namkhajjamsu. In other words, Mongols in this region receive basic education in their mother tongue. However, a harsh fact is that pupils at primary and middle schools teaching in Mongolian have rapidly decreased in recent years. More seriously, many Mongolian schools were streamlined or

amalgamated because of a short supply of school-age children and pupils. With several thousands of pupils, there were in all 104 Mongolian schools (67 primary schools, 26 junior middle schools and 11 senior middle schools) in Xinjiang Uighur Autonomous Region in early 1990s. Of them, only a few are today still existing by themselves and continuing to teach in Mongolian. In most places, however, all classes except *Mongolian language and literature* are taught in Chinese on the basis of bilingual educational system. At the same time, there are also some places without any Mongolian schools, including the counties Qinghe, Haiyan, Qilian, Mengyuan, Henan, and Mongolian townships in Zhangye City of Gansu Province, although where Mongols live. Mongols there who do not like to lose their language and culture have to send their children to schools in other places. For example, a few Khakha Mongolian pupils from Baiyin township of Zhangye City are studying in schools in the neighbouring counties such as Subei Mongolian Autonomous County of Gansu Province, Alashan League of Inner Mongolia. Additionally, Mongols left their native places for cities to earn their living have to send their children to Chinese schools as mentioned above. As a result, the younger generation has begun to forget their mother tongue, and the intergenerational transmission of the language will be interrupted.

(4) In addition to the reasons listed above, there also seem to be some other causes, including religious reason and language attitudes. As for the religious reason, complexion in Henan County is a case in point. According to the census in 2000, there are more than 28,000 Mongols living in the county, and the Mongols account for over 89% within the total population of the county. As brought up above, however, most people there have become Tibetan speakers except only a few elderly people. Experts think that the native language loss of them was partially caused by strong influence of the Lamaism, besides other causes. In 1980s, Henan Mongols tried to revive their own language by teaching Mongolian in schools. However, the attempt failed after more than 10 year efforts. An important cause of the failure is that people there do not like to lose their language of Buddhist scripture — Tibetan.

In many places, young people educated in Chinese usually gain the upper hand, for instance, they easier to obtain employment than those educated in Mongolian. Of course, this has led to some changes in Mongols' language attitudes towards their own language.

Obviously, Mongolian is a vulnerable language used in limited social domains in the north-western China. On the other hand, the endangered dialects themselves exhibit two outstanding characteristics: (a) in addition to the common corpus of loanwords, a number of loan elements provisionally borrowed are widely used in everyday life even

tough the conceptions can be expressed in Mongolian; (b) some borrowings are also seen at morphological level. Of course, the same phenomena are seen in some Inner Mongolian dialects as well.

Like a language, a dialect is an instrument for communication and a medium for expressing thoughts. At the same time, it is also a carrier of regional culture. Disappearance of a dialect means the permanent loss of the regional culture and the serious damage to the diversity of human language. Emergence of dialect endangerment within a language evidently presages endangerment of the language. As linguists as well as members of the speech community, we have a long-term task and responsibility to safeguard those endangered dialects. In recent years, some research projects and fieldworks on those endangered dialects were carried out. Besides collecting and archiving material sources, most importantly, what we should do is to attract attention from all circles by making an urgent appeal so that more effective and valuable policies and measures can be adopted.

**To save language is to save ethnos**  
**(on experience of the Kalmyk language revitalisation)**

**BITKEEVA Aisa**

Institute of Linguistics of Russian Academy of Sciences

125009 Russian Federation, Moscow,

B. Kislovsky per. 1/12

aisa\_bitkeeva@yahoo.com

**Abstract**

The paper considers revitalisation process of one of lesser-used languages of the Russian Federation the Kalmyk language, its role in life of the Kalmyks in Republic of Kalmykia who represent a part of Russian state super ethos, prospects of the Kalmyk language vitality and problems it faces in its current revitalisation process.

**Key words:** language in danger of extinction, language situation, language policy.

In modern world in conditions of globalisation the world community sets new requirements to multilingualism, it has come to conclusion that ethnic culture and ethnic languages are the main heritage that should be passed to future generations. The world has become more concerned about problems of minority and lesser-used languages. No doubt that the majority of languages are in danger of disappearance within several generations.

Linguists are of different points of view on the ways of managing the problem of linguistic endangerment. Some linguists are sure of possibility of saving endangered languages by active measures along with proper decision-making (Wurm, 1997), other linguists consider this endangerment linguistic problem as an inevitable natural evolution of languages and in the world there will be a single dominant language, for example English (Krauss Michael, 1997; Ladefoged Peter, 1992). Nevertheless, nowadays great attention is given to maintenance, preservation of language variety, revival of minority languages.

Some linguists are of the point of view that the greatest threats to linguistic diversity causes European model of nation-state that is followed by all European nation-states. In spite of the fact that this model was designed to stimulate the use of national languages and in the policy of these countries there is a tolerance towards different ethnicities and languages, yet programmes of nation-building based on the forced use of a single language, it does not favour linguistic diversity. Linguist Juha Janhunen considers that linguistic diversity can be better safeguarded in the countries build on empire model. It comprises several ethnic groups, speaking several different languages. The dominant language of an empire does not have to exterminate the other minority languages of the country. Empire model can be the only serious alternative to the nation-state as a basis for political consolidation. He assumes three important empires in present-day world that is China, Russia and India (Juha Janhunen, 2000). There is an opinion that linguistic process passes more quiet in the countries based on territory principle, more critical in the countries based on national-administrative division. In this context the Russian Federation is given a special role as it is a multiethnic state whose basis is formed by 176 national groups and a similar number of languages. It's quite natural that languages are on different levels of development. The languages which function within the Federation belong to different language families - Slavic, Turkic, Finno-Ugric, Caucasian, Mongolian and others. There exist old-written, new-written languages, languages without written tradition, most of them are severely threatened. Nowadays in Russia attempts are being made to make a transition to civic society. These features make the present language situation in Russia complicated, contradictory and fraught with potential conflicts. Many of ethnic languages mentioned above have been proclaimed the eponymous languages of the respective republics. National state bilingualism is quite pertinent as a way of compromise, that is the adoption of two national languages in accordance with federal and republican legislation. In this case certain republics within the Russian Federation become territories of national state bilingualism, in fact three-component multilingualism, since foreign languages are studied and partially used everywhere. The UNESCO Red Book of Endangered Languages identifies only three languages in Russia which are not threatened - Tatar, Yakut and Tuvinian. All other languages are "in process of extinction" or "endangered", the Kalmyk language included.

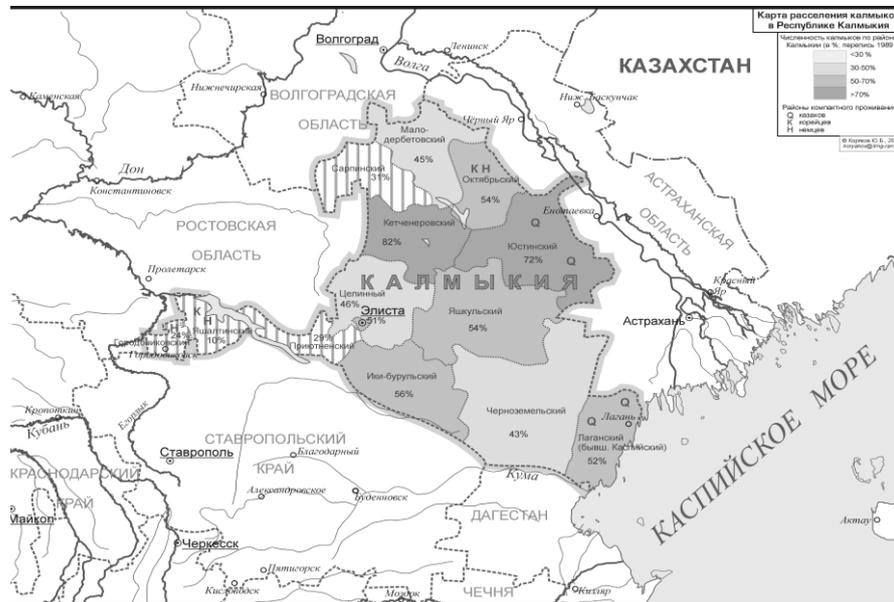

Experts point out several positive factors for revitalization process of ethnic languages in present-day Russia: 1) desire most of the native speakers of ethnic languages to expand the functions of their mother tongue, 2) definite linguistic ground for broadening of social functions of ethnic languages of Russia (publication of literature, availability of text-books, dictionaries, phrase-books in these languages etc., 3) formed traditions of national educational system where ethnic languages are languages of instruction, 4) definite social perspective for the use of these languages in different spheres of communication that is caused by the state status. But experts define also negative factors that do not favor the optimal development of ethnic languages in Russian Federation: 1) limited use of most of ethnic languages in official spheres, socio-political activity, mass-media etc., 2) “language nihilism” of some part of the population of republics, that is revealed in most cases through unwillingness to learn mother tongue on the reason of its social unprestigious status, 3) insufficiently developed language system of most of the languages to carry out functions in some important social spheres (Mikhalchenko, 1994:12-15).

Among the main trends of contemporary linguistic life in the republics of the Russian Federation is an active revitalisation process of ethnic languages and their expansion in various spheres of communication. But in most cases we face the striving for exaggeration of social role of these languages, very often insufficient lexical, semantic, functional, stylistic basis of the minority or lesser-used languages disturbs their functioning as state languages in official spheres of communication. Besides, in several republics there arises a very difficult problem of correlation between supposed communicative functions of the language and proficiency of the population in this language.

In the paper there will be considered the revival process of the present-day Kalmyk language that belongs to the west branch of Mongolian languages (Altaic language family). Nowadays Kalmyk is one of lesser-used languages of the Russian Federation, language of the ethnos that in its history went through great socio-political transformations, suffered from hardship and now happen to be scattered over different parts of the world. The Kalmyks living in the southeast part of Russia are the only Kalmyk group with a separate autonomous territory — The Republic of Kalmykia (see Tab. 1). The Kalmyks of the Republic of Kalmykia represent a part of Russian state

super ethos, their history is closely connected with all-Russian history and should be considered in all-Russian context.

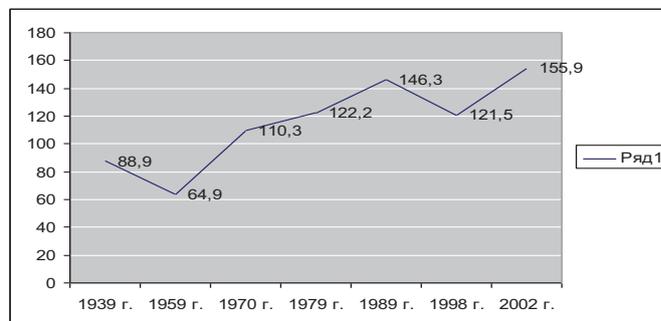

**Table 1**

Geographic situation of Kalmykia in the northern border of Caucasus on the one hand, its Asian origin as well as its cultural traditions on the other hand, have made of the Republic a crossroad of nationalities unique in Russia. The population of the Republic is 290,000 including 155,000 Kalmyks, representing 53 % of the whole population (Kegdeeva 2004) (see table 2).

**Table 2**

**Dynamics of Kalmyk population (1939-2002)**

Ethnic composition of Kalmykia is relatively balanced, according to the 2002 census about 60 ethnoses live in Kalmykia. All the factors cause a peculiar language situation and language policy in the region that is worth of special consideration.

Before the twentieth century the Kalmyks were mainly monolingual. The greatest changes in the Kalmyk language occurred after the Russian revolution of 1917. Yet with the formation of a national educational system with its plan to eradicate illiteracy Kalmyk–Russian bilingualism took off, and Kalmyk was subject to changing language policy. Kalmyk is an old-written language, the old-Kalmyk script “Todo bichg” (Clear Script) was worked out in 1648 by Zaya Pandita. In 1924 the old-Kalmyk script was replaced with Cyrillic with addition of six letters ә, ө, ү, һ, һ, ж. Later Kalmyk was transferred into Latin and then again back to Cyrillic. Nowadays Kalmyk in the Republic is written in Cyrillic.

Kalmyk language transmission patterns were weakening dramatically as far the deportation of the entire Kalmyk population during 1943-1956 produced a severe breakdown of the intergenerational transmission of the language and almost the loss of the native language by the Kalmyks. Much of this was the result of regulations prohibiting spoken Kalmyk and also the teaching of only Russian in school practised during the Soviet period. Yet in 1956 when the Kalmyks were exonerated and allowed to return to the Kalmyk Republic they tried to revive culture and language. Unfortunately, it has not been successful. Gradually Kalmyk lost its social status, most of Kalmyk speech community adopted negative attitude towards the mother tongue ceasing to pass it to the next generations.

The second half of 1980<sup>th</sup> is characterized by socio-economical, political, ideological changes in Russia. From this time there started the revision of language policy of previous years. It led to the adoption of language laws in allied republics then in autonomous republics of Russian Federation. Since 1990<sup>th</sup> there has started an aimed Kalmyk language revitalisation process. In 1991 Kalmyk was proclaimed the state language of Kalmykia along with Russian. The realization of the language legislation assumed creation of conditions for the further development of these languages, increase of the role of the languages in spiritual and cultural life of the Republic. The status of Kalmyk and Russian as state languages of Kalmykia doesn't limit rights and interests of other ethnic groups of the Republic as it guarantees and provides national equal rights,

governmental and financial assistance to cultural and language development of ethnoses living in Kalmyk Republic, preservation of their ethnic uniqueness.

In Kalmykia there is a three-component socio-communicative system: Kalmyk+Russian+other ethnic languages (including foreign ones). At the present time the first priority of language policy in Kalmykia is given to harmonization of social functions of two state languages of the Republic, moreover in the first instance enhancing of social functions of “the weak component of state bilingualism” – the Kalmyk language. The status of state one gives to the eponymous language of a particular republic more possibilities for its functional enhancement, that means its use in more various spheres of organised communication. But language that occupies high level in the system of spiritual values of society should have well-developed functional and style system for adequate representation of extra linguistic reality. There arises a very difficult problem of correlation between supposed communicative functions of the language and proficiency of its native speakers in it. Being juridically equal state languages of Kalmykia are not equal functionally in fact. Russian is used in all spheres of social activity of the Kalmyks, it carries out information, business, educational and scientific functions. Kalmyk functions in the spheres connected with national culture that is education, mass-media (TV, radio, periodicals), theatre, belles-lettres, folklore. It is partially used in the sphere of state administration, socio-political activity of the Republic of Kalmykia.

In cultural sphere the Kalmyk language is also actively promoted among the population. Kalmyk is widely used in the performances of the Kalmyk national drama theatre, folklore ensembles and groups. Traditional holidays and customs are being revived. Cultural and economic progress has promoted Kalmyk language in various spheres of mass-media. This sphere also contributes to language revitalization by popularization of Kalmyk language on TV, radio, in periodicals. The following periodicals are issued in Kalmyk language: a newspaper "Khalmg yunn" (Kalmyk truth), a literary magazine "Teegin gerl" (Light in the steppe), a magazine for children "Bair" (Happyness), an educational magazine "Gegyarlt" (Education). On Kalmyk TV and radio official languages of Republic are used in proportion 50 % of the local broadcasting time in Russian, 50 % in Kalmyk. Though for the recent time there has

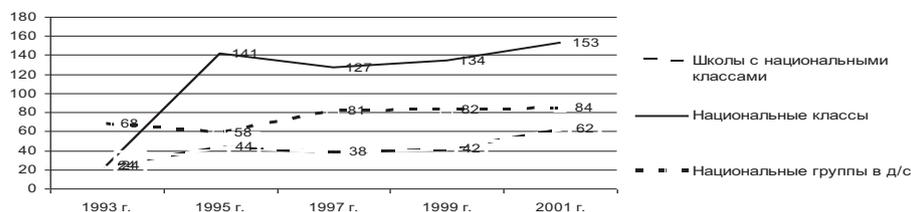

taken place a negative tendency of reduction of broadcasting time in ethnic languages, in Kalmyk in particular.

But as a rule in these spheres the use of Russian is predominant. Knowledge of Russian by Kalmyks is total as competence in Russian means social promotion, chance to get an education, good work, mobility in the all-Russian context.

One of the factors of language vitality is the use of mother tongue by the young generation. It is necessary to start the revival of the functions of the language with the sphere of school education. We can easily recount stories of the ways in which school was an important weapon in suppressing lesser-used or minority languages at some time in the past. Such facts happened to the Kalmyk language. It was the school that imposed the conviction of the superiority of Russian culture to the Kalmyk. A change in the mentality has certainly taken place. Pupils and parents blamed the ‘backwardness’ of Kalmyk for the poor career prospects of their children. It is strange that the same education system that was once used as important weapon in suppressing the language is currently playing a vital role in its preservation. Last national Kalmyk classes were closed at the beginning of 1960<sup>th</sup>. From the beginning of 1990<sup>th</sup> there has been started the process of restoration of national Kalmyk educational system. In 1993 after 30 years pause 67 national Kalmyk classes and 83 Kalmyk kindergarten groups were opened, where teaching process is carried out in Kalmyk (see Table 3).

**Table 3**

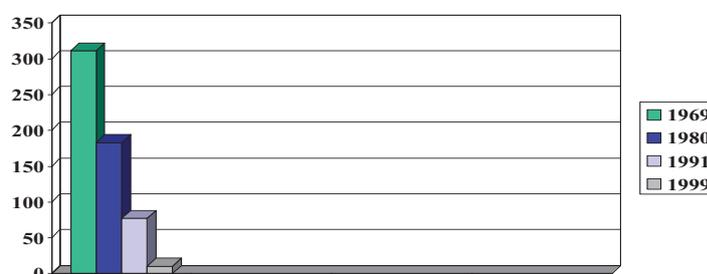

**Dynamics of the number of Kalmyk kindergartens, schools, classes (1993-2001)**

In 2001 there were already 153 Kalmyk classes and 84 Kalmyk kindergarden groups. The statistics of the Ministry of Education of Kalmykia shows the stable tendency of the rapid increase in the number of national classes with Kalmyk as a method of instruction and number of young people who speak Kalmyk. It proves the efficiency of the education system in language transmission. All the same the question remains whether that contribution is enough to ensure the long term future of the language. In spite of the positive changes the national school system doesn't work properly yet. Actually the teaching process in Kalmyk is limited to primary and secondary level of school even in Kalmyk national schools. It would appear that many of the children who have received a bilingual education make a clear division between their school and social lives and switch to Russian when they leave school. In fact the majority of children who haven't spoken in Kalmyk before school doesn't become bilingual after leaving it. There must be continuity in Kalmyk language teaching: kindergarden-secondary school-high school. Then there arises another problem the Kalmyk education system faces today, that is an urgent need in an optimal and efficient methodical complex that provided continuity in teaching process of Kalmyk as a method of instruction, this system should include various methods of teaching aimed at different social groups of population starting from children up to adults, who are eager to acquire or to improve their native language skills. There are conditions for this as nowadays the Kalmyk standard language has developed clearly defined norms that ensure its comprehensibility and accessibility to all its native speakers. The standard features have been elaborated and established in the rules of orthography and orthoepy, in bilingual and terminological dictionaries, in scientific works of Kalmyk researchers. But language of scientific sphere is mainly Russian while Kalmyk is used mainly in works, articles on the problems of Kalmyk philology (see Table 4).

**Table 4**

**Publication of Kalmyk literature  
(1969-1999)**

It is quite understandable that without social demand, incentive of the ethnos itself it is difficult to gain quick positive changes, but the case is that there exists social demand, there is corresponding legislation that regulates functional distribution of the languages in Republic, but the revitalisation process goes very slowly, to my mind it is caused mainly by the lack of language environment where Kalmyk language skills could be applied. First attention should be paid to family to attempt to influence the intergenerational transmission of languages. There is an urgent need in creation of natural language environment in which person will be surrounded by information written in his native language – advertisements, billboards, papers, TV, radio. The corresponding Kalmyk language environment should be provided in offices, transport, other spheres. In this way the media is assigned a special role in activation of interest towards the problems of the Kalmyk language. This is the main point for language revival, when language is the way of life of the ethnos. Only under these conditions language is able to survive.

Recent survey carried out by us (in the frames of Russian Presidential Programme on state support of research of young scholars) presented interesting data on real language situation among the present-day Kalmyks. Among important language vitality parameters there are demographic and communicative capacities of the language. The demographic capacity of Kalmyk is based on percentage of the Kalmyks speaking their native language in correlation to the whole number of population of the Republic. In Kamykia it makes up 43, 5 %. Communicative capacity includes the number of

communicative spheres served by the language in correlation to all the number of these spheres in the society. The Kalmyk language serves in 15 social spheres of 22 existing, but we should say in many spheres it functions partially. Age parameter of native speakers of the language is also one of the main factors of language vitality. If all age groups of the ethnos include those who speak it then next 40-50 years the language will keep its function.

The following specificity in distribution of the languages among Kalmyks was defined according to age, geographical, social parameters. Kalmyk is mainly spoken by elder generation of Kalmyks (above 60 years), it is rare used by the middle-age (30-40 years) and young (below 30 years) generations of the Kalmyks.

89 % of surveyed elder generation speak in Kalmyk intensively in everyday communication with people of their age and 12,4 % respondents use Kalmyk in communication with youngsters. Kalmyk is used by 3 % of respondents of young generation in communication with middle generation, 35,8 % of respondents among middle generation speak in Kalmyk in communication with elder generation (see Table 5).

**Table 5**

Parameter	In communication of youngsters with middle generation	In communication of middle generation with elder generation	In communication of elder generation with youngsters
Speak in Kalmyk	3 %	35,8 %	12,4 %
Speak in Russian	35,4 %	22,6 %	57 %
Speak in Kalmyk and Russian	64,6 %	63,6 %	75,9 %

The correlation of Kalmyk use by different age groups is variable and it is explained by the following reasons. The elder generation uses Kalmyk in everyday situations, in communication with the representatives of their age, middle generation and younger generation. The fact that Kalmyk youngsters communicate with each other

in Russian can be explained that education system at school is based mainly on Russian. If the interlocutor is a representative of middle and young generations he is addressed in Russian, it is explained by the fact that this generation of Kalmyks do not know or have passive skills of Kalmyk language and prefers Russian in everyday communication.

Concerning the qualitative parameter of native language proficiency then on the first place is elder generation of Kalmyks (above 60 years), students and pupils who studied in schools with Kalmyk as a method of instruction. Most of them speak fluently, understand Kalmyk speech. The worst knowledge or lack of it presented the age of 35 years, some of them understand Kalmyk speech but can't answer, native language skills are passive, some of them refuse speaking in Kalmyk being afraid of making mistakes.

The language assimilation goes faster among urban Kalmyks, it is caused by multinational structure of the town population and high percentage of international marriages. In office, in public places mainly Russian is used. But there are regions in Kalmykia (Ketchenerovsky, Yustinsky, Iki-Burulsky) where Kalmyks live compactly. In these regions the number of the Kalmyks in comparison with other ethnic groups is higher, compact living provides natural language environment, therefore this group of Kalmyks always present good knowledge of Kalmyk.

Subjective estimations of native speakers on their mother tongue independently of their veritability or falsity are very important elements reflecting the language situation. This is very interesting material from scientific point of view as it represents orientations of the ethnos, the stereotypes deep-rooted in ethnic identity of the language community. Kalmyk as mother tongue has stable position in ethnic identity of the Kalmyks. But it should be told that this correlation between native language and ethnic identity is controversial. In fact, among the Volga Kalmyks there exists a correspondence between low level of Kalmyk language proficiency and high level of ethno-language identity. In previous Soviet population censuses there was a category "native language," and the 1989 census showed that of 146,000 Kalmyks — 3.9 % claimed Russian as their native language, 96 % marked Kalmyk as their mother tongue (Goskomstat SSSR 1991: 97). In the course of the survey, however, it turned out that the census data actually represent an emotional factor. It reflects mainly the wish of Kalmyks to know their native language. Thus 96 % of respondents may consider Kalmyk as their mother tongue, but among them there are also those who do not know it

at all. The term “native language\mother tongue” usually means language of family communication since first speech skills are formed in this language. “Ethnic language,” on the other hand, means language as an ethnic symbol. Most Kalmyks confuse these two concepts. Being unable to speak their native language they identify it as their mother tongue and subconsciously take it for an ethnic symbol. Moreover, this gap is also compensated by other important elements of national identification: common historical past, ethnic traditions, customs, religion etc. It also shows that native language is still a key to Kalmyk ethnic identity in spite of the fact that in the course of recent transformations it has started to yield functionally to the language of the dominant culture — Russian. The fact that in many cases the Kalmyks do not speak Kalmyk in everyday communication is explained by unequal functional distribution of Kalmyk and Russian in Kalmykia. Everyday language need turns to be more important factor than innovations in language legislation. Nevertheless the Kalmyks are conscious of importance of preservation of their ethnic specificity. This fact depends on internal unity of the group. It turns out that at low and high degree of the native language competence the mother tongue remains an important factor of ethnic identification of the ethnic group.

During the last decades of the twentieth century the Kalmyks experienced great changes, but their mother tongue problems are still urgent issues of the day. Real language situation in Kalmykia in regard of Kalmyk is still critical. It is obvious that Kalmyk language revitalisation process faces pluses and minuses. Although Kalmyks have a sentimental attachment to their language and culture, this may not be enough to ensure that young people will acquire a good command of the language or, more importantly, that they will use it. I share the point of view of the independent consultant on language planning Dónall Ó Riagáin that the Acquisition planning (teaching the language to children) alone doesn't work. Status planning and Corpus Planning need to go hand in hand with it (Donall O'Riagain 2006). That is one of the main problems that the Kalmyk language revitalisation faces. Some other important points that should be covered by the language planning are as follows. Language problems mustn't be treated isolated but in complex way, for example there is little sense in teaching language if its use inside the educational sphere is not realised, as it happens in Kalmykia, then the revitalisation program shouldn't be burdened with unnecessary political, religious or

ideological meaning as it usually happens, there should be created an image of modern, dynamic language.

These are the results of the Kalmyk revitalisation process, how this will develop is still unclear. Experts are mostly of optimistic point of view, that is encouraged by the fact that the overwhelming majority of young people have positive emotional attitude to the mother tongue as a part of their ethnocultural identity and express readiness to take part in language preservation activities, it indicates positive results of language policy in the Republic of Kalmykia. I'm inclined to believe in the wisdom "make haste slowly" and hope that Kalmyk will get its former prestige and social meaning in life of the Kalmyk community as in previous times.

**The vocabulary of games and competitions non-involved in Altaic studies  
(from Tungusic-Manchurian and Turkic languages)**

**Gavril Robbek,**

research associate, Section of Even Philology,  
Institute of the Humanities and the Indigenous Peoples of the North of SB RAS,  
Yakutsk, Russia  
E-mail: [inip@ysn.ru](mailto:inip@ysn.ru)

There are no any serious doubts that the comparative and historical research of, the Altaic languages as a whole or, their separate groups – Turkic, Mongolian, Tungusic-Manchurian as well as Korean and Japanese is important notwithstanding the considerable difficulties arising in this area of comparative studies. One of the problems in this area is that not all the actual materials on some languages of Altaic family are collected yet. The more and more new facts, which may serve as the confirmation of the genetic kinship of languages while conducting the comparative linguistic research, continue to be elicited.

The given below words are not mentioned in the comparative research of Altaic languages or these words are not involved in the mentioned meanings of word.

For example:

Even *dović* means ‘draughts’. Evenki *dovat* - ‘draughts’. Orok *dovitu* - ‘draughts, chess’. Buryat *doibod* - ‘draughts’. Sakha (Yakut) *duobat* - ‘draughts’.

Even *kurukän* – ‘top (child’s toy)’.

Even *munükan* – ‘to compete in lassoing a moving object which is tied to a pole’.

Even *nedaldavun* – ‘throw of stone’. Its synonym is the word *ulä* – ‘to throw’, ‘to throw away’. Evenki *ulä* – ‘to spawn’. Nanai *ol’a* – ‘to throw’, ‘to cast a sweep-net’, ‘to lose’. Manchurian *val’a* – ‘to throw’, ‘to throw away (something as an unnecessary thing)’.

Even *ninkami* – ‘running with pole’. Its synonym is the word ‘*ninkan*’ – ‘crook’, ‘stick (for leaning when riding on reindeer-back)’, ‘walking stick’, ‘crutch’, ‘pole’, ‘landmark’. Evenki *nginnukan* – ‘(dry and thin) larch’, ‘dead standing trees’, ‘pole’.

Even *tangchinmai* – ‘pulling’. Its root is *tang* – ‘to pull out’. Evenki *taldi* – ‘to help to pull’. Solon *tan* – ‘to pull’. Orochi *tan-a* – ‘to pull’. Udegei *tan-a* – ‘to pull’, ‘to pull out’. Ulchi *tami* – ‘to stretch’, ‘to spread’. Oroki *ton* – ‘to pull’, ‘to tug’, ‘to stretch’, ‘to cock a gun’, ‘to bite (of fish)’. Nanai *toan* – ‘to pull’, ‘to

weave a net'. Manchurian *tanggiku* – ‘machine (for stretching a bowstring to a bow)’. Korean *tanggi-da* – ‘to pull’, ‘to attract’.

Èven *hamnubahah* – ‘a fish-leather sac used in a game’. Its root is *ham* – ‘to mix (with)’, ‘to intermix’, ‘to connect’, ‘to unite’. Oroki *poptali* – ‘to mix (with)’, ‘to intermix’.

Èven *bul'divun* – ‘a wood stick which is decorated from its both ends with tin’. It is used in the *ninkami* game (‘running with stick’) as well as it serves as a protector which is hanged up to a handle of cradle and which wishes a child to have many reindeer in the future and which wishes his/her reindeer not to run away.

Èven *digapan* – ‘a men’s cap of elk’s or reindeer’s leather’. Men put it on, when they compete in tugging lasso with their neck.

Èven *dänngäpän* – ‘a women’s headgear’. Women put it on, when they participate in the games in tugging lasso with their neck.

Èven *imangga* – ‘a stick for high-jump competition and for competition in jumping from sledge’.

Èven *inngatac härächä* (idiom) – ‘a men’s decoration in a form of wide strip, which is made of elk mane and is sewed on to an elk’s or reindeer’s leather’. It shows elk’s or wild reindeer’s track and that a man is lucky in hunt. The winners of various games and competitions are awarded it.

Èven *inrämi* – ‘in Èven fairy-tales, it is a winter cap for bogatyrs’.

Èven *kangdun* – ‘a block of wood tied to a reindeer’s neck in order to prevent a reindeer from running far away’. It is used in a load-transporting (stone-transporting) game.

Èven *kamn'ai* – ‘a men’s costume for participating in summer games, competitions’.

Sakha *tutum ärgiir* (idiom) is a traditional competition of the Sakha people. *Tutum* – ‘fist-height-size distance’ (long measure of the Sakha). *Ärgiir* – ‘circle’, ‘turn’, ‘cycle’. Èven *ärgin* – ‘to circle’, ‘to soar’ (in the air – of birds, planes). Evenki *ärgäktä* – ‘to circle’, ‘to soar (in the air)’. Manchurian *ärguvä* – ‘to encircle’, ‘to go round’, ‘to take round’, ‘to tie round’, ‘to wind’, ‘to roll up’. Old-written Mongolian *ergi* – ‘to circle’, ‘to rotate’, ‘to revolve’. Mongolian *ärgüülä* – ‘to turn’, ‘to wind’. Buryat *är'e* – ‘to circle’, ‘to rotate’, ‘to revolve’.

Sakha *homuur hapsağai* (idiom) is Sakha wrestling. Verbatim: *homuur* comes from the word *homulunnar* – ‘to crush’, ‘to press in’. *Hapsağai* – ‘adroit’, ‘dexterous’, ‘quick’. *Hapsağai kihi* – ‘a quick person’.

Sakha *kilii* – ‘long jumps on one leg’.

Sakha *istanga* – ‘long jumps on each leg in turn’.

Sakha *kuobah* – verbatim: ‘hare’. It means ‘long jumps on both legs simultaneously’.

Sakha *oğus uonna chöngöchök* – ‘rope tugging’. Verbatim: *oğus* – ‘ox’, *chöngöchök* – ‘stump (of tree)’.

Sakha *külüüstähii* is the name of game. It means ‘tugging with fingers’. It comes from the word *külüüs* – ‘lock’.

Sakha *öhös torbos* – verbatim: ‘obstinate calf’. It means ‘competition in tugging with neck’.

Sakha *kirinaastiir* – ‘jumping while relying on hands’. It comes from the word *kirinaas* – ‘ermine’.

Sakha *harah simsii* – ‘to play hide-and-peek’. Verbatim: ‘to screw up one’s eyes’.

Sakha *halbas haratin miinii* (idiom) is the name of game. *Halbas* – ‘a rope hauled tight between two pillars’. Children are to sit down on the rope in special way and they are to try to keep their place, balancing. Here they are to count all the parts of horse, while striking the rope with stick.

Sakha *it buutun ohsuhuuta* (idiom) is the name of game. Verbatim: ‘wrestling while standing on one foot’.

Sakha *aiah hostoohuna* – ‘tugging’. Verbatim: ‘to pull out with one’s mouth’.

Sakha *ann’a bördö* (idiom) is the name of game. A participant is to push his rival beyond a certain line.

We have only emphasized the theme of the names of games and competitions. This layer of vocabulary is interesting, first of all, by the fact that some above mentioned words have no parallels in the noted above languages but they may be parallels in the other Altaic languages.

The main directions of the research in demonstrating the Altaic commonality are set forth in the works of the classical scholars, founders of the Altaic theory as well as in the published works of the Section of Altaic Languages at the Institute of Languages of the USSR Academy of Sciences founded in 1957 in Leningrad. From its foundation, the Section of Altaic Languages became an organizing and scientific centre of Altaic studies in the USSR. At present, there is no such united

centre except the Department of Ural-Altai Languages at the Institute of Linguistics of RAS (Moscow) and the foreign centres in Korea, the USA, Germany, China and other countries.

In this report, we have only touched on the question of, the non-involved layers of vocabulary, concretely, the part of the vocabulary of physical training.

We think that one should continue to collect the data.

After identifying the new lexemes, one has to work carefully to prove whether these lexemes belong true to the vocabulary of the Altaic commonality of languages.

## About creating the grammatical terminology in the Evenki language

**Kirill Struchkov**

research associate, Section of Evenki Philology,  
Institute of the Humanities and the Indigenous Peoples of the North of SB RAS,  
Yakutsk, Russia  
E-mail: [inip@ysn.ru](mailto:inip@ysn.ru)

Terminology is a special lexical layer and is one of aspects of the complex and multi-faceted problem of the development of languages that is connected with the development of society. Terminology is the area where one can see more brightly and clearly the connection between the development of language, its lexical system and the history of material and spiritual culture of people (Vinogradov, V.V. *O neobhodimosti usovershenstvovani'a nashego pravopisani'a*: 19-20). This thesis is true for all the languages: 1) for the languages having a written form since ancient times as well as 2) for the languages which recently developed a written form. In the second group of languages, one can see the formation of terminology as a consequence of the functional development of these languages stipulated by the needs of social development of their speakers.

The aim of this article is: to show how the need in creating the grammatical terminology in the Evenki language is realized in concrete way.

Terminology in different languages is not identical, it has different sizes. As linguists believe, it is stipulated by a number of social factors connected with the general objectives and the curriculum in a given language, with the size and system of teaching it in school, with the development of special linguistic literature in a given language (Treskova S.I. 1975. "K voprosu o sozdanii grammaticheskoi terminologii na mladopis'mennih iazikah," *Sb. Sotsiolingvisticheskie problemi razvivaiutshihs'a stran*: 315. M.)

The material for the article was extracted from the Evenki textbooks for schools and teachers training colleges.

The specialists conventionally divide languages into sub-groups from the point of view of teaching the languages in schools. These are 1) the languages in which they teach in all grades of secondary school; 2) the languages in which they teach in incomplete secondary school; 3) the languages in which they teach in elementary school; 4) the languages in which they teach in preparatory, first and second grades.

The decision about teaching the native Northern languages in secondary school was made at the federal level almost twenty years ago. These are Chukchi, Nenets, Èven, Evenki, Khanty, Nganasan languages (Burikin A.A. 2002. "Voprosi sozdani'a UMK dl'a srednei shkoli i podgotovki kadrov po iazikam narodov Severa," *Sb. Obrazovanie na Severe: rol' natsional'no-regional'nogo komponenta v sohranении edinstva obrazovatel'nogo prostranstva Rossii, etnicheskoi identichnosti i zdorovia detei Severa*: 94-95. M.)

The main way of creating and developing terminological systems in the languages of the numerically small indigenous peoples of the North is: to form the terminology on the basis of such main sources as the native lexical material of mother literary tongue and its dialects, as the generally accepted international terms, as the loan-translation and the loan-words.

In creating the grammatical terms on the basis of native vocabulary, one may distinguish the following methods: 1) extending the meaning of native words, for example, Evenki *ig*, Russian *zvuk* mean 'sound', Evenki *ävädi turän*, Russian *evenkiiskii iazik* – 'Evenki language', etc. 2) loan-translation: *äsipiti vrem'a*, *ucäläpti vrem'a*, *goropti vrem'a*, *umuntägir élenil*, *sotkul élenil*, *et al.*

Among these are the names of cases: *gärbivudi padezh*, *ovudi*, *gälävudi*, *buvudi*, *suruvudi*, *ämävudi*, *ngägävudi*, *nungnivudi*, *ngänuvudi*, *üvudi I*, *üvudi II*, *havalivudi*, *umunuvudi padezhil*, etc.

The Evenki language has many grammatical terms loaned from the Russian language. The group of terms was loaned without changes: *alfavit* – 'alphabet', *bukva* – 'letter', *glagol* – 'verb', *naklonenie* – 'mood', *vid* – 'aspect', *zalog* – 'voice', *číslitel'noe* – 'numeral', *pričastie* – 'participle', *deepričastie* – 'gerund', *mestoimenie* – 'pronoun', *narečie* – 'adverb', *mezhdometie* – 'interjection', *padezh* – 'case', *suffiks* – 'suffix', *sinonim* – 'synonym', *antonim* – 'antonym', *skazuemoe* – 'predicate', *soiuz* – 'conjunction', *fonetika* – 'phonetics', etc.

The grammatical terms loaned from, or through, the Russian language are formed according to the laws of this language. For example, the loan-terms are used in Evenki sounding: Evenki *častitsä*, Russian *častitsa* – ‘particle’, Evenki *soglasnäi*, Russian *soglasnii* – ‘consonant’, Evenki *glasnäi*, Russian *glasnii* – ‘vowel’, *prodol'nai* (from Russian *prodol'nii*), *otlozhitel'nai* (from Russian *otlozhitel'nii*), *napravitel'nai* (from Russian *napravitel'nii*), *napravitel'no-mestnai* (from Russian *napravitel'no-mestnii*), *lično-prit'azhatel'näi* (from Russian *lično-prit'azhatel'nii* – ‘personal possessive’), *bezlično-prit'azhatel'näi* (from Russian *bezlično-prit'azhatel'nii* – ‘impersonal possessive’), *vtorostepennai* (from Russian *vtorostepennii*), etc.

The compound loan-terms are also formed according to the laws of Evenki language: *sotkul členil*, *vtorostepennail členil* (from Russian *vtorostepennie členi*), *umukändi turärdi*, *pričastie grammatičeskäi razborin*, *glagol deistvitelnäi zalogin*, *perehodnail*, *neperhodnail glagolil* (from Russian *perehodnie*, *neperhodnie glagoli* – ‘transitive, intransitive verbs’), etc.

Thus, the creating and forming of the grammatical terminology in the Evenki language is a complicated process. The facts considered by us reflect some moments in this process. Among social factors playing a dominant role in the creating and developing of terminological system in the Evenki language, the factor of conscious influence of society on the functional development of languages is of the major place. The system of grammatical terminology was formed in the Evenki language in accordance with the intra-structural laws of its development. The methods of creating terms (usage of native lexical units, loanwords, etc.) are specific for the Evenki language.

## Abstract

The purpose of this paper is to inquire into some aspects of variations of vowels in spoken Manchu in Sanjiazi village, Fuyu County, Heilongjiang Province, China. Based on the data collected through fieldwork which had been carried out twice, we investigated variations of vowels in Manchu, by using a formant chart to decide the number and the inventory of vowels, and classifying them into two types of facultative and combinatory ones. Most of the variations belonged to the former. As a result, we established 16 phonetic vowels which were reduced to 5 phonemic vowels.

**Keywords:** vowel, Manchu, formant, facultative variation, combinatory variation, endangered language.

## 0. Introduction

The purpose of this paper is to inquire into some aspects of variations of vowels in spoken Manchu. It was reported that Manchu had nine phonemic vowels (Qinggeltei 1982), but it has only five phonemic vowels, that is /i, a, u, o, ə/, according to the result of our analysis. Some of these vowel phonemes are realized in various phonetic forms.<sup>2)</sup>

The subject for our Manchu data is Mr. Meng Xianxiao (孟憲孝), who was in his seventies and lived in Sanjiazi village, Fuyu County, Heilongjiang Province, China at that time. He spoke Manchu only in simple and daily conversation when he was a child, but began to study it from about 12 years old.

Fieldwork for collecting Manchu data was carried out twice. Dates and participants of the fieldwork are as follows:

(1) Preliminary fieldwork

Dates: May 3~ 8, 2005

Participants: KWON Jae-il, KIM Juwon, KO Dongho, Chaoke, Zhao Wenyu

Place: Qiqihar city

(2) Full fieldwork

Dates: February 7~14, 2006

Participants: SEONG Baegin, KIM Juwon, SHIN Yongkwon, KANG Huijo

Place: Qiqihar city

In the fieldwork, we prepared a questionnaire and asked him in Chinese, and he was requested to answer it twice in Manchu. After both fieldwork, we collected about 2,000 words, 300 basic dialogs, and 300 sentences for grammar, using the questionnaire. This paper is the result of analysis of some of these data. In principle, the data of our analysis are the forms which were uttered in the second answer.

We will decide the number and inventory of phonetic vowels in the first, and reduce them to phonemic ones by classification of them into facultative and combinatory variants.

## **1. Number and inventory of vowels**

To seize a phonemic vowel system of which we do not know, we must decide the number of phonetic vowels. In most of phonetic researches, it is assumed that in general the researcher does know a phonemic system of language concerned, and distribution of variants of vowel phonemes is dealt with. This is spoken well for by the following note in Ladefoged (2003: 1). "Without knowing the phonology of a language you cannot describe the phonetics." But, in the case of Manchu in Sanjiazi, the only and last investigation by Qinggeltei etc. was made in 1961.

(Ladefoged 1982: 178-179). The second base of this is the fact that, in usual books on phonetics, there are formant charts in which positions of vowels are presented in points, not in area divided by numerical value.

Thirdly, we made a final formant chart by correcting the tentative one, comparing it with the result of hearing and formants measuring of the rest data. We decided the phonetic value of vowels which is not clear according to the final formant chart.

As a result of analysis of 557 tokens of vowel in 230 words, there are the following 16 phonetic vowels in spoken Manchu: [i, y, ɪ, e, ø, ε, a, ɔ, ʌ, o, ɤ, u, ʉ, ɯ, ɨ, ə]. The followings are examples of these vowels, in which (3) is all of mono-syllabic words, and (4) is some of poly-syllabic words:

- (3) a. [ɑ]: [nɑ] 'earth', [pja] 'moon, month', [(ə)l'gəŋ] gam] 'to take (a breath)', [vɑ] 'smell'
- b. [ə]: [sə] 'age', [səŋ] 'blood', [nəm] 'to be sick'
- c. [i]: [pi] 'I', [çi] 'you (sg.)', [ni] 'sweat', [pim] 'to exist'
- d. [o]: [po] 'house', [tʰoŋ] 'thread', [so] 'undress (yourself)!', [kjo] 'roe (deer)', [dzɔ ('bjɑ)] '2 (month)' (=February), [(sə) tʰon] '(age) number'(=age)
- e. [u]: [ʃun] 'sun', [sun] 'milk', [nun] 'younger sister'
- f. [ʊ]: [tʰʊn] 'forest'
- g. [ʌ]: [tʃwʌn ('bjɑ)] '10 (month)' (=October)
- h. [y]: [tyn ('bjɑ)] '4 (month)' (=April)
- i. [ε]: [sɛ:n] 'good', [pɛ:m] 'to seek'
- (4) a. [ʉ]: [dʉlʌ] 'face', [ə'muŋ] 'saddle', [mʉl'γən] 'a fine-toothed bamboo comb', [ni'mjʉŋ] 'snow'
- b. [ɪ]
- i. [ç'ɪskʌ] 'yesterday', [tɕɪ'γɑ] 'money', [dʒɪl'γǎ] 'voice'
- ii. [qjɪ] 'year', [jʌmɕɪ] 'evening', [fa'kʰolɪ] 'trousers'
- c. [ɨ]: [xɨŋ'namʌ] 'woman', [sɨ'dzənsɑ] 'shafts'
- d. [e]
- i. [tɕʰe'ɲuŋ] 'the day before yesterday', [tʰujle] 'bean'
- ii. [ʌlke] 'alcohol', [tʃwɛjle] 'summer',
- e. [ɔ]
- i. [ʉʉzʌ] 'net', [ʉl'γwʌ] 'firewood', [pɕʉʃkʰwə] 'kidney'
- ii. [to'ʉolɔ] 'night', [ʉŋtʰɔ] 'bridle', [ʉktʰɔ] 'gunpowder, medicine'
- f. [ø]: [tø'lin] 'middle', [sø'jin] 'yellow'
- g. [ɤ]

- i. [ʰxŋgʌ] 'mother-in-law', [ʰsxwʌ] 'teacher', [ʰtʂxwʌ]
- ii. [ʰtʰoʷswxʰ] 'village', [ʰamxʰ] 'father', [xɑŋ]ʲnɑmʰ 'man'

In the next sections, we will reduce these phonetic vowels to 5 phonemic ones.

## 2. Facultative variation

There are cases in which different vowels appeared in the same position in one and the same word. It can be said that these vowels are not different phonemes. Of course, there is a possibility that, like the first vowel in English *economics*, the variants are different phonemes. But the rigid method of analysis cannot be applied to endangered languages, as mentioned above.

(5) a. [ə] ~ [ɤ] ~ [ʌ]

[i:ʲnʰŋ] 'day' ~ [i:ʲnʰŋ](dɛle) '(every) day' ~ [(ʰəmu)i:ʲnʰŋ] '(one) day'  
 [(ʰʌmm)ʌl'də] '(one) early' (=morning) ~ [(ʰʌmm) əl'dʌ] '(one) early'  
 (=forenoon)

b. [u] ~ [ə]

[ni:mjʷŋ] 'snow' [ʰu:ʲnɑ] 'mother' ~ [ʰə:ʲni (ʰamə)] 'mother (and) (father)' ~  
 [ʰu:dujʲni:mjʷŋ] 'snowstorm'

From examples in (5), we consider that [ə], [ɤ], [ʌ], and [u] belong to one phoneme of /ə/.

(6) a. [ɪ] ~ [i]

[ʰɛiskʌ] ~ [ʰɛiskʰʌ] 'yesterday', [mi'tɕʰin] 'an iron pot' ~ [mi'tɕʰɪn] 'pot'

b. [ɪ] ~ [e]

[ʰtʰɔjle] ~ [ʰtʰɔjli] 'bean' [ʲjʌmdʒes'kɔŋ] ~ [ʲjʌmdʒis'kon] 'afternoon'

c. [e] ~ [ɛ] ~ [i] ~ [ɪ]

[i'tɕʰi'ɑjɲe] 'new year' [ʰɑjɲi'bja] 'january' [ʰɑjɲi], [ʰɑjɲɛ] [tʌl'kʰɑɲɛ]

d. [ɛ] ~ [e]

[ʂɑ'lʌmbjɛ] 'to grow light' [u'tʂʰuləmbje]

From examples in (6), we consider that [i], [ɪ], [e], and [ɛ] belong to one phoneme of /i/. But [e] and [ɛ] in this case are confined only to word-final position, in view of

their environment of occurrence.

(7) [u] ~ [ʊ]

[ʊ:'duj (ni'mjiŋ)] 'wind (snow)' (=snowstorm) ~ [u'dun] 'wind', [tʰʊl'gɪn] ~ [tʰʊl'gɪn] 'cloudy', [pʊ'da] 'meal' ~ [pu'da (ɑləl) ('bɑ)] 'meal (to make) (place)' (=kitchen)

From examples in (7), we consider that [u] and [ʊ] belong to one phoneme of /u/.

(8) [ɛ] ~ [ɑj]

[sɛ:n] 'good', [(tʃə'tʃʰəl) sāj] '(to eat together) delicious'

From examples in (7), we consider that [ɛ] and [ɑj] belong to one phoneme of /ɑj/.

Many researchers regard  $\bar{u}$  as a phoneme in written Manchu.<sup>4)</sup> (9a), (9b), and (9c) show that reflexes of  $\bar{u}$  in written Manchu appears as [o], [ʊ], and [u]. In other words,  $\bar{u}$  in written Manchu corresponds to /o/ and /u/ in spoken Manchu.

(9) a. [xo'tɕʰin] 'well' (cf. hūcin), [tʃu'ʏon] 'way' (cf. jugūn)

b. [mo'kʰʊn] 'family' (cf. mukūn), [kuj'nin] 'will' (cf. gūnin)

c. [xul'ʏa] 'thief' (cf. hūlha), [kʰu'zun] 'power' (cf. hūsun)

### 3. Combinatory variation

There are three types of Combinatory variations. The first is *i*-umlaut which assimilates back vowels in preceding syllable when vowel *i* is in following syllable.

(10) a. [i'tʰim] 'to win' (etembi), [i'vɪʏʌ] 'to have a full stomach' (ebimbi)

b. [ʏjɛli] 'meat' (yali)

c. [vɛi'l'ʏm] 'expose to the sun' (waliyambi), [tʰɛl'kʰin] 'lightning' (talkiyan), [tɛl'tʰi] 'for a moment' (dartai)

d. [to'oldy'lin] 'midnight' (dabori dulin)

e. [tø'lin] 'middle' (dulin), [sø'jin] 'yellow'

(11) [i'tɕʰi'ɑjne] 'new year' (ici aniya), [tʃwɛjle] 'summer' (juwari), [i:'nəŋ'bɛjɛ] (inenggi baru) 'noon', [kuj'nin] 'will' (gūnin)

Vowels of [ɪ], [e], [ɛ], [y], [ø] in (10), and diphthongs of [aj], [ɛj], [uj] in (11) are all the result of the *i*-umlaut. Considering written forms which is presented in parentheses after meaning, relations of each variant with its phoneme are summed up as follows:<sup>5)</sup>

variants	[ɪ]	[e]	[ɛ]	[aj]	[ɛj]	[uj]	[y]	[ø]
phoneme	/ə/	/ɑ/				/u/		

Table 1. Variants according to *i*-umlaut

- (12) a. [ɪ'yin] 'husband' (eigen), [ti'ɕim] 'to burn' (deijimbi)  
 b. [ɲi] 'sweat' (nei)

(12a) is examples which are not obvious whether they are results of *i*-umlaut or not. But we think that they are not so, for (12b) is an obvious example of contraction. If we recognize this contraction, vowels in the first syllable are explained by it, and, furthermore, [ø] in [sø'jin] 'yellow' (suwayan) can be explained by the contraction, too.

The second type of combinatory variations is a tendency of lowering height of the highest point of the tongue in vowels /ə, i/ in the open word-final syllable.<sup>6)</sup> On chart 2, F1 of /ə/ in the open word-final syllable is about 100 Hz larger than those in the other positions, and F1 of /i/ in that position is also about 50 Hz larger than the others. This situation is the same as that of /o/, although the difference is not large.

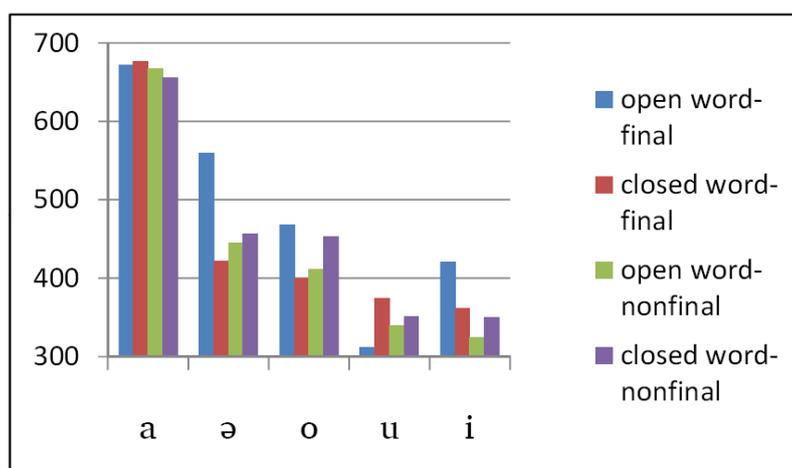

Chart 2. F1 of vowel phonemes according to syllable structure

But /a/ shows little difference between open word-final syllable and the other positions, and F1 of /u/ in open word-final syllable is smaller than those in the other positions, on the contrary.

The third type of combinatory of variations is a tendency of diphthongization of /i/ in front of /ŋ/. In such a position, /i/ is realized as a rising diphthong in which nuclear vowel is /ə/. Examples of this phenomenon are as follows:

- (13) a. [(u'duj) ni'mjɨŋ] '(wind) snow' (=snowstorm), [ɲɨŋ'niɮ] 'spring', [(fuy'zi) 'iɲɨŋ] '(first) day' (=the first day of the month), [(ʌm) 'iɲɨŋ] '(one) day'  
 b. [ni'mjuŋ] 'snow'
- (14) a. [ɲəm] 'to be sick', [i:'ɲəŋɔ] 'daytime', [i:'ɲəŋ ('bɛjɮɛ)] 'day (toward)' (=noon), [ɕəŋ'ɲən] 'smoke'  
 b. [tʰo'xoŋ'iɲɨŋ] 'the fifteenth day of a month', [i:'ɲɨŋ] 'daytime'
- (15) [ni'miŋ (tʰu'ɣuɣʌ)] 'snow (fell)', [e'ɲiŋɮ] 'this day' (=today)

Examples in (13a) are those appearing as [jɨ], (13b) as [ju]. (14a) and (14b) are examples of [jə] and [jɨ], respectively, because [ɲ] and [ɕ] are palatalized variants of /n/ and /s/. We look upon [jɨ], [ju], [jə], and [jɨ] in (13) and (14) as variants of /i/, because these diphthongs appear as [i] in the same words in (15).

#### 4. Concluding Remarks

In this paper, we investigated variations of vowels in Spoken Manchu, by using a formant chart to decide the number and the inventory of vowels, and classifying them into two types of facultative and combinatory ones. Most of the variations belonged to the former. As a result, we established 16 phonetic vowels which were reduced to 5 phonemic vowels.

A linguistically meaningful result of our work is that the so-called biuniqueness condition, that every allophone must be assigned to one and only one phoneme, cannot be applied to Manchu vowel phonology.

#### Notes

- 1) This work was supported by the Korea Research Foundation Grant funded by the Korean Government (MOEHRD) (KRF-2006-322-A00054).

2) With Enhebatu (1995), Qinggeltei (1982) is the only one which deals with Manchu in Sanjiazi village. On the works which deal with Manchu in other areas including this village, cf. Zhao (1989), Zhao and Chao (2001), and Wang (2005).

3) Of them, the number of central vowel is 4. But in the IPA vowel chart revised to 1993, corrected 1996, there are 8 central vowels.

4) Seong (1981: 93-95) considers this ū as a grapheme to write allophones of /u/ and /o/ in the 17th Manchu, not a phoneme.

5) In the light of vowel system, it is controversial that [e] and [ø] are regarded as variants of /a/ and /u/, respectively.

6) There is little difference F2's of vowels according to position and structure of syllable.

# **Revival movement of the Warrongo language (Australia): Progress report (2008)**

**Tasaku Tsunoda\* and Mie Tsunoda\*\***

University of Tokyo\* and Rissho University\*\*

Graduate School of Humanities and Sociology, University of Tokyo, Hongo, Bunkyo-ku,  
113-0033, Japan\*

tasaku@l.u-tokyo.ac.jp\*

## **Abstract**

From 1971 to 1974, the first author recorded the Warrongo language (northeast Australia) from its last fluent speakers. Towards the end of the last century, a movement to revive the Warrongo language started. In 2002, Warrongo language lessons, conducted by the first author, commenced. So far the lessons have been conducted five times — four or five days each time. The revival movement is making a slow but steady progress. Its developments are seen, for example, (1) increased local involvement, (2) increased teaching staff, (3) spontaneous use of the language, and (4) naming in Warrongo. However, this movement is beset with many problems, and lack of funding is one of the most difficult obstacles.

**Keywords:** Warrongo, linguistic heritage, language revival, spontaneous use, naming.

## **1. Introduction\***

The present paper is mainly concerned with one of the issues listed in ‘Description of Workshop on Endangered Languages: “what we can do for the endangered languages”.’

At the 17th International Congress of Linguists (Prague, July 2003), the first author of the present paper delivered an invited plenary paper on the revival movement of the Warrongo language of northeast Australia. The paper was published as Tsunoda (2004). The present paper briefly summarises the movement up to 2003, and then provides an updated report on the movement. Details of the progress are given in Tsunoda and Tsunoda (2007).

The present paper incorporates portions of Tsunoda (2004, 2005, 2006a, 2006b, 2007, forthcoming, an essay located at <http://www.sgu.ac.jp/com/ksasaki/kaken/essay/essay-tsn.htm>), and Tsunoda and Tsunoda (2006, 2007).

## **2. Brief contact history of Aboriginal Australians**

At the time of the first British colony at Port Jackson (Sydney) in 1788, there are estimated to have been about 250 languages. However, over the subsequent centuries, most Aboriginal Australians were dispossessed of their land, and their population was reduced drastically, due to massacres, introduced diseases, forced relocation, and so on. Most of the earlier Aboriginal languages are extinct, and there are only 100 or so languages still spoken, mostly by old people. (See Blake 1994.)

## **3. Fieldwork in north Queensland from 1971 to 1974**

In 1971, when the first author was an M.A. student of Monash University, Melbourne, he started fieldwork in and around Townsville, north Queensland, and carried out research there three times, until 1974. His main focus was on the Warrongo language (also spelt Warungu, Warrungu, etc.), which used to be spoken in the upper Herbert River area, northwest of Townsville. Other languages he recorded include Biri (Bowen area), Gabilgaba (Townsville-Magnetic Island area), and Buluguyban (Palm Island). One of the outcomes of that fieldwork is his M.A. thesis (Tsunoda 1974). Currently he is writing a Warrongo grammar for publication.

## **4. Importance of documenting endangered languages**

Already in the early 1970s, the above-mentioned languages of north Queensland were facing extinction. They each had just one or two speakers left. Warrongo had only two fluent speakers left. The first author recorded data from the last speakers of these languages.

In the case of languages that seem to have no or little chance of survival, the last speakers often wish, and indeed make every effort, to have their language recorded. This heartfelt desire and commitment were best expressed by the late Mr. Alf Palmer (Warrongo name: Jinbilnggay), one of the last two fluent speakers of Warrongo, who used to say to the first author:- “I’m the last one to speak Warrongo. When I die, this language will die. I’ll teach you everything I know, so put it down properly”. Indeed, Alf Palmer made admirable efforts to teach the first author everything he knew.

In retrospect, it was Alf Palmer who taught the first author the importance of

documenting endangered languages. His was perhaps one of the earliest responses to the crisis of language endangerment. It was made twenty years before the publication of works such as Hale et al. (1992) and Robins and Uhlenbeck (1991), which are possibly the first works that urged linguists to pay serious attention to language endangerment. Alf Palmer was a man of wisdom and foresight.

The last speakers of these languages of north Queensland passed away, and the languages became extinct. Alf Palmer passed away in 1981, and there was no one left who could speak Warrongo — except the first author.

## **5. Language revival movement starts.**

More than a quarter century later, towards the end of the last century, a few groups of people there, including Warrongo people, started a movement to revive their ancestral languages, and they approached the first author, requesting him to assist their activities.

In March 2000, the first author visited Townsville (where many Warrongo people live nowadays), after 26 years since his last visit of 1974 to the area. The visit was followed by another visit in March 2001.

The central figure in the Warrongo language revival movement is Rachel Cummins, who is Alf Palmer's granddaughter.

Many of the people involved in the language revival activities turned out to be grandchildren of the last speakers whom the first author had interviewed in the early 1970s. They already knew about him, and about his work. Some of them had obtained copies of relevant field tapes from the Australian Institute of Aboriginal and Torres Strait Islander Studies, Canberra (with which he lodges all his field tapes), and they even knew his voice.

The late Stephen Walsh, a member of the Biri group, said to the first author, “We are grateful that you recorded our languages”. This obliterated all the hardship that the first author had experienced during that fieldwork.

## **6. Value of linguistic heritage**

In March 2000 and March 2001, the first author had preliminary discussions with a number of people. He described one aspect of the Warrongo language roughly as

follows.

Warrongo had a phenomenon that linguists call syntactic ergativity. This phenomenon is unique among the world's languages. It mainly occurs in Australia, in Queensland, and in fact, in north Queensland. It occurs in Warrongo, and also Warrgamay, Girramay, Jirrbal, Mamu, Ngajan, Yidiny, and Djabugay. Because this phenomenon is unique among the world's languages, it is a very important part of the cultural heritage — not only for the people of this area, but also for the entire humankind.

Needless to say, the knowledge of the existence of a truly unique phenomenon in their ancestral language has enhanced Warrongo people's sense of pride and self-esteem, and also interest in the language. It has also proved to be an invaluable cultural heritage to them. (For syntactic ergativity, see Dixon (1972) on Girramay, Jirrbal and Mamu, Tsunoda (1974, 1988, 2004, 2005) on Warrongo, Hale (1976) on Djabugay, Dixon (1977) on Yidiny, and Dixon (1981) on Warrgamay.)

## **7. Warrongo language lessons start.**

After two series of preliminary discussions (March 2000 and March 2001), the first author started Warrongo language lessons in March 2002, in Townsville. So far, the lessons have been conducted five times — about four or five days each time: March and August 2002, March 2004, and March and August 2006. What we have dealt with includes the following:

- a. orthography;
- b. pronunciation;
- c. basic vocabulary, including ancestors' names, e.g. Jinbilnggay (Alf Palmer);
- d. simple sentences, such as:
  - d-i. declarative sentences;
  - d-ii. general questions and special questions;
  - d-iii. imperative sentences;
- e. complex sentences: syntactic ergativity;
- f. mini-conversations, and;
- g. socio-cultural background, e.g. kin terms, patterns of kin-based

behaviour, sections, totems, marriage rules, mythology, and naming.

The people in the class found the topic of g. really interesting, and welcomed the inclusion of cultural aspects in the Warrongo language lessons. They stated that they realised they still retain the traditional patterns of kin-based behaviour, despite the fact that they no longer know the traditional kinship system or kin terms. (They know a couple of kin terms, e.g. *yangana* “mother”.) They also stated that they now know why they behave the way they do. The inclusion of the cultural aspects turned out to be a great success.

In 2003, the first author prepared *A provisional Warrungu dictionary* (Tsunoda 2003), and sent 50 copies to Rachel Cummins, who in turn distributed them to other Warrongo people. Fortunately, the dictionary is in demand, and additional 60 copies were sent in 2008. Vivian (Peter) Lenoy — Alf Palmer’s grandson and Rachel Cummins’ cousin — indicated to the first author that he is proud to have a book on his ancestral language in his home.

## **8. Recent developments: slow but steady progress**

The Warrongo revival movement is making a progress — a slow but steady progress. Specific instances of the progress include the following. Most of them took place in 2006 — four years after the Warrongo language lessons started in 2002. They are all encouraging developments.

### *8.1. Local involvement*

Warrongo people began to participate in the revival movement more actively. Examples follow.

[1] Tahlia and Mheelin Cummins, who are Rachel Cummins’ daughters, prepared picture cards — a card with a picture of, say, a butterfly and the Warrongo word for it (*gomborrgomborr*).

[2] The people who came to the Warrongo lessons decided to have language activities at the weekend — while the first author is away in Japan.

### *8.2. Learners*

Children began to attend the lessons. The number of the children who attended

the classes was about 10. Their age ranged from about three or four to twelve.

Needless to say, if a given language is spoken by adults only and if it is not acquired by children, then it will have no chance of survival. Similarly, in a language revival movement, if the language is learnt by children, it will have a better chance of revival. Therefore, it is significant that Warrongo children began to attend the language lessons.

### 8.3. Teaching staff

The second author joined the first author in teaching. She had been attending the Warrongo lessons since the first lessons of March 2002 and had been learning the language. She has an M.A. degree in Teaching of Japanese as a Foreign Language, and a Ph.D. degree in Japanese Linguistics. She has many years of experience of teaching Japanese to overseas students and researchers, and she applied this experience to the Warrongo lessons. Two examples follow.

Example 1. Warrongo has the following cases: ergative (for transitive subject), nominative (for intransitive subject), accusative (for transitive object), dative, locative, genitive, and ablative. That is, it has the ergative case system. The cases are in the main expressed by suffixes. The Warrongo cases may be difficult for the current learners (whose first language is English) for two reasons. First, the ergative system is absent in English. Second, the cases are in the main expressed by suffixes — in contrast with English, where cases are often manifested by prepositions. Furthermore, word order in Warrongo is not fixed, in contrast with that in English. This may present some difficulty to the learners. The first author prepared language materials that show the use of the cases, among others. On the basis of these materials, the second author prepared the following materials.

- a. Picture cards, e.g. a picture of a woman walking, one of a man running, one of a man carrying a fish, and one of a woman drinking water.
- b. Cards with a verb, e.g. *yani-n* (“walk-NONFUT”), *wadali-n* (“run-NONFUT”), *ganyji-n* (“carry-NONFUT”), and *bija-n* (“drink-NONFUT”).
- c. Cards with a case suffix.
- d. A card with an arrow, and also one with the interrogative *wanyo-lo* (“who-ERG”), one with *wanyo-na* (“who-ACC”), one with a name (e.g. Mheelin — Rachel Cummins’ daughter), one with a kangaroo, one with a dog, and so on.

#### 8.4.1. Spontaneous use of the language

[1] On the afternoon of the 17th March 2002 (Sunday), i.e. the very first day of the Warrongo lessons, we were practicing the writing system and pronunciation, using a fair number of basic words. The words included the following two words.

*bija* “Drink!” (offering someone a drink of water)

*gamo* “water”

(The word *bija-Ø* can be glossed “drink-IMPERA”.) When we were practicing the word *bija* “Drink!” Rachel Cummins uttered the following sentence spontaneously.

(3) *bija-Ø*                      *gamo-Ø*.  
drink-IMPERA      water-ACC

The first author’s translation: “Drink water!”

The first author said that this was a correct Warrongo sentence, and provided the translation “Drink water!”.

The first author had explained individual words and imperative forms of verbs, but he had not taught this particular sentence. Despite this, Rachel composed this sentence, on the basis of what she had learnt. It is a correct Warrongo sentence. It was the first Warrongo word or sentence that the first author had ever heard uttered by a Warrongo person in the 28 years since 1974! — the year that he worked with Alf Palmer — Rachel’s grandfather — for the last time.

Note that this sentence has a VO order. It is no doubt based on the English word order. A more natural Warrongo sentence would have an OV order.

Regarding language death, Tsunoda (2005: 104) notes as follows: “among inflected forms of verbs, imperative forms appear to be the most resistant to loss”. Also, Tsunoda (2005: 115) notes as follows: “If verbs survive at all, they are most likely to survive in the imperative forms ... The reverse situation seems to obtain in child language”. In view of this, it would be expected that, in a language revival situation, if verbs are used at all, they will be likely to be used in the imperative forms. Indeed, this is exactly what happened in Rachel Cummins’ speech.

[2] Rachel Cummins stated probably in 2004 that two of her daughters — Tahlia (her fourth daughter; 19 years old at that time) and Mheelin (her fifth daughter; 17 years old at that time) — started using Warrongo in the home, teasing each other with Warrongo words. That is, they began to use Warrongo spontaneously.

[3] On the morning of the 26 March 2006 (Sunday), someone passed wind, and the first author said the following sentence:

(4) *boji-Ø*                      *banda-n*.      [TT]  
fart-NOM                      emerge-NONFUT

Literal translation by the first author: “Fart came out.”

Upon hearing this, Meaghan Cummins (Rachel Cummins’ eldest daughter) said the following sentence.

- (5) *wanyo-Ø*      *boji-Ø*      *banda-n?*  
who-NOM      fart-NOM      emerge-NONFUT

Literally: “Who fart came out?”, i.e. “Who farted?”

Almost certainly (5) is a correct Warrongo sentence.

This incident happened in March 2006. Meaghan Cummins started attending the Warrongo lessons probably only in March 2006. But she has already started saying sentences spontaneously. This is a remarkable progress.

#### 8.4.2. Vocabulary

As mentioned in Section 7, the first author sent 50 copies of *A provisional Warrungu dictionary* (Tsunoda 2003) to Rachel Cummins, who in turn distributed them to other Warrongo people.

The following anecdote concerns Tracy Palmer, who is Rachel Cummins’s elder sister’s daughter. She will be referred to in 8.4.5-[3] in connection with the naming of her son, Ronald.

In March 2006, the first author found that Tracy Palmer had worked hard through the dictionary. During the lessons of March 2006, there were a few occasions when the first author was unable to recall a Warrongo word. But on each occasion Tracy showed him where in the dictionary the word was. One of these words is *gobo* “leaf, tea leaf”. (He knew that *gobo* means “leaf”, but he could not recall the word for tea leaf.) It was clear that Tracy Palmer had studied the dictionary thoroughly and that she had gained a good knowledge of Warrongo vocabulary.

#### 8.4.3. Pronunciation

This anecdote concerns Shaqium (pronounced [shaki:m], stress on [ki:]) Palmer, who is Rachel Cummins’ younger sister’s daughter’s son, and who was probably about five years old at that time.

On the afternoon of the 27th March 2006 (Friday), after a visit to Aitkenvale Library in Townsville, in the car on the way back home, the first author said to Shaqium as follows.

- (6) Thank you very much for waiting for us. You have been very patient.  
You have been very good. [inda dyarribara kalbin].

The above contains the following Warrongo sentence:

- (7) [inda            dyarribara        kalbin] [TT]  
*yinda            jarribara-Ø       galbin-Ø.*  
 2SG.NOM    good-NOM        child-NOM

“You are a good child.”

The first author said to Shaqium that that this means “You are a good child”. Furthermore, he said the word [dyarribara] repeatedly.

To the great surprise of the first author, Shaqium said the word [dyarribara] voluntarily. He pronounced [rr] (a flap) and [r] (an approximant), correctly. That is, he observed the difference between /rr/ (a flap) and /r/ (an approximant), and furthermore he pronounced them correctly. This is despite the fact that the first author had not explained anything to Shaqium. He (the first author) just said [dyarribara dyarribara].

On the morning of the 28th March 2006 (Tuesday), the first author recorded Shaqium’s pronunciation. Again, Shaqium said [dyarribara] /jarribara/. Again he clearly distinguished between /rr/ and /r/.

The above shows that children acquire pronunciation very quickly, unlike adults.

#### 8.4.4. Song

At the beginning of the first lesson of March 2004, a group of Warrongo children, led by Kali Kemp (who is Rachel Cummins’ granddaughter), welcomed the authors by singing a song in Japanese and also one in Warrongo. On the 29th March, Meaghan Cummins wrote the Warrongo song in the first author’s field notebook.

- (8) *gaja binda jarra jina jarra jina jarra jina*  
*gaja binda jarra jina ngali mara balga*  
*jili walo jawa gajo jawa gajo jawa gajo*  
*jili walo jawa gajo ngali mara balga*  
 we will all clap hands together.

Consulting *A provisional Warrungu dictionary* (Tsunoda 2003), Meaghan composed the Warrongo lyrics, on the basis of an English song. The words of the English song appear to be as follows.

- (9) Head, shoulders, knees and toes, knees and toes  
 Head, shoulders, knees and toes, knees and toes  
       and eyes and ears and mouth and nose,  
 Head, shoulders, knees and toes, knees and toes  
 (<http://www.songsforteaching.com/learningstation/headshoulders.htm>)

Glosses by the first author for the words in (8) are as follows: *gaja* “head”, *binda* “shoulder”, *jarra* “upper leg”, *jina* “foot”, *ngali-Ø* “1DU-ERG”, *mara* “hand”, *balga-Ø*

“hit-IMPERA”, *jili* “eye”, *walo* “ear”, *jawa* “mouth”. The word that was written as *gajo* may be *gaja* “head”.

The singing of this Warrongo song was accompanied by gesture. As they sang it, the children touched the relevant part of their body. For example, when they said *gaja* “head”, they touched their head.

The song in (8) contains two occurrences of the following sentence.

- (10) *ngali-Ø*      *mara-Ø*      *balga-Ø*.  
1DU-ERG      hand-ACC      hit-IMPERA

The first author’s translation: “Let’s clap hands.”

No doubt, (10) is a correct Warrongo sentence. Again, this shows that Meaghan is rapidly acquiring fluency in Warrongo.

Rachel Cummins (e-mail message of 6 October 2008) welcomed the inclusion of this account of the Warrongo song in the present paper, and she stated as follows: [This Warrongo song is an instance of] “contemporary application of an ancient tongue. Shows that our culture is not stable but valuable in any time.”

In passing, we note the following two points.

First, *ngali* in (8) is the dual form. There is also the plural form *ngana* “1PL”. If (8) is intended to mean “Let’s all”, rather than “Let’s two”, then the plural form *ngana* “1PL” should be used.

Second, the song in (8) contains no word for “together”. The first author suggested the deletion of “together” from the translation. As an alternative, for “all together”, he suggested the following word:

- (11) *garo-bi-n*      [TT]  
all-INTR-NONFUT’  
“do together”

#### 8.4.5. Naming

[1] Tahlia Cummins’ baby was born in 2005. She chose a Warrongo name for her baby. According to Rachel Cummins (Tahlia’s mother), the name is “Youngali Munjani Binggany Cummins”. Tahlia found the word *binggany* in Tsunoda (2003) (*A provisional Warrungu dictionary*).

In this connection, the following comment is in order. The first author’s field notes indicate that, although *binggany* may possibly be Rachel’s Warrongo name, this is not certain. (*Youngali* and *Munjani* are not Warrongo words. Their respective etymologies are discussed in Tsunoda and Tsunoda 2007.)

[2] On the morning of the 26 March 2006 (Sunday), Norris Palmer (who is

Rachel Cummins' younger sister's son, and who was about 12 years old) told the first author that he wanted a Warrongo name. Rachel Cummins said that Norris was a fast runner. In view of this, the first author suggested the following name.

(12) *jina ngarrban* [TT]

foot fast

Literally: "fast foot"

(In Warrongo compound nouns, an adjective follows, rather than precedes, a noun.) Rachel approved this name, and Norris adopted it.

Later on the same morning, Norris told the first author the following. For his name, he wanted just *ngarrban* "fast". He did not want *jina* "foot".

As mentioned in 8.4.2, Tracy Palmer had worked hard through Warrongo dictionary. On the 28th (?) March 2006, she told the first author that she had found the name Wilbanyo "Norris Palmer" in the dictionary. This Norris Palmer (already deceased) is Alf Palmer's son. He is the young Norris' mother's mother's brother, and he is Rachel's mother's brother.

On the 29th March 2006 (Sunday), the first author mentioned to the young Norris Palmer that the late Norris Palmer's name is Wilbanyo. He showed the name in the dictionary, and stated that the young Norris and the late Norris are namesakes. The young Norris preferred the name Wilbanyo to the name *Ngarrban* ("fast"). He did not want the name *Ngarrban*. His request was approved by Meaghan, Tracy, and others. The young Norris adopted the name Wilbanyo.

[3] On the morning of the 26th March 2006 (Sunday), Tracy Palmer told the first author that her son, Ronald, wanted a Warrongo name, that he played football, and that he was a defense. So, the first author suggested the following name.

(13) *jabi-no* [TT]

stop-*no*

tentative translation: "stopper"

(The suffix *-no* occurs in names such as *Wambi-no* and *Jabi-no*. It is added to verb roots — e.g. *wambi-* "to rest", and *jabi-* "to stop [someone]" — and forms nouns. Its meaning is possibly — though by no means certain — 'agent', like the English suffix *-er*, as in *teach-er*.) The name *Jabino* 'stopper' (a tentative translation) will be suitable for someone who plays the position of defense in football. Furthermore, *Jabino* is the name of Roderick Palmer, who is Ronald's mother's mother's cousin (and who is also Rachel Cummins' cousin). In view of these, Tracy and Ronald were very happy with this name, and adopted it.

[4] The second author observed the following incident. After the lesson on the

morning of the 26th March 2006 (Sunday), in which Norris Palmer (see [2] above) and Ronald Palmer (see [3] above) adopted their Warrongo names, another boy — probably either Joshua Wilson or Michael Wilson — indicated that he, too, wanted a Warrongo name. Other boys teased him, using one of the words they had learned in previous lessons:- “How about *bojimborrowam* for your name?” (The word *bojimborrowam* means “cockroach”.) All the boys roared with laughter. But this anecdote shows that they began to use Warrongo spontaneously. (Joshua and Michael Wilson are Alf Palmer’s daughter’s daughter’s son’s sons. They are Rachel Cummins’ cousin’s son’s sons.)

The above-mentioned anecdotes about naming show that the younger generation, too, has begun to be interested in their traditional culture.

It is added in passing that the authors were each given a Warrongo name. In the early 1970s, Alf Palmer gave the first author the following name:

- (14) *goni-ra*  
kill, fight-agent  
“killer, fighter”

The suffix *-ra* “agent” is added to a noun root and derives a noun, like the English suffix *-er*, as in *teach-er*. Gonira is Alf Palmer’s (maternal?) uncle’s name. In 2006, Rachel Cummins gave the second author the following name:

- (15) *yimirri-n*  
be.glad/happy.and.smiling-NONFUT  
‘[She] is glad/happy and smiling.’

Rachel had learned this word in previous lessons. She thought that this name suits the second author.

To sum up, the Warrongo revival movement is making a slow but steady progress. This shows that Alf Palmer’s dedicated efforts to have his language documented have proved to be truly worthwhile. What he sowed more than 30 years ago is now beginning to be harvested by his descendants and his people.

## 9. Suggestions for language teaching method

In 2006, the authors noticed two interesting phenomena.

a. Grammar. Some aspects of the grammar were difficult for children. But adults found them less difficult, and they were explaining these points to children.

b. Pronunciation. The reverse situation was observed. Adults sometimes had a difficulty in pronouncing those sounds which were absent in English, but children

acquire such sounds easily.

In view of this, the second author suggested that the following may be a useful strategy for these language lessons.

a'. Difficult aspects of grammar: teach them to adults first, and get them to explain these points to children.

b'. Difficult aspects of pronunciation: teach them to children first, and then get them to teach the pronunciation to adults.

## **10. Prospects**

There are a number of plans that Warrongo people are entertaining. For example, they hope to have camps in their traditional land, for language and other activities. They also hope to have the Warrongo language taught at James Cook University in Townsville. To have an Aboriginal language taught at a university has an important implication, that is, it will help to enhance the status of Aboriginal languages:- 'Our language is taught at a university. It is not a primitive language. It is an important language — just like French, German, and Japanese'. Unfortunately, however, this plan is only "a dream" (Rachel Cummins, p.c.) at this stage.

As is almost always the case with language revitalisation efforts, the Warrongo movement is beset with numerous problems. The most serious problem is lack of funding. For example, there are people who wish to come to Townsville to attend the Warrongo lessons, but there is no funding for their expenses. As another example, the first author's applications to the Japan Society for the Promotion of Science, the Australia-Japan Foundation, and the University of Tokyo, to fund the authors' participation in the Warrongo language revival movement, were all unsuccessful.

The Warrongo language revival movement is an important component of the cultural activities of the entire humankind. It is hoped that the Japanese and the Australian governments recognise its importance and pay due attention to it. To assist such activities is a duty of these two — and indeed every responsible — governments.

## **11. Concluding remarks**

The present paper has shown the following, among others. (1) It is an extremely important and no doubt very urgent task of linguists to document endangered languages.

(2) The documentation of a given language will prove to be extremely valuable for the community concerned. (3) To conduct language revitalization activities, the expertise and experience of language teaching are invaluable. Finally, it is hoped that the governments of Japan and Australia among many others will recognise the importance of language activities and pay due attention to them.

### \*Notes

The present paper is dedicated to the memory of the late Mr. Alf Palmer, who taught the first author the importance of documenting endangered languages more than 30 years ago. The authors are grateful to Rachel Cummins (Alf Palmer's granddaughter) for supporting the presentation of this paper and other papers that report the Warrongo language revival movement.

For phonetic symbols, the present paper uses only those symbols which are available on an ordinary computer keyboard, and it avoids the use of IPA phonetic symbols. In particular, it uses the following symbols.

[dy] for a voiced palatal stop.

[ty] for a voiceless palatal stop.

[ny] for a palatal nasal.

[ng] for a velar nasal.

[rr] for an alveolar flap or trill.

[r] for a retroflex approximant.

[y] for a palatal semi-vowel.

[sh] for a palatal-alveolar fricative.

The phoneme inventory of Warrongo, written in a practical orthography is as follows:

/b, d, j, g, m, n, ny, ng, l, rr, r, w, y, a, i, o/

Note that /j/ indicates a palatal stop ([dy] or [ty]), and not a semivowel. /rr/ presents an alveolar flap or trill, and /r/ a retroflex approximant.

The vowel phonemes in Warrongo are /a, i, o/. The first author used to use the letter *u*, and not *o*, for example, in Tsunoda (2003). However, the practical orthography adopted by Warrongo people in March 2004 employs the letter *o* in place of the letter *u*. The reasons for this decision are as follows.

In March 2004, the first author mentioned to Warrongo people that it might be a good idea to use the letter *o* in place of the letter *u*. There are two reasons for this.

First, the letter *u* in the English orthography is confusing. It is pronounced at least in five different ways: (i) *put, bull, cushion*, (ii) *but, cut*, (iii) *cute, music*, (iv) *minute, business*, and (v) *bury* (Tsunoda 2005: 195).

Second, the sound presented by the letter *u* in the writing system that had been used is phonetically almost always [o], and it is [u] only in a very small number of words.

In view of the above, the Warrongo people concerned decided to use the letter *o* in place of the letter *u*.

In the present paper, the letter *u* is used when writing the names of other Australian languages.

Abbreviations and symbols employed are the following.

ACC:	accusative
DU:	dual
ERG:	ergative
IMPERA:	imperative
INTR:	intransitive-stem-forming suffix
NOM:	nominative
NONFUT:	nonfuture
p.c.:	personal communication
PL:	plural
SG:	singular
TT:	sentence or word suggested by Tasaku Tsunoda
-Ø:	zero suffix (e.g. nominative, accusative, imperative)
1:	1st person
2:	2nd person

# Preliminary Report on Fieldwork Studies on Mongolian Languages and Dialects<sup>1</sup>

Wonsoo Yu

Seoul National University  
151-745 Linguistics Department, Seoul National University  
[mongolyu@korea.com](mailto:mongolyu@korea.com)

## Abstract

This paper informs that most of the Mongolian languages and dialects are in danger of disappearing under the pressure of Chinese, Russian, Kazakh, or Tibetan. Readers find some of these languages and dialects already have lost their actual speakers. The Ü üriin Uriankhai case is introduced as an extreme example of Khalkhazation. Some interesting phenomena are introduced: 1) children spoke mother tongue better than parents in some communities, 2) good memory of the elements of one's mother tongue does not always go with the actual use, 3) most of the mother tongue-losses were completed in past several decades.

**Keywords:** Mongolian languages and dialects, danger of disappearing, "Khalkhazation", gap between the memory and the use

## 1. General introduction

The Altaic Society of Korea and Seoul National University have been doing a joint project called the ASK REAL(The Altaic Society of Korea, Researches on Endangered Altaic Languages) funded by Korea Research Foundation since September 2003. I have been participating to this project from the beginning to visit and study over 20 endangered Mongolian languages and dialects. A Mongolian fieldwork team is usually composed of four people: one Mongolist (overall process, transcription) who happens to be myself, one questioner (a Korean expert or a native speaker of either Khalkha Mongolian, Chinese, or Russian), one for sound recording, the other one for video recording. We have questionnaires prepared either in Khalkha Mongolian, Chinese, or Russian. We ask questions in either one of these three languages, and consultants are requested to reply twice at each word or sentence in their own mother

---

<sup>1</sup> This work was supported by the Korea Research Foundation Grant funded by Korean Government (MOWHRD) (KRF-2006-322-A00054).

tongue.

We usually get 2500~2700 words, 340~350 conversational expressions, 380~385 sentences (and constructions) for grammatical analysis from each survey which lasts 2~3 days in average. We record the life story of the consultants, their favorite folk songs and folk tales, explanations on customs and proprieties of their community, etc. The entire process is recorded with a sound recorder and a video camera. We study with one consultant at a time. When our work is completed, then we move to the second consultant of the dialect or to the second dialect.

All recorded words, expressions, sentences from the fieldwork studies are being transcribed both phonetically and phonologically. Several papers on findings of the fieldwork studies have been published or read in conferences in Korean or in English by myself as Yu (2006), Yu (2007a), Yu (2007b), and Yu (2008).

The ASK REAL published four books this year. The first book includes a general report on our fieldwork studies on Mongolian, Turkic, and Tungusic languages and dialects conducted from September 2003 to July 2006 as Kim et al. (2008a). It was written in Korean.

A fieldwork report and linguistic description on the Tacheng dialect of the Dagur language is also published this year as Yu et al. (2008). From this second book on, the books are written in English. The strongest candidate Mongolian language for the next book is the Khamnigan Mongolian in Mongolia. The Turkic languages team and the Tungus languages team of the ASK REAL also did fieldwork studies on some 10~30 languages and dialects, and they have the similar plans for publication as one may see in Kim et al. (2008b) and Li et al.(2008).

During our fieldwork studies, I felt all Mongolian languages and dialects, except Khalkha, are facing various degrees and natures of danger of disappearing by the pressure of Khalkha Mongolian, Chinese, Russian, Kazakh, or even Tibetan. This paper tries to describe the degrees and the natures of the dangers which these language and dialect are facing. I would like to introduce some interesting phenomena, episodes, or facts witnessed and heard during the fieldwork studies.

## **2. Current Situation of the Mongolian languages and dialects**

### *2.1. Mongolian languages and dialects in Russia*

Studies were carried out on the following Mongolian languages and dialects spoken in Russia. Information is given as the order of “the name of the language (dialect); place of investigation; date of investigation.

- (1) Buryat (Aga Khori); Ulaan-Ude; 2004. 4. 22 - 4. 23.
- (2) Buryat (Khori); Seoul, Korea: 2004. 10. 8. - 10. 10.
- (3) Buryat (Ekhirit-Bulagat); Ust-Ordynsk City, Irkutsk Oblast; 2007. 1. 19 - 1. 22.
- (4) Buryat (Alar); Cheremkhovo City, Irkutsk Oblast; 2007. 1. 23 - 1. 25.
- (5) Buryat (Tunka); Arshaan, Tunkiinskii Raion, Buryat Republic; 2007. 1. 27. - 1. 28.
- (6) Buryat (Oka); Arshaan, Tunkiinskii Raion, - Buryat Republic; 2007. 1. 29.
- (7) Buryat (Tsongool), Tashir Village, Selengiinskii Raion, Buryat Republic; 2007. 8. 3. - 8. 5.
- (8) Buryat (Sartuul); Ulzar Village, Dزيدinskii Raion, Buryat Republic; 2007. 8. 6. -8.7.
- (9) Buryat (Bargazaan); Bayangol Village, Barguzin Raion, Buryat Republic; 2007. 8. 10.
- (10) Kalmyk (Dörvöd); Elista City, Kalmyk Republic; 2006. 4. 18 - 4. 21.

It would be convenient for the discussion if Mongolian languages and dialects in Russia are grouped into several groups as below according to the degree and the nature of the danger they are facing.

### *2.1.1. Buryat dialects*

#### *2.1.1.1. Buryat dialects in Buryat Republic*

*2.1.1.1.1. Sartuul and Bargazaan.* These dialects seem to be in between “Stable yet threatened” ~ “Unsafe” if we consider "Intergenerational Language Transmission", "Absolute Number of Speakers", "Proportions of Speakers within the Total Population", three of the major evaluative factors of language vitality proposed by UNESCO Ad Hoc Expert Group on Endangered Languages(2003:7-9).<sup>i</sup> Consultants said that even the old Russians knew Buryat in their villages. I had no opportunity to talk with the local Russians there. Preschool children and teenagers understood my Mongolian<sup>ii</sup> and responded to my questions in their dialects. However, the Buryats in these areas are also fluent in Russian, which is the language of their children's computer games, favorite TV shows, idol stars, comic books, classroom, and everything.

2.1.1.1.2. *Tsongol, Tunka, Oka*. These dialects seem to be “Definitively endangered”. In Tsongool, villagers, in their 30s and over, conversed with me in their Buryat dialect. However, they depended heavily on Russian for the communication among themselves. Their teenagers understood my Mongolian and replied in Buryat but with certain degree of pain. The Tsongools believed that the Sartuul youngsters spoke Buryat better than theirs because the Sartuul land was nearer to Mongolia.

In Tunka area, I had no opportunity to converse with the villagers other than our 59 year old consultant, a fluent speaker of her mother tongue, who answered in Buryat forms for 89% of the 2757 words we asked.<sup>iii</sup>

It may not be proper to say about the situation of the Oka Buryat which I studied in Tunka area, only one day, with a consultant who was living 30 years in Tunka area. She answered in Buryat forms for 87% of the 880 words we asked.

2.1.1.1.3. *Aga and Khori*. It may not be proper to say about the situation of the Aga Buryat dialect which I studied in Ulaan-Ude because my consultant was a Mongolist who was living in Ulaan-Ude, the capital of the Buryat Republic for 40 years since her graduation from high school in Aga area.

It may not be proper either to say about the situation of the Khori Buryat dialect which I studied in Seoul, with a young Buryat scholar in Korean Studies. She was fluent in Buryat but she said that her Buryat was being recovered after she had found and shocked at the loss of her mother tongue while she was visiting Ulaanbaatar as an exchange student, where everybody was speaking in Mongolian.

According to our consultant, she regained much part of her native language by talking in Buryat with her mother at home. She heard from her mother that a person who knew only the Buryat was treated as a person without enough education, a country folk, a pitiable person, etc. in Ulaan-Ude when her mother was at her age. According to her observation, however, from early 1990s, atmosphere has been changed to regard a young mother who is trying to teach Buryat to her child is being regarded as "a great mother with right consciousness" in Ulaan-Ude.

Both consultants worried about the increasing number of the young Buryats who cannot speak their mother tongue, especially in Ulaan-Ude. As a whole, the Buryat language seemed to be in between "Definitively endangered" ~ “Severely endangered” in Ulaan-Ude.

2.1.1.2. *Buryat dialects in Irkutsk Oblast*. Both the Ekhirit-Bulagat and the Alar Buryat dialects seemed to be “Severely endangered”. It seemed that Buryat people in their 30s

and 40s understood their mother tongue in various levels in these areas. But only few of them were ready to respond in their Buryat dialects.

Our consultant, a 64 year old grandfather, spoke to his 10 year old grandson in Russian. He and his friend conversed in Russian right after they exchanged greetings in Buryat. He replied in Buryat forms for the 71% of the 2757 words we asked. He believed that his mother tongue would disappear in his lifetime.

A 41 year old Alar consultant spoke Buryat fluently with many Russian words. She replied with the Buryat forms for 67% of the 2757 words we asked. One of her female cousins, about the same age with her, spoke as fluently as eloquent talkers in Mongolia. However, 76 year old father of our consultant, who had the normal hearing ability, spoke in Russian to his daughter, son-in-law, and nieces. He needed his daughter's Russian translation to converse with me. Another cousin of our consultant, a principal of a primary school, which had only the first year and the second year classes, told me in Russian that they were worried that their children did not know how to speak in Buryat, and they were teaching (the Khori) Buryat at school one or two hours a week through a visiting teacher who taught "the Standard Buryat language", which is the another name for the Khori Buryat dialect in Buryatia.

### *2.1.2. The Kalmyk language in Kamyk Republic*

The Kamyk language is "Severely endangered" as the Buryat dialects in Irkutsk Oblast, Russia. When I was in Elista, the capital of the Kalmyk Republic, they had a newspaper in Kalmyk, *Kal'mg Unn*. Some books were being published in Kalmyk. TV broadcasting lasted around 8 minutes in Kalmyk in the morning news time. Our 76 year old consultant was fluent in his mother tongue. He and his Kalmyk friends in their 60s and 70s, however, exchanged their everyday greetings in Russian.

Several graduate students in their 20s, who helped and observed our fieldwork studies, spoke in Mongolian with me, which showed no actual difference from the Khalkha dialect. They spoke Kalmyk and Russian among themselves. They told me that they learned both the Kalmyk and the Mongolian as their major subjects after they entered the college. According to them, Kalmyk language is being taught in schools these days, it is however, hard to expect high level proficiency in that it is not spoken outside of those classes. They added that their parents were not able to speak in Kalmyk because their grandparents had lost their language during the years of the deportation (1943-1957) .

Some of them said that I should have visited the Ketchener area where the Kalmyks including the children spoke in their mother tongue in everyday life. The other

students refuted that the Ketcheners were over proud about their speaking Kalmyk, which in reality was a mere combinations of the simple Kalmyk words by Russian syntax. Two graduate students, who were with us throughout the survey, occasionally raised questions about the word order of our consultant.

## *2.2. Mongolian languages and dialects in China*

Fieldwork studies were carried out on the following Mongolian languages and dialects spoken in China.

- (1) Dagur (Meilis); Meilis Dagur Nationality district, Qiqihaer, Heilongjiang; 2003. 9. 23. - 9. 26.
- (2) Dagur (Ashir); Tacheng , Xinjiang; 2004.10.18. - 10. 21.
- (3) Khuuchin Barga; Hailaer, Hunlunbeier, Inner Mongolia; 2005. 2. 16. - 2. 19.
- (4) Shira Yogur; Hongwansi, Sunan, Gansu; 2005. 10. 17. - 10. 21.
- (5) Bonan (Nianduhu, Tongren); Xining, Qinghai; 2006. 8. 19. - 8. 21.
- (6) Monguor (Minhe); Xining, Qinghai; 2006. 8. 23. - 8. 25.
- (7) Oirat (Hoboksair); Hebukesai, Xinjiang; 2008.1. 6. - 1. 8.
- (8) Oirat (Bortala); Jinghe, Xinjiang; 2008. 1. 10.; Urumqi city, Xinjiang; 2008. 1. 13. - 1. 14.
- (9) Oirat (Bayanggol); Urumqi, Xinjiang; 2008. 1. 11. - 1. 12.
- (10) Baarin (Right banner); Huhhot, Inner Mongolia; 2008. 8. 2. - 8. 4.
- (11) Ordos (Üüshin banner); Huhhot, Inner Mongolia; 2008. 8. 5. - 8. 7.
- (12) Khorchin (Middle banner); Huhhot, Inner Mongolia; 2008. 8. 12. - 8. 14.

It would be convenient for the discussion if Mongolian languages and dialects in China are grouped into several groups as below according to the degree and the nature of the danger they are facing.

### *2.2.1. Dagur in Heilongjiang and in Xinjiang*

The Dagur dialects in both Heilongjiang and Xinjiang regions seem to be "Severely endangered". Dagur people are a minority even in their own autonomous nationality administrative units, and they have to be fluent speakers of Chinese, or Chinese and Kazakh, or Chinese and Mongolian, in schools, at works, and in the markets. Dagur is not used in mass media. It has no generally accepted writing system, therefore no literature. It has never been a classroom language. As a result, the Dagur youths of the urban area have no opportunity to learn their mother tongue in a natural

environment, or in a systematic way.

During our fieldwork studies in Meilis, which lasted three days, it was hard to encounter a Dagur person, regardless of age, who communicates in Dagur with another Dagur person - little more than the exchange of greetings, in the street, in shops, in the park where many seniors gather for their morning exercise, in the open market, and at the bus station of the main district. People in their 50s and under show great discrepancy in mother tongue proficiency. The Meilis subdialect has almost no “real” native speakers under age 40.

In Tacheng, Dagur ethnics are fluent in Kazakh and Chinese, both in language and literature. They use Chinese and Kazakh in their everyday life. It seemed that some people over their 50s and very few in their 30s and 40s use the Dagur language even in non-official domains. It seems that many of the Dagur people over their 50s in this area speak Kazakh and Chinese better than their mother tongue.

As a conclusion, the Dagur language is "Severely endangered". However, there still remains hope for revival of this language in that there are fluent speakers such as our consultants in their 50s, and there are places where Dagur is still "the first communication language" among the Dagurs as Piao (2003:118) informed us.<sup>iv</sup>

### 2.2.2. *Khuuchin Barga in Inner Mongolia*

This dialect is in between “Unsafe” ~ “Definitively endangered”. It is not an easy task to declare the right position of the Khuuchin Barga dialect which has some Buryat Mongolian and some non-Buryat Mongolian elements at the same time in phonological, morphological, lexical, and syntactic levels.

It is quite interesting that considerable portion of those non-Buryat Mongolian elements, including 4 affricate consonant phonemes (voiceless unaspirated/aspirated dental-alveolar, voiceless unaspirated/aspirated alveolo-palatal), are close to those in Khalkha Mongolian as suggested in Yu(2006). Consultant answered in Russian forms for 24 words among 2700 words he gave us including [xəlje : p] 'bread', [do : kt<sup>h</sup>or] '(medical) doctor', [no : mir] 'number', [minu : t<sup>h</sup>] 'minute', [səxo : nt] 'second', [χalnde : r] 'calendar', etc.

Both our consultant and his wife, an Ewenki, were fluent in Khuuchin Barga. Their children in 20s and 30s seemed to know the dialects. Their grandchild, around 10 years old, did not know the Mongolian. When our consultant invited us to a restaurant in his town, there was a big birthday party for a 73 year old lady in the main hall of that restaurant. The party host was using both Mongolian and Chinese to the congratulators.

### 2.2.3. *Shira Yogur or Eastern Yugur in Gansu*

This language seemed to be "Definitively endangered". There is no writing system for this language. Teenagers understood what their parents were saying but they were not ready to respond in their mother tongue. Shira Yogur people over their 30s seemed to communicate in their mother tongue among themselves.

Our consultants seemed to regard those Western Yugur or Tibetan elements in their language as native words, and Chinese elements as foreign words.<sup>v</sup> It is said that the Chinese population began to move into this area, in actual sense, from 1958. It may be the case that the Chinese elements have not become fully Shira Yogurized to our consultants. One of our consultants, a farmer, was born in 1942. Thus he had no school education, but he too had a sound command in spoken Chinese.

### 2.2.4. *Monguor, Baoan in Qinghai and Oirat in Xinjiang*

These languages and dialects seemed to be "Stable yet threatened". In these areas, even preschool children speak in their mother tongue among themselves. However, they are good at Chinese or Chinese and Tibetan, which are their class room languages and the dominant languages of the society they belonged to. There is no writing system for Monguor and Baoan.

Monguor people of Minhe County, Gansu Province use Chinese numerals for counting even in one digit numbers. Everyone, however, spoke in Monguor including preschool children in this village. The good memory of the native words and the actual use or the proficiency of the mother tongue, therefore, might not be directly related in this dialect.

Our 22 year Baoan consultant told us that people of all age of her village in Tongren County, Gansu Province spoke in their mother tongue in everyday life, despite the classroom language has been the Tibetan in primary and secondary schools.

Oirat children seemed not to have real difficulty to converse with me in Mogolian. But they knew Chinese, too. Some of the Oirat children in Hoboksair area may soon become fluent in Kazakh as some of their adults.

### 2.2.5. *Baarin, Ordos, and Khorchin dialects in Inner Mongolia*

These dialects seem to be "Unsafe", although everybody speaks in Mongolian there. Even an eight year old boy spoke and wrote traditional Mongolian perfectly and beautifully in Ordos. He said that the Mongolian is the classroom language in his school. His grandparents, parents, cousins, neighbors spoke only in Mongolian. But the boy was fluent in Chinese too. His grandfather told me that children learn Chinese in school, and

certain classes are being taught in Chinese. However, in my impression, many of the Mongolian children master their Chinese even before they go to school through many ways such as TV animations, computer games, etc.

### *2.3. Mongolian languages and dialects in Mongolia*

Fieldwork studies were carried out on the following Mongolian languages and dialects spoken in Mongolia.

(1) Ö öld (Düükhee/Döchin Tolgoi); Ö lziit sum, Arkhangai aimag; 2004. 6. 26.

(2) Darkhad; Jankhain Tsagaan Ereg, Alag-Erdene sum, Khövsgöl aimag; 2005. 6. 23. - 6. 26.

(3) Darkhad; Seoul, Korea; 2007. 6. 18., 6. 28.

(4) Arig Uriankhai; Byarangiin gol, Chandman-Ö ndör sum, Khövsgöl aimag; 2006. 6. 27. - 6. 29.

(5) Khamnigan (Binder, Dadal); Chingisiin Toonot of Binder sum and Gurvan nuur of Dadal sum, Khentii aimag ; 2007. 7. 6. - 7. 11.

(6) Ü üriin Uriankhai; Tsegtseriing Ü züür, Tsagaan Ü ür sum, Khövsgöl aimag; 2006. 7. 1. - 7. 3.

#### *2.3. 1. Khalkhazation of the Mongolian dialects*

The "Khalkhazation" must be the most serious problem which these dialects are facing. We asked 2716 words each to two Darkhad consultants, 816 words to one consultant, and 812 words to the other consultant to find only 6 words all together from these four consultants, which were different from the Khalkha forms.

The Ö öld, the Arig Uriankhai, the Khamnigan (Dadal) had no actual differences from the Khalkha. The only remarkable difference of the Khamnigan (Binder) from Khalkha seemed to be the aspirated velar (and post-velar) plosive at word-initial position, which is realized as voiceless fricative in Khalkha.

#### *2.3. 2. Ü üriin Uriankhai case*

Ü üriin Uriankhai deserves special remarks in that it is still well remembered as a Tuvan Turkic among the people over their 70s but not in use. Including those seniors, all Ü üriin Uriankhai people use Khalkha in everyday life even for the communication among family members.

Our 52 year old consultant remembered some Ӧ üriin Uriankhai words including the numbers from 'one' to 'eight', personal pronouns, verbal endings, however, he was unable to make sentences in his mother tongue.

According to him, he had used to speak in (Ӧ üriin) Uriankhai at home before he went to primary school. At school, however, classmates made fun of him and teachers reprimanded him using mother tongue. In the military where only the Khalkha was used, he was doing his telephone operator job so fine that his officers and sergeants tried to persuade him to consider becoming a career soldier. When he had returned home, however, to take care of his parents and started his career as an agriculture cooperative clerk, his supervisor had used to reprimand him of using (Ӧ üriin) Uriankhai with his (Ӧ üriin) Uriankhai colleague and customers that he lost his courage to speak in his mother tongue, then forgot how to speak it gradually. It sounds like the Khalkhazation of the Ӧ üriin Uriankhai population had completed in past several decades.

### **3. Summary**

This paper tried to inform that Mongolian languages and dialects spoken in Russia and China are in different degrees of danger of disappearing under the pressure of Chinese, Russian, Kazakh, or even Tibetan. We saw some of them already have lost their actual speakers.

This paper made a brief note that Mongolian dialects in Mongolia are facing another nature of serious threat, that is heavy Khalkhazation. Ӧ üriin Uriankhai case was introduced as an example of extreme Khalkhazation.

Several examples of interesting phenomena and episodes found and heard during the fieldwork studies were introduced. They include: 1) children spoke mother tongue better than parents in some communities, 2) good memory of the elements of one's mother tongue does not always go with the actual use of it, 3) most of the mother tongue-loss had been completed in past several decades ago, etc.

### **Notes**

---

<sup>i</sup> Levels are proposed as following orders in this document: Safe > (Stable yet threatened) > Unsafe > Definitively endangered > Severely endangered > Critically endangered > Extinct.

<sup>ii</sup> I would say that the nearest Mongolian dialect to "my Mongolian" is the Khalkha, which I began to study as a graduate student. There are certain degrees of differences between the Khalkha

---

and the Buryat at lexical, phonological, morphological, and syntactic levels.

<sup>iii</sup> We asked 2757 words, 344 conversational expressions, and 380 sentences and constructions intended to grasp the grammatical structure of this dialect, in the fieldwork studies in Russia, January, 2007. See Yu (2007a) for further information.

<sup>iv</sup> Woniutu and Manggetu townships of Meilis Nationality District and Duermenqin Dagur Ethnic Township of Fulaerji District, both in Qiqihaer City.

<sup>v</sup> They answered Western Yugur forms or Tibetan words as their own word. However, when the Chinese word is being used in their language, they said "We do not have that word in our language. We are using a Chinese word for that."

# A Web-Accessible Dictionary of Southeastern Pomo

**Yao Yao, Charles B. Chang, Shira Katseff,  
Russell Lee-Goldman, and Marta Piqueras-Brunet\***

University of California, Berkeley  
1203 Dwinelle Hall, Berkeley, CA 94720-2650, USA

rleegold@berkeley.edu, marta.piqs@gmail.com

## **Abstract**

In recent years, building web-accessible dictionaries has become a new way of organizing and publishing data from linguistic fieldwork on indigenous languages. This paper provides an overview of one such online dictionary. The language we worked on was Southeastern Pomo, an endangered native American language which was historically spoken in the area of Clear Lake, California. The structure of the dictionary and the files that are needed to construct it are introduced in detail. We also demonstrate three types of searches that are made available on the dictionary website.

**Keywords:** online dictionary, language documentation, native American languages.

## **1. Background**

In the past decade, as resources for linguistic analysis have entered cyberspace, so have the products of linguistic documentation. Online dictionaries have been created for a number of languages native to the Americas, including Yurok, Hupa, Washo, and Northern Paiute (cf. Babel et al. 2006, Dick and Haynes 2006). These online dictionaries make the information gathered through fieldwork accessible to researchers, tribe members, and in particular, young learners. In this paper, we present our work on an online dictionary for another native American language, Southeastern Pomo, with the goal of providing an overview for the linguistic fieldwork community of the technical details involved in building an online dictionary website.

---

\* For their help, feedback, and support throughout the course of this project, we are grateful to Jocelyn Ahlers, Zhenya Antić, Catherine Callaghan, Thera Crane, Donna Fenton, Andrew Garrett, Robert Geary, Hannah Haynie, Leanne Hinton, Jisup Hong, Loretta Kelsey, Julius Moshinsky, Lindsey Newbold, Ronald Sprouse, Maziar Toosarvandani, Corey Yoquelet, the audience at CIL 18, and the Department of Linguistics at the University of California, Berkeley. Any errors remain our own.

### 1.1. The Southeastern Pomo dictionary project

Southeastern Pomo (Northern Hokan, Pomoan) is an acutely endangered language historically spoken in the area around Clear Lake, California (Moshinsky 1974, Gordon 2005, cf. Figure 1).

**Figure 1.** Locations of the Southeastern Pomo speech communities (from Haynie 2007)

Speakers and learners are mostly affiliated with the Elem Pomo Tribe. Today only two fluent speakers remain. However, revitalization efforts are underway, led by Loretta Kelsey, one of the two remaining speakers, and Robert Geary (cf. Shavelson 2006, Fagan 2007). Through collaboration with linguists, they have developed a community orthography, teaching materials, and a print dictionary with pictures of local flora and fauna. Language camps have also been organized for people to learn the language.

The present online dictionary is another component of this revitalization work. We started working with Kelsey and Geary in the fall of 2006, and have so far elicited hundreds of hours of data comprising word lists, sentences, and texts. In order to

organize and publish the data in the most efficient and user-friendly way, we constructed a web-accessible dictionary. The dictionary has three main functions: searching for words, searching for audio files, and searching for sentences/texts.

### 1.2. Transcribing the sounds of Southeastern Pomo

Southeastern Pomo (henceforth, SEP) has a rich inventory of consonants covering a wide range of places of articulation, including labial, dental, alveolar, velar, post-velar, and glottal. In addition to a voiced/voiceless laryngeal distinction, the language also has a series of ejectives (both in stops and affricates). Table 1 below shows the inventory of consonant phones, as well as our practical ASCII orthography (which differs in some respects from the community orthography) in parentheses underneath the IPA forms.

	LABIAL	DENTAL	ALVEOLAR	PALATAL	VELAR	POST-VELAR	GLOTTAL
STOP	p p' b (p p' b)	t t' (th th')	t t' d (t t' d)		k k' (k k')	q q' (q q')	ʔ (ʔ)
AFFRICATE			ts ts' (ts ts')	tʃ tʃ' (ch ch')			
FRICATIVE	f (f)		s (s)	ʃ (sh)	x (x)	χ (X)	h (h)
NASAL	m (m)		n (n)		ŋ (ng)		
FLAP			r (r)				
APPROXIMANT	w (w)		l (l)	j (y)			

**Table 1.** Consonant inventory of Southeastern Pomo

The vowel inventory of SEP is much simpler. The language basically has a five-vowel system, with an additional schwa that appears predictably in epenthetic positions (and therefore is not spelled out in our orthography). Table 2 shows the vowel system together with the orthography in parentheses beside the IPA forms.

	FRONT	CENTRAL	BACK
HIGH	i (i)		u (u)
MID	ɛ (e)	ə	o (o)
LOW		a (a)	

**Table 2.** Vowel inventory of Southeastern Pomo

## 2. Dictionary Structure

The online dictionary is composed of three subparts: a lexicon, an audio dictionary, and a text archive.

### 2.1. *Lexicon*

The lexicon contains entries for individual words, affixes, and fixed expressions. Each entry displays the following information about an item: (1) its SEP transcription, (2) its part of speech, (3) an English gloss, and (4) links to sound clips in the audio dictionary (if available). Different lexicon entries correspond to different forms, but not necessarily different lexemes (e.g. different morphological forms of a verb get separate, though linked, entries).

### 2.2. *Audio dictionary*

In addition to the lexicon, there is a separate audio dictionary. Each entry in the audio dictionary corresponds to an audio file clipped out of master field recordings to correspond to a lexicon entry. An entry in the audio dictionary displays the following information about an item: (1) its SEP transcription, (2) an English gloss, (3) the name of the speaker who produced the item, (4) a link to the corresponding lexicon entry, and (5) a reference to its source, i.e. the filename of the master field recording together with the time point within it at which the relevant audio begins (for developers).

The audio dictionary is independent of the lexicon, but corresponding lexical entries and sound clippings are linked to each other from both sides. The two dictionaries are kept apart for the purposes of facilitating two different types of searches – word searches and audio searches (see §4).

### 2.3. *Text archive*

The text archive contains entries for elicited sentences, narratives, and other discourse above the sentence level. Each entry displays the following information about an item: (1) the name of the speaker who produced the text, (2) the genre of the text, (3) transcriptions of individual sentences, (4) free translations, and (5) interlinear glosses.

### 3. Building the Website

In this section, we briefly review the construction of the website, in terms of data preparation and storage, query processing, and results display.

In the preparation stage, fieldwork recordings are manually processed and clippings of individual words, sentences, and texts are saved individually. Meanwhile, information about these data is entered into three separate databases corresponding to the subparts of the dictionary. Lexicon entries are first entered into a mySQL database and then converted into a grand XML (eXtensible Markup Language) file, while information about audio clippings and texts is entered into separate XML files directly.

The mySQL database of lexicon entries has the following fields:

- SEP transcription
- transcriptions of variants (if any)
- community orthography (if available)
- part of speech
- free gloss & interlinear gloss
- semantic domain
- source file & start time
- links to other morphologically related entries
- notes

The mySQL database has a number of desirable features. For one, it automatically generates an unique ID number for each new entry, and is fully sortable and searchable. It also allows several researchers to make and edit entries at the same time without overwriting each other's work. In addition, the database can be easily converted into XML format, which is essentially a text file with all the above information in a fixed format. Figure 2 below shows a sample entry in the lexicon XML file. As shown below, the SEP word *kachuchu* (ID = 101) is transcribed as *kuchechoo* in the community orthography. It is a noun; means 'cap' in English; belongs to the semantic domain of clothes; and is a headword. Furthermore, it was first elicited in the recording named 21sep06\_LK1b, at time 18:39.

The information in the audio dictionary and the text archive is stored in XML files directly, in a similar format as the lexicon XML file. Thus, all the information contained in the dictionary is stored in three separate XML files: one for the lexicon, one for the audio files, and one for the texts. Such a text-based file format allows the data to be easily manipulated into other formats as the technology of documentation changes over time.

```
<lemma>
  <id>101</id>
  <lx>kachuchu</lx>
  <community_orthography>kucechoo</community_orthography>
  <ps>n</ps>
  <ge>cap</ge>
  <short-gloss>cap</short-gloss>
  <ref>21sep06_LK1b</ref>
  <time>18:39</time>
  <sd>clothes</sd>
  <is-headword>yes</is-headword>
</lemma>
```

Figure 2. Sample XML for a lexicon entry

Separate XSL (eXtensible Stylesheet Language) files are written to process search queries and control the display of the results. The function of the XSL files is essentially to decide what information from the XML files needs to be retrieved in response to a certain query and how the retrieved information should be formatted on screen. It should be noted that by having separate XML and XSL files, we are able to separate data processing from data storage, which prevents accidental data overwriting and also allows more flexibility in data processing and display.

To sum up, all relevant information in the dictionary is saved in XML files, and the processing is taken care of by XSL stylesheets. Figure 3 illustrates the data flow in the processing of an incoming query.

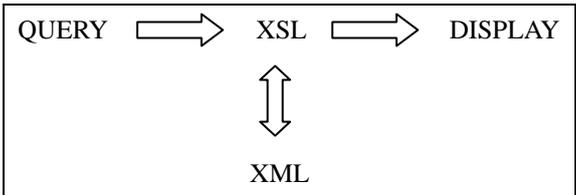

Figure 3. Illustration of query processing

4. Dictionary Searches

In this section, we demonstrate three types of searches handled on the dictionary website: word search, audio search, and text search. As mentioned above, the three sub-dictionaries are stored separately, but cross-linking between any two is possible.

#### 4.1. Word search

Lexicon entries can be searched using up to three search criteria: SEP transcription, English gloss, and semantic domain. Users can also choose whether affixes are to be included in the search. Figure 4 demonstrates a search for lexicon entries for which the English glosses contain the word *black*.

Figure 4. Web interface for a sample lexicon search

Figure 5. Results of a search for words with English glosses containing *black* (entry *k7afal* selected)

Five lexicon entries are returned by the query, and their SEP transcriptions and English glosses are shown in the left pane of the results page (cf. Figure 5 above). Upon

clicking on an individual entry in this list, say *k7afal* ‘blackbird’, the full entry for the word and a link to the corresponding audio file will appear in the main pane on the right.

#### 4.2. Audio search

Audio clippings can be searched by SEP transcription, English gloss, speaker, or any combination of the three.

Figure 6. Web interface for a sample audio search

Figure 7. Results of a search for words with the segment sequence *-ka-* spoken by speaker John Kelsey

As a demonstration, if the user searches for all sound clippings of words with *-ka-* in their transcription that are spoken by John Kelsey (cf. Figure 6), six search results will be found and displayed (cf. Figure 7). Each search result can be clicked to play the audio, and a link is provided below the audio entry to the corresponding lexicon entry.

#### 4.3. Text search

Finally, users can also search for texts using multiple search criteria.

**Figure 8.** Web interface for a sample text search

**Figure 9.** Results of a search for elicited sentences containing *hekath7e* from speaker Loretta Kelsey

On the text search page, users can search by the SEP/English words contained in the text, text genre (dialogue, elicited sentences, procedural text, remarks, and stories), or speaker. We demonstrate a sample search for elicited sentences that contain the SEP word *hekath7e* ‘how’ and are spoken by Loretta Kelsey (cf. Figure 8 above).

Three instances are found and displayed on the results page (cf. Figure 9 above). Each sentence is listed with the English translation and references to the original elicitation file and sound clipping. A ‘full context’ link can be clicked to view the whole text with detailed interlinear glosses. Figure 10 below shows the full text page for the third search result *theak kwik hekath7e?* ‘How are your children?’, with detailed glosses (the original search result sentence appears in red).

The screenshot shows the website interface for the Southeastern Pomo Language Project. At the top, there is a header with the project name and a navigation menu on the left. The main content area displays search results for the text 'SE Pomo [hekath7e]'. The results are listed in a numbered format, with the third result, '[3] theak kwik hekath7e?', highlighted in red. This result includes the English translation 'How are your children?', the audio file reference '14sep06\_LK6a\_1786', and a detailed interlinear gloss: 'theak kwik hekath7e / your children why/how'. Other results include '7a xa klakdith' (I'm fishing) and '7omet hekath q'owliith' (How is she doing?).

**Figure 10.** Full text page for the selected sentence *theak kwik hekath7e* ‘How are your children?’ with detailed glosses. The selected sentence is in red.

## 5. Concluding Remarks

In this paper, we presented our work on an online dictionary for Southeastern Pomo. Specifically, we introduced the structure of the dictionary and demonstrated how the data are stored and processed on the website. We also showed the search interface of the website and demonstrated sample queries. However, this only represents the first step of the dictionary project. In the near future, we plan to develop and improve the dictionary website in the following ways. First, the data structure of the lexicon data file needs to be more elaborated (e.g. with nested structure) in order to accommodate polysemy more neatly. Second, the data of the print dictionary will be merged with that of the online dictionary, and all entries will be updated with their spelling in the Elem orthography. Third, different types of multimedia (e.g. photos of local flora and fauna, videos of the actions described by verbs of motion and placement) will be added to make the dictionary more informative and easier to use. Our ultimate goal, however, is to make the dictionary website widely accessible to teachers and learners so that they can make regular use of it as a CALL (Computer-Aided Language Learning) tool.

# Endangered Turkic Languages

## — Preliminary Report on Fieldwork Studies —\*

Yongsōng Li

Seoul National University  
Yangcheon-gu Sinjeong 6-dong 314(24/9), Seoul 158-768, Korea  
yongsongli1964@empal.com

### Abstract

Turkic Languages and dialects are spoken widely in Eurasia. Many of them are in danger of disappearing by the influence of Chinese, Khalkha Mongolian, Russian, etc. The ASK REAL (The Altaic Society of Korea, Researches on Endangered Altaic Languages) has been doing fieldwork studies on Endangered Altaic Languages since September 2003. I have been participating to this project from the beginning for the studies of Endangered Turkic languages in China, Mongolia, Russia, Kyrgyzstan, Ukraine, and Lithuania. I have collected word material of some 20 Turkic languages.

**Keywords:** Chinese, danger of disappearing, Khalkha Mongolian, Russian, Turkic languages and dialects

### 1. Preface

Turkic Languages and dialects are spoken widely in Eurasia. Many of them are in danger of disappearing by the influence of Chinese, Khalkha Mongolian, Russian, etc. The ASK REAL (The Altaic Society of Korea, Researches on Endangered Altaic Languages) has been doing fieldwork studies on Endangered Altaic Languages since September 2003. I have been participating to this project from the beginning for the studies of Endangered Turkic languages as below:

- (1) Fuyu Kirghiz in the villages of Wujiazi and Qijiazi, Fuyu County, Qiqihar, Heilongjiang Province, China: September 23-24, 2003
- (2) Fuyu Kirghiz in the village of Qijiazi, Fuyu County, Qiqihar, Heilongjiang Province, China: January 15-16, 2004
- (3) Shor (Mrass-Upper Tom dialect) in Myski, Kemerovo Province, Russia: April 20-23,

---

\* This work was supported by Korea Research Foundation Grant (KRF-2006-322-A00054).

2004

- (4) Chuvash in Cheboksary, Chuvash Republic, Russia: April 19-22, 2005
- (5) Tuvan (Kök Monchak dialect) in Qanas and Aqqaba, Altay Prefecture, Xinjiang Uygur Autonomous Region, China: April 28- May 4, 2005.
- (6) Tuvan (Tsaatan dialect) in Khatgal, Khövsgöl Aymag, Mongolia: June 23-26, 2005
- (7) Western Yugur in Hongwansi, Sunan Yugur Autonomous County, Gansu Province, China: October 17 -21, 2005
- (8) Gagauz in Kiev, Ukraine: February 5 and 17, 2006
- (9) Urum (Oghuz dialect) in Mariupol', Donetsk Province, Ukraine: February 7-11, 2006
- (10) Urum (Kypchak dialect) in Mariupol', Donetsk Province, Ukraine: February 8-9, 2006
- (11) Krymchak in Simferopol', Autonomous Republic of Crimea, Ukraine: February 12-14, 2006
- (12) Karaim (Crimean dialect) in Jevpatorija and Simferopol', Autonomous Republic of Crimea, Ukraine: February 15-16, 2006
- (13) Chulym Tatar (Middle Chulym dialect) in Tomsk, Tomsk Province, Russia: May 15-18, 2006
- (14) Baraba Tatar in Tomsk, Tomsk Province, Russia: May 18 and 20, 2006
- (15) Chulym Tatar (Lower Chulym dialect) in Tomsk, Tomsk Province, Russia: May 19 -21, 2006
- (16) Tuvan (Uriankhai dialect) in Tsagaan-Üür, Khövsgöl Aymag, Mongolia: July 1-3, 2006
- (17) Salar in Xining, Qinghai Province, China: August 19-26, 2006
- (18) Kirghiz (Talas subdialect of Northern dialect) in Bishkek, Kyrgyzstan: December 22-25, 2006
- (19) Kirghiz (Ichkilik subdialect of Southern dialect) in Bishkek, Kyrgyzstan: December 28-30, 2006 and January 2, 2007
- (20) Kirghiz (Narın subdialect of Northern dialect) in Bishkek, Kyrgyzstan: January 2-3, 2007
- (21) Kirghiz (Chuy subdialect of Northern dialect) in Bishkek, Kyrgyzstan: January 3-5, 2007
- (22) Kirghiz (İşik-Köl subdialect of Northern dialect) in Bishkek, Kyrgyzstan: January 6-8, 2007
- (23) Dolgan in Yakutsk, Sakha Republic, Russia: January 30 -February 5, 2007
- (24) Yakut in Yakutsk, Sakha Republic, Russia: February 3-5, 2007

- (25) Karaim (Trakai dialect) in Trakai, Lithuania: July 17-28, 2007
- (26) Bashkir (Ėyĕk-Haqmar subdialect of Southern dialect) in Ufa, Republic of Bashkortostan, Russia: August 8-10 and 21, 2007
- (27) Bashkir (Urta subdialect of Southern dialect) in Krasnousol'sk, Republic of Bashkortostan, Russia: August 11-13, 2007
- (28) Bashkir (Zelin subsubdialect of Urta subdialect of Southern dialect) in Krasnousol'sk, Republic of Bashkortostan, Russia: August 14, 2007
- (29) Bashkir (Dim subdialect of Southern dialect) in Rajevka, Republic of Bashkortostan, Russia: August 14-16, 2007
- (30) Bashkir (Qïðil subdialect of Eastern dialect) in Asqar, Republic of Bashkortostan, Russia: August 19-20, 2007
- (31) Chuvash in Ufa, Republic of Bashkortostan, Russia: August 22, 2007
- (32) Tatar in Ufa, Republic of Bashkortostan, Russia: August 22, 2007
- (33) Khakas (Sagay dialect) in Abakan, Republic of Khakassia, Russia: August 2-4, 2008
- (34) Khakas (Shor dialect) in Chernogorsk / Abakan, Republic of Khakassia, Russia: August 5-7 / 15, 2008
- (35) Khakas (Koibal subdialect of Kacha dialect) in Abakan / Bejskij rajon selo Kojbaly / Abakan, Republic of Khakassia, Russia: August 7 / 12 / 13, 15-16, 2008
- (36) Khakas (Kïžil dialect) in Abakan, Republic of Khakassia, Russia: August 8-11, 13, 16, 18, 2008
- (37) Khakas (Beltir subdialect of Sagay dialect) in Askizskij rajon selo Apchinajev / Abakan, Republic of Khakassia, Russia: August 12 / 13, 18, 2008
- (38) Khakas (Kacha dialect) in Abakan, Republic of Khakassia, Russia: August 13-16, 2008

This paper introduces current situation of above languages and dialects, discusses the degree and aspect of danger of disappearing of each of them according to the criteria 'Intergenerational Language Transmission' and 'Proportion of Speakers within the Total Population' of UNESCO Ad hoc expert group on endangered languages (2003).

## **2. Turkic languages and dialects studied by the author**

### *2.1. Fuyu Kirghiz*

#### *2.1.1. population*

875 with 10 speakers (1982, Ethnologue)

61 farmhouses and 276 inhabitants out of 148 farmhouses and 551 inhabitants in Wujiazi (五家子) (Wu 2003: 180, 186)

151 out of 397 (59 Mongolians, 6 Dagurs, 3 Koreans, 5 Orochons, 4 Xibes, 4 Manchus, etc) in Qijiazi (七家子) (Wu 2003: 217).

#### 2.1.2. *informants*

1<sup>st</sup> fieldwork: 2 females (born in 1934, 1936), 1 male (born in 1952) in Wujiazi  
2 females (born in 1935, 1928), 2 males (born in 1934) in Qijiazi<sup>1</sup>

2<sup>nd</sup> fieldwork: 2 females (born in 1935, 1924), 1 male (born in 1934) in Qijiazi

#### 2.1.3. *result*

1<sup>st</sup> fieldwork: 216 words, 22 conversational expressions in Wujiazi  
305 words, 32 conversational expressions in Qijiazi

2<sup>nd</sup> fieldwork: 363 words, 43 conversational expressions in Qijiazi

#### 2.1.4. *daily language*

Mongolian and Chinese in older generation

Chinese in younger generation

Our informants were not able to construct any long sentence. There is no fluent speaker in “Fuyu Kirghiz”. There is no hope for its revitalization. Therefore, this language lies between ‘critically endangered’ and ‘extinct’.

#### 2.2. *Shor*

Shor has two dialects: Mrass-Upper Tom and Kondoma-Lower Tom. The Mrass-Upper Tom dialect belongs to *azaq*-group like Khakas, Western Yugur and Middle

---

<sup>1</sup> One female informant (born in 1928) and one male informant have almost forgotten their mother tongue.

Chulym whereas Kondoma-Lower Tom belongs to *ayaq*-group like Lower Chulym, Turkish, Tatar, Uzbek, etc.

#### 2.2.1. *population*

The population of the Shors was 13,975 with 6,210 persons knowing Shor in 2002 (Russia). There were 16,000 Shors with 9,760 native speakers in 1979 (Soviet Union).

#### 2.2.2. *informant*

1 male (born in 1932; speaker of Mrass-Upper Tom dialect)

#### 2.2.3. *result*

most of 2,728 words, 276 conversational expressions, 280 grammatical constructions

#### 2.2.4. *daily language of the informant*

Russian

Shor became a written language, but it was not used as a written language since 1937 approximately 50 years. There are signs of Shor lingual revival: this language is now being taught at the Novokuznetsk branch of the Kemerovo State University.

In Myski (= Tomazaq), only a few persons were recommended as informants for us. There are very few fluent speakers. The Shors speak only Russian or they are bilingual in Russian and Shor. They are a minority in their homeland and mixed severely with other nationalities. Therefore, this language seems to lie between 'definitely endangered' and 'severely endangered'.

### 2.3. *Chuvash*

Chuvash has two dialects: Viryal (= Upper) and Anatri (= Lower). The written Chuvash is based on the Anatri dialect.

#### 2.3.1. *population*

The population of the Chuvash was 1,637,094 with 1,325,382 persons knowing Chuvash in 2002 (Russia). There were 10,593 Chuvash with 2,268 native speakers in 2001 (Ukraine).

### 2.3.2. *informants*

2 males (born in 1956, 1950) in 2005

1 male (born in 1962) in 2007

### 2.3.3. *result*

2,721 words, 344 conversational expressions and 380 grammatical constructions from the 1<sup>st</sup> informant in 2005

812 words from the 2<sup>nd</sup> informant in 2005

806 words and free talking in 2007

### 2.3.4. *daily language of the informants*

Russian and Chuvash

Chuvash seems to lie between ‘safe’ and ‘unsafe’. The children of the 1<sup>st</sup> informant in 2005 understand Chuvash but they cannot speak their mother tongue fluently.

## 2.4. *Tuvan*

Tuvan and its related languages/dialects (= Sayan Turkic): a) steppe area: Tuvan in Tyva Republic, Tuvan in Tsengel sum of Mongolia, and Kök Monchak in Mongolia and China; b) Taiga area: Tofa and Soyot in Russia, Tsaatan (= Dukha) and Üürin Uriankhai in Mongolia.<sup>2</sup>

### 2.4.1. *population*

---

<sup>2</sup> Rassadin, V. I. 2005. The Tofa Language. *Endangered Languages of Indigenous Peoples of Siberia* In <http://lingsib.iea.ras.ru/en/languages/tofa.shtml>.

The population of the Tuvans was 243,442 with 242,754 persons knowing Tuvan in 2002<sup>3</sup> (Russia). The population of the Tuvans is 27,000 in Mongolia and 2,600 in China.

#### 2.4.2. *informants*

Kök Monchak<sup>4</sup>: 1 female (born in 1949) and 1 male (born in 1962)

Tsaatan: 1 male (born in 1954) and 1 female (born in 1972)

Üürin Uriankhai: 2 males (born in 1955, 1941)

#### 2.4.3. *result*

Kök Monchak: 2,243 words, 344 conversational expressions and 374 grammatical constructions from the female informant

2,715 words, 344 conversational expressions and 374 grammatical constructions from the male informant

Tsaatan: 2,768 words, 345 conversational expressions, 385 grammatical constructions and free talking from the male informant

385 grammatical constructions and free talking from the female informant

Üürin Uriankhai: 2,749 words (some of them are not answered), 345 conversational expressions and 384 grammatical constructions from the 1<sup>st</sup> informant

2,749 words (2,466 words were answered), 345 conversational expressions, 384 grammatical constructions and free talking from the 2<sup>nd</sup> informant

#### 2.4.4. *daily language of the informants*

Kök Monchak: Mongolian, Tuvan, Kazakh, and Chinese for the female informant

Tuvan, Chinese, Kazakh, and Uyghur for the male informant

Tsaatan: Khalkha Monolian

Üürin Uriankhai: Khalkha Monolian

---

<sup>3</sup> There are also 4,442 Todzhas and 2,769 Soyots according to the same census.

<sup>4</sup> Another fieldwork was carried out by the ASK REAL team during 21 – 22 October in 2004. I did not participate to this fieldwork. The informant was a man born in 1963. His daily languages were Tuvan and Kazakh.

The instruction language is Mongolian for the K k Monchak children. The K k Monchaks live together with the Kazakhs. At present this dialect seems to lie between ‘safe’ and ‘unsafe’ but the new influx of the Chinese can threaten the future of this dialect.

The children of the Tsaatan and   rin Uriankhais seem to speak only Khalkh Mongolia. Therefore, these dialects seem to lie between ‘severely endangered’ and ‘critically endangered’.

## 2.5. *Western Yugur (Yellow Uyghur, 西部裕固)*

### 2.5.1. *population*

The population of Yugurs was 13,719 in 2000. The Yugurs comprise 4,600 Turkic speakers (= Western Yugur, Yellow Uyghur, 西部裕固), approximately the same number of Chinese speakers, a little fewer of Mongolian speakers (= Eastern Yugur, 东部裕固), and some Tibetan speakers.

### 2.5.2. *informants*

2 females (born in 1966, 1957) and 1 male (born in 1939)

### 2.5.3. *result*

some 60 words and 110 conversational expressions from the 1<sup>st</sup> female informant

1,995 words, 344 conversational expressions and 380 grammatical constructions from the 2<sup>nd</sup> female informant

some 800 words from the male informant

### 2.5.4. *daily language of the informants*

#### Western Yugur and Chinese

The 1<sup>st</sup> female informant thinks first in Chinese and then speaks in her mother tongue. Her children cannot speak fluently their mother tongue. The 2<sup>nd</sup> female informant speaks her mother tongue in most cases, but her children cannot speak fluently their mother tongue. The male informant forgot much of his mother tongue. His

children cannot speak fluently their mother tongue. Therefore, this language seems to lie between 'definitely endangered' and 'severely endangered'.

## 2.6. *Karaim*

Historically Karaim had 3 dialects: Crimean (spoken until the early 1900s), Trakai (= Troki) and Lutsk-Halicz (which seems to be extinct).

### 2.6.1. *population*

The population of the Karaims was 1,196 (mainly in Crimea) in 2001 (Ukraine), 366 in 2002 (Russia), 258 in 2001 (Lithuania), 45 in 2002 (Poland), 50 in Turkey (Istanbul), etc. Due to the assimilation and emigration, the number of the Karaims decreased constantly in the former Soviet Union as follows: 5,900 (1959), 3,341 (1979, with 535 speakers of mother tongue), 2,602 (1989). There only remain about 200 Karaim in Lithuania, only one quarter of them are competent speakers of the Karaim language.

### 2.6.2. *informants*

Crimean dialect: 1 male (born in 1928)

Trakai dialect: 2 females (born in 1922, 1964) and 3 males (born in 1927, 1934, 1938)

### 2.6.3. *result*

Crimean dialect: 151 words, some conversational expressions, 117 grammatical constructions (very vague remembrance in many words; sentences according to the Russian order; complete confusion of case suffixes and personal endings)

Trakai dialect

668 words and free talking from the 1<sup>st</sup> female informant

general information on Karaims in Russian from the 2<sup>nd</sup> female informant

2,435 words, 344 conversational expressions, 380 grammatical constructions (self formation of some words with literal translation from Russian; translation and arrangement according to Russian in many sentences) and free talking from the 1<sup>st</sup> male informant

606 words and some 180 conversational expressions from the 2<sup>nd</sup> male informant

2,144 words, 344 conversational expressions, 380 grammatical constructions (endeavor to turkicize the already slaviced Karaim syntax) and free talking from the 3<sup>rd</sup> male informant

#### 2.6.4. *daily language of the informants*

Crimean dialect: Russian (and Karaim)

Trakai dialect:

Polish, Russian (according to Polish word order), Lithuanian, (and Karaim) for the 1<sup>st</sup> female informant

Polish for the 2<sup>nd</sup> female informant (she understands Karaim very well but cannot speak it)

Polish, Russian, Lithuanian, and Karaim for the male informants

The Crimean dialect seems to lie between ‘critically endangered’ and ‘extinct’. The Karaim Summer School is held yearly in Trakai. The Trakai dialect has seemingly good chance for its survival. This dialect nevertheless seems to lie between ‘definitely endangered’ and ‘severely endangered’.

### 2.7. *Gagauz*

#### 2.7.1. *population*

The population of the Gagauz was some 250,000: 147,500 in 2004 (Moldova), 31,923 with 22,822 native speakers in 2001 (Ukraine), 14,000 (Turkey), 12,000 in 1990 (Bulgaria), 12,210 in 2002 (Russia).

#### 2.7.2. *informant*

1 female (born in 1970)

#### 2.7.3. *result*

970 words

#### 2.7.4. *daily language of the informant*

Gagauz, Ukrainian, Russian, and Turkish

Gagauz seems to lie between 'safe' and 'unsafe'.

## 2.8. *Krymchak subdialect of Crimean Tatar*

Krymchak is one of the subdialects of the central dialect of Crimean Tatar. It is also called Judeo-Crimean Tatar or Judeo-Crimean Turkish.

### 2.8.1. *population*

The number of the Krymchaks was supposedly 2,500 in 2000, but the censuses gave their number as 406 in 2001 (Ukraine) and as 157 in 2002 (Russia). There were 1,448 Krymchaks in the former Soviet Union according to the 1989 census. Due to the genocide by the Nazis during World War II, 80 % of the 6,000 Krymchaks were killed.

### 2.8.2. *informant*

Our informant was a male born in 1922. He is seemingly the last full-fluent speaker of Krymchak.

### 2.8.3. *result*

548 words and 380 grammatical constructions

### 2.8.4. *daily language of the informant*

Russian (and Krymchak)

Krymchak seems to lie between 'critically endangered' and 'extinct'.

## 2.9. *Urum*

Urum is the Crimean Tatar language spoken by the people of Greek origin. It has two dialects: Kypchak and Oghuz. The Kypchak dialect has two subdialects: Kypchak-

Polovets and Kypchak-Oghuz. The Oghuz dialect also has two subdialects: Oghuz-Kypchak and Oghuz.<sup>5</sup>

#### 2.9.1. *population*

45,000 in 1989

#### 2.9.2. *informants*

Oghuz dialect: 1 male (born in 1951)

Kypchak dialect: 1 male (born in 1942) and 1 female (born in 1928)

#### 2.9.3. *result*

Oghuz dialect: 2,154 words, 344 conversational expressions, 380 grammatical constructions and free talking

Kypchak dialect:

118 words and 104 grammatical constructions from the male informant

275 words from the female informant

#### 2.9.4. *daily language of the informants*

Oghuz dialect: Russian, Urum

Kypchak dialect:

Russian, Ukrainian and Urum for the male informant

Russian and Urum for the female informant

The informant for the Oghuz dialect had a good command on his native tongue. The male informant for the Kypchak dialect did not remember many words. The female informant did not have a good command on her native tongue. We could not find any other informant with a good command on his/her native tongue. Therefore, the Urum language seems to lie between ‘severely endangered’ and ‘critically endangered’.

#### 2.10. *Chulym Tatar*

---

<sup>5</sup> Cf. Garkavec 2000, p. 6.

Chulym Tatar has two dialects: Middle Chulym and Lower Chulym. The Middle Chulym dialect belongs to *azaq*-group like Khakas, Western Yugur and the Mrass-Upper Tom dialect of Shor whereas Lower Chulym belongs to *ayaq*-group like Kondoma-Lower Tom dialect of Shor, Turkish, Tatar, Uzbek, etc.

#### 2.10.1. *population*

The population of the Chulym Tatars was 656 with 270 persons knowing Chulym in 2002. There are some 100 fluent speakers and these persons are certainly the Middle Chulyms. It seems that there is no Lower Chulym speaker at present.

#### 2.10.2. *informants*

Middle Chulym: 1 male (born in 1952)

Lower Chulym: 1 male (born in 1921)

#### 2.10.3. *result*

Middle Chulym: some 500 words, 344 conversational expressions, 239 grammatical constructions (almost always according to the Russian word order) and free talking

Lower Chulym: some 400 words

#### 2.10.4. *daily language of the informants*

Middle Chulym: Russian and Middle Chulym

Lower Chulym: Russian, (and Lower Chulym before World War II)

The Lower Chulym dialect seems to be ‘extinct’. The Middle Chulym dialect seems to lie between ‘severely endangered’ and ‘critically endangered’.

#### 2.11. *Tatar*

Tatar has 3 dialects broadly: Middle Tatar (= Kazan), Western Tatar (= Misher) and Eastern Tatar (= Siberian Tatar). Eastern Tatar has following subdialects: Tobol-

Irtys, Baraba, Tom.

#### 2.11.1. *population*

The population of the Tatars was 5,554,601 with 5,347,706 persons knowing Tatar in 2002 (Russia), 248,952 in 1999 (Kazakhstan), 45,438 in 1999 (Kyrgyzstan), 30,000 in 1999 (Azerbaijan) and 19,000 in 2000 (Tajikistan). There are also some 370,000 Tatar native speakers among the Bashkirs.

#### 2.11.2. *informants*

Baraba Tatar: 1 female (born in 1948)<sup>6</sup>

Tatar in Ufa: 1 female (born in 1953)<sup>7</sup>

#### 2.11.3. *result*

Baraba Tatar: 744 words and free talking

Tatar in Ufa: 732 words and free talking

#### 2.11.4. *daily language of the informants*

Baraba Tatar: Russian and Tatar

Tatar in Ufa: Russian, Bashkir and Tatar

The Tatar language is certainly ‘safe’, but its many dialects seem to lie between ‘definitely endangered’ and ‘critically endangered’. Our Tatar informant in Ufa seems to have a better command on Russian than Tatar.

### 12. *Salar*

#### 2.12.1. *population*

The population of the Salars was 104,503 in 2000. There are some 35,000 native

---

<sup>6</sup> Her father is a local Tatar and her mother a Kazan Tatar.

<sup>7</sup> She is of mixed origin from non-Kazan Tatars and other peoples. Her husband is a Bashkir.

speakers.

#### 2.12.2. *informants*

2 males (born in 1936, 1978) and 1 female (born in 1986)

#### 2.12.3. *result*

1,891 words, 344 conversational expressions, 379 grammatical constructions and free talking from the 1<sup>st</sup> male informant

916 words, 344 conversational expressions, 379 grammatical constructions and free talking from the 2<sup>nd</sup> male informant

734 words and free talking from the female informant

#### 2.12.4. *daily language of the informants*

Chinese for the 1<sup>st</sup> male informant

Salar and Chinese for the 2<sup>nd</sup> male informant and for the female informant

Salar is not a written language. Moreover, some two third of the Salar people are not native speakers of it. Therefore, Salar seems to lie between ‘unsafe’ and ‘definitely endangered’.

#### 2.13. *Kirghiz*

Kirghiz has 2 dialects broadly: Northern Kirghiz and Southern Kirghiz. Northern Kirghiz has 4 subdialects: Īsik-köl, Chuy, Talas and Narĭn. Southern Kirghiz has 2 subdialects: Osh and Ichkilik. The Kirghiz written language is based on Northern Kirghiz. Southern Kirghiz was influenced by Uzbek.

#### 2.13.1. *population*

The population of the Kirghiz was 3,128,147 in 1999 (Kyrgyzstan), 160,823 in 2000 (China), 31,808 in 2002 (Russia) and 10,896 in 1999 (Kazakhstan).

#### 2.13.2. *informants*

İsik-köl subdialect: 1 female (born in 1973)  
Chuy subdialect: 1 female (born in 1939)  
Talas subdialect: 1 female (born in 1947)  
Narın subdialect: 1 male (born in 1936)  
Ichkilik subdialect: 2 females (born in 1946, 1947)<sup>8</sup>

### 2.13.3. *result*

İsik-köl subdialect: 2,720 words, 344 conversational expressions, 380 grammatical constructions, free talking and minimal pairs  
Chuy subdialect: 2,663 words, 344 conversational expressions, 380 grammatical constructions and free talking  
Talas subdialect: 1,515 words, 344 conversational expressions and 380 grammatical constructions  
Narın subdialect: some 2,000 words, 344 conversational expressions and 380 grammatical constructions  
Ichkilik subdialect:  
47 words, 99 conversational expressions and free talking from the 1<sup>st</sup> informant  
2,654 words, 344 conversational expressions, 380 grammatical constructions and free talking from the 2<sup>nd</sup> informant

### 2.13.4. *daily language of the informants*

#### Kirghiz and Russian

The Kirghiz language is certainly ‘safe’. However, our informants were influenced by the written language. Probably this is also the case for the other speakers of any dialect.

### 2.14. *Dolgan*

Dolgan was originally a dialect of Yakut. Some scholars regard still Dolgan as a dialect of Yakut.

---

<sup>8</sup> They are sisters.

#### 2.14.1. *population*

The population of the Dolgans was 7,261 with 4,865 persons knowing Dolgan in 2002. The majority of the Dolgans lives on Taimyr peninsular.

#### 2.14.2. *informants*

2 females (born in 1946, 1944)

#### 2.14.3. *result*

2,506 words, 344 conversational expressions, 380 grammatical constructions and free talking from the 1<sup>st</sup> informant

1,115 words, 344 conversational expressions, and 380 grammatical constructions from the 2<sup>nd</sup> in-formant

#### 2.14.4. *daily language of the informants*

Russian, Dolgan for the 1<sup>st</sup> informant

Russian, Yakut and Dolgan for the 2<sup>nd</sup> informant (her tongue is a mixed language of Dolgan and Yakut)

Dolgan became a written language recently. Some one third of the Dolgans do not know their mother tongue. Therefore, Dolgan seems to lie between ‘unsafe’ and ‘definitely endangered’.

### 2.15. *Yakut*<sup>9</sup>

#### 2.15.1. *population*

The population of the Yakuts was 443,852, but the number of persons knowing Yakut was 456,288 in 2002.

---

<sup>9</sup> Another fieldwork was carried out by the ASK REAL team during 16 – 19 February in 2005. I did not participate to this fieldwork. The informant was a man born in 1963. His daily languages were Russian and Yakut.

### 2.15.2. *informant*

1 female (born in 1964)

### 2.15.3. *result*

55 words, 340 conversational expressions, 237 grammatical constructions and free talking

### 2.15.4. *daily language of the informants*

Yakut (and Russian)

The Yakut language is certainly ‘safe’.

## 2.16. *Bashkir*

### 2.16.1. *population*

The population of the Bashkirs was 1,673,389 with 1,379,727 persons knowing Bashkir in 2002 (Russia) and 23,224 in 1999 (Kazakhstan)

### 2.16.2. *informants*

Ėyĕk-Haqmar subdialect: 2 females (born in 1940, 1949)

Urta subdialect: 2 females (born in 1960)

Zelin subsubdialect of Urta subdialect: 1 female (born in 1982)

Dim subdialect: 1 female (born in 1945)

Qıđıl subdialect: 2 males (born in 1936, 1960)

### 2.16.3. *result*

Ėyĕk-Haqmar subdialect:

2,532 words, 344 conversational expressions and 380 grammatical constructions from the 1<sup>st</sup> informant

2,678 words, 344 conversational expressions, 380 grammatical constructions and free talking from the 2<sup>nd</sup> informant

Urta subdialect:

2,596 words, 344 conversational expressions, 380 grammatical constructions and free talking from the 1<sup>st</sup> informant

2,637 words, 344 conversational expressions, 380 grammatical constructions and free talking from the 2<sup>nd</sup> informant

Zelin subsubdialect of Urta subdialect: 101 grammatical constructions and free talking

Dim subdialect: 2,216 words, 344 conversational expressions, 380 grammatical constructions and free talking

Qïdïl subdialect:

898 words, 344 conversational expressions, 380 grammatical constructions and free talking from the 1<sup>st</sup> informant

1,138 words, 344 conversational expressions, 380 grammatical constructions and free talking from the 2<sup>nd</sup> informant

#### 2.16.4. *daily language of the informants*

Bashkir and Russian except for the 2<sup>nd</sup> informant of Qïdïl subdialect. His daily language is Bashkir.

The Bashkir language is certainly ‘safe’, but its many dialects seem to lie between ‘definitely endangered’ and ‘critically endangered’. Our informants were influenced by the written language.

#### 2.17. *Khakas*

Khakas has 4 dialects: Sagay, Kacha, Shor and Kïzïl. In addition to these dialects, formerly there were 2 dialects: Beltir and Koibal. Now Beltir is regarded as a subdialect of Sagay whereas Koibal is regarded as a subdialect of Kacha. The Khakas written language is based on Sagay and Kacha.

##### 2.17.1. *population*

The population of the Khakasses was 75,622 with 52,217 persons knowing Khakas in 2002.

### 2.17.2. *informants*

Sagay dialect: 1 male (born in 1954) and 1 female (born in 1925)

Kacha dialect: 1 male (born in 1945)

Shor dialect: 1 male (born in 1954)

Kizil dialect: 4 females (born in 1952, 1929, 1928, 1951) and 2 males (born in 1955, 1972)<sup>10</sup>

Beltir subdialect: 2 females (born in 1962, 1951)

Koibal subdialect: 5 females (born in 1952, 1966, 1926, 1940, 1951) and 1 male (born in 1957)

### 2.17.3. *result*

Sagay dialect:

2,731 words, 344 conversational expressions, 380 grammatical constructions and free talking from the male informant

free talking and songs from the female informant

Kacha dialect: 2,611 words, 344 conversational expressions, 380 grammatical constructions and free talking

Shor dialect: 2,709 words, 344 conversational expressions, 380 grammatical constructions and free talking

Kizil dialect:

688 words, 203 conversational expressions and free talking from the 1<sup>st</sup> female informant

1,535 words, 344 conversational expressions, 160 grammatical constructions and free talking from the 2<sup>nd</sup> female informant

free talking from the 3<sup>rd</sup> female informant

free talking and songs from the 4<sup>th</sup> female informant and from the 2<sup>nd</sup> male informant

178 words and free talking from the 1<sup>st</sup> male informant

Beltir subdialect:

381 words from the 1<sup>st</sup> informant

free talking from the 2<sup>nd</sup> informant

---

<sup>10</sup> The 4<sup>th</sup> female informant is the mother of the 2<sup>nd</sup> male informant.

Koibal subdialect:

657 words from the 1<sup>st</sup> female informant

1,082 words and 183 grammatical from the 2<sup>nd</sup> female informant

free talking from the 3<sup>rd</sup>, 4<sup>th</sup> and 5<sup>th</sup> female informants

246 words and free talking from the male informant

#### 2.17.4. *daily language of the informants*

Khakas and Russian

The Khakasses made up only 12 % of the population of Khakassia in 2002. Although Khakas and Russian are the official languages of Khakassia, the instruction language is mainly Russian. The road signs etc. are in Russian in the capital city of Abakan. Many Khakasses living in cities cannot speak their mother tongue. We stayed a day in a Kacha village named Malyj Kobezhikov (Xizil aal “Red village” in Khakas). Almost all of the residents were Khakas (Kacha). But the children spoke only Russian whereas the adults spoke both Khakas (Kacha dialect) and Russian. Therefore, Khakas seems to lie between ‘severely endangered’ and ‘critically endangered’.

## Abstract

The paper adopts split degree analysis drawing a distinction between Deg(P) and Q (P) in TSM. There are two subtypes of Q(P), viz., Q(P)-X and Q(P)-Y. It explores the issue of compatibility of two kinds of derived scalar APs, viz., DVAPs and DNAPs with Deg head, be it Deg (P) or Q (P). The basic claim is that only Deg can accommodate derived scalar APs. It is established that Q(P)s which originates in DPs are compatible with scalar APs only when they change into Deg.

**Keywords:** Quantity Deg AP scalar TSM

## 1. Introduction

The paper sets out by posing a question as to whether quantity figures in APs in Taiwanese Southern Min (henceforth TSM), a southern Sinitic language prevalent in Southern Fujian, Taiwan and many parts of the world. Towards the goal of answering this question attention is focused on establishing two types of degree elements (Deg (P) and Q (P)) in the light of the split degree approach. It also examines two types of derived scalar APs (DVAPs and DNAPs). It is argued that each scalar AP has an open g-position which has to be bound and saturated by a Deg head. It is found that whereas compatibility of Deg (P) with derived scalar adjectives is expected, Q (P) can not

---

\* An earlier version of this paper based on my research endeavor (NSC project (NSC 94-2411-H-007-007) and campus project (Linguistic Corpora in Taiwan Area and Explorations of Theoretical Issues)) was presented at the workshop of Argument Realization in Asian Languages organized by Yungli Chang, the 18<sup>th</sup> International Congress of Linguistics held at Korea University, Seoul, on July 21, 2008, I would like to thank the audience in particular Jane Grimshaw, Shuanfan Huang and Chaolin Li for extremely useful comments. Thanks are also due to Chun Chang for help check the final versions. All errors remain mine.

accommodate scalar APs unless the Q (P) has taken on the feature of degree. Thus the answer to the question is quite obvious and will be given toward the end of the paper.

## 2. Split Degree system

Rather than a single degree system a split degree system hypothesis was proposed in Bresnan (1973) and the proposal was elaborated on in Corver (1997ab). This proposal involves two types of functional degree words in adjectival projection, (1) Deg (P) (degree phrase), and (2) Q (P) (quantity phrase).<sup>1</sup> It is claimed in Corver (1997a), in particular, that a distinction should be made between determiner-like elements (Deg<sup>0</sup>s) such as *too*, *as*, *so*, *how* and *that*, and quantifier-like elements (Q<sup>0</sup>s) such as *more*, *less*, *much*, *little* and *enough* and both Deg<sup>0</sup>s and Q<sup>0</sup>s occur as pre-adjectival elements. Such claims are valid as they are based on solid empirical evidence. The determiner-like elements (Deg<sup>0</sup>s) select quantity phrases (QPs), and the quantifier-like elements (Q<sup>0</sup>s) select adjectival phrases (APs).

A distinction between two types of degree elements (Deg P and Q (P)) can also be made in TSM. But the picture is somewhat more complicated, since, as shown below, a further distinction between Q(P)-X and Q(2)-Y has been made in Q(P).

### Deg (P)

siunn<sup>1</sup> 傷 (too), hiah<sup>4</sup> 遐 (so), chiah<sup>4</sup> 遮 (so), joa<sup>7</sup> 若 (how),  
khah<sup>4</sup> 較 (more), kau<sup>3</sup> 夠 (enough)

### Q(P)

**Q(P)-X** chio<sup>2</sup> 少 (few/little), choe<sup>7</sup> 濟 (many/much)

**Q(P)-Y** chit<sup>8</sup>-tiam<sup>2</sup>-a<sup>2</sup> 一點仔 (a bit), chit<sup>8</sup>-koa<sup>2</sup>-a<sup>2</sup> 一寡(仔) (some)

Whereas Deg (P) can collocate with APs in TSM and English, Q(P)-Y rather than Q(P)-X can be co-occur with APs in TSM. The paper will try to explain why APs can take one type of Q(P)s. But before we provide the answer let's first examine the internal structure of a DP.

---

<sup>1</sup> Here are abbreviations used in this paper: AP (adjectival phrase), CL (classifier), Deg (degree), Deg P (degree phrase), DN (denominal), DP (determiner phrase), DS (diminutive suffix), DV (deverbal), G (grade), PRF (prefix), and Q (quantifier).

### 3. Three variable positions in DPs

According to Borer (2005a) a determiner (DP) features three basic elements, viz., (1) determiner (<e>det), (2) quantity (<e>#), and (3) divisiveness (<e>div), in addition to L-D (lexical domain) (Borer 2005ab). Take a prototypical DP like ‘the three dogs’. Its counterpart in TSM would be *chit<sup>4</sup> sann<sup>1</sup> chiah<sup>4</sup> kau<sup>2</sup>* this three CL dog ‘the three dogs’. Its internal makeup is shown in the following table.<sup>2</sup>

DETERMINER	QUANTITY	DIVISIVENESS	L-D
chit4	sann1	chiah4	kau2
此	三	隻	狗
this	three	CLASSIFIER	dog

What is shown here is a canonical type of DP, but not all positions must be filled in syntactic realization.

One of the most conspicuous constraints is that classifiers in TSM as well as Mandarin have to be present when an NP in a (DP) is individuated or rather accompanied by a numeral, whereas the classifier in English is not mandatory when a numeral occurs with a noun phrase denoting individuated objects in English. Of course, the noun has to be suffixed with a plural ending if it denotes individuated objects, as there is number agreement between numeral and the noun phrase. As shown in the following table *three books* in English, for example, corresponds to *sann1 pun2 chul* in TSM.<sup>3</sup>

quantity	*(classifier)	noun phrase
Sann1	*(pun)	chul
三	*(本)	書
three	classifier	book
three		books

<sup>2</sup> All the spelling of Southern Min in this paper is indiscriminately rendered in Taiwanese Southern Min pronunciation based on Church Romanization codified in Douglas (1873). I have made some modifications, however. For example, the diacritic tone marks have been abandoned in favor of numerical superscripts. No distinction is made between *ch* and *ts* or *chh* and *tsh* as they do not stand for phonemic contrast. The open *o* and the closed *o* are rendered as *oo* and *o*, as in *khoo<sup>2</sup>* ‘bitter’ and *kho<sup>2</sup>* ‘thick’. Nasalization is indicated by a double *n*.

<sup>3</sup> \*(*)* indicates that the expression will be ill-formed if nothing occurs in the parentheses. (\*) means that the presence of something in the parentheses will render the expression ungrammatical, and (*)* means that the element in the parentheses is optional.

Individuation of an NP operates in tandem with its categorization. A well-formed DP construction can be captured in terms of two axes: (1) syntagmatic relationship and (2) paradigmatic relationship. (Saussure 1916, Helmslev 1970) Each position of the internal structure of a DP reflects combined effects of the two axes. DIVISENESS and QUANTITY are marked on classifiers and quantifiers rather than head nouns. Classifier is not obligatory for a DP which does not involve divisiveness. Thus, QUANTITY can occur with an NP without being mediated by CLASSIFIER if what is involved is an approximative quantity, as in *\*(chin<sup>1</sup>) choe<sup>7</sup> chu<sup>1</sup>* \*(真)濟書 real many book ‘many books’.<sup>4</sup>

A DP shedding DETERMINER, viz., QUANTITY + DIVISIVENESS + LD, is a very common pattern where no restriction is imposed on the realization of QUANTITY, as in *chit<sup>8</sup> tiam<sup>2</sup> loo<sup>7</sup>-chui<sup>2</sup>* 一點露水 one drop dew ‘a drop of dew’, where the numeral *chit<sup>8</sup>* ‘one’ can be replaced by other numbers such as *goo<sup>5</sup>* 五 ‘five’, as in *goo<sup>5</sup>tiam<sup>2</sup> loo<sup>7</sup>-chui<sup>2</sup>* 五點露水 five drop dew ‘five drops of dew’. However, when a DS like *a<sup>2</sup>* 仔 is added to QUANTITY + DIVISIVENESS, the resulting form, viz., QUANTITY + DIVISIVENESS + DS, exemplified by *chit<sup>8</sup> tiam<sup>2</sup> a<sup>2</sup> siann<sup>1</sup>-im<sup>1</sup>* 一點仔聲音 a dot DS sound ‘a little sound’, QUANTITY should be inevitably realized as *chit<sup>8</sup>* 一 ‘one’. In this case the numeral has to remain unchanged. Any other numeral in place of it will yield ill-formed expressions, as in *\* sann<sup>1</sup> tiam<sup>2</sup> a<sup>2</sup> siann<sup>1</sup>-iam<sup>1</sup>* \*三點仔聲音. In such a case, approximative diminution has been coerced at the expense of the property of DIVISIVENESS.

#### 4. Two kinds of APs in TSM

Having articulated the internal make-up of DP let’s turn to the main focus of the paper, viz., the step-wise formation of APs with an added but no less important Deg element. There are at least two kinds of APs in TSM; (1) deverbal adjectival phrases (DVAPs), and (2) denominal adjectival phrases (DNAPs). In the formation of DVAPs, as I will argue, deverbal adjectives are derived by combining each of stative predicates such as *ho<sup>2</sup>*- 好- ‘good, easy’, *phai<sup>2</sup>*- 歹 ‘bad’, *oh<sup>4</sup>*- 惡 ‘difficult’, *u<sup>7</sup>*- 有- ‘have’, and *bo<sup>5</sup>* 無- ‘not have’ with each of activity transitive verbs such as *chiah<sup>8</sup>* 食 ‘eat’, *khoann<sup>3</sup>* 看 ‘look’, *ka<sup>3</sup>* 教 ‘teach’, and *chhing<sup>7</sup>* 穿 ‘wear’.. The stative predicate functions as a converter coercing an activity predicate into a stative and gradable

<sup>4</sup> Like other scalar adjectives, the quantitative adjective *che<sup>7</sup>* 濟 ‘many’ features an open G position which has to be bound and saturated by a Deg such as *chin<sup>1</sup>* 真 ‘very’.

adjective. The morphological structure of DVAPs can be captured in the following formulas, as in (1):

(1) [Y [X]<sub>vt</sub>]<sub>adj</sub>

X stands for transitive verbs denoting activity, and Y represents a set of stative predicates listed above. The effect of attaching Y to X serves to convert the verb to a quality-denoting adjective. Some examples are given in table (2).

(2)

ho <sup>2</sup> -chiah <sup>8</sup> 好食	good eat	delicious
phai <sup>2</sup> -khoann <sup>3</sup> 歹看	bad look	ugly
oh <sup>4</sup> -ka <sup>3</sup> 惡教	tough teach	tough to teach
u <sup>7</sup> -chhing <sup>7</sup> 有穿	have wear	durable

Below are two examples where the DVAPs are used in sentences (3a,b).

(3) a. Chit<sup>4</sup> liap<sup>8</sup> si<sup>1</sup>-koe<sup>1</sup> chiann<sup>5</sup> ho<sup>2</sup>-chiah<sup>8</sup>

此粒西瓜成好食

This CL water melon very good-eat

‘The water melon is very delicious.’

b. Chit<sup>4</sup> khoan<sup>2</sup> oe<sup>5</sup> chin<sup>1</sup> u<sup>7</sup> chhing<sup>7</sup>

此款鞋真有穿

This type shoe really have wear

‘The shoes of this type are really durable.’

DVAPs as discussed in the above can be regarded as a type of middle construction on the following grounds. First, it involves transitive verbs, or rather two-argument predicate. Second, attachment of head elements like *ho<sup>2</sup>* 好 ‘good’, *phai<sup>2</sup>* 歹 ‘bad’, *u<sup>7</sup>* 有 ‘have’ and *bo<sup>5</sup>* 無 ‘not have’ leads to externalization of internal argument and suppression of external argument. Such a measure results in a reduction of arguments. Thirdly, it carries a generic rather than episodic meaning

Likewise, DNAPs are derived from combining each of stative predicates such as *u<sup>7</sup>*- 有 ‘have’ and *bo<sup>5</sup>*- ‘not have’ with a nominal NP, as in (4):

(4)

u <sup>7</sup> -chinn <sup>5</sup> 有錢	have money	rich
bo <sup>5</sup> -chinn <sup>5</sup> 無錢	not-have money	poor
u <sup>7</sup> -mia <sup>5</sup> 有名	have name	famous
u <sup>7</sup> -lat <sup>8</sup> 有力	have strength	strong

The morphological structure of the DNAPs can be specified by a formulas like (5):

(5) [Y [X]<sub>n</sub> ]<sub>adj</sub>

X stands for nouns, and Y represents stative predicates such as *u*<sup>7</sup> ‘have’ and *bo*<sup>5</sup> ‘not-have’. The effect of attaching Y to X amounts to converting the verb to a quality-denoting adjective.

Both DVAPs and DNAPS are the one-place predicates which originate as two-place predicates. DVAPs involve the suppression of external argument and externalization of internal argument.<sup>5</sup> For example, the external argument of the two-place predicate *khoann*<sup>3</sup> 看 ‘watch’, an agent, in

(6) has been suppressed, and the internal argument, *Chit*<sup>4</sup> *liann*<sup>2</sup> *sann*<sup>1</sup> 此領衫 ‘the clothes’, is externalized as the subject of the sentence.

(6) *Chit*<sup>4</sup> *liann*<sup>2</sup> *sann*<sup>1</sup> *chin*<sup>1</sup> *ho*<sup>2</sup>-*khoann*<sup>2</sup>

此領衫真好看

This CL clothes really good-look

‘The clothes are pretty.’

The change of two-place predicates to one-place predicates leads to a reduction of the number of arguments. DNAPs also involve the formation of one-place predicate out of two-place predicates. But the operation takes place in a different light. *U*<sup>7</sup> is a two-place predicate. *U*<sup>7</sup> *le*<sup>2</sup>-*mau*<sup>7</sup> 有禮貌 have courtesy is a V+NP where the NP is an internal argument. However, when it turns into an AP, as in (7), the NP *le*<sup>2</sup>-*mau*<sup>7</sup> 禮貌 has lost its status of argument. Put differently, it has been incorporated into the AP.

(7) *Chit*<sup>4</sup> *e*<sup>5</sup> *chinn*<sup>1</sup>-*hun*<sup>7</sup> *lang*<sup>5</sup> *chiann*<sup>5</sup> *u*<sup>7</sup> *le*<sup>2</sup>-*mau*<sup>7</sup>

此個生份人誠有禮貌

This CL strange person really have courtesy

‘The stranger is polite.’

## 5. Constraints of Scalar APs

There are two dimensions to constraints of scalar APs: (1) as shown in 5.1., a scalar AP features an open g-position, which has to be saturated by a degree head, and

<sup>5</sup> See Grimshaw (1991) for the notion of suppression of external argument.

(2), as discussed in 5.2., Deg(P) is compatible with scalar APs, whereas only when Q(P) sheds the feature of divisiveness can it be compatible with scalar APs.

### 5.1. Degree heads

Since both DVAPs and DNAPs involve scalar domain, they feature an open g-position in each expression, viz., g referring to degree, which has to be saturated by its degree binder. The saturation is accomplished through theta identification. (Higginbotham 1985, Doetjes 1997) There is a range of determiner-like Degs, as in

(8), forming the head of DegP that can execute the task

(8)

chin <sup>1</sup> 真	real	really
chiok <sup>4</sup> 足	sufficient	very
chiann <sup>5</sup> 誠	honest	truly
hiah <sup>4</sup> -nih <sup>4</sup> 赫爾	that so	so
chiah <sup>4</sup> -nih <sup>4</sup> 遮爾	this so	so
joa <sup>7</sup> -nih <sup>4</sup> 若爾	how so	how
u <sup>7</sup> -kau <sup>3</sup> 有夠	have enough	so

While degree head can be an implicit element in English, it is indispensable in TSM as well as Mandarin, as in

(9)

(9) Chit<sup>4</sup> pak<sup>4</sup> too<sup>5</sup> \*(chiann<sup>5</sup>) ho<sup>2</sup> khoann<sup>3</sup>

此幅圖\*(成)好看

This CL picture very good look

‘The painting is beautiful.’

It is a well-known fact that Chinese, TSM included, is a tenseless language, whereas like many other Indo-European languages English is a tensed language. The optionality of degree head in English might have to do the obligatory presence of T in a clause. Just as T is a head and an obligatory element in a clause in languages like English, the scalar or gradable domain in a clause is headed by Degs (formerly adverbs of degree), as in (8), in TSM forming a DegP. A scalar AP, be it a DVAP or a DNAP, has an open G position indicating an underspecified scale that has to be saturated or settle for a certain

definitive value. The task of saturation is accomplished by a binding relationship between binder (Deg) and bindee (the open g-position). So Deg categorial-selects an AP as its complement, and they form a DegP. A clause featuring a scalar AP will be left in air if the AP is not bound by its head Deg. In short, Deg is indispensable.

## 5.2. Quantity to Degree

As shown in Section 2, there are two types of degree elements: Deg (P), and Q (P). All Deg (P)s are compatible with scalar APs, since the examples as the head of scalar APs are all Deg (P). The status of Q (P)s regarding compatibility with scalar APs has yet to be tested. Q (P)s have been divided into subtypes in Section 2: Q(P)-X and Q(P)-Y. Let's now examine the two subtypes.

Scalar APs, be they DVAPs or DNAPs, can not accommodate the presence of a Q(P)-X, as in (10ab).

- (10) a. \*Keng<sup>1</sup>-chio<sup>1</sup> choe<sup>7</sup> ho<sup>2</sup>-chiah<sup>8</sup>  
 \*弓蕉濟好食  
 Bananas many good eat  
 \* 'Bananas are many delicious.'
- b. \*I<sup>1</sup> chio<sup>2</sup> u<sup>7</sup>-le<sup>2</sup>-mau<sup>7</sup>  
 \*伊少有禮貌  
 He few have-etiquette  
 \* 'He is few polite'

However, Q(P)-Y seems to be more complicated. Although

(11) is still bad, some cases of *chit<sup>8</sup>-koa<sup>2</sup>* 'some' such as (12) seems to be well-formed.

- (11) \* keng<sup>1</sup>-chio<sup>1</sup> chit<sup>8</sup> koa<sup>2</sup> ho<sup>2</sup>-chiah<sup>8</sup>  
 \*香蕉一寡好食  
 Bananas some good eat  
 \* 'Bananas are some delicious.'
- (12) Ke<sup>3</sup>-siau<sup>3</sup> khah<sup>4</sup> kui<sup>3</sup> chit<sup>8</sup>-kua<sup>2</sup>  
 價數較貴一寡  
 Price more expensive some  
 'It is a little bit more expensive.'

Another example of Q (P)-Y that shows a deeper extension of quantifier to degree is *chit<sup>8</sup>-tiam<sup>2</sup>-a<sup>2</sup>* 一點仔 ‘a little bit’. It has shed its divisiveness in the sense of Borer (2005a) and acquires the property of degree, as in (13).

- (13) I<sup>1</sup> u<sup>7</sup> chit<sup>8</sup>-tiam<sup>2</sup>-a<sup>2</sup> chui<sup>3</sup>  
伊有一點仔醉  
He have a little bit drunk  
‘He is a bit drunk.’

However it has to be licensed by the operator *u<sup>7</sup>* 有.

Thus, the answer to the question as to whether Quantity Figure in APs raised in the title is, therefore, that the two kinds of Degs in construction with As in APs that Corver (1997ab) postulates are also attested in TSM and that Q<sup>0</sup>s can be accommodated only if it sheds the property of divisiveness.

## 6. Conclusion

In this paper I adopt the split degree hypothesis and establish two types of degree words, viz., Deg (P) and Q (P) in TSM. Q(P) falls into two subtypes: Q (P)-X and Q (P)-Y. Among a wide range of APs I focus on two kinds of derived scalar APs (DVAPs and DNAPs).<sup>6</sup> Unlike the optionality of Deg as head of scalar APs in English Deg is the indispensable and explicit head for scalar APs in TSM. While it is expected that Deg (P) are compatible with scalar APs, Q (P) seems to be a problem of compatibility as it originates as an internal element in DPs. The exploration in the paper points to a ultimate solution. The answer to the question as to whether quantify figures in APs is yes, if QPs sheds the feature of divisiveness and take on the feature of degree. It is shown in the above discussion that argument realization based on predicate-complement pairing can be extended to QPs where Deg head is construed as an obligatory element. This is a theoretical stand which departs from the earlier view that Deg in the APs is an optional element.

---

<sup>6</sup> Any one who takes a theoretical stand that there is no distinction between adjectives and verbs in TSM can convert APs into stative predicates without seriously undermining the conclusion that I have reached in the paper.

# Argument Unification in the Quasi-Existential Construction

Chizuru Ito

ito.chizuru@gmail.com

## Abstract

This paper investigates what I call the Quasi-Existential Construction (QEC), where a transitive verb combines with a verb *iru* which has been considered just as an auxiliary, and a theme argument looks to receive an apparently non-canonical case marking. This construction possesses a number of puzzling properties in the light of well-understood phenomena of Japanese. I depart from the existing assumption that *iru* is only an auxiliary, instead showing the evidence that it is also an existential verb, which thus can form a complex predicate with a preceding verb. After an overview of the general properties of complex predicates in Japanese and the previous approaches are presented, I provide a new unified analysis of the phenomenon as well as the QEC.

**Keywords:** Complex Predicates, Argument Suppression, Existential Verbs, Auxiliary

## 1. Introduction

This paper deals with some unusual facts regarding the aspectual form *te-iru* in Japanese. The *te-iru* form consists of a gerund *te-* and an auxiliary *iru* whose original meaning was ‘exist’. In Japanese, a subject NP is normally case-marked by the nominative case, whereas an object NP is case-marked by the accusative. With the aspectual form *te-iru*, the case marking pattern is still nominative-accusative, as shown in (1b).<sup>1</sup>

- (1) a. Ken-ga ringo-o {kir/ur}-u.  
Ken-NOM apple-ACC cut/sell-PRES  
‘Ken {cuts/sells} apples.’

---

<sup>1</sup>In this paper, I employ a phonological underlying form rather than a surface form in representing examples. For example, while the surface form of the verb *uru* ‘sell’ with the auxiliary *iru* is *ut-te-i-ru*, the underlying form ‘*ur-teiru*’ is used in (1b).

- b. Ken-ga ringo-o {kir/ur}-te-i-ru.  
 Ken-NOM apple-ACC cut/sell-GER-AUX-PRES  
 ‘Ken is {cutting/selling} apples.’

I am concerned with a construction with a *te-iru* form in which some argument is marked by a non-canonical case given its thematic role and grammatical function, as illustrated in (2).

- (2) Ringo-ga ur-te-i-ru.  
 apple-NOM sell-GER-exist-PRES  
 ‘Apples are for sale.’

This construction, to the best of my knowledge, has almost never been discussed in the literature on the Japanese syntax. In this paper, I refer an instance of (2) as the *Quasi-Existential Construction* (QEC), where a transitive verb combines with a verb *iru* and a theme argument is marked by nominative. As shown in (3), the nominative on the theme argument is not acceptable without *te-iru* form. It is thus this aspectual form *te-iru* that plays a crucial role in licensing such case alternations.

- (3) \*Ringo-ga ur-u.  
 apple-NOM sell-PRES

Of course, there are also case alternation phenomena in Japanese. Such instances include: transitive-intransitive alternation, potential alternation, and passive formation. However, it is well-known that case alternations in Japanese always involve a morphological change in the verb (see Jacobsen 1992 for Japanese derivational affixation patterns). For example, the transitive-intransitive pair in (4) is morphologically differentiated: a transitive verb (*war* ‘break<sub>tr</sub>’) has no suffix, while the intransitive counterpart (*war-e* ‘break<sub>in</sub>’) bears a suffix *-e*.

- (4) a. Ken-ga kabin-o war-ta.  
 Ken-NOM vase-ACC break<sub>tr</sub>-PAST.  
 ‘Ken broke the vase.’  
 b. Kabin-ga war-e-ta.  
 vase-NOM break-INTR-PAST.  
 ‘The vase broke.’

In the QEC example (2), the verb form is still morphologically transitive *ur-*. This phenomena looks mysterious in that case alternation is observed without no particular morpheme (e.g. *e*, *ar*, etc.) attaching to the verb.

One may consider the possibility that (2) is an instance of Japanese middle construction. In English, middles do not show morphological mark to distinguish it from the canonical transitive form, as show in (5).

- (5) a. I read this book.  
b. This book reads well.

In Japanese, it is not crystal clear whether middles exist as a distinct construction. Given the semantic interpretation of English middles (5b), (6) might be considered to be a Japanese middle sentence because it has a generic reading.

- (6) Kono kusuri-ga yoku ur-e-ru.  
this medicine-NOM well sell-INTR-PRES  
'This medicine sells well.'

In the absence of an explicit definition of middles, I will not consider what is the Japanese middle construction in this paper. But what is important here is the fact that case alternation in (6) involve a suffixed verb form, *ur-e*.

The goal of this paper is to provide a unified account for a number of peculiar properties of the QEC, and to capture the argument realization pattern in a general way. In section 2, I describe that a verb *iru* in the QEC differs from an auxiliary *iru*, suggesting that it involves existential properties in nature. In section 3, I present a complex predicate analysis of the QEC, which captures both the puzzling argument realization, and at the same time, the unusual locative markings.

## 2. Facts

It has been claimed that the verb *iru* attaching to another verb is an aspectual auxiliary. However, as I showed, when it occurs in the QEC, the non-canonical case markings can be obtained. This section further examines other main two intriguing but apparently mysterious properties in the QEC in terms of argument realization, and the form of unusual locative adjuncts.

### 2.1. Argument Blocking

An auxiliary lacks argument structure. If we assume that the verb *iru* is just an

auxiliary, then there arises one puzzle with regard to argument realization in the QEC; “argument blocking” occurs for agent and recipient arguments of the main verb.

I begin with agent blocking. Although a transitive verb is employed, the agent argument ‘seller’ cannot surface in the QEC, as illustrated in (7a). This is in a sharp contrast with standard aspectual auxiliary constructions in (7b).

- (7) a. \*Ken-ga ringo-ga ur-te-i-ru.  
Ken-NOM apple-NOM sell-GER-exist-PRES  
‘Apples are for sale by Ken.’  
b. Ken-ga ringo-o ur-te-i-ru.  
Ken-NOM apple-ACC sell-GER-AUX-PRES  
‘Ken is selling apples.’

One may perhaps assume that Japanese grammar does not allow double nominatives in a single clause, but it is in fact possible in Japanese, as shown in (8). It is thus the overt agent itself that causes ungrammaticality in (7a), but not case-markings.

- (8) Ken-ga Naomi-ga sukida.  
Ken-NOM Naomi-NOM like  
‘Ken likes Naomi’

Further evidence that the agent argument is totally missing in the QEC comes from the incompatibility with an agent-oriented adverb, as illustrated in (9).

- (9) \*Wazato ringo-ga ur-te-i-ru.  
deliberately apple-NOM sell-GER-exist-PRES  
‘Apples are for sale deliberately.’

Secondly, another argument, recipient, cannot occur in the QEC, neither. The verb *uru* ‘sell’ is associated with three arguments (agent, theme and recipient). Yet, the QEC is ill-formed if the recipient argument *gakusei-ni* ‘to students’ is expressed, as in (10a). Again the auxiliary construction (10b) is not subject to such a constraint.

- (10) a. \*Kuruma-ga gakusei-ni ur-te-i-ru.  
car-NOM student-DAT sell-GER-exist-PRES  
‘Cars are for sale to students.’  
b. Kuruma-o gakusei-ni ur-te-i-ru.  
car-ACC student-DAT sell-GER-AUX-PRES  
‘(They) are selling cars to students.’

Another difference between subcategorized and non-subcategorized arguments is worth mentioning. Unlike (10a), the QEC is compatible with non-subcategorized benefactive phrases with a recipient interpretation.

- (11) *Zitensya-ga sinnyuusei no-tameni/mukeni ur-te-i-ru.*  
 bicycle-NOM new.student GEN-for/for sell-GER-exist-PRES  
 ‘Bicycles are for sale to new students.’

These facts above show that this construction requires two theta roles (agent and recipient) of the main verb to be suppressed, and indicate that the verb *iru* is not a purely auxiliary which is always irrelevant to argument realization.

## 2.2. “Thing”-Related Locatives

In Japanese, spatial locations can be marked by either *de* or *ni*. The common assumption is that while *de* can occur in any sentences, *ni* can appear only in stative sentences. More specifically, *ni* is used only when referring to a location of some existence or “Thing” in Jackendoff (1983)’s term (see Nakau 1998; Ueno 2001 for more distributional facts about *de* and *ni*). In the typical existential sentences (i.e. “Thing”-denoting sentences) only a *ni*-locative is acceptable, as illustrated in (12).<sup>2</sup>

- (12) a. *Gakkou-{ni/\*de} Ken-ga i-ru.*  
 school-LOC Ken-NOM exist<sub>anim</sub>-PRES  
 ‘Ken is at school’  
 b. *Heya-{ni/\*de} hon-ga ar-u.*  
 room-LOC book-NOM exist<sub>inan</sub>-PRES  
 ‘There are books in the room.’

On the other hand, in the “Event/State”-denoting sentences, only a *de*-locative can be employed, as shown in (13). Note that the location must be marked by *de* when a NP in an existential sentence indicates activity as in (13c).

- (13) a. *Kafe-{\*ni/de} Naomi-ga hon-o yom-u.*  
 cafe-LOC Naomi-NOM book-ACC read-PRES  
 ‘Naomi reads a book in the cafe’

---

<sup>2</sup>Most of the verbs in Japanese do not have agreement morphology with respect to person, number and gender. However, existential verbs *iru* and *aru* exhibit animacy agreement on its subject: *iru* requires an animate subject, while *aru* requires an inanimate subject.

- b. Ano mise-{\*ni/de}-wa sono kamera-no nedan-ga takai.  
 that shop-LOC-TOP the camera-GEN price-NOM high  
 ‘The price of the camera is high at that shop.’ (Ueno 2001: 110)
- c. Kono heya-{\*ni/de} kaigi-ga ar-ta.  
 this room-LOC meeting-NOM exist<sub>inan</sub>-PAST  
 ‘There was a meeting held in this room.’

I now examine which locative marker, *de* or *ni*, would be used in the QEC. While the aspectual auxiliary construction in (14b) takes only *de*-locatives, the QEC in (14a) interestingly can take either *de* or *ni* to mark the location.

- (14) a. Friimaaketto-{\*ni/de} sinzyu-no-nekkuresu-ga ur-te-i-ta.  
 flea.market-LOC pearl-GEN-necklace-NOM sell-GER-exist-PAST  
 ‘At the flea market, a pearl necklace was for sale.’
- b. Friimaaketto-{\*ni/de} sinzyu-no-nekkuresu-o ur-te-i-ta.  
 flea.market-LOC pearl-GEN-necklace-ACC sell-GER-AUX-PAST  
 ‘At the flea market, (they) were selling a pearl necklace.’

Given that the interpretation of location is crucially related to the selection of locative markers, then we expect that two different readings can be obtained in (14a): *ni*-marked PP refers to the place of the existence of a thing, whereas a *de*-marked PP refers to the place of a selling state/event. This is further evident from (15). In (15a), beds cannot physically exist at the advertisement paper. Thus, this location cannot be marked by *ni*. On the other hand, the selling event cannot be going in a small space like ‘inside the display showcase’, which is only marked by *ni* as (15b) shows.

- (15) a. Kinou-no orikomi-koukoku-{#ni/de} beddo-ga ur-te-i-ta.  
 yesterday-GEN inserted-ads-LOC bed-NOM sell-GER-exist-PAST  
 ‘At yesterday’s newspaper inserts (I found) beds were for sale.’
- b. Syookeesu-no-naka-{\*ni/\*de} tyiara-ga ur-te-i-ta.  
 display.showcase-GEN-inside-LOC tiara-NOM sell-GER-exist-PAST  
 ‘Inside the display showcase, tiaras were for sale.’

### 3. Complex Predicates

I have argued that a verb *iru* in the QEC does not pattern with an auxiliary *iru* with regard to argument realization, and locative markings. The next question is what the verb

*iru* is. I will show that all the properties of the QEC follow primarily from the status of *iru* as an existential verb.

### 3.1. Existential Properties

Let me start by its existential properties of the QEC. As I showed in (14a), the QEC is parallel to the true existential construction in locative selection. There are another striking parallel with a lexical existential verb *iru*. In Japanese, yes/no questions are generally answered with the usage of the same verb as that of the question. When the question is made with an existential verb, the typical answer would be A1, where the same existential verb is used. It is thus not surprising that A2 is not an appropriate answer for this question, because the aspectual auxiliary construction does not involve the existential verb at all. However, the question can be answered in the form of the QEC (A3). The alternation between the existential sentence (A1) and the QEC (A3) strongly indicates that *iru* in the QEC maintains its status as an existential verb.

- (16) Q: Ano mise-ni-wa nani-ga ar-u-no?  
that store-LOC-TOP what-NOM exist-PRES-Q  
'What are there at that store?'
- A1: Ooganikku yasai-ga ar-u-yo.  
organic vegetable-NOM exist-PRES-VOC  
'There are organic vegetable (there).'
- A2: #Ooganikku yasai-o ur-te-i-ru-yo.  
organic vegetable-ACC sell-GER-AUX-PRES-VOC  
'(They) are selling organic vegetables (there).'
- A3: Ooganikku yasai-ga ur-te-i-ru-yo.  
organic vegetable-NOM sell-GER-exist-PRES-VOC  
'Organic vegetables are for sale (there).'

The existential status of Japanese auxiliary *irularu* has been also found in other constructions. Miyagawa (1989) discusses the construction with another existential verb *aru* and suggests that some stative (resultative) meaning in (17a) may result from the existential meaning of the verb *aru*. Nakajima (2000) argues about the structure with locative *ni* and *iru* such as (17b). He refers to the verb *iru* as a existential affix, which designates basically the same existential meaning as that of the main verb *iru*.

- (17) a. Mado-ga war-te-ar-u.  
 window-NOM break<sub>tr</sub>-GER-exist-PRES  
 ‘The window is broken.’
- b. Kyousitu-ni-wa sin-nyuusei-ga mar-te-i-ru.  
 classroom-LOC-TOP new-pupils-NOM wait-GER-exist-PRES  
 ‘In the classroom are waiting new pupils.’

(17b) looks quite similar to the QEC in that they both involve *te-iru* form and allow a *ni* locative. However, they differ in the acceptability of the occurrence of transitive verbs. Assuming that (17b) is an instance of locative inversion, Nakajima argues that transitive verbs are not allowed in this construction, as shown in (18).

- (18) \*Douro-ni-wa kodomotati-ga bouru-o ker-te-i-ru.  
 street-LOC-TOP kids-NOM ball-ACC kick-GER-exist-PRES.  
 (Lit.) ‘On the street are kicking a ball kids.’

The verb *iru* in (18) is a canonical auxiliary because the case marking pattern is nominative-accusative (cf. (14b)). However, as I showed, the QEC is the construction with a morphologically transitive verb combining with a verb *iru*. It thus shares some essential properties of the verb *iru*, but I assume that it is a different construction from (17b). Although there is a restricted set of verbs that can participate in the QEC, as listed in (19), they all are morphologically transitive. Those examples are shown in (20) respectively.<sup>3</sup>

- (19) a. Caused possessive verbs  
*uru* ‘sell’, *hanbai-suru* ‘sell’, *yasu-uri-suru* ‘undersell’, *mae-uri-suru* ‘sell in advance’, *kasu* ‘lend/rent’, *kasi-dasu* ‘lease/check out’, *rentaru-suru* ‘rent’, *uri-dasu* ‘offer’, *uri-hazimeru* ‘begin to sell’, *zyouei-suru* ‘show’, *zyouen-suru* ‘present’, *yaru* ‘give’
- b. Caused motion verbs  
*hosu* ‘hang out’, *oku* ‘put’, *kazaru* ‘decorate’, *simau* ‘keep’, *haru* ‘post’, *keizi-suru* ‘post’, *sasu* ‘pin’, *kaku* ‘write’
- (20) a. Furansu-no-eiga-ga zyoueisi-te-i-ta.  
 France-GEN-movie-NOM show-GER-exist-PAST  
 ‘The French movie was showing.’

---

<sup>3</sup>The verbs in (19b) require a more restricted environment – they can appear in the QEC only when sentential negation is also present. Although it is an interesting and significant issue why negation makes it possible for these verb to appear in the QEC, I will leave this for future research.

- b. Saikin kousou-mansyon-ni-(wa) sentakumono-ga  
 recently high.rise-apartment-LOC-TOP laundry-NOM  
 hosi-te-i-nai.  
 hang.out-GER-exist-NEG  
 ‘Recently at the high-rise apartments, laundry is not hung out (to dry).’

### 3.2. Transitive-Unaccusative Complex Predicates

I have shown that a verb *iru* in the QEC behaves as an existential verb. Since the QEC carries a progressive meaning due to the presence of the verb *iru*, I thus assume that the verb *iru* is taken to be not only an auxiliary but also a full verb. The full verb *iru* can then form a complex predicate structure with a preceding verb. Adopting the claim that existential verbs are unaccusative (cf. Burzio 1986; Levin and Rappaport Hovav 1995), I assume that the existential verb *iru* is unaccusative, too. In the QEC, the initial verb ( $V_1$ ) and *iru* ( $V_2$ ) would thus fall under transitive-unaccusative complex predicates.

There is good reason to believe that the QEC is in the form of transitive-unaccusative complex predicates: they exhibit “argument blocking”. In Japanese, complex predicates with a transitive and an intransitive are abundant.<sup>4</sup> For example, the transitive  $V_1$ , *utu* ‘hit’, and the unaccusative  $V_2$ , *agaru* ‘rise’ form a complex predicate. In (21), the theme argument of  $V_1$  is also understood as the theme of  $V_2$ , and is marked by nominative.

- (21) a. Booru-ga uti-agar-ta.  
 ball-NOM hit<sub>tr</sub>-rise-PAST  
 ‘The ball popped up.’  
 b. Tegami-ga kaki-agar-ta.  
 letter-NOM write<sub>tr</sub>-rise-PAST  
 ‘The letter was written up.’

In these transitive-unaccusative predicates, agent and recipient arguments cannot appear. (22) indicates that neither the overt agent nor the agent-oriented adverb is compatible with this construction. The recipient argument must also be absent, as shown in (23).

- (22) a. \*John-ga booru-ga uti-agar-ta.  
 John-NOM ball-NOM hit<sub>tr</sub>-rise-PAST  
 ‘John popped the ball up.’

---

<sup>4</sup>The  $V_2$  of some of these predicates has been claimed to express aspectual meanings (see Shibatani 1973; 1978; Kuno 1987; Kageyama 1993; Matsumoto 1996; Tsujimura 2006 for aspectual verbs).

b. \*Booru-ga wazato uti-agar-ta.  
 ball-NOM intentionally hit<sub>tr</sub>-rise-PAST  
 ‘The ball popped up intentionally.’

(23) \*Tegami-ga Naomi-ni kaki-agar-ta.  
 letter-NOM Naomi-DAT write<sub>tr</sub>-rise-PAST  
 ‘The letter was written up to Naomi.’

If the QEC is an instance of transitive-unaccusative predicates, then the issue of why the agent and the goal arguments are missing in the QEC can be explained by the general condition on argument realization in Japanese complex predicates.

### 3.3. Previous Accounts for Argument Blocking

There are two approaches to explaining the fact about the suppression of agent arguments: intransitivization and structural blocking. The former assumes that such transitive-unaccusative predicates derive from the transitive-transitive counterpart. The latter argues that a particular argument (i.e. agent) cannot be licensed by the structure.

Let me begin with intransitivization accounts. Kageyama (1993) proposes the *transitivity harmony principle* that requires both  $V_1$  and  $V_2$  to involve an external argument. This means that the compounding of transitive and unaccusative is impossible due to a violation of this principle. He thus postulates the operation *back formation* which generates transitive-unaccusative predicates from corresponding transitive-transitive predicates. The similar intransitivization analysis is proposed by Matsumoto (1996;1996) and Fukushima (2005).

Although they all just argue that agent is suppressed through intransitivization, it is unclear how such arguments really can be suppressed. Furthermore, if transitive-unaccusative predicates are formed via intransitivization, the suppression of recipient would also be observed in a typical intransitivization process. Consider a verb pair, *tuta-e* ‘tell<sub>tr</sub>’ and *tuta-war* ‘tell<sub>in</sub>’, which has been claimed as an example of intransitivization (cf. Okutsu 1967). Unlike (23), the recipient argument survives through intransitivization, as illustrated in (24b). Thus, intransitivization accounts need to stipulate additional constraints in order to rule out (23).

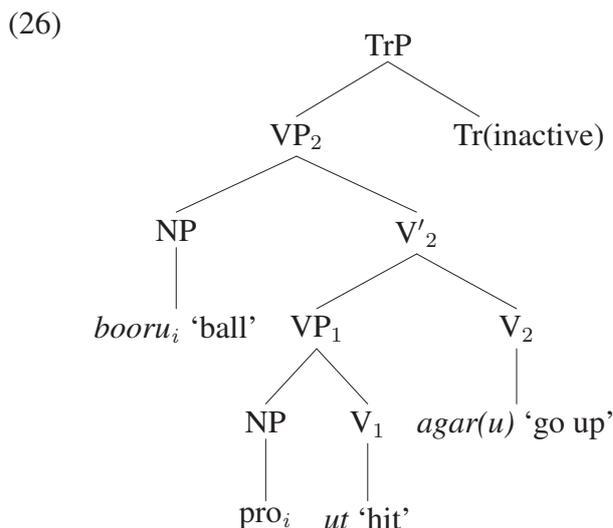

(24) a. Haha-ga kodomo-ni sinzitu-o tuta-e-ta.  
 mother-NOM children-DAT truth-ACC tell-TR-PAST  
 ‘The mother told her children the truth.’

- b. Sinzitu-ga kodomo-ni tuta-war-ta.  
 truth-NOM children-DAT tell-INTR-PAST  
 ‘The truth was told to the children.’

Next, these accounts wrongly predict that there are no transitive-unaccusative compounds which do not have corresponding transitive-transitive counterparts. This prediction is not born out however, as shown in (25). Although there exists no transitive-transitive counterpart, the complex predicate *syaberi-tukare* is fully grammatical.

- (25) Naomi-ga syaberi-tukare-ta.  
 Naomi-NOM speak-get.tired-PAST  
 ‘Naomi got tired from speaking (too much).’

A different structural explanation is proposed by Nishiyama (1998), and Naumann and Gamerchlag (2003). Adopting Kratzer’s (1996) theory of Voice Phrase, Nishiyama assumes that an external argument is not included in the immediate projection of VP, and proposes that an active Tr(ansitivity) head (i.e. the Voice head in Kratzer’s term) introduces an external argument of the verbal compound in its Spec position, whereas an inactive Tr does not. For instance, in the complex predicates *uti-agaru* as in (21a), the argument structure of the transitive verb *ut* ‘hit’ is <Theme> (or  $\lambda x\lambda e$  [hitting (e) & Theme (x)(e)] in Kratzer’s representation). An inactive Tr then selects an unaccusative VP-shell, as illustrated in (26). Thus, the external argument (agent) will not be introduced in this structure.

In line with the lexicalist approaches (Kageyama 1993; Matsumoto 1996), Naumann

& Gamerschlag (2003) argue that the argument structures of  $V_1$  and  $V_2$  are merged, sharing at least one argument. For transitive-unaccusative predicates, the formed argument structure still involves an agent argument. Then, they postulate a rule that blocks agent realization based on their assumption that an external argument is structurally higher than internal arguments. The rule says that an argument of  $V_1$  is *structurally* blocked which (i) is not identified with an argument of  $V_2$ , and (ii) is structurally higher than the argument of  $V_1$  identified with an argument of  $V_2$ .

These structural accounts either by Nishiyama or by Naumann & Gamerschlag seem plausible on the absence of the agent. Yet, the fact that the recipient is missing as shown in (23) is a problem for their accounts. First, Nishiyama's claim that external arguments come into the clause through the functional head (active Tr) does not prevent a recipient argument of  $V_1$ . Even if we assume that the transitive-unaccusative compounds is selected by inactive Tr, (in)active Tr has nothing to do with internal arguments of verbs, and the prediction would be that the internal argument, i.e. recipient, is acceptable in its syntactic structure. Next, Naumann & Gamerschlag's structural blocking analysis could block the recipient arguments if they assumed that recipient is structurally higher than theme. As many linguists (cf. Larson 1988; Grimshaw 1990, among many others) assume that arguments of a verb are associated with positions in the syntax, interacting with their thematic roles, they need to show the empirical evidence that recipient outranks theme in a thematic hierarchy as well as in the syntactic structure. However, there is little consensus on the ranking of arguments in a thematic hierarchy (except agent). With regard to the ranking of recipient and theme, some argue that theme is ranked above recipient (Larson 1988; Baker 1989 *inter alia*), and some argue that theme is ranked below recipient (Jackendoff 1972; Grimshaw 1990 *inter alia*).

#### 3.4. A New Account: Argument Unification

I have argued that neither the intransitivization nor the structural blocking analysis is without major problems. Alternatively I propose a more generalized process *argument unification* for the suppression of arguments. With this account, I make sense of not only missing arguments but also locative-markings in the QEC. Following the claim by Matsumoto (1996) and Kageyama (1993) that at least one argument should be shared by  $V_1$  and  $V_2$  in complex predicates, I propose the argument unification in (27).

##### (27) Argument Unification

When the two verbs of a complex predicate  $V_1$ - $V_2$ , where  $V_2$  is the head, share some arguments, the shared arguments are unified; furthermore, it is only the

shared arguments of  $V_1$  that are mapped to the syntactic structure.

(27) provides a simple unified account for the suppression of agents and recipients. Take the complex predicate *kaki-agaru* as in (21b) as an example, where each argument structure is  $V_1$ : < Agent, Recipient, Theme>, and  $V_2$ : < Theme>. What is shared is *theme*, so that only this theme can be mapped to syntax. The absence of agents and recipients as in (22) and (23) can be simply attributed to the fact that they both are not shared arguments.

One may of course claim that, given that  $V_2$  is the head, transitive-nergative compounds would violate argument unification in (27). The complex predicate with a transitive  $V_1$  and an unergative  $V_2$  does allow a non-shared argument (i.e. theme) of the non-head  $V_1$  to be realized, as illustrated in (28).

- (28) Ken-ga kagi-o sagasi-mawar-ta.  
Ken-NOM key-ACC search-go.around-PAST  
'Ken searched about the key.'

One solution would be that the head in these complex predicate is a  $V_1$ , not a  $V_2$ , as claimed in Matsumoto (1996) and Naumann & Gamerschlag (2003). This left-headedness in the transitive-nergative predicates does not seem ad hoc in term of the semantic structure. Unlike other complex predicates (i.e. transitive-transitive, unergative-transitive, unergative-nergative, unaccusative-unaccusative, and transitive-unaccusative predicates), the transitive-nergative compounds like *sagasi-mawaru* in (28) do not involve causal relation. Rather the most prominent reading is that event denoted by  $V_1$  and the one by  $V_2$  should take place at the same time. Given that the head verb is  $V_1$  in transitive-nergative compounds, one can reformalize (27) by saying that only the shared arguments of non-head verb are mapped to the syntactic structure. In this paper, however, I limit myself to suggesting that it may be more reasonable to capture this apparent exceptional complex predicate by resorting to a different mechanism.

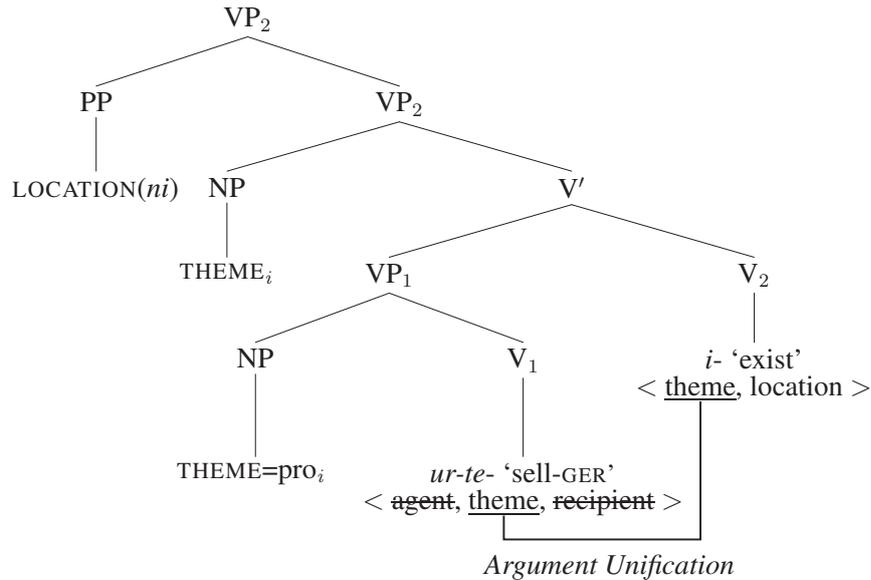

With this argument unification in mind, I now turn to the QEC. I have argued that *iru* is a verb that serves double duty: existential and auxiliary, and it forms a complex predicate with the  $V_1$ . Significantly, the QEC, where  $V_1$  (e.g. *ur-te* 'sell-GER') is transitive and  $V_2$  (i.e. *iru* 'exist') is unaccusative, falls under transitive-unaccusative predicates. In the QEC, the verb *iru* is the head  $V_2$ , and takes theme and location arguments. The agent and the recipient of  $V_1$ , which are not shared by the head  $V_2$ , must be suppressed because of argument unification in (27), and hence are not mapped to the syntactic structure, as illustrated in (29b).<sup>5</sup>

---

<sup>5</sup>I assume that the locative PP is an argument of the existential verb *iru*, but syntactically that it is mapped to a VP adjoined position (Kishimoto 2000).

- (29) a. Honya-ni zassi-ga ur-te-i-ru.  
 bookstore-LOC magazine-NOM sell-GER-exist-PRES  
 ‘Magazines are for sale in the bookstore.’

b.

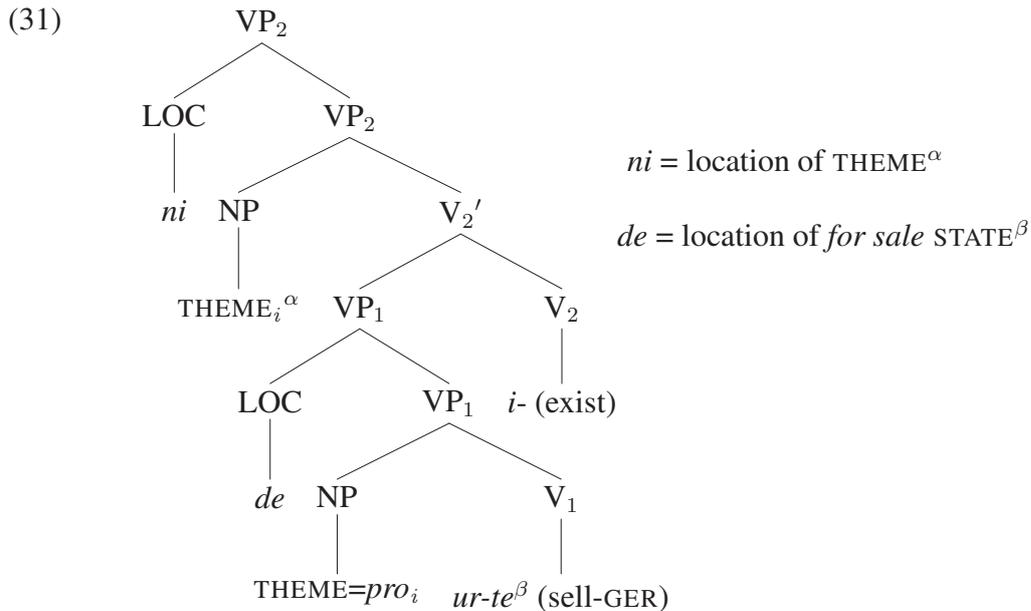

Following Nishiyama (1998), I assume that the structure in (29b) is a VP-shell structure: the existential verb ( $V_2$ ) takes a transitive verb ( $V_1$ ) as the complement. The two attested locative positions are evident from (30), where the *ni* locative and the *de* locative can co-occur in the QEC.<sup>6</sup>

- (30) a. Tawareko-de rezi-mae-ni ame-ga ur-te-i-ta.  
 Tower.Record-LOC cashier-front-LOC candy-NOM sell-GER-exist-PAST  
 ‘At Tower Records, candies were for sale in front of the cashier.’  
 b. Rezi-mae-ni Tawareko-de ame-ga ur-te-i-ta.  
 cashier-front-LOC Tower.Record-LOC candy-NOM sell-GER-exist-PAST

In Section 2.2, I claimed that in the QEC, the *ni* locative should be associated with the place where a sold object is located, whereas the *de* locative should be associated with the place where the *for sale* state takes place. In (30), it is at the *ni*-marked location (i.e. *in front of the cashier*) that the candies are really located, whereas it is *at Tower Records*

<sup>6</sup>Japanese is a relatively free word-order language, and the order of the two locatives in (30) does not matter here.

where the whole selling event happens. My complex analysis has two VP, one headed by the  $V_1$ , and the other headed by the existential  $V_2$ . The locative PPs (i.e. the *ni*-PP and the *de*-PP) can be attached to  $VP_1$  and  $VP_2$ , respectively, as illustrated in (31).

This structural difference also reflects the distinct interpretations regarding the locative *ni* and *de*; the *ni*-marked PP (i.e. the place of the entity) is adjoined to the  $VP_2$ , while the *de*-marked PP (i.e. the place of the event/state) is adjoined to the lower  $VP_1$ .

#### 4. Conclusion

I argued that the apparently puzzling case marking on the theme argument result from the existential status of the verb *iru* and independently motivated general principle on argument realization in Japanese. In this paper, I departed from the assumption that a transitive verb combines with an aspectual auxiliary which is grammaticalized; rather I argued that it combines with an existential verb in the QEC. Assuming that the two verbs form a complex predicate, I showed that the missing two arguments (i.e. agent and

recipient) can be simply explained by the process of argument unification.

### Acknowledgement

I would like to thank Beth Levin, Jane Grimshaw, Ken Hiraiwa, Peter Sells, and Yoshiko Matsumoto for their valuable comments and discussions. Thanks are also due to the participants of CIL 18, and the audience in English Linguistics Seminar at Osaka University for their feedback and/or discussions. Needless to say, all remaining errors are my responsibility.

# The grammar of *hitting* and *breaking* (and *cutting*) in Kimaragang Dusun

Paul R. Kroeger

Graduate Institute of Applied Linguistics & SIL Intl.  
7500 W. Camp Wisdom Rd., Dallas, TX 75236, USA  
paul\_kroeger@gial.edu

## Abstract

The *hit*, *break* and *cut* classes of verbs are grammatically relevant in both English and Kimaragang. The relevance of such classes for determining how arguments are expressed suggests that the meaning of a verb is composed of (a) systematic components of meaning (EVENT STRUCTURE); and (b) idiosyncratic properties of the individual root. In addition, the distribution of the instrumental alternation in Kimaragang is claimed to provide support for the hypothesis that “affected” arguments must be event structure participants.

**Keywords:** *lexical semantics, argument realization, affectedness, verb classes, Austronesian morphology.*

## 1. Verbs of *hitting* and *breaking* in English<sup>1</sup>

This paper discusses the relationship between verbal semantics and clause structure in Kimaragang Dusun, an endangered Austronesian language of northern Borneo. It builds on a classic paper by Charles Fillmore (1970), in which he distinguishes two classes of transitive verbs in English: “surface contact” verbs (e.g., *hit*, *slap*, *strike*, *bump*, *stroke*) vs. “change of state” verbs (e.g., *break*, *bend*, *fold*, *shatter*, *crack*). Fillmore showed that the members of each class share certain syntactic and semantic properties which distinguish them from members of the other class. He further argued that the correlation between these syntactic and semantic properties supports a view of lexical semantics under which the meaning of a verb is made up of two kinds of elements: (a) systematic components of meaning that are shared by an entire class; and (b) idiosyncratic components that are specific to the individual root. Only the former are assumed to be “grammatically relevant.” This basic insight has been foundational for a large body of subsequent work in the area of lexical semantics.

One syntactic test that distinguishes *hit* verbs from *break* verbs in English is the “causative alternation”, which is systematically possible with *break* verbs (*John broke the window* vs. *The window broke*) but systematically impossible with *hit* verbs (*John hit the window* vs. *\*The window hit*). A second test involves a kind of “possessor ascension” or paraphrase in which the possessor of a body-part noun can be expressed as direct object. This paraphrase is grammatical with *hit* verbs (*I hit his leg* vs. *I hit him on the leg*) but not with *break* verbs (*I broke his leg* vs. *\*I broke him on the leg*). A third diagnostic relates to the potential ambiguity of the passive participle. Participles of both classes take a verbal-eventive reading; but participles of *break* verbs also allow an ad-

---

<sup>1</sup> I would like to thank Jim Johansson, Farrell Ackerman and John Beavers for helpful discussion of these issues. Thanks also to Jim Johansson for giving me access to his field dictionary (Johansson, n.d.), the source of many of the Kimaragang examples in this paper. Special thanks are due to my primary language consultant, Janama Lantubon. Part of the research for this study was supported by NEH-NSF Documenting Endangered Languages fellowship no. FN-50027-07.

jectival-stative reading (*the window is still broken*) which is unavailable for participles of *hit* verbs (*\*the window is still hit*).

Semantically, the crucial difference between the two classes is that *break* verbs entail a result, specifically a “separation in [the] material integrity” of the patient (Hale and Keyser 1987). This entailment cannot be cancelled (e.g., *I broke the window with a hammer; #it didn't faze the window, but the hammer shattered*). The *hit* verbs, in contrast, do not have this entailment (*I hit the window with a hammer; it didn't faze the window, but the hammer shattered*). A second difference is that *break* verbs may impose selectional restrictions based on physical properties of the object (*I {folded/?bent/\*broke/\*shattered} the blanket*) whereas *hit* verbs do not (*I {hit/slapped/struck/beat} the blanket*). Selectional restrictions of *hit* verbs are more likely to be based on physical properties of the instrument.

In the years since 1970, these two classes of verbs have continued to be studied and discussed in numerous publications. Additional diagnostics have been identified, including the *with/against* alternation (Fillmore 1977; see examples 1–2 below); the CONATIVE alternation (*Mary hit/broke the piñata* vs. *Mary hit/\*broke at the piñata*; Guerssel et al. 1985); and the Middle alternation (*This glass breaks/\*hits easily*; Fillmore 1977, Hale and Keyser 1987). These tests and others are summarized in Levin (1993).

## 2. Some hypotheses about the structure of verb meanings

My assumptions about verbal semantics are largely based on the work of Levin and Rappaport Hovav (1995, 1998, 2005; henceforth L&RH). First, as mentioned above, I assume that verb meanings are composed of two kinds of information. Some components are systematic, forming a kind of “template” for the verb’s lexical semantic structure, while others are idiosyncratic, specific to that particular root. Following L&RH, I will refer to the systematic part of the meaning as the verb’s EVENT STRUCTURE.

Second, I assume that only the systematic aspects of meaning are grammatically relevant (i.e., relevant to argument realization). Grammatically determined verb classes, such as *hit* verbs or *break* verbs, are sets of verbs that share the same event structure. Thus the systematic aspects of meaning distinguish one class from another, while roots belonging to the same class are distinguished by features of their idiosyncratic meaning. I will refer to arguments that are specified by the event structure as “event structure participants” (cf. RH&L 1998).

Levin (1993) states: “[T]here is a sense in which the notion of verb class is an artificial construct. Verb classes arise because a set of verbs with one or more shared meaning components show similar behavior... The important theoretical construct is the meaning component, not the verb class...” Identifying semantically determined sets of verbs is thus a first step in understanding what elements of meaning are relevant for determining how arguments will be expressed. The comparison of verb classes across languages is also important in order to distinguish those principles of argument realization which are truly universal from those that are language-specific.

In the remainder of this paper I demonstrate that the *hit* and *break* verb classes are grammatically relevant in Kimaragang, just as they are in English. In fact, some of the same properties discussed in sec. 1 to distinguish these two classes in English can also be used in Kimaragang for the same purpose. I go on to discuss certain patterns of ar-

gument realization in Kimaragang that seem to involve an alternation in the identity of the “affected argument”.

Fillmore (1977) uses the *with/against* alternation in English, illustrated in (1), as an example of how a speaker may adopt two different PERSPECTIVES on the same event:

(1) (Fillmore 1977:75)

a. *I hit the fence with the stick.*

b. *I hit the stick against the fence.*

Sentence (1a) seems to answer the question, ‘What did you do to the fence?’, while sentence (1b) answers the question, ‘What did you do to the stick?’ The speaker may choose to adopt one perspective or the other depending on a variety of semantic and pragmatic factors. If the patient is human, for example, the *with* form (2a) would normally be strongly preferred over the *against* form (2b).

(2) (Fillmore 1977:75)

a. *I hit Harry with the stick.*

b. *??I hit the stick against Harry.* (somewhat unnatural)

I will use the term AFFECTED ARGUMENT to refer to the argument that the speaker views as being primarily affected or acted upon. Thus in (1a) the affected argument is the fence, while in (1b) the affected argument is the stick. In discussing the Kimaragang evidence presented below, I will suggest that affected arguments must be event structure participants; but whether this is a universal principle or a language-specific requirement, it is too early to say.

### 3. Verbs of *hitting* and *breaking* in Kimaragang

#### 3.1 *Causative-inchoative alternation*

Kimaragang is structurally very similar to the languages of the central Philippines. In particular, Kimaragang exhibits the rich Philippine-type voice system in which the semantic role of the subject (i.e., the NP marked for nominative case) is indicated by the voice affixation of the verb.<sup>2</sup> In the Active Voice, an additional “transitivity” prefix occurs on transitive verbs; this prefix is lacking on intransitive verbs.<sup>3</sup>

Many verbal roots occur in both transitive and intransitive forms, as illustrated in (3) with the root *patay* ‘die; kill’. In the most productive pattern, and the one of interest to us here, the intransitive form has an inchoative (change of state) meaning while the transitive form has a causative meaning. However, it is important to note that there is no causative morpheme present in these forms (morphological causatives are marked by a different prefix, *po-*).

(3) a. Minamatay(<in>m-poN-patay) oku do tasu.<sup>4</sup>  
 <PST>AV-TR-die 1sg.NOM ACC dog  
 ‘I killed a dog.’

<sup>2</sup> See Kroeger (2005) for a more detailed summary with examples.

<sup>3</sup> For details see Kroeger (1996); Kroeger & Johansson (2005).

<sup>4</sup> The following abbreviations are used in this paper: ACC ‘accusative case’; AV ‘active voice’; CAUS ‘causative’; COMP ‘complementizer’; COMPL ‘completive’; DAT ‘dative case’; DUP ‘reduplication’; DV ‘dative voice’; FRUST ‘frustrative’; GEN ‘genitive case’; HABIT ‘habitual’; IMPER ‘imperative’; ITER ‘iterative’; IV

- b. Minatay(<in>m-patay) it tasu.  
 <PST>AV-die NOM dog  
 ‘The dog died.’

Virtually all *break*-type roots allow both the causative and inchoative forms, as illustrated in (6–7); but *hit*-type roots generally occur only in the transitive form. Thus just as in English, the causative alternation is highly productive with *break* verbs but impossible with *hit* verbs. Note also that, as suggested by the glosses in (4–5), selectional restrictions for *break* verbs are based on properties of the patient, whereas selectional restrictions for *hit* verbs are more likely to be based on properties of the instrument. Again, this is highly reminiscent of the situation in English.

(4) *break* verbs:

ROOT	GLOSS	INTRANSITIVE	TRANSITIVE
<i>babak</i>	‘shatter’	<i>mabak</i>	<i>mamabak</i>
<i>gapas</i>	‘tear’ (e.g. ear, nose)	<i>gumapas</i>	<i>mangagapas</i>
<i>kinis</i>	‘tear’ (e.g. cloth)	<i>kuminis</i>	<i>monginis</i>
<i>lapak</i>	‘split’	<i>lumapak</i>	<i>mangalapak</i>
<i>lupi</i>	‘fold (e.g. cloth)’	<i>lumupi</i>	<i>mongolupi</i>
<i>pika</i>	‘fold (e.g. leaf, perpendicular to stem)’	<i>mika</i>	<i>momika</i>
<i>putut</i>	‘break (rope etc.)’	<i>mutut</i>	<i>momutut</i>
<i>susak</i>	‘ruffle, roughen’	<i>sumusak</i>	<i>monusak</i>
<i>tangi</i>	‘dissolve’	<i>tumangi</i>	<i>manangi</i>
<i>tipu</i>	‘break (stick etc.)’	<i>tumipu</i>	<i>monipu</i>
<i>uyas</i>	‘pull apart’	<i>muyas</i>	<i>monguyas</i>
<i>wi’is</i>	‘split, strip’ (cane, bamboo, etc.)	<i>mi’is</i>	<i>momis</i>
<i>winsar</i>	‘splinter’	<i>minsar</i>	<i>mominsar</i>

(5) *hit* verbs:

ROOT	GLOSS	INTRANSITIVE	TRANSITIVE
<i>bobog</i>	‘beat (with stick)’	* <i>mobog</i>	<i>momobog</i>
<i>duntuk</i>	‘bump, knock’	* <i>dumuntuk</i>	<i>mongoduntuk</i>
<i>duntung</i>	‘punch (with fist)’	* <i>dumuntung</i>	<i>mongoduntung</i>
<i>lapis</i>	‘slap’	* <i>lumapis</i>	<i>mangalapis</i>
<i>lapos</i>	‘cane, whip’	<i>lumapos</i> <sup>5</sup>	<i>mangalapos</i>
<i>pasut</i>	‘cane’	* <i>masut</i>	<i>mamasut</i>
<i>puyay</i>	‘stroke, caress’	* <i>muyay</i>	<i>momuyay</i>
<i>sudsur</i>	‘poke’	* <i>sumudsur</i>	<i>monudsur</i>
<i>suntuk</i>	‘punch (with fist)’	* <i>sumuntuk</i>	<i>monuntuk</i>
<i>tutu</i>	‘pound in mortar and pestle’	* <i>tumutu</i>	<i>Monutu</i>
<i>puyay</i>	‘stroke, caress’	* <i>muyay</i>	<i>momuyay</i>

‘instrumental voice’; NEG ‘negative’; NOM ‘nominative case’; NVOL ‘non-volitive’; OV ‘objective voice’; PRCL ‘particle’; PST ‘past tense’; pl ‘plural’; sg ‘singular’; TR ‘transitive’; <x> = infix.

<sup>5</sup> *lumapos* is not an inchoative form; it has an idiosyncratic reflexive meaning ‘hurl oneself down; fall down flat (e.g. in pain or fatigue)’.

- (6) a. Minomutut(<in>m-poN-putut) nopo yalo' dilo' tangaw tu'  
 <PST>AV-TR-break PRTCL 3sg.NOM that(ACC) vine for

 AV-TR-tear 3sg.NOM that(ACC) shirt 3sg.GEN for  
 pongongkos dilo' pilat.  
 IV:TR:wrap that(ACC) wound  
 'He is *tearing* (trans.) his shirt to bind up his wound with.'
- b. K<um>inis noono mari a kadut dilo' ong s<um>unut no.  
 <AV>tear PRITCL PRITCL NOM gunny that if <AV>fray COMPL  
 'That gunnysack is about to *tear* (intrans.) if it is fraying already.'

### 3.2 Denying a result

We noted in sec. 1 that *break* verbs entail a result, whereas *hit* verbs do not. Kimaragang grammar provides a very interesting means of demonstrating this fact. Like many other Philippine-type languages, Kimaragang verbs may be optionally marked for NON-VOLITIVE modality (used to encode ability, involuntary actions, etc.). As Dell (1983) points out for Tagalog, the non-volitive form is under-specified with respect to intentionality, but entails that the described event has actually taken place, i.e. that the intended result has actually been achieved.<sup>6</sup> The (morphologically unmarked) volitive form, in contrast, asserts that the action was intentional but is neutral with respect to the outcome of the action. In most contexts the volitive form creates a pragmatic implicature that the intended result has been achieved, but this implicature can be denied as in (8a). However, with the corresponding non-volitive form this negation would lead to self-contradiction, as in (8b).

- (8) a. Minamatay oku do wulanut nga' amu' minatay  
 PST:AV:TR:die 1sg.NOM ACC snake but NEG PST:AV:die  
 'I killed a snake, but it didn't die.'
- b. \*Naka-patay oku do wulanut nga' amu' minatay.  
 AV.PST.NVOL-die 1sg.NOM ACC snake but NEG PST:AV:die  
 \*'I happened to/managed to kill a snake, but it didn't die.'

The pattern seen in (8a), where the same verb root is used to both assert the action and deny the result, is possible with most, if not all, *break* verbs, as illustrated in (9). It is systematically impossible with the *hit* verbs (10), because these verbs do not lexically

<sup>6</sup> See also see Kroeger (1990).

encode a result. In order to deny that the intended result was achieved, a different root must be used (11).

 (intended: 'I (tried to) pound rice, but it didn't pound/get pounded.')
- c. \*Minamasut oku do karabaw nga', amu n-a-pasut-∅.  
 PST:AV:TR:whip 1sg.NOM ACC buffalo but not PST-NVOL-whip-OV  
 (intended: 'I (tried to) whip a buffalo, but it didn't whip/get whipped.')
- (11) B<in>obog-∅ ku it tasu nga', amu n-o-onong-∅.  
 <PST>beat-OV 1sg.GEN NOM dog but not PST-NVOL-hit<sup>7</sup>-OV  
 'I (tried to) beat the dog, but I didn't hit it.' (i.e., failed to make contact)

### 3.3 Adversative construction

The Dative Voice suffix can be used with some unaccusative roots to add a “maleficiary” argument, someone who suffers as a result of the described event, as illustrated in (12a). The truth of the adversative clause implies that the corresponding unaccusative (12b) is also true.

- (12) a. N-a-patay-an yalo do tanak.  
 PST-NVOL-die-DV 3sg.NOM GEN child  
 'He suffered the death of a child.'
- b. Minatay(<in>m-patay) it tanak yo.  
 <PST>AV-die NOM child 3sg.GEN  
 'His child died.'

The adversative construction is possible with a number of the *break* verbs (13a-b), but systematically impossible with the *hit* verbs (13c). This is probably related to the fact that *hit* verbs do not allow an unaccusative form.

<sup>7</sup> *onong* means 'hit' in the sense of 'hitting the target; making contact'

- (13) a. N-o-tipu-an            oku            do    takod.  
 PST-NVOL-break-DV 1sg.NOM    GEN leg  
 ‘I suffered the breaking of a leg. (i.e., I broke my leg.)’
- b. Naka-labus                i            karabaw tu’  
 AV.PST.NVOL-escape    NOM buffalo    because
- n-a-gapas-an            do    todung.  
 PST-NVOL-tear-DV    GEN nose  
 ‘The buffalo got loose because his nose tore through.’  
 (lit: ‘suffered the tearing of a nose’; so came free from nose ring or rope)
- c. \*N-a-babag-an            oku            do    tanak.  
 PST-NVOL-beat-DV 1sg.NOM    GEN child  
 (intended: ‘I suffered the beating of a/my child.’)

#### 4. Verbs of *cutting* in Kimaragang

The use of the Instrumental Voice provides another useful diagnostic for distinguishing verb classes in Kimaragang. Before describing that construction, however, it will be helpful to mention a third class of verbs that has been extensively studied, both in English and in other languages, namely verbs of *cutting*. These verbs involve the use of a sharp instrument to bring about a “separation in material integrity” of the patient. Some examples of this class are provided in (14).

(14) *cut* verbs:

ROOT	GLOSS	INTRANSITIVE	TRANSITIVE
<i>ansap</i>	‘scrape’	* <i>mansap</i>	<i>mangansap</i>
<i>gamas</i>	‘cut (grass, weeds etc.)’	* <i>gumamas</i>	<i>mangagamas</i>
<i>lapak</i>	‘split’	<i>lumapak</i>	<i>mangalapak</i>
<i>pudung</i>	‘chop (e.g. branches, firewood)’	* <i>mudung</i>	<i>momudung</i>
<i>purok</i>	‘chop up (meat, fish, etc.)’	* <i>murok</i>	<i>momurok</i>
<i>tobok</i>	‘stab’	* <i>tumobok</i>	<i>monobok</i>
<i>tobuk</i>	‘slit open (e.g. stomach)’	* <i>tumobuk</i>	<i>monobuk</i>
<i>totok</i>	‘cut (wood, rope, vines, etc.)’	* <i>tumotok</i>	<i>monotok</i>
<i>wi’is</i>	‘split, strip’	<i>mi’is</i>	<i>momi’is</i>

The *cut* verbs are similar to *hit* verbs in that they do not participate in the adversative construction or, as indicated in (14), the causative-inchoative alternation. The roots *lapak* ‘split’ and *wi’is* ‘strip (e.g., ratan)’ seem to be exceptions to the latter generalization, since they (unlike the other *cut* verbs) have intransitive (inchoative) senses in addition to the normal transitive form. However, there is an important difference in meaning between the transitive and intransitive uses of these roots: the transitive forms imply the use of a sharp bladed instrument, but this is not part of the meaning of the (intransitive) inchoative forms.

For example, the orangutan is said to be powerful enough to split open a *durian* (a large spiky fruit with a very tough husk) with its bare hands; but this interpretation is not available for the transitive form used in (15a). That sentence can only be interpreted to mean that the orangutan used a bush-knife, axe, or other sharp instrument. In contrast, the intransitive form used in (15b) is normally interpreted as a spontaneous event involving neither instrument nor agent. Thus it appears that the transitive senses of *lapak* and *wi'is* belong to the *cut* class, while their intransitive senses belong to the *break* class.

- (15) a. Minangalapak(<in>m-poN-lapak) it kogiw do ratu.  
 <PST>AV-TR-split NOM orangutan GEN durian  
 'The orangutan split (open) a *durian*.'
- b. L<in><um>apak ilot niyuw.  
 <PST><AV>split that(NOM) coconut  
 'The coconut split.'

Most *cut* verbs do not lexically specify a result. Evidence for this comes from the fact that these roots cannot be used to deny that an intended result was achieved (16a-b). In order to deny the result, a different root must be used (16c). However, there are a few roots of this type that can be used in this way, as illustrated in (17), suggesting that these roots do lexically specify a result state. Levin (1993) distinguishes two classes, *cut* verbs which do not lexically specify a result and *carve* verbs which do. The semantic properties of the individual roots in this class are not yet understood well enough to know whether this distinction is valid for Kimaragang as well.

- (16) a. \*T<in>obok-∅ ku yalo nga', amu n-o-tobok-∅.  
 <PST>-stab-OV 1sg.GEN 3sg.NOM but not PST-NVOL-stab-OV  
 (intended: 'I (tried to) stab him, but he didn't stab/get stabbed.')
- b. \*P<in>urok-∅ ku ilo' tonsi nga', amu n-o-purok-∅.  
 <PST>-chop-OV 1sg.GEN that(NOM) meat but not PST-NVOL-chop-OV  
 (intended: 'I (tried to) chop up that meat, but it didn't get chopped up.')
- c. T<in>obok-∅ ku yalo nga', amu n-o-togu-∅  
 <PST>-stab-OV 1sg.GEN 3sg.NOM but not PST-NVOL-pierce-OV  
 tu', ki-kobol yalo.  
 because have-invulnerability 3sg.NOM  
 'I (tried to) stab him, but I didn't/wasn't able to pierce him because he has *kebal* protection (i.e., has been made invulnerable by performing certain rituals).'
- (17) T<in>otok-∅ ku ilo' tangaw nga',  
 <PST>-chop-OV 1sg.GEN that(NOM) vine but  
 amu n-o-totok-∅.  
 not PST-NVOL-chop-OV  
 'I (tried to) cut that vine, but it didn't cut.' (it was too tough)

## 5. The instrumental alternation

An alternation in the form of the Instrumental Voice provides another means for distinguishing the three verb classes under consideration here. Verbs marked for Instrumental Voice (IV) normally require the transitivity prefix *poN-*, which triggers a null allomorph of the IV prefix (18a). This construction is highly productive, and can be formed with a large number of transitive verb roots. A smaller number of transitive verbs can take the IV prefix without any transitivity prefix, as seen in (18b).

- (18) a. *Pinomoli*( $\langle in \rangle \emptyset$  -*poN-boli*) ku do tasin it siin nu.  
 <PAST>IV-TR-buy 1sg.GEN ACC salt NOM money 2sg.GEN  
 ‘I bought some salt with your money.’
- b. *N-i-boli* ku do tasin it siin nu.  
 PAST-IV-buy 1sg.GEN ACC salt NOM money 2sg.GEN  
 ‘I spent your money on salt.’

As these examples illustrate, both IV forms are grammatical with the root *boli* ‘buy’ and both can be used to describe the same basic type of event: the same participants appear in both clauses in the same semantic roles and with the same case marking. This does not mean that the two forms are semantically equivalent: the “bare” IV form in (18b) implies that all of the money was spent, whereas (18a) does not carry this implication.

This alternation between the two IV forms, with both forms describing the same type of event, is the pattern that I refer to as the INSTRUMENTAL ALTERNATION. We turn now to the question of which roots participate in this alternation.

The instrumental alternation is highly productive with *cut* verbs, as illustrated in (19–21). With these roots the two Instrumental Voice forms provide different descriptions for the same type of event, taking the same arguments with the same case marking. There is, however, a subtle semantic difference. The “bare” IV form in (21a), for example, addresses the question, ‘What will you do to my bush knife?’; whereas the normal IV form in (21b) answers the question, ‘What will you do to that leech?’

- (19) a. *Nokuro.tu*’ *n-i-ansap* nu do poring  
 why PST-IV-scrape 2sg.GEN ACC bamboo  
 ino dangol ku?  
 that(NOM) bush.knife 1sg.GEN  
 ‘Why did you use my bush knife to scrape bamboo?’
- b. *Dangol* tagayo ot awasi dot *pangansap*( $\emptyset$  -*poN-ansap*)  
 bushknife big NOM good COMP IV-TR-scrape  
 do poring.  
 ACC bamboo  
 ‘A big bushknife is what is good to scrape bamboo with.’
- (20) a. *Okon.ko*’ *i-tibas* dot okodou ino dangol ku,  
 do.not IV-slash ACC hard that(NOM) bush.knife 1sg.GEN

opodi dati’.

NVOL-chip PRCL

ponibas( $\emptyset$ -poN-tibas) di wulanut dara.

IV-TR-slash ACC snake FRUST

‘He had already drawn out his bush knife to slash the snake with (but didn’t slash it).’

- (21) a. Okon-ko *i-totok* do tulang ino dangol ku ki.  
do.not IV-chop ACC bone that(NOM) bush.knife 1sg.GEN PRCL  
‘Don’t chop bones with my bush knife, okay?’

- b. Titio peno(po.ino) gampa, ponotok( $\emptyset$ -poN-totok) ku  
give.here PRCL.that(NOM) bush.knife IV-TR-chop 1sg.GEN

diti limbata.

this leech

‘Give that bush knife here, I will chop up this leech with it.’

With *cut* verbs (and with certain other verbs) the bare IV form (*i-ROOT*) indicates that the speaker is adopting a perspective in which the instrument (rather than the patient) is viewed as the affected entity, or the entity being acted upon. I refer to this use of the bare IV form as the AFFECTED INSTRUMENT construction. This is of course a relatively marked perspective; the Affected Instrument form occurs with much lower frequency than the normal IV form ( $\emptyset$ -poN-*ROOT*), even for roots which allow the Affected Instrument usage.

The instrumental alternation is much less productive with most other verb classes. It is systematically impossible with the *break* verbs (22a). Even though most if not all of these roots can occur in the normal Instrumental Voice form illustrated in (22b–c), they do not occur in the Affected Instrument construction. The “bare” IV form is idiosyncratically allowed with a few roots of this class, but gives rise to unpredictable secondary or metaphorical senses like that in (23). These are not Affected Instrument forms.

- (22) a. \**i-babak* (IV-shatter); \**i-putut* (IV-break); \**i-lupi* (IV-fold); \**i-uyas* (IV-pull apart); etc.

- b. Dunsul ot pinangababak(<in> $\emptyset$ -poN-babak) dilot pampang.  
hammer NOM IV-TR-chop that rock

‘It was a hammer that that rock was broken up/shattered with.’

- c. It dunsul ot awasi ponguyas( $\emptyset$ -poN-uyas) di jijing.  
NOM hammer NOM good IV-TR-dismantle ACC zinc  
‘The hammer is what is good for tearing out zinc sheets (off the roof).’

- (23) *I-kinis* ku dikaw it sonsibor dot tanaman nu  
IV-tear 1sg.GEN 2sg NOM one.square COMP plant.DV 2sg.GEN

do paray.

ACC rice

‘I will give you (lit: ‘tear off for you’) a small portion (of the paddy field) for you to plant rice on.’

The instrumental alternation seems (superficially) to be possible with some of the *hit* verbs, as seen in (24), (25) and (26). Notice, however, that the two IV verb forms in these pairs of sentences do not really describe the same type of event. The “instruments” in the (a) examples are not instruments in the normal sense. Note also the difference in the case marking patterns: the patients in (25a) and (26a) are marked for DAT case, rather than the expected ACC seen in (25b) and (26b). The patient in (24a) is totally unspecified, which is not normally possible with that root. Thus strictly speaking, the instrumental alternation is not productive with *hit* verbs either.

- (24) a. Okon.ko’ *i-bobog* ino payung ku tu’,  
do.not IV-beat that(NOM) umbrella 1sg.GEN because  
ara’ag dati’.  
ruined likely  
‘Don’t beat (anything) with my umbrella, it might get broken.’  
(or: ‘Don’t beat my umbrella against anything...’)
- b. Tongo ot *pinomobog*(<in>∅ -poN-bobog) nu dilo’ tasu oy?  
what NOM <PAST>IV-TR-beat 2sg.GEN that dog Q  
‘What did you beat that dog with?’
- (25) a. *N-i-duntung* dialo sid tobon a tonggom yo.  
PST-IV-punch 3sg DAT wall NOM fist 3sg.GEN  
‘He punched his fist against the wall.’
- b. Gibang nopo ot *pongoduntung*(∅ -poN-duntung) ku dialo,  
left only REL IV-TR-punch 1sg.GEN 3sg.ACC  
aba no.  
faint PRCL  
‘Even if I only hit him with my left (hand), he will pass out.’
- (26) a. Matay beno(bo.ino) wulanut kukuyutan nu  
die PRCL.that(NOM) snake holding 2sg.GEN  
ong *i-lapos* sid pampang.  
if IV-whip DAT rock  
‘That snake you are holding will die if you whip it against a rock.’
- b. Iri tikuw ot babanar no ko’ abasag  
this(NOM) tail NOM truly PRCL PRCL strong  
dot *pangalapos*(∅ -poN-lapos) di sada.  
COMP IV-TR-whip ACC fish  
‘It was the tail that was really powerful to strike the fish with.’  
(from a folk-tale about a giant python)

I suggest that these pairs involve a kind of polysemy: certain roots in the *hit* class have secondary senses which describe a particular manner of moving a theme in order to bring it into contact with a surface. These secondary senses pattern very much like the source-theme-goal verbs to which we now turn.

There is one other type of verb for which the alternation between the two IV forms is productive, namely source-theme-goal verbs such as ‘give’, ‘pour’, ‘put’, etc. Further work is needed to clarify how many distinct classes of these verbs are grammatically relevant in Kimaragang, but some examples are provided in (27–29).

- (27) a. Subay.ko *i-suwang* ino paray sid kadut.  
 should IV-enter that(NOM) rice DAT gunnysack  
 ‘You should/must put that rice into a gunnysack.’
- b. Amu kosukup ilo’ weeg dot *ponuwang*( $\emptyset$ -poN-suwang)  
 NEG enough that(NOM) water COMP IV-TR-enter  
 do botung.  
 ACC paddy.field  
 ‘There is not enough water to flood the paddy field with.’
- (28) a. *I-ta’ak* ku iti siin sid tanak ku.  
 IV-give 1sg.GEN this(NOM) money DAT child 1sg.GEN  
 ‘I will give this money to my child.’
- b. Nunu ot *pana’ak*( $\emptyset$ -poN-ta’ak) nu ong orugi ko?  
 what NOM IV-TR-give 2sg.GEN if fined 2sg.NOM  
 ‘What will you give if you have to pay a fine?’
- (29) a. *N-i-tunguw* ku it weeg di sada sid  
 PST-IV-pour 1sg.GEN NOM water GEN fish DAT  
 poonumadan(<DUP>poN-sumad-an) do tasu.  
 HABIT-TR-feed-DV GEN dog  
 ‘I poured the water from (cleaning) the fish into the dog’s feeding dish.’
- b. I weeg sid gilán dñino ot *ponunguw* dino tinorimo.  
 NOM water DAT container that.one NOM IV:TR:pour that cooked.rice  
 ‘The water in that container there is what you should pour on/into the rice you are cooking.’

With verbs of this type, the bare IV form (*i-ROOT*) does not get the Affected Instrument reading. It is used rather to mark a perspective in which the displaced theme (the thing which is transferred or caused to move) is viewed as the affected entity or entity being acted upon. (In Austronesian studies this usage is sometimes referred to as “Conveyance Voice” or “Conveyance Focus”.) The  $\emptyset$ -*poN-ROOT* form used in the (b) examples marks the goal as the affected entity (Kroeger 1996; Kroeger & Johansson 2005). Note that with these source-theme-goal verbs, in contrast to the *cut* verbs, the bare IV form is much more frequent than the  $\emptyset$ -*poN-ROOT* form.

## 6. Accounting for the instrumental alternation

In the previous section it was demonstrated that the instrumental alternation is productive with *cut* verbs but not with *hit* or *break* verbs. Intuitively, it seems likely that this difference is related to the fact that the class of *cut* verbs is in part defined by the use of a sharp instrument. In other words, the use of an instrument is part of the core meaning that all members of this class share in common.

Let us assume that the instrument is part of the systematic meaning (i.e., the event structure) of the *cut* verbs, but not of the other two classes under discussion.<sup>8</sup> This means that both the instrument and the patient (in addition to the agent) are event structure participants, in the sense of RH&L (1998). For the source-theme-goal verbs, it seems natural to assume that both the theme and the goal are event structure participants.

The generalization that emerges, then, is that the instrumental alternation is productive only for verb classes with (at least?) two non-agentive event structure participants. This generalization would be predicted under the following assumptions: (a) the instrumental alternation involves a change in the identity of the affected argument, but no change in the event structure; and (b) affected arguments in general must be event structure participants.

The distribution of the instrumental alternation is strikingly different from that of other morphological operations, such as the morphological causative (*po-*) or benefactive applicative (*-an*). These operations are not sensitive to the kinds of verb class distinctions discussed above. The morphological causative is highly productive, and can be formed from virtually any verbal root. The benefactive construction can be formed from transitive roots of any verb class, as long as the specified action is conventionally understood as a means of obtaining or providing the substance named by the patient phrase.

I suggest that operations of this type are not sensitive to verb class distinctions precisely because they do change the event structure, by adding a participant of the appropriate type (causer or beneficiary). The instrumental alternation, in contrast, does not change the event structure. Speakers have a choice of perspective, that is, the option of expressing either of two arguments as the affected argument, only if the verb's event structure already contains two non-agentive participants. This is possible with *cut* verbs and source-theme-goal verbs, as discussed above. It is not possible with *hit* or *break* verbs, even though such verbs may take instrument arguments, because these instruments are not event structure participants.

## 7. Conclusion

The grammatical criteria used to distinguish the *hit*, *break* and *cut* classes in Kimaragang are summarized in (30). It is striking that the same classes are grammatically relevant in two languages as different from each other as English and Kimaragang. This similarity offers additional support for the existence of strong cross-linguistic principles which govern the relationship between verbal semantics and argument expression.

---

<sup>8</sup> Of course instruments can optionally be expressed with both *hit* and *break* verbs. They are not part of the systematic meaning of these verbs, but they may be part of the idiosyncratic meaning of some roots of the *hit* class; for example, selectional restrictions imposed by specific *hit* verbs may be based on the choice of instrument.

(30) Summary of three verb classes in Kimaragang:

	<i>hit</i> verbs	<i>break</i> verbs	<i>cut</i> verbs
selectional restrictions	instrument	patient	??
causative alternation	no	yes	no
used to deny result	no	yes	few
adversative construction	no	some	no
instrumental alternation	no	no	yes

I have suggested that the instrumental alternation in Kimaragang provides evidence supporting the claim that affected arguments must be event structure participants. As noted above, however, I feel that it is too early to say whether this is a universal principle or a language-specific requirement.

# Identifying non-realized arguments in Vietnamese: a lexical orientation approach to argument structure

**Theresa Hanske**

Department of Linguistics

University of Cologne

50923 Cologne

theresahanske@yahoo.de

For Vietnamese verbs that participate in a transitive / intransitive alternation, I propose a classification according to orientation towards agent and/or patient in their intransitive use. This raises the question whether or not intransitively used verbs in Vietnamese should be regarded as real intransitives where no second argument is present at any level of representation relevant to transitivity. Alternative analyses which assume here transitive uses with zero anaphors in object position are discussed. Following Goldberg (2000, 2005) I argue that in Vietnamese real intransitive use of these verbs obtains with backgrounding of participants when the verbal action is emphasized at the same time.

**Keywords:** verb classes, orientation, transitivity, zero anaphora, backgrounding of participants

## 1 Orientation of verbs in Vietnamese

In Vietnamese, many verbs can be used in a transitive construction with two arguments, a subject and an object, and in an intransitive construction with only one argument, their subject. Depending on lexical information of the verbs which take part in this alternation, the intransitive subjects can be interpreted only as an agent (1) or as a patient (2) or as either an agent or a patient (3).

- (1) a. Con chuột hất trứng trong chảo.  
CL mouse toss egg in pan  
'The mouse is tossing the egg in the pan.'
- b. Hai con hất qua hất lại nhau như kiểu chơi bóng  
two CL toss cross toss come back each other like style play ball  
chơi cầu lông í.  
play badminton PRT  
'The two of them are tossing [a ball] back and forth to each other as if [they were] playing badminton.'

- c. \*Quả trứng hất.  
 CL egg toss  
 intended: the egg is being tossed.
- (2) a. Anh ấy treo bức tranh.  
 he hang CL picture  
 'He hung up the picture.'
- b. Bức tranh treo trên tường.  
 CL picture hang on wall  
 'The picture hangs on the wall.'
- c. \*Anh ấy treo.  
 he hang  
 intended: he hung up [something].
- (3) a. Chị ấy vẽ một bức tranh.  
 she paint one CL picture  
 'She is painting a picture.'
- b. Chàng trai vẽ rất đẹp.  
 boy paint very beautiful  
 'The boy is painting very beautifully.'
- c. Bức tranh vẽ rất đẹp.  
 CL picture paint very beautiful  
 'The picture has been painted very beautifully.'

Transitive-/intransitive-alternating verbs can be classified according to whether their intransitive subjects bear the same thematic role as the subject, the object or both in the transitive use of the respective verbs. The three verb classes differ in whether the verbs describe the state of affairs from the perspective of the agent and/or the patient. A verb's potential to perspectivize the agent, the patient or both has also been called orientation in the literature. In this sense, verbs that are oriented towards an agent are a-oriented, those which are oriented towards a patient are o-oriented. Verbs that are oriented towards either an agent or a patient are labile in orientation, having an a-reading and an o-reading respectively (cf. Drossard 1998, Serzisko 1991).

Relating the argument realization of intransitive verbs to the argument realization patterns of transitive verbs is widely known as alignment. However, as opposed to orientation, alignment patterns are mostly stated in terms of morphosyntactic alignment (cf. Dixon 1979, Comrie 1978). Although mere semantic alignment, the intransitive subject's thematic role in relation to the role of the transitive subject and/or object, is

briefly discussed in Dixon 1979, he is mainly concerned with morphosyntactic alignment to cover the differences between accusative, ergative and active languages.

In the literature, a-oriented verbs, with an intransitive agent-subject, are often referred to as unergative verbs as opposed to unaccusative verbs, which correspond to o-oriented verbs in my terminology, with an intransitive patient-subject. The unergative/unaccusative distinction has been claimed to manifest itself independently in the different behavior of the two classes. Therefore it has been suggested that the patient-subjects of unaccusatives are underlying objects (for an overview cf. Burzio 1986, Levin/Rappaport 1989, Perlmutter 1978). In Vietnamese, as will be shown, their morphosyntactic behavior does not reflect their difference in subject's thematic role selection in any consistent way.

For Mandarin it has been claimed that unaccusatives can be distinguished from unergatives, because only unaccusative verbs permit their sole argument to appear preverbally as well as postverbally (cf. Polley 2008). Whereas a subclass of o-oriented verbs shows the same word order variation with the intransitive subject in Vietnamese as well, this is not the case for all o-oriented verbs. Only o-oriented verbs which do not directly<sup>1</sup> take part in the transitive-/intransitive alternation allow their sole argument to occur in preverbal as well as in postverbal position (cf. (4)). For those o-oriented verbs, however, which can be used transitively and intransitively, the intransitive subject has to be in preverbal position. With them, an argument occurring in the postverbal position qualifies as the object of the verb in its transitive use (cf. (5)).

- (4) a. Đê vỡ.  
dike break  
'The dike broke.' (Emeneau 1951:52)
- b. \*Nước vỡ đê.  
water break dike  
intended: The water broke the dike.
- c. Vỡ đê.  
break dike  
'The dike broke' (Emeneau 1951:52)

- (5) a. Anh ấy treo bức tranh.  
he hang CL picture  
'He hung up the picture.'

---

1 These verbs cannot be used transitively. However, they are included in the class of o-oriented verbs because they can be related to a causative, that is transitive counterpart which can be a different inherently causative verb or a causative construction with *làm* 'make'.

- b. Bức tranh treo trên tường.  
 CL picture hang on wall  
 'The picture hung on the wall.'
- c. treo bức tranh trên tường.  
 hang CL picture on wall  
 '[he] hung the picture on the wall.'  
 '\*the picture hung on the wall.'

A-oriented and o-oriented verbs (except for the above mentioned subclass) exhibit only lability in transitivity, whereas orientation labile verbs show two kinds of lability: they also take part in transitive-/intransitive alternation and are, thus, labile in transitivity. Unlike with a-orientation and o-orientation, when used intransitively, subjects of labile verbs are not determined either for agent or patient interpretation, but can show both interpretations and therefore are labile in this respect, too.

## 2 Orientation and the transitive / intransitive distinction

With the orientation approach on Vietnamese verbs that I propose, the classification of verbs depends on the possibility to distinguish transitive and intransitive uses of verbs. In Vietnamese discourse, however, non-realized arguments are prevalent. Often these arguments can be reconstructed from context and can be termed as 'understood' in this sense. This raises the problem whether the intransitive uses of verbs that also can appear in a transitive constructions are real intransitive uses or, in fact, transitive uses with empty arguments. In the following I will confine the discussion to the question whether or not there should be assumed non-realized second arguments to be present with the a-readings of orientation labile verbs. Therefore, with these verbs two structures are under consideration, a transitive argument structure (the present but non-realized second argument is indicated by  $\emptyset$ ) in (6) and a real intransitive structure where no second argument is assumed on any level of representation relevant for argument structure in (7).

- |     |  |     |  |
|-----|--|-----|--|
| (6) | Chàng trai vẽ $\emptyset$ rất đẹp.         | (7) | Chàng trai vẽ rất đẹp.                     |
|     | boy            paint        very beautiful |     | boy            paint        very beautiful |

In Vietnamese, non-realized subjects as well as non-realized objects occur, as the following part from a retold narrative of a cartoon film illustrates:

(8) [The mouse is making an omelette and is trying to turn it by tossing it up in the pan...]

Cũng vẫn Ø<sub>i</sub> tung Ø<sub>j</sub> lên nhưng mà vẫn Ø<sub>i</sub> tung Ø<sub>j</sub> ra ngoài đất  
also still toss go up but still toss go out earth  
mặt buồn rười rượi rồi.  
face sad very then

'[The mouse] is still tossing [the egg] up but [it] throws [the egg] out and onto the ground and looks sad.

In example (8), none of the relevant discourse entities, the mouse and the egg, is expressed overtly but since they are well established discourse referents, they are understood in the respective argument slots of the verbs. In contrast to English equi-NP deletion, in Vietnamese the antecedents need not to appear in the immediately preceding clause. Therefore it has been claimed that what is critical for a discourse entity to be non-realized is its status as a discourse topic (cf. Duffield 1998, Butt&King 1996, for Chinese see Huang 1984).

Even though often arguments are not overtly expressed in languages like Vietnamese and Chinese, they are commonly assumed to be present at some level of representation, since they are understood from context and interpreted as salient discourse referents. In the literature they have been described as zero anaphors, the term I use in the following, as well as zero or empty pronouns, zero topics or anaphoric zero (cf. Li & Thompson 1979, Rosén 1998, Huang 1984, Givón 2001). The respective verbs are commonly considered to be used transitively.

However, it is a moot point if zero anaphors should be assumed in any case where a verb shows up with less arguments than it could or actually does in other instances of occurrence. In principle this concerns non-realized subjects and objects in Vietnamese likewise, however, the actual question raised in this paper is whether the a-readings of orientation labile verbs are indeed intransitive uses or in fact transitive uses with a non-realized but present object. Therefore, I am going to confine my discussion on non-realized or non-present objects only.

Contrasting the two structures proposed in (6) and (7) leads to two hypotheses concerning the argument structure of those syntactically intransitive uses of verbs which also can be used with a transitive argument frame:

- I. All-transitive-hypothesis: Intransitive uses of verbs which also can appear with two (or more) overt arguments are in fact transitive uses with non-realized arguments in the respective argument slots. Syntactic non-realization of their arguments has no impact on other levels of linguistic representation relevant for transitivity.
- II. Some-intransitive-hypothesis: Some of the intransitive uses of verbs which also can appear transitively are real intransitives, where no argument is assumed at any other level of linguistic representation regarded as relevant for transitivity.

Systematic optionality of arguments always poses a problem on the establishment of the transitive / intransitive distinction, because it rules out the obligatoriness criterium of transitivity. This is well known from the ongoing debate on facultative objects (also called inherent, unspecified, unexpressed or implicit objects) in English and similar languages. Fakultativity of objects in English is often presented as applying only to certain verbs as opposed to others, or even most of the transitive verbs where obligatoriness of their objects has been claimed. True or not for English, the problem of determining transitive or intransitive uses is intensified considerably in languages like Vietnamese, since they allow objects to be left out for reference tracking purposes with most verbs. This poses the question on which basis transitive vs intransitive use can be distinguished in languages that employ zero anaphora systematically.

### 3 Transitive or intransitive in Vietnamese

In the literature the notion of "understood" or "expected" arguments is adduced when it comes to the question on which basis a zero anaphor can be assumed (cf. Li&Thompson 1979, Rosén 1996, Mosel 1991). Although the concept remains rather vague, two positions can be singled out:

- I. Zero anaphors are regarded as empty argument positions, irrespectively of their interpretation as definite or indefinite. They are understood, because they are lexically or semantically entailed.
- II. Only zero anaphors are taken into consideration which get a definite interpretation since they corefer to some antecedent's referent. They are regarded as arguments. Indefinite interpretations of non-realized arguments as well as the question whether or not these are present in the verbs' argument structures at all are factored out. Definite zero anaphors are understood, because of their coreference relationship to some salient antecedent or discourse topic.

Both positions on zero anaphora combine well with the all-transitive-hypothesis, but they imply certain requirements that are hardly met by Vietnamese. While position I requires that argument slots of verbs can be specified independently of definite or indefinite interpretations of the argument referents, position II depends on the possibility to determine whether real coreference to an antecedent is existent which, in turn, qualifies for an argument position.

I have already pointed out that the obligatoriness criterion cannot be resorted to in Vietnamese and similar languages. However, in order to identify a verb's number of arguments, a relation between the transitive use of a verb where its arguments are expressed overtly and the use where some or all of these arguments do not show up has been postulated. The number of arguments is claimed to be the same in both uses of the verb. In generative works this is ensured by the Projection Principle. Even though coming from a functional perspective, Li/Thompson's (1979:32) heuristic procedure for

identifying zero anaphors in Mandarin is also based on an assumed relationship between verb uses with and without overt arguments.

The term ZERO-PRONOUN [zero anaphor, TH] will be used to refer to the "hole" where an NP is understood and would have to be present in the fully specified version of the sentence.

Li/Thompson suppose arguments to be semantically required and lexically governed by the verb (that is, understood) as well as syntactically obligatory in an elaborated version of the sentences. It is questionable, however, whether a 'fully specified version of the sentence' can be determined in Vietnamese. But even if so, arguments are not obligatory in Vietnamese, therefore, they neither are obligatory in any elaborated version. Yet, the procedure fails to single out necessary arguments when overtly expressed, because it fails to distinguish arguments from adjuncts. This is illustrated by the examples in (9).

- (9) a. Bạn em tặng em quà này sinh nhật này.  
friend I give I present this birthday this  
'My friend gave me this present for this (year's) birthday.'
- b. Cậu cho em năm xu một con.  
you give I five sous one CL  
'Give me five sous for one (crab).' (Emeneau 1951:48)
- c. Em khóc anh nước mắt giàn giụa.  
I cry you tear overflow profusely  
'I am crying for you with tears overflowing profusely.'

I argue that the number of lexical arguments cannot be determined by analogy to the number of NPs with which the verb occurs in another kind of construction. Purpose NPs might be regarded as bad candidates for lexically governed arguments of the verb due to their thematic role. However, with respect to obligatoriness in the elaborated version of the sentence, they do not differ from the other NPs. They are not less obligatory, but none of the NPs is obligatory. Relating fully specified versions and, say, truncated versions does not help to save the obligatoriness criterion, since there is no such a thing as 'would have to be present' in Vietnamese. Whether or not a purpose for these verbs might be 'understood' in cases where it is not overtly expressed, remains open as well. This procedure does not equip us with means to distinguish 'understood' due to argument structure, especially lexical argument structure, as opposed to inference.

While zero anaphors would require to identify argument slots independently, it is exactly prevalent use of zero anaphors which renders the identification of argument structures highly problematic. Yet, it lends itself to examine whether the characteristics of so called definite zero anaphors to establish a coreference link to an antecedent provides a way out of this dilemma. If it is accepted that a coreference relation between a definite zero anaphor and its antecedent suffices to justify the assumption of an argument slot, this could possibly be exploited for determining argument structures. In this case, 'understood' is a heuristics for zero anaphor in itself that applies on the

pragmatic level and therefore, at first, is outside the realm of argument structure proper. However, most approaches would assume a lexical argument slot here.

In the following I am going to argue, however, that coreference of definite zero anaphors cannot be used for distinguishing transitive and intransitive argument structures for the verbs in question either. Combining position II with the all-transitive-hypothesis, it could be hypothesized that there is no transitive / intransitive lability of the type AVO/AV at all in Vietnamese. Hereafter, all these syntactically intransitive uses are in fact transitive structures with AVØ, where Ø is a definite zero anaphor referring to a linguistic antecedent or, as proposed in most approaches, a topical discourse referent. This seems to be evidenced by the fact that in isolated sentences, where no antecedent is provided, the syntactically intransitive use is blocked (cf. (10b)).

- (10) a. Cô ấy vẽ một bức tranh.  
she paint one CL picture  
'She is painting a picture.'
- b. \* cô ấy vẽ.  
she paint  
'She is painting.'

Furthermore, the object is overtly expressed as a bare noun without classifier and determiner, when no anaphoric relation is intended as it is the case with indefinite interpretations of the objects in (11).

- (11) a. ăn cơm 'to eat (rice)'  
eat rice
- b. đọc sách 'to read (a book)'  
read book
- c. vẽ tranh 'to paint (pictures)'  
paint picture

Contrasting these argument realization patterns with their English translation equivalents suggests that Vietnamese exhibits a mirror-reverted system of the English patterns. In Vietnamese, indefinite objects show up syntactically because they do not bear anaphoric relations to topical discourse referents, whereas anaphors that refer to topical discourse referents can be left out. English realization patterns work the other way round. Here non-topical objects can be suppressed under the right conditions (cf. Goldberg 2005, and §4 below) and topical ones appear overtly.

The examples in (12), however, reveal that syntactic non-realization and discourse topic status do not correlate as strongly as suggested by example (10) and

(11). Verbs can be used syntactically intransitively, even though, there is no previously established discourse topic that could be understood in the second argument slot.

- (12) a. Cô ấy luôn luôn vẽ.  
she always paint.  
'She always paints.'
- b. Cô ấy thích vẽ.  
she like paint  
'She likes to paint.'
- c. Cô ấy vẽ rất đẹp.  
she paint very beautiful  
'She is painting very beautifully.'
- d. Cô ấy lăn đi lăn lại  
she roll go roll come back  
'She is rolling [something] back and forth.'

The examples in (12) comprise three different linguistic contexts, in (12a) the verb is in a habitual context marked as such through the adverbial *luôn luôn* 'always' and in (12b) the verb occurs in a modifying serial verb construction expressing an attitude of the subject. This reading can be regarded as a subtype of habitual contexts. In (12c) the verbal action is adverbially modified, whereas in (12d) the serial verb construction indicates the repetitive manner of the action. In these contexts intransitive uses of verbs are frequent without a specific interpretation for second participant in the state of affairs.

Additionally, bare nouns in object position do not always get an unspecific interpretation, but they can corefer to an established discourse referent (13a). Depending on context, they can be used as non-discourse referents or as discourse referents which is demonstrated by the anaphor-test in (13b) and (13c), respectively.

- (13) a. Tôi muốn cho em mượn một quyển sách<sub>i</sub> vì vậy em có thể đọc sách<sub>i</sub>.  
I want give you borrow one CL book so that you can read book  
'I want to lend you a book so that you can read it.'
- b. Luôn luôn khi tôi đi làm về, nghỉ một chút. Tôi đọc sách<sub>i</sub>.  
always when I go make come back rest one little I read book  
\*Nó<sub>i</sub> rất hay.  
(s)he/ it very good  
'Always when I come home from work, I rest a little bit. I read (a book). It is very good.'

- c. Cô ấy đọc sách<sub>i</sub>. Nó<sub>i</sub> rất hay.  
 she read book he/she/it very good  
 'She is reading a book. It is very good.'

Any attempt to identify a verb's argument slots by the anaphoric relationship which they might bear, even though, they are not overtly filled, requires that the existence of an anaphoric relationship can be unambiguously determined. On the one hand, zero anaphors exhibit, however, a high degree of freedom in their antecedent selection. The difficulties to limit down the domain of coreference for zero anaphors are reflected by the range of domains in which the antecedents of zero anaphors are found as discussed in the literature (Huang 1984, Rosén 1996, 1998, Givón 2001, Ariel 1990, Butt & King 1996)

On the other hand, zero anaphors are also allowed for associative reference<sup>2</sup> in Vietnamese. This especially casts doubts whether any kind of coreference is a sufficient condition for assuming an argument slot.

The various approaches on zero anaphora resolution in Vietnamese and languages alike agree on the fact that the distribution of zero anaphors is far less restricted in these languages than in languages like English. Zero anaphors occur regularly in subject and object position (cf. also (8)) and the domain of their coreference is not at all limited to the immediately preceding clauses. Furthermore, their reference may be ambiguous including even associative reference, as (14) illustrates.

- (14) a. Có một con voi và một đĩa nhạc cổ ngày xưa ấy,  
 There is one CL elephant and one disk music antique long ago  
 một cái máy nghe nhạc.  
 one CL player  
 'There is an elephant and an old record [and] a record player.'
- b. Nó đặt cái đĩa vào đấy thế nhưng mà cái đĩa không phát ra tiếng nhạc.  
 it put CL disk enter there but CL disk not emit sound music  
 'It is putting the disk on there, but the disk is not making any music.'
- c. Ø Phát ra tiếng động rất là lạ và nó đi quanh xem xét xem xét.  
 emit sound noise very be strange and it go around look examine look examine  
 '[It] is making a very strange noise and it is going around examining (why).'

---

2 Associative reference is here understood as an extension of Hawkins's concept of associative anaphor, which originally has only been used for anaphoric NPs which indirectly refer to their antecedent by an associative link (cf. Hawkins 1978, Schwarz 1997, and for application of the term to pronominal anaphors Behrens/Sasse (2003:54ff)).

d. Nó lại cho Ø xuống nhưng nó vẫn không chạy.  
 it again put go down but it still not run

'It (the elephant) is again putting [it] down, but it (the player) is still not working.'

Example (14), again a retold cartoon film, shows with (14d) that zero anaphors do not necessarily refer to antecedents in the immediately preceding clause. Yet, more important here, there are actually two possible referents for the zero anaphor in (14d), the record and the tone arm of the record player. The record is a well established discourse referent, and it is the record which most of my informants understood when listening to the narration. However, from the film it becomes clear, that the speaker must have had in mind the tone arm. This referent is only indirectly introduced by associative part-whole relationship with the 'record player' in (14a). The record player, though, can be assumed to be a discourse topic.

If the hypothesis is correct that any intransitive use of a verb which also can be used transitively involves a definite zero anaphor in object position, one expects that an intransitive use of these verbs is only felicitous if an antecedent is available. Consequently, it would also be expected that if there is a potential antecedent a zero anaphor must corefer with it. Of special interest here is how intransitive uses are distributed in contexts where a switch from episodic to habitual reading is intended. Episodic readings have an affinity with a specific interpretation of their objects, whereas habitual readings often (but not necessarily) imply an unspecific interpretation of their objects. In most cases, thus, a switch from episodic to habitual reading also implies a switch from a specific reading to an unspecific reading of the objects. The assumption that the respective intransitive uses involve definite zero anaphora which must corefer with an antecedent predicts that zero anaphors do not occur where episodic reading switches to habitual reading. A comparison of examples (15) and (16) conduces to explore further the relationship between episodic vs habitual reading, intransitive use and coreference.

(15) a. và con chuột cầm một quả bóng bóng chuyền đến và rủ con voi  
 and CL mouse hold one CL ball volleyball arrive and invite CL elephant  
 chơi bóng chuyền.  
 play volleyball

b. Đầu tiên thì đá qua đá lại, không phải là đá mà  
 first then kick cross kick come back not be kick but  
 nó con voi dùng vòi chuột thì nó đẩy được qua đúng  
 it CL elephant use trunk mouse TOP it push be successful cross correct  
 không nó tung được.  
 not it throw can

'and the mouse, holding a ball, a volleyball, came and invited the elephant to play volleyball. First, [they] kicked [it] back and forth, [they] didn't kick [it] but

the elephant used its trunk [and] the mouse, in fact, pushed [it] across not being able to throw [it].'

(16) a. và con chuột cầm một quả bóng bóng chuyền đến và rủ con voi  
and CL mouse hold one CL ball volleyball arrive and invite CL elephant  
chơi bóng chuyền  
play volleyball

b. và chúng thường chơi bóng chuyền như thế này đá qua đá lại,  
and they usual play volleyball like this kick cross kick come back

không phải là đá mà nó con voi dùng vòi chuột thì nó đẩy  
not be kick but it CL elephant use trunk mouse TOP it push

được qua đúng không nó tung được.  
be successful cross correct not it throw can

'and the mouse, holding a ball, a volleyball, came and invited the elephant to play volleyball and they usually play volleyball like this: [they] kick back and forth, not [actually] kicking but the elephant uses its trunk and the mouse, in fact, pushes [something] across not being able to throw.'

In both examples, the a-sentence is the same and has an episodic reading. In (15b) the zero anaphors must indeed be interpreted strictly coreferential and the reading for (15b) is only episodic. A habitual reading, where the manner of the actions is characteristic of the mouse and the elephant, is not available here. In (16b), the habitual reading is made explicit by *chúng thường chơi bóng chuyền như thế này* 'they usually play volleyball like this'. The respective verbs are used intransitively as well, but are interpreted here as habitual or even characteristic of the mouse and the elephant. From the perspective of the state of affairs, the participant being kicked etc. is likely to change over the single instances of the habitual actions, in that it remains unspecific and even unspecified. The afore mentioned '(volley-) ball' may possibly be included in the class of these participants, but in (16b), it does not function as a linguistic antecedent.

Example (16) disproves the hypothesis for Vietnamese that AVO/AV-lability excludes a real intransitive use, so that AV, in fact, is AVØ with a definite zero anaphor occupying the second argument slot. Assuming that in these cases there is always a definite zero anaphor overgeneralizes, since these intransitively used verbs do not always imply coreference (cf. (16b), see also (13) and its interpretations, as well as the associative anaphoric relation in (14)).

#### 4 Intransitive use as backgrounding of participants

Goldberg (2000, 2005) proposes an intransitive construction for certain cases of the syntactically intransitive uses of verbs that traditionally are regarded as lexically transitive verbs in English. The following examples (cf. Goldberg 2005:29) illustrate the phenomenon:

- (17) a. The chef-in-training chopped and diced all afternoon.  
b. Tigers only kill at night.  
c. Pat gave and gave, but Chris just took and took.  
d. These revolutionary new brooms sweep cleaner than ever.

According to Goldberg, this kind of intransitive construction requires (or has the meaning, in her approach) that the verbal action is emphasized whereas at the same time the second participant in the state of affairs is discourse pragmatically backgrounded. The construction applies only when the backgrounded participant is non-topical and non-focal, that is when it is a non-discourse referent. Goldberg's evidence conveys mainly types of examples that have been discussed vividly in the literature for the relationship between transitivity and referential status of arguments as habituals, verbs with unspecified objects and generic sentences. Beside others, adverbs and intensifying of the action by reduplication of the verb often fulfill the function of emphasizing.

Omission of the patient argument is possible when the patient argument is construed to be deemphasized in the discourse vis à vis the action. That is, omission is possible when the patient argument is not *topical* (or *focal*) in the discourse, and the action is particularly *emphasized* (via repetition, strong affective stance, contrastive focus, etc.). (Goldberg 2000, emphasis original)

In Vietnamese, participants can also be left unspecific and unexpressed exactly in constructions where the verbal action is emphasized, which is exemplified in (12) and (16). This is what I regard as real intransitive uses where no second argument slot should be assumed.

The means employed in order to emphasize the action have in common that they explicitly express or contrast the manner or attitude in which the verbal action is conducted, as the following list illustrates:

- i. Repetitive Serial Verb Construction:  $V_1$  đi / qua  $V_1$  lại (cf. (12d), (16b))
- ii. Attitude Serial Verb Construction: thích V (cf. (12b)).
- iii. Adverbial modification (manner):  $V_1$  rất  $V_2$  (cf. (12c))
- iv. Explicit habitual adverbials: luôn luôn / thường V (cf. (12a), (16b))
- v. Contrast: không phải là  $V_1$  mà (là)  $V_2$  (cf. (16b))

Vietnamese is quite similar to English in allowing participants to be backgrounded if the verbal action is emphasized, yet, it differs from English in an important aspect. Contrary to English, the syntactically intransitive construction with emphasis on the verbal action does not unambiguously entail backgrounding of the second participant. In Vietnamese, a reading as definite zero anaphor, where an empty second argument can be assumed, is still possible in many cases. However, it is exactly in these constructions where the indefinite interpretations of second participants and, hence, real intransitive uses of verbs are found.

These kinds of intransitive constructions work differently in English and Vietnamese. In English, there is an interaction between syntactic non-realization of the object and the reading of the predicate which actually favors backgrounding of participants. This is widely known with some inherent object verbs that receive a professional reading when used habitually (e.g. *Mary writes*. 'Mary is an author.'). In Vietnamese, due to definite zero anaphora as a reference tracking mechanism, syntactically intransitive use per se does not influence the reading of the predicate with respect to episodic or habitual interpretation. If not indicated explicitly, the sentence retains its episodic reading (compare the respective contrastive topics *không phải là đá Ø<sub>volleyball</sub> mà...* in (15b) with *không phải là đá mà...* in (16b), where a habitual reading was made explicit in the preceding context). It is habitual adverbials as well as other means of emphasizing the verbal action that enable backgrounding of participants.

Furthermore, the different means to indicate emphasis of the verbal action seem to favor backgrounding of participants to various extent. Repetitive serial verb construction (cf. (18a) vs (18b)) and adverbial modification (cf. (18c) vs (18d)) render unacceptable intransitive uses in isolated sentences acceptable, but are ambiguous between a definite zero anaphor or backgrounded participant reading.

- (18) a. \*Cô ấy lăn.  
           she   roll  
           'She is rolling.'
- b. Cô ấy lăn đi lăn lại.  
           she   roll go roll come back  
           'She is rolling (it/something) back and forth.'
- c. \*Cô ấy viết.  
           she   write  
           'She is writing.'
- d. Cô ấy viết nhanh.  
           she   write fast  
           'She is writing (it/something) fast.'

Habituals and serial verb constructions with *thích* 'like' obviously privilege a backgrounded reading of the respective participants. In that, Vietnamese is consistent

with cross-linguistic tendencies concerning the connection between backgrounding and predicate type. Cross-linguistically, certain predicate types are more likely to allow backgrounding of participants. Behrens (2007) provides the following hierarchy of likelihood of predicate types for acceptance of an impersonal reading with reciprocal constructions, that is also a construction where the second participant is backgrounded.

Predicate Type Hierarchy (Behrens 2007:398)

Particular Telic Events > Particular Atelic Events > Habitual Events > Generic Characterizations

Backgrounding may be regarded as a pragmatic strategy with or without any impact on the transitivity of the verbs. Which position is taken in that matter depends on the question which notion of "argument" one assumes to be relevant for transitivity. Argumenthood manifests itself on different levels of representation, as lexical arguments, semantic arguments, referential and syntactically manipulable arguments and syntactic arguments.

Whether argumenthood on the different levels is independent or being an argument on one level also entails being an argument on the other levels has been vividly debated in the literature and the various approaches come to quite different ends. For Vietnamese, I propose that it is argumenthood in the sense of referential and syntactically manipulable arguments which is crucial for transitivity. Definite zero anaphors are arguments, because they are referential and syntactically manipulable, backgrounded participants, however, are not assigned argument status.

## 5 Conclusion

In this article I have proposed a classification of verbs according to orientation in Vietnamese, as a-oriented, o-oriented and orientation labile. The three verb classes differ whether the state of affairs is described from the perspective of the agent and/or patient in their intransitive uses. In that, the classified verbs are assumed to exhibit also a transitive / intransitive lability. Given prevalent use of zero anaphora in Vietnamese, the question is raised whether real intransitive uses in the a-reading of orientation labile verbs can be justified or whether they should, in fact, be regarded as transitive uses with zero anaphors in object position. I advocate an analysis of the intransitive uses as real intransitives. It has been shown that determining the number of arguments a verb provides fails if it resorts either to the obligatoriness criterion or to definite coreference. I have argued for a real intransitive use when the second participant is backgrounded with the verbal action simultaneously being emphasized (cf. Goldberg 2000, 2005). It is assumed that backgrounded participants, as opposed to zero anaphors, are not referential and syntactically manipulable and therefore, do not receive argument status in any sense that is relevant for transitivity in Vietnamese.

## **Résumé**

La présente étude se fixe comme objectif de proposer une méthode de description des verbes supports dans un dictionnaire actif qui permettrait de mettre en évidence leur sens grammatical et par conséquent de rendre explicite le sens des phrases qu'ils composent avec un nom prédicatif. Pour cela, nous mettons tout d'abord en évidence les problèmes qui se posent lors de la description du sens grammatical des verbes supports. Nous révélons ainsi que différentes fonctions sémantiques sont assumées par les verbes supports et qu'elles peuvent d'ailleurs être assumées par un seul verbe support morphologiquement identique ; ce qui entraîne la difficulté d'identifier la fonction sémantique des verbes supports et aussi celle de décrire leurs sens grammaticaux de façon exacte et adéquate. En tenant compte de ces problèmes, nous proposons enfin une méthode de description qui consiste à décrire le sens grammatical des verbes supports en fonction du sens de la phrase qu'ils composent avec un nom prédicatif et de discriminer préalablement les sens du nom prédicatif, eux aussi en fonction du sens de la phrase tout entière. Et cela en montrant son intérêt avec un exemple de description dans un dictionnaire actif.

**Mots-clés :** verbe support, sens grammatical, nom prédicatif, structure argumentale, description des verbes supports, dictionnaire actif.

## **1. Introduction**

La présente étude se fixe comme objectif de proposer une méthode de description des verbes supports dans un dictionnaire actif qui permettrait de mettre en évidence leur sens grammatical et par conséquent de rendre explicite le sens des phrases qu'ils composent avec un nom prédicatif. Nous entendons par sens grammatical les

informations que les verbes supports véhiculent selon leurs fonctions sémantiques : celles concernant le temps, l'aspect, la voix, le factitif, le registre, etc.

Suite aux travaux menés dans le cadre du lexique-grammaire ainsi que des classes d'objets, il a bien été montré que de nombreux verbes fonctionnent comme des verbes supports et que leur fonction sémantique varie selon les noms prédicatifs avec lesquels ils se combinent pour les « actualiser » ou « conjuguer ». Ainsi, nous distinguons actuellement divers types de verbes supports à une différence terminologique près : verbes supports standard (ou de base), verbes supports stylistiques (ou variantes lexicales), verbes supports aspectuels, verbes supports intensifs, verbes supports de conversion, verbes supports causatifs, verbes supports conjonctifs, verbes supports événementiels, verbes supports honorifiques, etc.<sup>1</sup>

**Table 1.** Exemples de divers types de verbes supports

- Verbes supports standard (ou de base)
  - Npr-*eul hada* (=: faire Npr)  
Npr : *yeohaeng*(voyage) ⇨ [=: faire un voyage]
  - Npr-*eul juda* (=: donner Npr)  
Npr : *doum*(aide) ⇨ [=: donner une aide à]
  - Npr-*eul naerida* (=: baisser Npr)  
Npr : *gyeolron*(conclusion) ⇨ [=: tirer une conclusion]
- Verbes supports aspectuels
  - Npr-*eul peobusda* (=: verser sur)  
Npr : *yok*(injurer) ⇨ [=: lancer des injures/accabler d'injures]
  - Npr-*eul ilsamda* (=: s'adonner)  
Npr : *dodukjil*(vol) ⇨ [=: s'adonner au vol]
- Verbes supports de conversion
  - Npr-*eul batda* (=: recevoir)  
Npr : *gyeong*(avertissement) ⇨ [=: recevoir un avertissement]

<sup>1</sup> Voir entre autres Vivès, R. (1993) ; Gross, G. (1996) ; Gross, M. (1998) ; Lee, S.-H. (2001).

- Npr-*eul danghada* (=: subir)  
Npr : *moyok*(humiliation) ⇨ [=: subir une humiliation]
- Npr-*eul sada* (=: encourir, s'attirer, attirer)  
Npr : *ohae*(soupçon) ⇨ [=: attirer les soupçons]
- Verbes supports honorifiques
  - Npr-*eul deurida* (=: donner *honorifique*)  
Npr : *gamsa*(remerciement) ⇨ [=: témoigner de la reconnaissance]
  - Npr-*eul olida* (=: adresser *honorifique*)  
Npr : *malsseum*(parole) ⇨ [=: adresser la parole]
- Verbes supports causatifs
  - Npr-*eul sikida* (=: faire *causatif*)  
Npr : *haego*(renvoi) ⇨ [=: donner son congé]
  - Npr-*eul juda* (=: donner *causatif*)  
Npr : *yonggi*(courage) ⇨ [=: donner du courage]

Cette diversité des verbes supports entraîne des difficultés dans la description lexicographique, notamment les deux difficultés suivantes : difficulté à identifier le sens grammatical des verbes supports et difficulté à le décrire de façon systématique et adéquate dans un dictionnaire. Dans ce qui suit, nous allons mettre en évidence ces difficultés et proposer une méthode de description lexicographique qui permettrait de résoudre ces problèmes.

## 2. Les différents sens grammaticaux des verbes supports

### 2.1. Verbe support à plusieurs fonctions sémantiques

La difficulté à identifier le sens grammatical des verbes supports est étroitement liée aux caractéristiques des combinaisons des verbes supports avec les noms prédicatifs. En fait, un verbe support morphologiquement identique peut avoir différentes fonctions

sémantiques selon les noms prédicatifs avec lesquels il se combine.<sup>2</sup> A titre d'exemple, les verbes supports *juda*(donner) et *sikida*(faire) peuvent assumer différentes fonctions sémantiques. Ils fonctionnent tantôt comme verbes supports standard, tantôt comme verbes supports causatifs :

- (1) a. *Insu-ga Minu-ege doum-eul ju-eot-da.*  
 Insu-Nom Minu-Dat aide-Acc donner-Pas-Déc  
 [= : *Insu a apporté son aide à Minu.*]
- b. *Geu sosik-I Mina-ege yonggi-reul ju-eot-da.*  
 CE nouvelle-Nom Mina-Dat courage-Acc donner-Pas-Déc  
 [= : *Cette nouvelle a donné du courage à Mina.*]

- (2) a. *Sajang-i Minu-reul haego-reul siki-eot-da.*  
 patron-Nom Minu-Acc licenciement-Acc faire-Pas-Déc  
 [= : *Le patron a licencié Minu.*]
- b. *Minu-ga Insu-reul gongbu-reul siki-eot-da.*  
 Minu-Nom Insu-Acc études-Acc donner-Pas-Déc  
 [= : *Minu a fait faire des études à Insu.*]

Comme on le voit dans les exemples en (1), le seul verbe *juda*(donner) fonctionne avec le nom *doum*(aide) comme verbe support standard et aussi comme support causatif en se combinant avec le nom *yonggi*(courage). Il en est même pour le verbe *sikida*(faire) en (2) qui peut fonctionner respectivement comme support standard et comme support causatif selon qu'il se combine avec les noms *haego*(licenciement) et *gongbu*(études).

Le cas est identique pour le verbe *boda*(= : *voir* au sens littéral) qui s'analyse comme ayant deux fonctions : celle de support standard et celle de support de conversion. En voici un exemple :

- (3) a. *Insu-ga eoje buleo siheom-eul bo-at-da.*

---

<sup>2</sup> Nous nous limitons ici à parler des verbes supports ayant diverses fonctions sémantiques et nous notons simplement qu'un verbe morphologiquement identique comme par exemple *donner* peut fonctionner tantôt comme verbe prédicatif (*Max a donné une rose à Léa*), tantôt comme verbe support (*Max a donné une aide à Léa. / Max a apporté son aide à Léa.*).

Insu-Nom hier examen de français-Acc voir-Pas-Déc

[= : *Insu a passé un examen de français hier.*]

b. *Mina-ga ibeon taepung-e pihae-reul bo-at-da.*

Mina-Nom CE typhon-Obl dégâts-Acc voir-Pas-Déc

[= : *Mina a subi des dégâts à cause du typhon.*]

Nous voyons dans les exemples en (3) que le verbe *boda*(voir) « se comporte » dans sa fonction de support standard lorsqu’il se combine avec le nom prédicatif *buleo siheom*(examen de français), alors qu’il se montre avec le nom *pihae*(dégâts) dans sa fonction de support de conversion qui véhicule un sens passif.

Ainsi, les verbes supports peuvent avoir différentes fonctions sémantiques selon les noms prédicatifs avec lesquels ils se combinent. C’est de là que découle la difficulté d’identifier la fonction sémantique des verbes supports.

## 2.2. Difficulté à identifier la fonction sémantique

Nous venons de voir qu’un verbe support morphologiquement identique peut avoir différentes fonctions sémantiques selon les noms prédicatifs avec lesquels il se combine. Cela dit, il faut aussi noter qu’il n’est pas toujours évident d’identifier la fonction sémantique des verbes supports. Cette difficulté se constate sur deux plans : elle réside d’une part dans l’identification même de la fonction sémantique en question ; d’autre part, elle réside aussi dans l’identification de la fonction sémantique *standard* devant une paire de supports qui représentent l’un et l’autre un sens actif et un sens passif. Mais nous nous concentrerons ici seulement sur la première difficulté.

Pour ce qui est de cette première difficulté, elle revient à dire si les verbes supports *sikida*(faire) et *juda*(donner) en (4) sont utilisés dans leur fonction de supports *standard* ou de supports *causatifs* :

(4) a. *Minu-ga Ina-reul gamdong-eul siki-eot-da.*

Minu-Nom Ina-Acc émotion-Acc faire-Pas-Déc

[= : *Minu a ému Ina.*]

b. *Minu-ga Ina-ege gamdong-eul ju-eot-da.*

Minu-Nom Ina-Dat émotion-Acc donner-Pas-Déc  
 [= : *Minu a ému Ina.*]

Certes, on peut parler de causatif si l'on analyse le verbe *hada*(faire) en (5) comme étant un verbe support standard, mais on peut aussi le dire standard si on l'analyse comme un verbe support de conversion :

(5) *Ina-ga Minu-ege gamdong-eul hae-t-da.*  
 Ina-Nom Minu-Obl émotion-Acc faire-Pas-Déc  
 [= : *Ina a été émue par Minu.*]

Notons que la phrase (5) est en relation de paraphrase avec la (6) :

(6) a. *Ina-ga Minu-ege gamdong-eul bat-at-da.*  
 Ina-Nom Minu-Obl émotion-Acc recevoir-Pas-Déc  
 [= : *Ina a été émue par Minu.*]  
 b. *Ina-ga Minu-ege gamdong-i doe-eot-da.*  
 Ina-Nom Minu-Obl émotion-Nom devenir-Pas-Déc  
 [= : *Ina a été émue par Minu.*]

Le problème revient ici à savoir quelle est la structure argumentale du nom prédicatif *gamdong*(émotion) : s'agit-il d'un prédicat à un argument ou à deux arguments ? S'il relève du premier cas, *sikida*(faire) et *juda*(donner) en (4) s'analysent comme des verbes supports causatifs tandis que *hada*(faire) en (5) s'analyse comme un verbe support standard. En revanche, s'il relève du second cas, *sikida*(faire) et *juda*(donner) en (4) s'analysent alors comme des supports standard alors que *hada*(faire) en (5) s'analyse, ainsi que les verbes *batda*(recevoir) et *doeda*(devenir), comme un verbe support de conversion.

Pour que l'on soit en mesure d'analyser la structure argumentale du nom *gamdong*(émotion), il nous faut examiner de façon exhaustive toutes les constructions possibles dans lesquelles il apparaît avec ses différents verbes supports.

- (7) a. *Minu-eui yeonseol-i chingu-deul-eul gamdong-eul siki-eot-da.*  
 Minu-Gén discours-Nom ami-Pl-Acc émotion-Acc faire-Pas-Déc  
 [= : *Le discours de Minu a ému ses amis.*]
- b. *Minu-eui yeonseol-i chingu-deul-ege gamdong-eul ju-eot-da.*  
 Minu-Gén discours-Nom ami-Pl-Dat émotion-Acc donner-Pas-Déc  
 [= : *Le discours de Minu a ému ses amis.*]
- (8) a. *Chingu-deul-i Minu-eui yeonseol-e gamdong-eul bat-at-da.*  
 Ami-Pl-Nom Minu-Gén discours-Obl émotion-Acc recevoir-Pas-Déc  
 [= : *Les amis de Minu ont été émus par son discours.*]
- b. *Chingu-deul-i Minu-eui yeonseol-e gamdong-eul hae-t-da.*  
 Ami-Pl-Nom Minu-Gén discours-Obl émotion-Acc faire-Pas-Déc  
 [= : *Les amis de Minu ont été émus par son discours.*]
- c. *Chingu-deul-i Minu-eui yeonseol-e gamdong-i doe-eot-da.*  
 Ami-Pl-Nom Minu-Gén discours-Obl émotion-Nom devenir-Pas-Déc  
 [= : *Les amis de Minu ont été émus par son discours.*]

Les constructions (7) et (8) laisseraient croire que le nom *gamdong*(émotion) est un prédicat à deux arguments : *gamdong*(*x*, *y*) où *x* est une cause alors que *y* est un patient ou un expérimentateur. Dans ce cas, les verbes supports *juda*(donner) et *sikida*(faire) ne s’analysent pas, ni l’un ni l’autre, comme étant causatifs mais ils s’analysent comme étant des supports standard qui sont alors en relation de voix avec les verbes supports *batda*(recevoir), *hada*(faire) et *doeda*(devenir). Autrement dit, ce n’est pas le sens grammatical (ou la fonction sémantique) du verbe support *juda*(donner) et *sikida*(faire) qui apporte le sens causatif à la construction, mais c’est le sens lexical même du nom *gamdong*(émotion) qui contient le sens causatif.

Cela dit, ce n’est pas si facile que cela. En fait, examiné de près, le nom *gamdong*(émotion) peut également apparaître dans les constructions suivantes :

- (9) a. *Minu-ga yeonseol-ro chingu-deul-eul gamdong-eul siki-eot-da.*  
 Minu-Nom discours-Obl ami-Pl-Acc émotion-Acc faire-Pas-Déc  
 [= : *Minu a ému ses amis par son discours.*]

- b. *Minu-ga yeonseol-ro chingu-deul-ege gamdong-eul ju-eot-da.*  
 Minu-Nom discours-Obl ami-Pl-Dat émotion-Acc donner-Pas-Déc  
 [= : *Minu a ému ses amis par son discours.*]

Compte tenu de ces constructions, nous sommes en mesure d'analyser le nom *gamdong*(émotion) comme étant un prédicat à trois arguments. Pourtant, ce n'est pas si évident. A côté des exemples ci-dessus, nous avons des phrases comme en (10) :

- (10) a. ??*Chingu-deul-i Minu-ege yeonseol-lo gamdong-eul bat-at-da.*  
 Ami-Pl-Nom Minu-Obl discours-Obl émotion-Acc recevoir-Pas-Déc  
 [= : *Les amis de Minu ont été émus par son discours.*]
- b. \**Chingu-deul-i Minu-ege yeonseol-lo gamdong-eul hae-t-da.*  
 Ami-Pl-Nom Minu-Obl discours-Obl émotion-Acc faire-Pas-Déc  
 [= : *Les amis de Minu ont été émus par son discours.*]
- c. ??*Chingu-deul-i Minu-ege yeonseol-lo gamdong-i doe-eot-da.*  
 Ami-Pl-Nom Minu-Obl discours-Obl émotion-Nom devenir-Pas-Déc  
 [= : *Les amis de Minu ont été émus par son discours.*]

Les phrases en (10) sont toutes trois composées avec les supports de conversion qui véhiculent un sens passif et qui entretiennent ainsi une corrélation de voix avec les supports *juda*(donner) et *sikida*(faire) en (9). Mais, les phrases en (10) sont peu naturelles. En revanche, leur acceptabilité s'améliore si on modifie la postposition de l'argument introduisant la cause :

- (11) a. ? *Chingu-deul-i Minu-ege yeonseol-lo inhae gamdong-eul bat-at-da.*  
 Ami-Pl-Nom Minu-Obl discours-à cause de émotion-Acc recevoir-Pas-Déc  
 [= : *Les amis de Minu ont été émus à cause de son discours.*]
- b. ?*Chingu-deul-i Minu-ege yeonseol-lo inhae gamdong-eul hae-t-da.*  
 Ami-Pl-Nom Minu-Obl discours-à cause de émotion-Acc faire-Pas-Déc  
 [= : *Les amis de Minu ont été émus à cause de son discours.*]
- c. *Chingu-deul-i Minu-ege yeonseol-lo inhae gamdong-i doe-eot-da.*  
 Ami-Pl-Nom Minu-Obl discours-à cause de émotion-Nom devenir-Pas-Déc

[= : *Les amis de Minu ont été émus à cause de son discours.*]

Cela nous conduit à nous demander si la structure argumentale du nom *gamdong* (émotion) ne varierait pas selon les supports avec lesquels il se combine. Ce qui demande une étude plus approfondie. Mais nous n'entrerons pas plus dans le détail. Nous nous contenterons tout simplement de faire remarquer que l'identification de la fonction sémantique n'est pas toujours évidente et qu'elle dépend en grande partie de la structure argumentale du nom prédicatif, autrement dit du sens lexical de ce dernier, étant donné qu'un nom prédicatif morphologiquement identique peut avoir différentes structures argumentales selon ses sens.

Ce qui nous intéresse ici, c'est que les phrases en (7) et en (8) se différencient les unes des autres par leurs sens respectifs et de savoir comment représenter ces sens distincts, en particulier du point de vue lexicographique, plus précisément dans un dictionnaire actif.

### **3. Représentation lexicographique du sens grammatical des verbes supports**

#### *3.1. Problèmes soulevés dans la description du sens grammaticale*

La difficulté à identifier le sens grammatical des verbes supports est étroitement liée à celle de le décrire de façon systématique et adéquate dans un dictionnaire. Reprenons comme exemple le cas des phrases en (7) et en (8).

Nous avons vu précédemment que ces phrases ne se différencient les unes des autres que par les différentes fonctions sémantiques des supports : supports standard pour les phrases en (7) et supports de conversion pour les phrases en (8). Autrement dit, sans que le sens lexical du nom prédicatif soit modifié. Cela dit, ces phrases ne représentent pourtant pas le même sens.

En effet, les phrases en (7) renvoient à « une action provoquant la réaction psychologique » tandis que les phrases en (8) dénotent une action couramment dite « psychologique » qui parle en fait « d'une action passive qui connaît un état psychologique ». Cela étant, on est amené à dire que cette différence de sens provient

du sens grammatical apporté par le verbe support, mais non pas du sens lexical même du prédicat, étant donné que celui-ci reste le même.

C'est à partir de cela que le problème se pose de savoir comment représenter cette différence de sens. Deux questions se posent alors : où décrire le sens, autrement dit dans le dictionnaire des noms où les entrées sont des noms ou bien dans le dictionnaire des verbes où les entrées sont des verbes ? ; et que décrire dans chaque cas ?

### 3.2. Où décrire le sens grammatical des supports

A ces questions nous sommes en mesure de répondre sans hésitation que le sens grammatical des verbes supports doit être décrit sous les entrées des noms prédicatifs. Car, comme nous l'avons mentionné précédemment, un verbe support morphologiquement identique peut avoir différentes fonctions sémantiques (ou différents sens grammaticaux) ; celles-ci ne peuvent être appréhendées de façon exacte que dans le cadre de la phrase, autrement dit dans la combinaison des verbes supports avec les noms prédicatifs.

Certes, ces différents sens grammaticaux que les verbes supports véhiculent pourraient être décrits sous les entrées verbales, mais dans ce cas, la description se limiterait à énumérer simplement quelques fonctions sémantiques typées. A titre d'exemple, pour décrire les différents sens grammaticaux du verbe support *boda*(voir), il faudrait se contenter d'énumérer sous son entrée toutes ses possibles fonctions sémantiques : verbe support standard, verbe support de conversion. Mais cela ne suffirait pas, car cela ne permettrait pas de préciser dans quelles conditions, autrement dit avec quels noms prédicatifs, le verbe *boda*(voir) peut avoir de telles fonctions.

De plus, le cas serait pire si l'on voulait décrire de façon exacte le sens de la phrase que ce verbe support compose avec son nom prédicatif. Comment pourrait-on représenter ainsi la différence de sens des trois phrases suivantes ? :

- (12) a. *Insu-ga Ina gyeolhonsik sahwoe-reul bo-at-da.*  
Insu-Nom Ina noce animateur-Acc voir-Pas-Déc  
[= : *Insu a animé la noce d'Ina.*]  
b. *Insu-ga eoje buleo siheom-eul bo-at-da.*

Insu-Nom hier examen de français-Acc voir-Pas-Déc

[= : *Insu a passé un examen de français hier.*]

c. *Insu-ga ibeon il-ro keun pihae-reul bo-at-da.*

Insu-Nom CE affaire-Obl gros dégâts-Acc voir-Pas-Déc

[= : *Insu a subi de gros dégâts suite à cette affaire.*]

Il va de soi qu'en n'évoquant que le sens grammatical des verbes supports, on ne peut préciser les sens de ces phrases étant donné que le sens de la phrase (12a) relève d'une « action verbale » ; la phrase en (12b) dénote une action passive, plus précisément une « mise à l'épreuve » ; (12c) renvoie, elle aussi, à une action passive, ou plus exactement à « l'épreuve des événements fâcheux ». Il est évident que ces sens ne peuvent être détectés et précisés que dans leur combinaison avec les noms prédicatifs ayant le sens lexical.

C'est ainsi que le sens grammatical des verbes supports doit être décrit dans le dictionnaire des noms, sous l'entrée du nom prédicatif avec lequel ils se combinent. Cela dit, il reste encore un problème à résoudre : que décrire dans ce cas-là ?

### 3.3. *Que décrire ?*

Cette question est étroitement liée au problème de la polysémie des noms prédicatifs. Devrait-on discriminer le sens du nom prédicatif *pihae*(dégâts) dans les deux cas présentés en (13a) et en (13b) ?

(13) a. *Ibeon taepung-i Minane-ege keun pihae-reul ju-eot-da.*

CE typhon- Nom Chez Mina-Dat gros dégâts-Acc provoquer-Pas-Déc

[= : *Ce typhon a provoqué de gros dégâts chez Mina.*]

b. *Minane-ga ibeon taepung-e keun pihae-reul bo-at-da.*

famille de Mina-Nom CE typhon-Obl gros dégâts-Acc voir-Pas-Déc

[= : *La famille de Mina a subi de gros dégâts à cause du typhon.*]

Le nom prédicatif *pihae*(dégâts), prédicat ayant deux arguments - *cause* et *lieu affecté* -, compose deux phrases à voix différentes en se combinant avec des supports

qui ont des sens grammaticaux différents : verbe support standard et verbe support de conversion. (13a) dénote une « action de causer des événements fâcheux » alors que (13b) dénote, comme nous venons de le voir, une action passive relevant de « l'épreuve des événements fâcheux ». Et cela sans que le sens lexical du nom prédicatif *pihae*(dégâts) soit modifié. De là découle le problème de traiter la polysémie des noms prédicatifs : peut-on analyser ce nom *pihae*(dégâts) comme étant polysémique ?

Notre réponse est positive. A cela, plusieurs raisons. Mais notons simplement ici celle qui est la plus connue : le sens d'un mot doit être décrit dans le cadre de la phrase, en fonction de sa relation avec ses co-occurents. Cela étant, il est également bien connu qu'un nom prédicatif morphologiquement identique sélectionne, selon le sens qu'il réalise, un verbe support qui l'aide à « se conjuguer » en plus de ses arguments. Rappelons G. Gross (1999) qui a proposé d'introduire la notion d'*emploi* dans la description des mots basée sur les propriétés sémantiques et syntaxiques pour éviter la gêne terminologique. Ce qui conduit à analyser le nom *pihae*(dégâts) en (13) comme étant polysémique.

La nécessité d'adopter cette solution est très marquée avec le coréen. En coréen, il est de nombreux cas où le combinatoire « nom prédicatif + support » forme des composés. Ce type de cas n'a cessé d'augmenter. En effet, toutes les combinaisons du type « nom prédicatif+verbe support *hada*(faire) » disposent des verbes composés correspondant :

- (14) a. *gongbu-reul hada* vs *gongbuhada*  
           études-Acc faire           étudier  
       b. *seontaek-eul hada* vs *seontaekhada*  
           choix-Acc faire           choisir

Par ailleurs, les combinaisons contenant d'autres verbes supports comme *juda* (donner) et *boda*(voir) montrent, eux aussi, de plus en plus cette tendance.

- (15) a. *pihae-reul juda* vs *pihaejuda*  
           dégâts-Acc donner   provoquer des dégâts  
       b. *sonhae-reul boda* vs *sonhaeboda*

pertes-Acc voir subir des pertes

Pour permettre de mettre en évidence ce type de corrélation, il faut absolument discriminer les emplois (ou bien sens) des noms prédicatifs qui diffèrent selon leurs combinaisons avec des verbes supports ayant des fonctions grammaticales distinctes.

### 3.4. Exemple de description dans un dictionnaire actif

Partant de tous ces constats, nous proposons ainsi de décrire le sens grammatical des verbes supports en fonction du sens de la phrase qu'ils composent avec un nom prédicatif et de discriminer préalablement les sens du nom prédicatif, eux aussi en fonction du sens de la phrase tout entière. Ce qui permettra de décrire de façon systématique et adéquate les différents sens grammaticaux véhiculés par les verbes supports.

Voyons maintenant l'intérêt que notre méthode de description apporte, cela par exemple avec des verbes supports susceptibles de se combiner avec le nom prédicatif *yonggi*(courage).

- (16) a. *Insu-ga yonggi-ga iss-da.*  
Insu-Nom courage-Nom il y a-Pré-Déc  
[=: Insu a du courage.]
- b. *Insu-ga yonggi-ga na-t-da.*  
Insu-Nom courage-Nom se produire-Pas-Déc  
[=: Il s'est produit du courage en Insu.]
- c. *Insu-ga yonggi-reul nae-t-da.*  
Insu-Nom courage-Acc prendre-Pas-Déc  
[=: Insu a pris courage.]
- d. *Insu-ga geu sosik-e yonggi-reul eot-eoss-da.*  
Insu-Nom CE nouvelle-Obl courage-Acc obtenir-Pas-Déc  
[=: Insu a été encouragé par cette nouvelle.]
- e. *Geu sosik-i Insu-ege yonggi-reul ju-eoss-da.*  
CE nouvelle-Nom Insu-Dat courage-Acc donner-Pas-Déc

[=: Cette nouvelle a donné du courage à Insu.]

On voit bien en (16) qu'il est difficile de saisir le sens grammatical des verbes supports sans tenir compte du sens des phrases tout entières, étant donné que le sens lexical du nom prédicatif *yonggi*(courage), noyau du sens des phrases, reste identique dans toutes les phrases en (16a)-(16e). Mais, en adoptant notre méthode, nous sommes en mesure de fournir une analyse selon laquelle toutes ces phrases représentent au moins quatre sens différents : une qualité humaine en (16a), un phénomène psychologique en (16b) et (16d), une action psychologique en (16c) et une action d'encouragement en (16e).

Cela étant, tous les verbes supports en (16) s'analysent comme fonctionnant tels des supports standard. Ce qui va permettre de décrire à juste titre leur sens grammatical et de mettre en évidence une corrélation des combinaisons « nom prédicatif+verbe support » avec les verbes ou les adjectifs équivalents. Voici l'extrait de la description des verbes supports dans un dictionnaire actif :

**Table 2.** Exemples de description dans un dictionnaire actif

Les rubriques d'informations dans la table 2 sont empruntées au dictionnaire électronique *Sejong* et elles représentent respectivement les informations suivantes<sup>3</sup> :

- <orth> : forme de l'entrée
- <sem> : classe sémantique de l'entrée dont le sens est discriminé au niveau de la polysémie
- <n\_v type="npred\_vsup"> : type de combinaison de l'entrée avec des verbes où *npred\_vsup* renvoie à la combinaison du type « nom prédicatif + verbe support »
- <form vcompound="yes"> : existence de verbes composés correspondant à la suite « Npréd+Vsup » qui est marquée par *yes* ou *no*.

#### 4. Conclusion

Nous avons ainsi mis en évidence les problèmes qui se posent lors de la description du sens grammatical des verbes supports et proposé une méthode de description permettant de résoudre ces problèmes.

Nous avons vu en effet que différentes fonctions sémantiques sont assumées par les verbes supports et qu'elles peuvent d'ailleurs être assumées par un seul verbe support morphologiquement identique. Nous avons également constaté que ces caractéristiques entraînent entre autres la difficulté d'identifier la fonction sémantique des verbes supports et aussi celle de décrire leurs sens grammaticaux de façon exacte et adéquate.

A partir de ces constats, nous avons proposé de décrire le sens grammatical des verbes supports en fonction du sens de la phrase qu'ils composent avec un nom prédicatif et de discriminer préalablement les sens du nom prédicatif, eux aussi en fonction du sens de la phrase tout entière.

Comme nous l'avons vu avec un exemple de description, la méthode de description proposée permet de traiter de façon systématique et adéquate les différents

sens grammaticaux véhiculés par les verbes supports, et aussi de mettre en évidence la corrélation des combinaisons « nom prédicatif+verbe support » avec les verbes ou les adjectifs équivalents. Ce qui revient à laisser deviner son intérêt dans la construction d'un dictionnaire actif qui demande des informations décrites et organisées de telle sorte qu'elles soient utiles à produire des phrases et non pas à comprendre des phrases.

# **Représentation d'informations lexico-syntaxiques du lexique-grammaire : à propos de certains verbes "à montée"**

**Takuya Nakamura**

Université Paris-Est, Institut Gaspard-Monge  
5, bld. Descartes, 77454, Champs-sur-Marne, Cedex 2, France  
nakamura@univ-mlv.fr

## **Abstract**

In this paper, after a brief presentation of two distinct classical approaches, derivational and non derivational, of representing "rising verbs" and "control verbs", we examine the state of affairs of the lexicon-grammar concerning these classes. Existing properties in lexicon-grammar tables are not sufficient to determine if a verb is of one of the two types, we propose to add some additional properties in the lexicon-grammar tables, so that the verification of a class of properties may indicate the rising or control nature of a verb.

**Keywords:** raising, control, lexicon-grammar.

## **1. Introduction**

Nous examinons la validité de la représentation d'informations lexicales et syntaxiques du lexique-grammaire commencé il y a 40 ans par Maurice Gross et son équipe en prenant comme exemple un groupe de verbes connus sous le nom de "verbes à montée". La catégorie de verbes dits « à montée », telle qu'elle est définie dans un cadre dérivationnel, est une entité dépendante de l'interaction entre le lexique, la syntaxe et la sémantique. Nous présentons rapidement la description de ces verbes dans une théorie dérivationnelle comme celle du gouvernement et du liage (Chomsky 1981) et dans la théorie non dérivationnelle de grammaire d'arbres adjoints (Abeillé 1992, 1998, 2002).

Ensuite, nous examinons une classe de verbes du lexique-grammaire qui comprend à la fois les verbes à montée et ceux à contrôle, et montrons que la lecture des propriétés existantes seule ne permet pas suffisamment de distinguer ces deux classes de verbes, bien que la distinction soit déjà faite indépendamment.

Nous espérons améliorer le lexique-grammaire qui va servir de lexique électronique pour divers formalismes syntaxiques orientés vers le TAL.

## 2. Analyses et représentations dans plusieurs cadres

### 2.1. Analyse transformationnelle

Dans le cadre générativiste, où l'on cherche à décrire et expliquer le mécanisme qui lie la réalisation syntaxique de surface (S-structure) et la base syntaxique et sémantique reflétant une relation prédicat-arguments (D-structure), deux grands types sont à distinguer parmi les verbes qui se construisent avec un infinitif post-verbal : verbes à montée et verbes à contrôle. Ruwet (1983) présente ces deux types de verbes en français avec les exemples suivants :

- (1) a. Noam semble être parti sans laisser de traces
- b. Noam prétend être parti sans laisser de traces

Les verbes *sembler* et *prétendre* sont des verbes "à montée" et "à contrôle", respectivement. Les phrases de surface (1a) et (1b) pourraient avoir pour structures profondes les représentations suivantes :

- (2) a. [NP *e*] semble [S' COMP [S Noam INFL être parti . . .]]
- b. Noam prétend [S' COMP [S PRO INFL être parti . . .]]

Les verbes à montée sont caractérisés par les faits suivants : ils sont sous-catégorisés pour un complément phrastique et ils possèdent au moins une position syntaxique de surface à laquelle aucun rôle thématique n'est assigné. Les verbes à contrôle, par contre, possèdent, en plus d'un complément phrastique, au moins une position syntaxique à laquelle un rôle thématique est assigné : le sujet de la subordonnée PRO est coréférent à l'élément nominal qui occupe cette position. Sans entrer dans le détail du développement des mécanismes dérivationnels selon l'évolution de la grammaire générative transformationnelle, le consensus partagé depuis Chomsky (1981) est de considérer que le sujet de la subordonnée du type (2a) est déplacé transformationnellement dans la position non thématique du verbe principal, suite à l'interaction de diverses contraintes modulaires, notamment celles sur les cas et celles sur les rôles thématiques. Ce mouvement laisse derrière lui une trace coïncidée avec l'élément déplacé. L'exemple (3a) montre la transformation de "montée" :

- (3) a. Noam<sub>i</sub> semble [s t<sub>i</sub> INFL être parti . . .]
- b. Noam<sub>i</sub> prétend [S' COMP [S' PRO<sub>i</sub> INFL être parti . . .]]

Il faut remarquer que les catégories dominant la séquence post-verbale sont différenciées : dans le cas du verbe à montée, la catégorie est S' (CP) qui permet au verbe principal de "gouverner" la trace *e* du sujet *Noam*, déplacé en position sujet de la phrase principale ; par ailleurs, le verbe à contrôle est suivi d'une véritable proposition, empêchant que le sujet vide anaphorique PRO soit gouverné. Les verbes à contrôle

sélectionnent un argument phrastique et un autre argument, préférentiellement agentif. Le sujet de la subordonnée PRO, phonétiquement nul donc imperceptible dans la forme de surface, est interprété comme coréférent à l'argument agentif du verbe à contrôle, d'où la coïndexation de (3b).

## 2.2. Analyse non transformationnelle

Des alternatives à l'analyse transformationnelle ont été proposées dans les grammaires non transformationnelles souvent appelées "grammaire d'unification" (cf. Abeillé 1992) : voir Bresnan (1982) pour le traitement de ces verbes en LFG, Sag & Pollard (1991) pour HPSG, Abeillé (1998, 2002) pour le traitement de ces verbes en français dans le cadre de la grammaire d'arbres adjoints (TAG).

Abandonnant les transformations, ces cadres théoriques différencient ces deux types de verbes au niveau des traits syntaxiques (LFG, HPSG) et/ou des représentations en constituants (TAG). Ils partagent cependant l'idée que ces phénomènes sont, au fond, sémantique : l'idée fondamentale est de distinguer deux types différents de mise en relation sémantique de l'infinitive et de son sujet interprétatif (cf. Baschung (1998)).

### 2.2.1. Les verbes à montée dans la représentation TAG

Selon la représentation des faits syntaxiques en TAG, Abeillé (1998) propose de distinguer les deux types de verbes par les types d'arbres qu'ils ancrent. Par exemple, les verbes à montée sont représentés par un arbre auxiliaire, ce qui, d'après elle, permet de saisir une des caractéristiques syntaxiques communes aux verbes à montée et aux auxiliaires du temps *être* et *avoir* en français : la séquence post-verbale autour d'un verbe non fini, l'infinitive dans le cas du verbe à montée, le participe passé dans le cas des auxiliaires du temps, ne forme pas un constituant syntaxique. Pour étayer cette caractéristique, Abeillé cite le fait qu'elle ne subit pas de déplacement par clivage ou que sa pronominalisation par *cela* est impossible. Ainsi, un verbe comme *sembler* peut s'exprimer par un arbre auxiliaire représenté dans la Figure 1 :

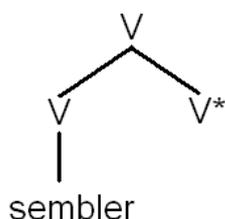

Figure 1

Ce type d'arbre auxiliaire s'adjoit à un arbre élémentaire dont la tête est un verbe à l'infinitif. Par exemple, un arbre élémentaire de la Figure 2 :

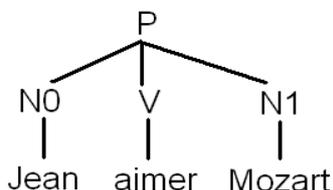

Figure 2

Les deux arbres précédents peuvent se combiner pour donner la représentation syntaxique d'une phrase dont le verbe principal est un verbe à montée :

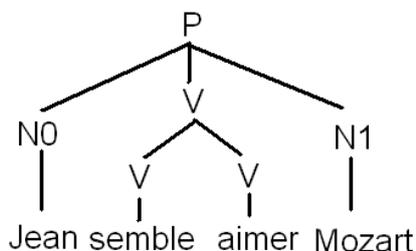

Figure 3

Cet arbre montre qu'un verbe à montée, ici le verbe *sembler*, s'adjoit à un verbe à l'infinitif, qui est sémantiquement le prédicat principal, avec ses deux arguments. Le sujet de la phrase est sémantiquement interprétable comme le sujet du verbe à l'infinitif. Le verbe à montée n'apporte pas ses propres restrictions de sélection : les arguments du prédicat sont ceux du verbe à l'infinitif *aimer*.

Cette structure d'attachement empêche la formation d'un syntagme verbal infinitif, ce qui correspond à la réalité syntaxique que la séquence *aimer Mozart* ne se comporte pas comme un constituant syntaxique : les phrases (4b,c) montrent l'impossibilité du clivage et de la pronominalisation de la séquence post-verbale du verbe *sembler* :

- (4) a. Jean semble aimer Mozart  
 b.\*Ce que Jean semble, c'est (d') aimer Mozart  
 c.\*Aimer Mozart, Jean (le semble + semble cela)

D'après l'analyse d'Abeillé, cette configuration des arbres est similaire à celle qu'on observe dans une phrase à temps composé : les auxiliaires de temps *avoir* et *être* ancrent un arbre auxiliaire, qui s'unifie avec un arbre élémentaire dont la tête est un verbe au participe passé. Voici l'arbre auxiliaire dont la tête est un auxiliaire du temps composé :

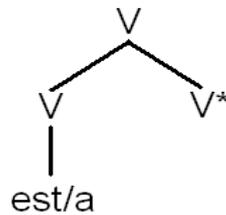

Figure 4

Ce type d'arbre peut s'unifier avec un arbre élémentaire dont la tête est un verbe au participe passé :

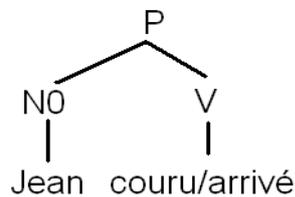

Figure 5

Pour donner les arbres représentant deux phrases *Jean a couru* et *Jean est arrivé* :

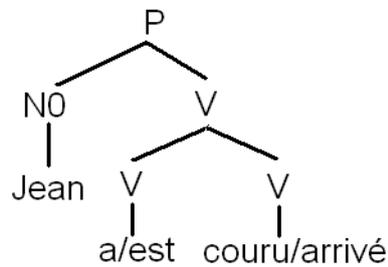

Figure 6

La représentation dans le cadre TAG d'une phrase avec un verbe à montée est similaire à celle d'une phrase à temps composé quelconque. La généralisation formelle est atteinte dans la mesure où ni auxiliaire, ni verbe à monté ne permette la formation d'un syntagme dont la tête est un verbe non fini.

### 2.2.2. Remarques

Dans le cadre des grammaires d'unification, la distinction entre D-structure et S-structure n'existe pas. L'idée du mouvement d'un sujet d'une subordonnée de base n'a donc pas de sens. Ainsi, Abeillé (1998) constate clairement que dans le cadre du

formalisme TAG, « la relation entre les phrases *il V que P* et *NO V Inf* (peu régulière) [est] une relation sémantique et non syntaxique ». En effet, la métaphore explicitement « spatiale » qu'on peut percevoir dans l'appellation de « verbes à montée » n'a plus de sens, puisqu'il n'y a aucun mouvement de « montée ».

L'intérêt initial de la notion de « montée » comme transformation syntaxique qui met un lien entre une proposition subordonnée de base et une structure discontinue de syntagme nominal et groupe infinitif, qu'on trouve chez Ruwet (1972, 1982a, 1982b) ou Postal (1974), a clairement reculé pour privilégier la différenciation de structures et de comportements de séquence infinitive introduite par deux types différents de verbes principaux, c'est-à-dire les verbes à montée et les verbes à contrôle.

En effet, comme Baschung (1998) le montre, parmi les verbes suivis d'un infinitif, la distinction entre les verbes à contrôle et les verbes à montée « est de nature fondamentalement sémantique plutôt que syntaxique ». Elle a appliqué un groupe de tests formels pour découvrir « un continuum de propriétés » entre ces deux classes : en effet, aucun des traits évoqué n'est suffisant pour définir l'une ou l'autre des deux classes. Il y a toujours des exceptions. Voici les traits qu'elle a vérifiés : + et – indique la tendance générale :

	V à C	V à M
Commutation de l'infinitive avec un SN ou un SP	+	-
Extraction de l'infinitive	+	-
Omission de l'infinitive complément	+	-
Correspondance compléments-arguments	+	-
SP contrôleur	+	-
Paraphrase entre infinitive active et passive	+	-

Tableau 1

Mais les résultats de son examen montre qu'il n'y a pas un seul critère qui soit suffisant pour discriminer les deux classes de verbes, bien que la tendance générale se dégage. Elle est marquée par + et – dans le tableau. D'où sa conclusion que la distinction entre verbe à contrôle et verbe à montée est fondamentalement sémantique.

### 3. Analyse du lexique-grammaire

Le lexique-grammaire peut être vu comme un dictionnaire syntaxique dont une entrée est constituée d'un élément prédicatif défini dans une structure de phrase simple particulière (voir M. Gross (1968, 1975)). Dans une même entrée, on peut regrouper

toutes les constructions syntaxiques, formellement différentes mais sémantiquement équivalentes, (par exemple, la structure passive, la structure avec extraposition, etc.), ainsi que diverses propriétés syntaxiques et sémantiques associées à ces constructions (la pronominalisation des constituants, les traits référentiels des arguments, etc.). La relation d'équivalence entre deux types de phrases est appelée "transformation", selon le cadre théorique de Harris (1970).

### 3.1. *Les verbes à montée et à contrôle*

Les verbes dits « à montée » et « à contrôle » dans la littérature ont fait l'objet de descriptions distributionnelles, lexicales et transformationnelles du lexique-grammaire dans M. Gross (1968, 1975).

Dans ces études, M. Gross a dressé une liste de 19 constructions syntaxiques de base mettant en jeu, au moins, une complétive ou une infinitive et a recensé les verbes français qui sont susceptibles d'y figurer. M. Gross a constaté que, sur la totalité du lexique verbal en français, il y a très peu de verbes qui manifestent le parallélisme entre construction impersonnelle à complétive et construction infinitive du type (6), exemple phare de la transformation de montée du sujet au sujet, tandis que le parallélisme entre deux phrases de (5), qui montre typiquement la configuration de « contrôle », est abondant :

- (5) a.  $N_0 V \text{ Que } P =$  : Luc pense qu'il ira voir Léa chez elle  
b.  $N_0 V V^0_{\text{inf}} =$  : Luc pense aller voir Léa chez elle
- (6) a.  $Il V \text{ Que } P =$  : Il semble qu'il pleut  
b.  $N_0 V V^0_{\text{inf}} =$  : Il semble pleuvoir

Les phrases de (5) sont reliées par une relation appelée réduction de la complétive à l'infinitive, semblable à la transformation de « Equi-NP deletion » de Rosenbaum (1967) : dans la structure profonde, si un argument du verbe principal est coréférent au sujet de la proposition subordonnée, cette dernière se réduit à la proposition infinitive.

Pour relier les deux phrases de (6) par l'opération formelle de réduction, il faut une certaine acrobatie par rapport à la même opération appliquée à la phrase (5a), parce que la phrase à complétive (6a) n'a pas d'argument nominal référentiel qui puisse être le contrôleur. M. Gross (1968) a mentionné la possibilité d'analyser la phrase du type (6b) par l'application successive des transformations de [Que T z.], qui enlève, dans la phrase (6a), le temps fini du verbe de la subordonnée, ainsi que la conjonction de subordination, et de [impersonnel -1] qui substitue le sujet de la subordonnée au sujet impersonnel, c'est-à-dire la transformation de [it replacement] de Rosenbaum (1967). Or, l'idée n'a pas été approfondie dans M. Gross (1975).

Les verbes qui se comportent d'une façon similaire au verbe *penser* dans les phrases (5) se trouvent dans la classe 6, définie par le fait qu'ils sous-catégorisent une complétive directe et un substantif sujet, éventuellement caractérisée par le parallélisme avec une phrase « réduite » en infinitive du type (5b). Les verbes du type *sembler*, peu nombreux, sont catalogués dans la classe 17. Ils sont définis par la construction de base qui est une phrase impersonnelle. Il va sans dire que ces deux classes n'épuisent pas tous types de constructions où apparaissent les verbes à contrôle et les verbes à montée.

Voici une rapide représentation du lexique-grammaire, basée sur la description des verbes à contrôle et des verbes à montée. Dans ce qui suit, nous prenons une classe de verbes appelée traditionnellement « verbes semi-auxiliaires », représentés pour la plupart dans la classe 1 du lexique-grammaire et examinons si la représentation actuelle du lexique-grammaire est suffisamment opératoire pour distinguer les deux classes de verbes.

### 3.1. Verbes à montée et leur représentation dans la Table 1

Les verbes étudiés dans les *Méthodes en syntaxe* de Maurice Gross sont par principe définis par la présence d'au moins une complétive ou d'une infinitive. Dans la plupart des cas, une construction à infinitive est considérée comme le résultat de la réduction d'une complétive du type (5), réalisant typiquement la configuration d'un verbe à contrôle.

L'exception à cette alternance entre complétive et infinitive est la classe 1, où l'infinitive post-verbale n'alterne pas avec une complétive, à moins de changer totalement le sens. Cette classe est donc définie, à la fois, par la présence de l'infinitive et l'absence de la complétive dans la première position post-verbale :

$N_0 V (\text{Prép}) V^0_{\text{inf}} W$

Et  $*N_0 V (\text{Prép ce}) Q u P$

Voici quelques exemples de constructions que forment les verbes de cette classe :

- (7) Luc a (commencé à + fini de + continué de +...) lire Proust
- (8) Luc s'est (décidé à + grouillé de) partir en Corée

Voici un extrait de la table 1 actuel :

l'aspect perfectif l'infinitif. Nous allons examiner les propriétés qui différencient les deux emplois et proposons d'y en ajouter d'autres.

### 3.2.1. Traits du sujet

Seul l'emploi épistémique peut avoir un sujet « non restreint ». Cela signifie dans le cadre du lexique-grammaire que cette position syntaxique n'assigne aucune contrainte sur les propriétés formelles du terme qui l'occupe : il peut être un syntagme nominal, une complétive ou une infinitive. Cela ne signifie pas que la position en question ne reçoive pas de rôle thématique. Ce trait s'observe également dans la position sujet d'un groupe de verbes appelé « verbes psychologiques » :

(Cette femme + son départ + qu'elle doit faire ça +...) énerve Léa

Le verbe *énervé* peut prendre n'importe quel type de sujet, sans contraintes sur la nature référentielle. Ce verbe a donc  $N_0 = Nnr$  dans la table 4 du LG. Le sujet porte incontestablement le rôle de "thème". L'interprétation d'une phrase construite sur ce verbe avec un sujet humain est, de surcroît, ambiguë : le sujet peut être agentif (donc il n'est plus un "thème") ou non agentif, comme c'est le cas de l'exemple ci-dessus :

Max a volontairement énervé Léa

Dans ce cas là, la double vérification des traits  $N_0 = Nhum$  et  $N_0 = Nnr$  peut noter l'existence de cette ambiguïté, ce que n'a pas la double vérification de ces traits dans la table 1 avec le verbe *pouvoir* épistémique. La distribution du  $N_0 = Nhum$  peut être couvert par  $N_0 = Nnr$ , dans ce cas là.

Ainsi, la vérification du seul trait distributionnel  $N_0 = Nnr$  ne montre pas que le sujet ne porte aucun rôle thématique. La description distributionnelle qui pourrait manifester cet aspect est la possibilité du sujet impersonnel : en effet, un verbe psychologique ne peut pas accepter un sujet impersonnel de l'infinitif ;

\*Il énerve Luc de pleuvoir (cf. Léa énerve Luc de vouloir partir)

Il peut pleuvoir

Ainsi, nous proposons d'ajouter la propriété distributionnelle  $N_0 = il\ impersonnel$  qui distingue deux emplois du verbe *pouvoir* :

$N_0 = Nhum$	$N_0 = Nnr$	$N_0 = il\ imp$	
-	+	+	pouvoir
+	-	-	pouvoir

Tableau 2

### 3.2.2. Contraintes sur l'infinitive

Un deuxième trait qui figure déjà dans la table du lexique-grammaire servant à distinguer les deux emplois du verbe *pouvoir* concerne les possibilités de modalisation et de mise au parfait de l'infinitive :

\*Max peut volontairement avoir lu Proust (= \* Max est capable d'avoir lu Proust)

Max peut avoir lu Proust (= Il est possible que Max ait lu Proust)

Les exemples ci-dessus montrent que quand le contexte ne permet que l'interprétation déontique du verbe *pouvoir*, l'infinitive qui le suit ne peut pas être mise au parfait.

L'infinitive de l'emploi épistémique peut être suivie d'un autre semi-auxiliaire, tandis que l'emploi déontique ne le permet pas :

\*Max peut volontairement (pouvoir + devoir +...) lire Proust

Max peut (devoir + pouvoir + ...) lire Proust (= Il est possible que Max (doive + puisse +...) lire Proust)

### 3.2.3. Constituance

#### 3.2.3.1. ppv le, reprise par cela

Comme Abeillé (1998) l'a montré, la séquence post-verbale d'un verbe à montée ne forme pas de constituant, d'où son rejet du noeud SV. Dans la table existante, la possibilité de remplacer cette séquence par un pronom clitique neutre *le* vérifie ce trait. En effet, dans la phrase suivante :

Luc ne peut pas nager, mais Léa le peut

où l'infinitive peut être pronominalisée par *le*, le verbe *pouvoir* a le sens déontique, donc c'est un verbe à contrôle. Par contre, dans l'exemple suivant :

\*Léa peut être déjà arrivée et Luc le peut aussi

l'infinitive ne peut pas être pronominalisée. Le verbe a donc l'emploi de V à M. La reprise par *cela*, par contre, ne marche dans aucun des deux cas :

\*Luc ne peut pas nager mais Léa peut cela

\*Léa peut être déjà arrivée et Luc peut cela aussi

#### 3.2.3.2. Omission

Si le contexte est approprié, l'infinitive peut être omise d'une façon anaphorique. Cette caractéristique est considérée comme un indice pour l'existence d'un noeud SV. Généralement, un V à C accepte cette propriété :

- Léa a pu nager, et Luc ?

- Luc a pu, lui aussi

mais un V à M difficilement :

?\*Max peut être déjà arrivé à Séoul, mais Léa ne peut pas

### 3.2.3.3. *Extraction de l'infinitif*

L'extraction de l'infinitive dans une phrase clivée ou dans une phrase pseudo-clivée est également utilisée pour démontrer l'existence d'un SV. Avec l'emploi déontique du verbe *pouvoir*, seul la pseudo-clivée fonctionne, tandis que la phrase clivée ne marche pas :

?\*C'est (de) nager que Luc peut

? Ce que Luc peut, c'est (de) nager

Il n'est pas possible de construire ce type de phrases avec l'interprétation épistémique du verbe :

\*C'est (de) être parti que Luc peut

\*Ce que Luc peut, c'est (de) être parti

### 3.2.4. *Alternance avec SN/Qu P*

Il est souvent considéré qu'une infinitive d'un verbe à montée ne doit pas alterner avec un *SN*. Indépendamment de la validité de cette idée, le verbe *pouvoir* n'a pas de *SN* qui remplace *Vinf*.

Luc peut (nager + \* la natation)

Luc peut (venir à tout moment + \* la venue)

Il va sans dire qu'une complétive ne puisse remplacer l'infinitive :

\*Luc peut qu'il nage

Le verbe *pouvoir*, que ce soit d'un emploi épistémique ou d'un emploi déontique, n'accepte ni *SN*, ni *Qu P*.

### 3.3. *Conclusions et perspectives*

Ces propriétés se résument dans le tableau suivant :

	Sujet			Vinf							Vinf = SV					Alt.	
	N0 = Nhum	N0 = Nnr	N0 = il impersonnel	Tp=tc	Tc=passé	Tc=présent	Tc=futur	Vc=devoir	Vc=pouvoir	Vc=savoir	N0 le V	N0 V cela	N0 V	C'est (Prép) Vinf que N0 V	Ce que N0 V, c'est (Prép) Vinf W	N0 V N1	N0 V Qu P
pouvoir	-	+	+	+	+	+	+	+	+	+	-	-	-	-	-	-	-
pouvoir	+	-	-	+	-	-	-	-	-	-	+	-	+	-	?	-	-

Tableau 3

Prenant un seul exemple de verbe dont deux emplois constituent une paire minimale de verbe à montée et verbe à contrôle, nous avons examiné comment les informations syntaxiques et sémantiques sont représentées dans la description du lexique-grammaire et si elles sont suffisantes pour la distinction de ces deux classes. Nous avons proposé d'ajouter quelques propriétés portant sur la nature du sujet et sur les comportements de la séquence infinitive. Nous devons généraliser l'ajout de ces propriétés à d'autres tables pour que cette distinction puisse être calculée à partir de l'ensemble des tables du lexique-grammaire.

# When Lexical Meanings Meet Constructions: “V-*ge*-N” Versus “V-CL-N” Constructions in Mandarin Chinese

Yu-Fen Yao

National Taiwan University  
r94142010@ntu.edu.tw

## Abstract

In Mandarin Chinese, “*ge*” is the most common and unique classifier (CL) of all, which differs from other specific classifiers, having little semantic restrictions to modify its following nouns. The present study aims to investigate the distributional differences between “V-*ge*-N” and “V-CL-N” constructions in Chinese. The “V-*ge*-N” constructions involve the insertion of the general classifier “*ge*” into VN compounds. Similar insertion is also permitted in some more specific classifiers such as nominal classifiers “*wei4*” as well as verbal classifier “*ci4*”, which are termed as “V-CL-N” construction. The result of this study shows various degrees of acceptability for inserting three types of classifiers into various types of VN compounds. According to Construction Grammar, constructions are defined as form-meaning pairs. In this case, different kinds of classifiers, when they are inserted into distinct types of VN compounds, have dissimilar constructional meanings and pragmatic functions, causing different forms and meanings in “V-*ge*-N” and “V-CL-N” patterns.

## 1. Introduction

As Mandarin Chinese is considered to be a classifier language, there are various types of classifiers. Among all classifiers, “*ge*” is the most general and unmarked in that it can be substitute for any other classifiers without semantic restriction of its following nouns, as in (1). Moreover, “*ge*” is regarded to emphasize the quantity of events rather than its following nouns in VN compounds (Liu 1994). On the contrary, some specific classifiers<sup>1</sup> such as nominal classifiers “*wei4*” and “*zhi1*” in (2), are used to modify their following nouns and foreground the saliency of semantic features

---

<sup>1</sup> There are other types of classifiers in Mandarin Chinese. Only nominal classifiers and verbal classifiers are discussed in this paper due to the classifiers in V-CL-N constructions.

of nouns in discourse (Li et al. 1981, Myers 2000) while verbal classifiers “*ci4*” and “*chang3*” in (3), are used to express the frequency of an action or an event (趙 1980, 呂 1980, 方 2003).

(1) *yi1 ge ren2* / *yi1 ge jia1*  
 one GE person / one GE home  
 ‘one person’ / ‘one home’

(2) *yi1 wei4 lao3shi1* / *yi1 zhi1 bi3*  
 one CL teacher / one CL pen  
 ‘one teacher’ / ‘one pen’

(3) *yi1 ci4 you2 xi4* / *yi1 chang3 dian4ying3*  
 one CL game / one CL movie  
 ‘one game’ / ‘one movie’

In this paper, the insertion of different types of classifiers into a variety of VN compounds is discussed and analyzed. The insertion of the general classifier “*ge*” into VN compounds is termed as “V-*ge*-N” construction while the insertion of other specific classifiers is called “V-CL-N” constructions. “V-*ge*-N” construction has been investigated in previous studies (Liu 1994, Biq 2002, 2004). Biq (2004) has claimed that “V-*ge*-N” construction is one variant of “V-*yi*-*ge*-N” constructions. Since “*yi*” in Mandarin Chinese reveals the minimal quantity and appears the most frequently in colloquialism, “V-*ge*-N” construction still retains the semantic feature of “*yi*”, indicating the quality of trivialness and casualness in action events (Biq 2004, Chen 2003, Liu 1994,). In addition, “*ge*” can be further inserted into lexicalized idioms or phrases such as *kai1-ge-daol* ‘open-GE-knife = operate’. However, Biq (2004) did not mention the restriction of ‘*ge*’-insertion; besides, she mentioned the similarity between “V-*ge*-N” and “V-CL-N” constructions without providing further explanations for the functional or distributional differences between the two formally similar constructions. In Biq (2004), both “V-*ge*-N” and “V-CL-N” constructions are considered to be a device for trivializing action events; “V-CL-N” can be replaced with “V-*ge*-N” while the reverse is not allowed.

Based on the framework of Construction Grammar (Fillmore et al. 1988, Goldberg 1995, 2003), in which constructions are defined as form-meaning pairs and viewed as three-dimensional interaction among syntax, semantics, and pragmatics,

this paper argues that “V-ge-N” and “V-CL-N” should be considered dissimilar patterns and further attempts to account for the semantic differences and somewhat distinct pragmatic functions in contexts of the two as a result of the different essence of various types of classifiers.

This paper is organized as follows: section 2 focuses on data analysis and identifies three types of classifiers as well as five types of VN compounds; section 3 then investigates inner dissimilarities in “V-ge-N” and “V-CL-N” constructions and different degrees of insertion for classifiers VN compounds. The contexts of “V-ge-N” and “V-CL-N” constructions and their distributional differences are discussed in section 4. The conclusion is given in section 5.

## **2. Data analysis**

The data containing “V-ge-N” and “V-CL-N” constructions were collected from NTU spoken corpus of Mandarin Chinese, online blogs by the Google Search Engine, and BBS. Since “V-ge-N” and “V-CL-N” constructions are extremely colloquial and prevailing only in recent days, few tokens can be found in spoken corpus; therefore, online searching engine was selected to collect more data. In on-line searching, only blogs and websites in Taiwan were adopted, avoiding different usage between Taiwan and Mainland China. Although blogs and personal diaries are originally written forms, their language usage and style are exceedingly closed to spontaneous speech. As for VN compounds, examples were partially selected from Li and Thompson (1981), Chen and Bates (1998), Her (1996) as well as Tang (1981).

### *2.1 Three types of classifiers*

Despite of various classifiers in Mandarin Chinese (Biq 2004, Li et al. 1981, Li 2000, Myers 2000, 趙 1980, 呂 1980, 方 2003), only three types of classifiers are identified and discussed in this study, which are nominal classifiers, verbal classifiers, and general classifiers as shown in Table 1.

**Table 1: Types of classifiers**

	Types of classifiers	Example
<b>Type 1</b>	Nominal classifiers	<i>wan3</i> ‘bowl’, <i>bei1</i> ‘cup’, <i>wan3</i> ‘bowl’, <i>ke1</i> ‘grain’, <i>tiao2</i> ‘long narrow strip’,
<b>Type 2</b>	Verbal classifiers	<i>ci4</i> ‘once’, <i>hui2</i> ‘once’, <i>bian4</i> ‘once’, <i>chang3</i> ‘stanza’, <i>dun4</i> ‘classifier for a meal’
<b>Type 3</b>	General classifiers	<i>ge</i>

As mentioned before, these three types of classifiers have distinct semantic and pragmatic functions. Nominal classifiers are used to modify nouns and foreground the semantic features of their following nouns. For example, the nominal classifier *tiao2* in *yi4 tiao2 sheng2zi* ‘a string’ shows that characteristics of the string, which is narrow and long. On the other hand, verbal classifiers reveal the frequency of events and actions. For instance, *ci4* in *wan2 yi1 ci4 you2xi4* ‘play the game once’ expresses how many times of the action, ‘playing games’. Unlike specific classifiers, general classifier, *ge*, has no semantic restrictions and can modify both nouns and action events.

## 2.2 Five types of VN compounds

There are various types of compounds in Mandarin Chinese, including VV compounds, NN compounds, and so forth. In this paper, only verbal VN compounds<sup>2</sup> were collected and investigated. According to Her (1996, 1997), four types of VO sequences have been categorized on the basis of syntactic rules. In this study, one more VO type is further identified. These five VN compounds are classified by syntactic and semantic features in this study.

The VN compounds in Type A are identified as regular phrases, in which O<sub>1</sub> can be viewed as the direct object and the prototypical patient of V whereas O<sub>2</sub> in Type B are still the direct object, but not the most typical patient of V; rather, they might be the interface between a patient and a theme. For instance, “*fan4*” in *chi1 fan4* ‘have a meal’ originally refers to “rice”; however, after high frequently used, it represents for the concept of “a meal”<sup>3</sup>, which is not a specific object, might not be the most typical

<sup>2</sup> In Chinese, VN compounds include nominal VN compounds, such as *shui4 yi1* ‘seep-clothes = pajamas’, and verbal VN compounds such as *tiao4 wu3* ‘jump-dance = dance’.

<sup>3</sup> If someone says *wo3 yao4qu4 chi1fan4* ‘I’m going to eat a meal’, he may eat noodles instead of rice.

patient of V. The other case is “*wu3*” in *tiao4wu3* ‘dance’, the verb “*tiao4*” ‘jump’ is originally an intransitive verb; therefore “*wu3*” could not be a typical patient and more like a theme. In general, the only difference between Type A and Type B is the semantic features of O.

However, O from Type C to Type E are all non-prototypical patients of V, which have metaphorical or metonymic meanings. VO<sub>3</sub> in Type C are used as idiomatic phrases, which are lexically encoded and have fixed expression. Although compounds in this type are more lexicalized, phrasal meanings still can be slightly revealed from their individual literal meanings of V and O. Moreover, since VO<sub>3</sub> are idiomatic phrases, syntactic rules can be assigned for them; therefore, additional elements, such as aspect markers or modifiers can be inserted into V and O<sub>3</sub> as in (4).

- (4) *ta1men yi3jing1 kai1 guo4 hui4 le*  
 they already open ASP<sup>4</sup> meeting particle  
 ‘They have already had a meeting.’

Similarly, VO<sub>5</sub> in Type E acquire metaphorical or metonymic readings as VO<sub>4</sub> in Type D, but the meaning is not revealed from separate lexicons such as V or O<sub>5</sub>; rather, it should be read from the entire VO<sub>5</sub> compounds. Furthermore, VO<sub>5</sub> in Type E are considered to be words rather than phrases, indicating that no syntactic rule is applied for them and no assertion is allowed between V and O<sub>5</sub> as in (5).

- (5) *ni3 bu2young4 dui4 ta1 \*guan1 zhe xin1*  
 you no need to he close ASP heart  
 ‘You don’t need to be concerned about him.’

Back to Type D, VO<sub>4</sub> have dual status, implying that compounds in this type function both as words and idiomatic phrases depending on contexts. Therefore, VO<sub>4</sub> combine both features in Type C as phrases and Type E as words, which is shown examples in (6) and (7).

- (6) *ta1 mei2 hui2lai2, wo3 bu4neng2 \*fang4 le xin1*  
 he not return I cannot put ASP hear  
 ‘I don’t feel relieved if he doesn’t return yet.’

---

<sup>4</sup> ASP means aspect markers.

(7) *ta1 hui4 hui2lai2 de, ni2 ke3yi3 fang4 yi1bai3 ke1 xin1*  
 he can return particle, you can put one hundred CL heart  
 ‘You can feel relieved that he must return.’

These five types of VN compounds are identified by several criteria mentioned above, including semantic features and syntactic rules. Except objects in Type A, those in Type B to Type E are not the prototypical patients of verbs in VN compounds. Some VN compounds can be viewed as regular and idiomatic phrases while others are considered to be words, and still others have dual status of phrases and words, which may not be comprehended only by their literal meanings. The summary of these five types of VN compounds is presented in Table 2.

**Table 2: Types of VN compounds**

	<b>Form and Feature</b>	<b>Example</b>
<b>Type A</b>	VO <sub>1</sub> (typical patient) as regular phrases	<i>da3 zhang1lang2</i> ‘hit (kill) a cockroach’ <i>sha3 ji1</i> ‘kill a chicken’
<b>Type B</b>	VO <sub>2</sub> (patient / theme) as regular phrases	<i>chi1fan4</i> ‘have a meal’ <i>chang4ge1</i> ‘sing songs’
<b>Type C</b>	VO <sub>3</sub> (non-patient) as idiomatic phrases	<i>da3qiu2</i> ‘hit ball = play balls’ <i>kai1dao1</i> ‘open knife = operate’
<b>Type D</b>	VO <sub>4</sub> (non-patient) have dual status	<i>fang4xin1</i> ‘put heart = feel relieved’ <i>kai1xin1</i> ‘open heart = be happy’
<b>Type E</b>	VO <sub>5</sub> as words	<i>guan1xin1</i> ‘close heart = be concerned with’ <i>liu2yi4</i> ‘keep mind= pay attention to’

### 3. V-ge-N construction vs. V-CL-N construction

Since the essential quality in three types of classifiers is different from one another, the collecting data presents that there is indeed various degrees of acceptability and pragmatic functions for insertion of classifiers into five types of VN compounds. In this case, again, V-ge-N and V-CL-N should be viewed as different constructions. The different degrees of acceptability for inserting nominal classifiers, verbal classifiers and the general classifier “ge” into various types of VN compounds are discussed in the following sections.

### 3.1 V-CL (nominal)-N constructions

In the investigation of insertion for nominal classifiers into five types of VN compounds, the result shows that nominal classifiers only can be inserted into Type A and B as regular phrases, which is the least acceptable kinds of classifiers into VN compounds (See Table 3).

**Table 3: Acceptability of insertion in V-CL (nominal)-N**

	Form and Feature	Example
<b>Type A</b>	VO <sub>1</sub> as regular phrases	<i>da3-zhi1-zhang1lang2</i> ‘hit (kill) a cockroach’ <i>sha3-zhi1-ji1</i> ‘kill a chicken’
<b>Type B</b>	VO <sub>2</sub> as regular phrases	<i>chi1-wan3-fan4</i> ‘have a bowl of meal’ <i>chang4-shou3-ge1</i> ‘sing a song’
<b>Type C</b>	VO <sub>3</sub> as idiomatic phrases	* <i>da3-ke1-qiu2</i> ‘hit-a grain of-ball = play ball’ * <i>kai1-ba3-dao1</i> ‘open knife = operate’,
<b>Type D</b>	VO <sub>4</sub> have dual status	* <i>fang4-ke1-xin1</i> ‘put-a grain of-heart = feel relieved’ * <i>kai1-ke1-xin1</i> ‘open-a grain of-heart = be happy’
<b>Type E</b>	VO <sub>5</sub> as words	* <i>guan1-ke1-xin1</i> ‘close-a grain of-heart = be concerned with’

Since the original function of nominal classifiers is used to foreground the saliency of their following nouns, the pragmatic function of “V-CL (nominal)-N” is also to focus on the following nouns rather than action events. Since the objects in Type C, VO<sub>3</sub> compounds, are not much interpreted in its literal sense, which have the metonymic reading of the nouns, nominal classifiers are not always acceptable for insertion. As for Type E<sup>5</sup>, which is viewed as a word, can be regarded as metaphors. If nominal classifiers cannot be inserted into Type C and Type E, then there is certainly no acceptable insertion in Type D, which has dual functions as Type C and Type E. In sum, because the nouns in Type C, D, and E have lost their original literal meanings, the insertion of noun classifiers is not permitted.

### 3.2 V-CL (verbal)-N constructions

Dissimilar to nominal classifiers, verbal classifiers are used for counting the times or frequency of the event or action in question so that “V-CL (verbal)-N”

<sup>5</sup> In Type E, there is originally no nominal classifier to modify “*yi4*” in *liu2yi4* ‘keep mind= pay attention to’, so there is no discussion in this example here.

constructions have the pragmatic function of trivializing the frequency of the events. Thus, verbal classifiers are allowed to be inserted in Type A, Type B, Type C, and partially Type D, only not in Type E, which should be more acceptable into VN compounds (See Table 4).

It is worth mentioning that verbal classifiers can only be partially inserted into Type D. Since VO<sub>4</sub> compounds in Type D have dual status, the insertion is more acceptable into compounds, which might incline towards phrases. By comparison, compounds that might tend to be words are more difficult to have the insertion of verbal classifiers. The other reason might be related to the semantic meanings of VO<sub>4</sub> compounds. While the semantic meaning is related to seriousness, responsibility or worry, which delivers negative personal feelings, the insertion is hard to be acceptable<sup>6</sup> because it is hard and unwilling to trivialize the frequency of negative emotions or events.

**Table 4: Acceptability of insertion in V-CL (verbal)-N**

	Form and Feature	Example
<b>Type A</b>	VO <sub>1</sub> as regular phrases	<i>da3-ci4-zhang1lang2</i> ‘hit (kill)-once-a cockroach’ <i>sha3-ci4-ji1</i> ‘kill-once-a chicken’
<b>Type B</b>	VO <sub>2</sub> as regular phrases	<i>chi1-dun4-fan4</i> ‘have-a bowl of-meal’ <i>chang4-ci4-ge1</i> ‘sing-once-a song’
<b>Type C</b>	VO <sub>3</sub> as idiomatic phrases	<i>da3-chang3-qiu2</i> ‘hit-once-ball = play balls’ <i>kai1-ci4-dao1</i> ‘open-once-knife = operate’,
<b>Type D</b>	VO <sub>4</sub> have dual status	<i>kai1-ci4-xin1</i> ‘open-once-heart = be happy’ <i>*fang4-ci4-xin1</i> ‘put-once-heart = feel relieved’
<b>Type E</b>	VO <sub>5</sub> as words	<i>*guan1-ci4-xin1</i> ‘close-once-heart = be concerned with’ <i>*liu2-ci4-yi4</i> ‘keep-once-mind= pay attention to’

### 3.4 V-ge-N constructions

Although the general classifier “ge” has the similar function of nominal and verbal classifiers, it is the most acceptable, which can be inserted from Type A to Type D, but partially in Type E since VO<sub>5</sub> compounds are as (?) words and essentially hard to be inserted into any additional elements. In “V-ge-N” constructions, the original meaning of general classifier “ge” has been entrenched and thus could modify any kinds of nouns. “ge” is also used exclusively for modifying the whole event expressed

<sup>6</sup> For example, *dan1xin1* ‘carry-heart = worry’ and *fu4ze2* ‘bear-duty = be responsible’ of VO<sub>4</sub> compounds in Type D.

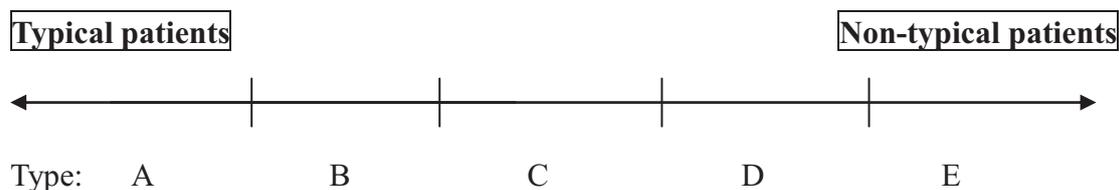

in VN compounds. When “*ge*” is inserted into more stative VN compounds in Type D and E, V-*ge*-N could be coerced to denote an event-like state, such as *kai-ge-xin* “doing something to have happy feelings”. Besides, the more frequently use of compounds in Type E is, the more likely the insertion of “*ge*” into it is allowed. In this case, the pragmatic function of “*ge*” insertion is to trivialize the whole event, representing the speakers’ casual attitudes toward these events and even decrease the extent of the speaker’s feelings, attitudes or emotions. The summary of the insertion of “*ge*” is shown in Table 5.

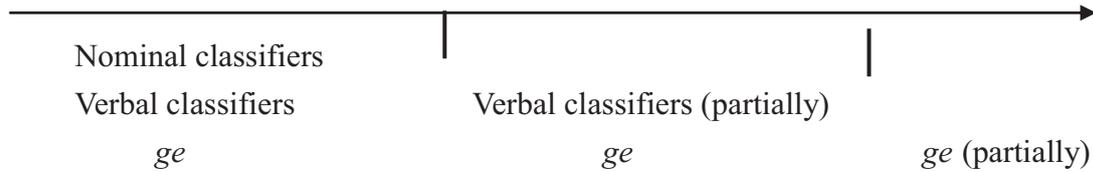

**Table 5: Acceptability of insertion in V-*ge*-N**

	Form and Feature	Example
<b>Type A</b>	VO <sub>1</sub> as regular phrases	<i>da3-ge-zhang1lang2</i> ‘hit (kill)-GE-a cockroach’ <i>sha3-ge-ji1</i> ‘kill-GE-a chicken’
<b>Type B</b>	VO <sub>2</sub> as regular phrases	<i>chi1-ge-fan4</i> ‘have-GE-meal’ <i>chang4-ge-ge1</i> ‘sing-GE-song’
<b>Type C</b>	VO <sub>3</sub> as idiomatic phrases	<i>da3-ge-qiu2</i> ‘hit-GE-ball = play balls’ <i>kai1-ge-dao1</i> ‘open-GE-knife = operate’,
<b>Type D</b>	VO <sub>4</sub> have dual status	<i>kai1-ge-xin1</i> ‘open-GE-heart = be happy’ <i>fang4-ge-xin1</i> ‘put-GE-heart = feel relieved’
<b>Type E</b>	VO <sub>5</sub> as words	<i>guan1-ge-xin1</i> ‘close-GE-heart = be concerned with’ <i>liu2-ge-yi4</i> ‘keep-GE-mind= pay attention to’ <i>shi1-ge-wang4</i> ‘lose-GE-hope = be disappointed’ <i>de2-ge-yi4</i> ‘gain-GE-will = be proud’

### 3.5 Summary

There is a continuum for three types of classifiers to insert into VN compounds as the following diagram and table. Nominal classifiers are more acceptable towards VN compounds, in which nouns tend to be typical patients while the general classifier *ge* has the most acceptability in the insertion. The acceptability of verbal classifiers is intermediary between nominal classifiers and the general classifier.

Type	Feature	Acceptability
Type A	Regular phrase	“ge” and both CL are acceptable in insertion.
Type B	Regular phrase	“ge” and both CL are acceptable in insertion.
Type C	Idiomatic phrase	“ge” and verbal CL are acceptable in insertion.
Type D	Dual status	Verbal CL is partially acceptable in insertion. “ge” and verbal CL is acceptable in insertion.
Type E	Words	Only “ge” is partially acceptable in insertion

The various degrees of acceptability of inserting distinct types of classifiers into different kinds of VN compounds could be accounted for by the semantic compatibility between the two constructions. If the noun components in the compounds have more literal interpretations, the integration of nominal classifiers tends to be allowed. On the contrary, once the nouns acquire metaphorical or metonymic readings, verbal classifiers and “ge” are more compatible with such VN compounds and thus their insertions are more acceptable. One observation worth noting is that the original meanings of CL are preserved when they are embedded into VN structures. In contrast, the general classifier “ge” originally serves to modify mostly nouns, similar to noun classifiers yet with less restriction. Moreover, “ge” gradually extends its functions, which is also used to modify the whole event and even the state of human’s feelings and emotions designated in given VN structures.

#### 4. Contexts of V-ge-N and V-CL-N

As the pragmatic function of V-ge-N and V-CL-N constructions is dissimilar, the contexts for these two constructions are different from each other. In V-ge-N construction, the topic of the contexts does not focus on the VN events or nouns only, which has a variety of topic which may not be the same as previous one as in (8).

(8) *xiang3 zhe guo4qu4 yi4 nian2 hen3 xing4yun4 de zai4*  
 want ASP past one year very lucky particle on

*bu4luo4ge2 shang ren4shi4 le yi4xie1 peng2you3, ke2neng2*  
blog on know particle some friend if possible

*dehua4, xi1wang4 zao3wan3 neng2 you3 ji1hui4 yi4qi3*  
hope early or late can have chance together

*chi1-ge-fan4*

have a meal

‘(I) think that I am lucky to know some friends on blogs in past one year. If possible, I hope we can have a meal sooner or later.’

On the contrary, in V-CL-N constructions, the topic of contexts is clearer and specific, which is always fixed on the nouns in the VN compounds as in (9).

(9) *zhe4shi4 er2zi zui4 xi3huan1 chi1 de fan4, ping2shi2*  
this is son most like eat modifier rice usually

*qing4 ta1 chi1-wan-fan4 du1 dei3 san1cui1si4qing3 de,*  
please he eat a-bowl-of rice all need wait particle

*dan4 mei3ci4 zhi3you4 shu3 she4ge fan4 ta1 dou1 ke3yi3*  
but every time only cook this rice he all can

*chi1 liang2wan3*  
eat two bowl

‘This is my son's favorite meal. Every time I need to wait for him to eat a bowl of meal, but as long as I cook this meal, he can eat two bowls of rice.’

The different contexts of V-ge-N and V-CL (nominal)-N constructions explain that their distinct pragmatic functions. V-ge-N construction is used to trivialize the nouns, events, status, or personal emotions while V-CL (nominal) -N constructions still maintain the original function of nominal classifier, which are used to modify the following nouns. In the contexts, the topic in V-CL (nominal) -N constructions puts emphasis on the noun rather than event whereas that in V-ge-N construction diversity to all kinds of topic.

## 5. Conclusion

In conclusion, according to Construction Grammar, constructions are defined as form-meaning pairs. In this case, different kinds of classifiers, when they are inserted into distinct types of VN compounds, have dissimilar constructional meanings and pragmatic functions of trivializing and focusing, causing different forms and meanings in “V-*ge*-N” and “V-CL-N” patterns. Moreover, the topic of the contexts is distinct in “V-*ge*-N” and “V-CL-N” constructions. Therefore, “V-*ge*-N” and “V-CL-N” constructions should be viewed as different constructions in Mandarin Chinese.

# Korean Vowel Harmony and Grammatical Change

Hijo Kang

Stony Brook University  
Department of Linguistics, Stony Brook University, Stony Brook, NY 11794-4376  
[hikang@ic.sunysb.edu](mailto:hikang@ic.sunysb.edu)

## Abstract

The purpose of this paper is to investigate the phonological factors affecting the acceptability of disharmonic forms in Korean verbal conjugation. Intervening consonant, trigger vowel, and target position turned out to be significant factors by means of an experiment where subjects rated the well-formedness of harmonic and disharmonic forms. The results show that vowel harmony is more likely to be retained in places where it assists with lexical retrieval. This supports Kaun (1995)'s argument that VH should be viewed as a means of enhancing the perceptibility of the triggering element.

**Keywords:** Vowel harmony, Historical change, Perceptibility, Lexical access, Korean.

## 1. Introduction

What motivates vowel harmony (VH)? There have been two answers in literature. From the viewpoint of articulation, the occurrence of shared features and/or gestures increases articulatory economy (Lindblom 1983). Based on this assumption, Cole et al. (2002) show that front/back VH facilitates fast speech production, reducing the incidence of errors. On the other hand, Kaun (1995) argues that VH should be viewed as a means of enhancing the perceptibility of the triggering element. Focusing on round harmony, she shows harmony serves to extend the duration of phonetic information.

Sometimes diachronic changes of language reveal what synchronic grammar is like, in a more dynamic way. VH in Korean verbal conjugation is such a case. In Korean, some verbal suffixes have two allomorphs, *a*-initial for [-ATR] stems and *ʌ*-initial for [+ATR] stems. Modern Korean is losing the *a*-initial forms, which means the leveling of suffix forms is in progress. However, it is not the case that all [-ATR] stems are selecting the disharmonic forms at the same rate. In this paper, with the results of an experiment which was conducted to measure the acceptability of harmonic and disharmonic forms, I will show what factors affect the acceptability of the disharmonic

forms. I will then, argue that they are accounted for by perception, rather than by articulation in that VH is more likely to be retained in places where it assists with lexical retrieval. In addition, I will show that frequency, which is a well-known factor in historical change, does not show a significant correlation with the acceptability. In the following section, I will show what the historical change in Korean VH is and what factors can be relevant to the change. In section 3, the experiment will be described focusing on the design and the results. In section 4, I will discuss each significant factor before I suggest that VH enhances the perceptibility of the stems and facilitates lexical access.

## 2. Korean VH and the tendencies in historical change

### 2.1. Korean vowel inventory

The vowel inventory of Korean has changed over time. Older speakers, over 60, have up to 10 monophthongs, as in (1a), while younger speakers have seven, as in (1b). The two front round vowels in (1a) has been diphthongized in the younger generation's pronunciations (/y/ → /wi/ and /ø/ → /wɛ/), and front mid and low vowels have merged (/e/ and /æ/ → /ɛ/, Silva and Jin 2008). This change in the vowel system has resulted in a disproportion with regard to the [ATR] feature, with only 2 [-ATR] vowels.

#### (1) Korean vowel inventory

##### a. Older generation

	[+ATR]		[-ATR]	
[+hi], [-lo]	i / y	ɯ / u		
[-hi], [-lo]	e	ʌ	ø	o
[-hi], [+lo]			æ	a
	[-bk]	[+bk]	[-bk]	[+bk]

##### b. Younger generation

	[+ATR]		[-ATR]	
[+hi], [-lo]	i	ɯ / u		
[-hi], [-lo]	ɛ	ʌ		o
[-hi], [+lo]				a
	[-bk]	[+bk]	[-bk]	[+bk]

## 2.2. VH in verbal conjugation

There is no consensus with regard to the harmonic feature in Korean. Some researchers regard Korean VH as horizontal harmony (i.e., [+high] vs. [-high], Moon 1974, Huh 1985, among others). Others take it to be vertical or palatal harmony (i.e., [-back] vs. [+back], Lee 1968, Lee 1984, among others). Here I assume that [ATR] is the harmonic feature, following Cho (1994), Ahn (1998), Kim (2003), etc.

Some verbal suffixes<sup>1</sup> have a pair of allomorphs containing /a/ or /ʌ/, one of which is selected in accordance with the [ATR] feature of stems. As the examples in (2) show, [+ATR] stems always take the [+ATR] suffix form.

(2) Examples of VH in verbal conjugation : [+ATR] stems  
phonetic forms Gloss

- a. tɕu-ʌ/\*a to give-imperative
- b. mʌk-ʌ/\*a to eat-imperative
- c. pɛ-ʌ/\*a to cut-imperative
- d. tɕ'ik-ʌ/\*a to vote-imperative
- e. kuʌs-ʌ/\*a to draw-imperative

When a stem contains more than one vowel, the last vowel is the trigger vowel, as in (3).

(3) Trigger vowels in heterosyllabic stems : [+ATR] stems

- a. pot<sup>h</sup>ɛ-ʌ/\*a to add-connective
- b. tat<sup>h</sup>u-ʌ/\*a to fight-connective
- c. s'otatɕi-ʌ/\*a to pour-connective
- d. ans'urʌp-ʌ/\*a to be pitiful-connective

However, while most [-ATR] stems take only [-ATR] suffixes, some may also take [+ATR] suffix forms as in (4b):

(4) Examples of VH in verbal conjugation : [-ATR] stems

- a. top-a/\*ʌ to help-imperative
- b. tɕap-a/ʌ to catch-imperative

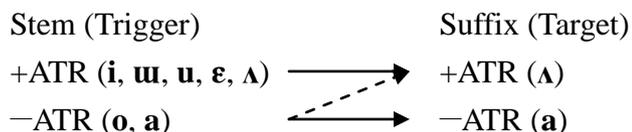

---

<sup>1</sup> Suffixes which begin with /a/ or /ʌ/ belong to this type (e.g., -a/ʌ□ 'imperative, declarative, or connective', -a/ʌss 'past', -a/ʌto 'though', etc.).

Consonant- or other vowel- initial suffixes (e.g., -ko 'and', -umjan 'if') don't harmonize with stems.

Thus, while Korean verbal stems generally undergo [ATR] harmony, the [+ATR] suffix has begun to be used with both [+ATR] and [-ATR] stems. Suffixes are in the process of leveling to the [+ATR] form:

(5) The direction of diachronic change

However, this leveling is not across the board, as not all stems are equally likely to take the generalized [+ATR] suffix. The question, then, is what factors determine the likelihood that a given stem will take the generalized suffix. In the remainder of this paper, I will focus on the [-ATR] stems (/o/-stems and /a/-stems), which show variation with regard to VH. The horizontal combination of [-ATR] stems with [-ATR] suffixes in (5) will be called ‘harmonic form’ and the diagonal combination with [+ATR] suffix will be called ‘disharmonic form’, in the rest of this paper.

### 2.3. Factors to be investigated

In this research, I will investigate how 7 factors affect the speakers’ choice of suffix:

(6) Factors in the variation of VH and expectations

- |   |  |
|---|--|
| a. Intervening Consonant  | No intervening consonant, no variation                   |
| b. Trigger Vowel  | More variation in /a/-stems than in /o/-stems            |
| c. Stem Length  | More variation in long stems                             |
| d. Target Position  | More variation in sentence-final position                |
| e. Morphological Structure Similarity among morphologically-related stems |  |
| f. <i>P</i> -irregularity   | More variation in <i>p</i> -irregular stems <sup>2</sup> |
| g. Frequency  | More variation in low-frequency stems                    |

#### 2.3.1. Intervening consonant

---

<sup>2</sup> These are irregular in that /p/ becomes [w] between vowels. E.g., /komap-a/Λ/ → [komaw-a/Λ]

The first factor is the absence of an intervening consonant, which has been reported to bring about categorical results (Kim 2000, Kang 2002). VH applies in vowel-final stems:

- (7) No intervening consonant<sup>3</sup>
- a. t<sup>h</sup>εΛna-a/\*Λ to be born-declarative
  - b. torapo-a/\*Λ to take care of-declarative

In contrast, the consonant-final stems in (8) with the same vowel can take both harmonic and disharmonic forms.

- (8) Intervening consonant
- a. pujaΛtɕap-a/Λ to take hold of-declarative
  - b. nalk<sup>h</sup>arop-a/Λ to be sharp-declarative

In most cases of VH, consonants are known not to play any role. As van der Hulst & van de Weijer (1995) point out, VH is rarely blocked by consonants with no secondary articulation, although Kim (2000) argues that consonants block VH.

### 2.3.2. Trigger vowel

The second factor is the quality of the trigger vowel. The two [-ATR] vowels in modern Korean, /a/ and /o/, behave differently when they appear in monosyllabic stems. As (9a) and (9b) show, the trigger vowel /a/ can take either suffix, while /o/ takes only the harmonic suffix (9a' and 9b')<sup>4</sup>.

- (9) Trigger vowels : /a/ vs. /o/
- a. tɕap-a/Λ to catch-declarative
  - a'. tɕop-a/\*Λ to be narrow-declarative
  - b. mal-a/Λ to roll-imperative
  - b'. mol-a/\*Λ to drive-imperative

The difference between /a/ and /o/ does not seem to be restricted to monosyllabic

<sup>3</sup> Hiatus is avoided through deletion or gliding.

<sup>4</sup> Kang (2002: 8) presents some exceptions to this generalization, where monosyllabic /o/-stems are combined with [+ATR] suffix forms. e.g., tor-a 'to return-connective'

stems. Hong (2008) reports the overall percentages of disharmonic forms as 10.27% for /a/-stems and 0% for /o/-stems (excluding *p*-irregular stems).

### 2.3.3. Stem length

The third factor affecting harmony is the length of the stem. Kim (2000) notes that there is a categorical difference between monosyllabic /o/-stems and the other /o/-stems: monosyllabic /o/-stems do not allow disharmonic suffixes:

(10) Monosyllabic /o/-stem (Kim 2000: 344)

- a. tot-a/\* $\Lambda$  to sprout-declarative
- b. top-a/\* $\Lambda$  to help-declarative

However, polysyllabic /o/-stems do allow disharmonic suffixes:

(11) Polysyllabic /o/-stem (Kim 2000: 346)

- a. s $\epsilon$ rop-a/ $\Lambda$  to be new-declarative
- b. w $\epsilon$ rop-a/ $\Lambda$  to be lonely-declarative

Hong (2008)'s data show that this categorical difference exists only in *p*-irregular stems. In my intuition, there seems to be another effect of stem-length, which is that longer stems are more likely to accept disharmonic suffix forms, while shorter stems are likely to refuse them.

(12) Stem-length ('A  $\gg$  B' means 'A is better than B')

- |    |                |       |                              |       |  |                   |
|----|----------------|-------|------------------------------|-------|--|-------------------|
| a. | mak- <b>a</b>  | $\gg$ | k' $\epsilon$ tat- <b>a</b>  | $\gg$ | kamt $\zeta$ 'okkat <sup>h</sup> - <b>a</b>  | harmonic forms    |
| b. | mak- $\Lambda$ | $\ll$ | k' $\epsilon$ tat- $\Lambda$ | $\ll$ | kamt $\zeta$ 'okkat <sup>h</sup> - $\Lambda$ | disharmonic forms |
|    | to block       |       | to realize                   |       | to be as good as                             |                   |

### 2.3.4. Target position

The fourth and last phonological factor is the sentential position of the target vowel. When the target vowel (*a* or  $\Lambda$ ) belongs to the final syllable of sentence, in my intuition, it is more likely to be disharmonic (generalized to / $\Lambda$ /). This is complicated to describe, because two sub-conditions must be met to satisfy this condition: 1) The suffix has only one syllable; 2) The suffix is sentence-final (does not have any following (auxiliary) verbs or other suffixes). These two conditions result in the target vowel

being the final syllable of sentence, as in (13)<sup>5</sup>. In this case, the disharmonic form sounds more natural than the other cases.

- (13) Sentence-final position  
 ... tɕap-a/ʌ ]<sub>S</sub>                    to catch-imperative

In (14a), though the suffix is a sentence-ending, the target vowel is not in the final syllable because the suffix has two syllables. In (14b) and (14c), the suffix is followed by other verbs. In these cases, the disharmonic forms sound much worse than in (13).

- (14) Non-sentence-final positions
- a. ... tɕap-a.ra/?ʌ.ra ]<sub>S</sub>                    to catch-imperative
  - b. ... tɕap-a/?ʌ kanta ]<sub>S</sub>                    to catch-connective progressive
  - c. ... tɕap-asʌ/?ʌsʌ kat'a ]<sub>S</sub>            to catch-connective and go

### 2.3.5. Frequency

The last factor is frequency, which is a well-known factor in historical change (Bybee 2001, Corbett et al. 2001, Phillips 2006, among others). Bybee (2001) argues that, by and large, morphosyntactic change tends to spread to low-frequency words first, while phonetically based change occurs first in high frequency words. If the leveling of suffix forms is due to speakers' intention to decrease the size of the lexicon by eliminating the alternation, as Kang (2002) argues, then we could expect that low-frequency words will be the first to accept the linguistic innovation or the generalized suffix forms, as in English irregular verbs (Bybee 2002: 34).

- (15) Summary of the phonological factors
- a. Factor I – Intervening C :            Without intervening consonants,  
the non-harmonic form is not allowed.
  - b. Factor II – Trigger vowel :            Monosyllabic stems with /o/ trigger vowel  
do not allow the non-harmonic form.  
/o/ triggers VH more often than /a/.
  - c. Factor III – Stem-length :            Longer stems are more likely to be  
non-harmonic than shorter stems.
  - d. Factor IV – Target-position :        When the target vowel is in the sentence-

---

<sup>5</sup> There are only three suffixes which satisfy the two conditions. They share the same phonological form, -a/ʌ, but have different functions, declarative, imperative, and interrogative.

- e. Factor V – Frequency :                      final syllable, it is more likely to be non-harmonic.  
 Low frequency stems are more likely to be non-harmonic than high frequency ones.

## 2.4 Hypotheses

Based on the previous literature and my intuition, I hypothesized as follows:

### (16) Summary of hypotheses

- a. Hypothesis I :            /o/-stems are less likely to take non-harmonic suffixes than /a/-stems.
- b. Hypothesis II :        Longer stems are less likely to take non-harmonic suffixes than shorter stems.  
       Hypothesis II-1 :    Monosyllabic /o/-stems do not take non-harmonic suffixes.
- c. Hypothesis III :       Non-harmonic target vowel is more likely to be selected at sentence-final position than in other positions.
- d. Hypothesis IV :       Low frequency words are more likely to take non-harmonic suffixes than high frequency ones.

An experiment was conducted to test the hypotheses. The details of the experiment will be described in the following section.

## 3. Experiment

### 3.1. Design

For the stimuli, ‘real’ Korean words were selected for two reasons. First, nonce words have no frequency. Second, [-ATR] stems in Korean seem to constitute a ‘closed’ category, because only [+ATR]-triggering verbal suffixes (e.g., *-ha*<sup>6</sup> and *-twe-*) are used in the formation of new verbal stems. 44 stems were selected and 60 tokens were

---

<sup>6</sup> Though the trigger vowel is /a/, it takes /-jA/-initial suffixes. This will be discussed later.

made. Only stems with stem-final consonant were selected because stems without stem-final consonants do not show the variation. 44 stems, half with /o/ and half with /a/, were used to produce 30 tokens of each stem vowel type. For each of /o/ and /a/ stems, 9 monosyllabic stems, 9 bisyllabic stems, and 4 trisyllabic stems were selected. Monosyllabic and bisyllabic stems, respectively, consisted of the same number (3) of low, mid, and high frequency stems and trisyllabic stems consisted of the same number (2) of low and mid frequency stems<sup>7</sup>. Lastly, *p*-irregular stems are more likely to be disharmonic, as mentioned in the previous section. Three bisyllabic and four trisyllabic *p*-irregular stems were included where there were no other regular stems which fit for other conditions like trigger vowel, stem length, and frequency. To test the target position effect, 16 stems out of 44 stems were selected since they can be used naturally irrespective of the position in a sentence. The 16 stimuli contained 2 tokens of each stem. In one of the two tokens, the target vowel is in the final syllable and in the other, it is not. The 16 stems are balanced in terms of other conditions like trigger vowel, stem-length, and frequency. Based on the frequency data presented by The National Institute of the Korean Language (NIKL, www.korean.go.kr), The 44 stems are classified as 16 low frequency stems (0 to 9 occurrences), 16 mid frequency stems (10 to 99 occurrences), and 12 high frequency stems (more than 100 occurrences). Each group is balanced in terms of other conditions, except that there is no high frequency trisyllabic stem. I call this ‘written frequency’, because the frequency data were made based on written corpus. Besides the question of whether frequency is relevant, we’ve got another question about frequency. That is, which frequency, if any, is relevant. In Bybee’s exemplar model, the memory unit is a word (real form), not analyzed stem or suffix (Bybee 2001: 187). From this, it is inferred that the frequency should be based on real forms (suffixed forms) rather than pure stems. Therefore, other frequencies were obtained as follows: based on the ‘spoken’ part of the Sejong Balanced Corpora<sup>8</sup>, ‘spoken-stem frequency’ was measured and there all the occurrences of the stems are included (21 lows, 14 mids, and 9 highs). Lastly, ‘spoken-word frequency’, where only *a/ʌ*-initial suffixed forms are considered (26 lows, 16 mids, and 2 highs), was obtained.

(17) The questionnaire – an example

- 감기가 이렇게 \_\_\_\_\_ . - Context
- kamki-ka irʌŋk<sup>h</sup>ε \_\_\_\_\_.
- Flu-Nom like\_this \_\_\_\_\_.

<sup>7</sup> Here, the frequency is based on the frequency data presented by The National Institute of Korean Language (written language corpus).

<sup>8</sup> They are compiled by the 21st Sejong Project and distributed by the National Institute of Korean Language in 2002.

읍어	읍아	- Target forms
olm-Λ	olm-a	
spread-declarative	spread-declarative	
(Non-harmonic)	(harmonic)	
○ ○ ○ ○ ○ ○ ○		- Choices
① ② ③ ④ ⑤ ⑥ ⑦		
		Preference Value
① Only the form on the left ( <b>non-harmonic</b> ) is possible.		(-3)
② Both are possible, but the lefthand form is highly preferred.		(-2)
③ Both are possible, but the lefthand form is slightly preferred.		(-1)
④ Both forms are equally good.		(0)
⑤ Both are possible, but the righthand form is slightly preferred.		(1)
⑥ Both are possible, but the righthand form is highly preferred.		(2)
⑦ Only the form on the right ( <b>harmonic</b> ) is possible.		(3)

After the 44 stems were selected, I googled each stem in order to find a natural sentence or context. With the sentences, a questionnaire was created. An example is presented in (17). Subjects were requested to read the context and then the target forms (harmonic and disharmonic). Based on the criteria in (17), they selected one of given seven choices. The choices were converted to numerical value equivalents (PV, preference value) given in the latter part in (17).

### 3.2. Participants

28 native speakers of Korean (11 males and 17 females), in their 20's and 30's took part in this experiment. Most of them were undergraduate or graduate students at Stony Brook University, who had been in the US for less than 5 years. 20 speakers were from Seoul or Gyeonggi Province, where standard Korean is spoken.

### 3.3. Procedure

Every subject was requested to fill out a form about demographic information like age, place of birth, duration of living in the US, and so on. They were trained with 5 questions, which were not used in the main questionnaire. They were then asked if they understood how to select one out of the seven choices. If the answer was yes, the main questionnaire was given. Their choices were converted to PV's, which were the

corresponding numbers ranging from -3 to 3 (see (17)). 1680 PV's (60 questions \* 28 subjects) were obtained. Then a series of two-tailed *t*-tests were performed for all the factors.

### 3.4. Results

#### 3.4.1. Trigger vowel

PV's were significantly higher in /o/-stems than in /a/-stems, which means that /a/-stems are more likely to take the generalized [+ATR] suffix forms. This confirms the hypothesis 1 in (16). The average values for the two trigger vowels were 2.18 and 1.78 ( $t(839) = 4.496, p < 0.001$ ).

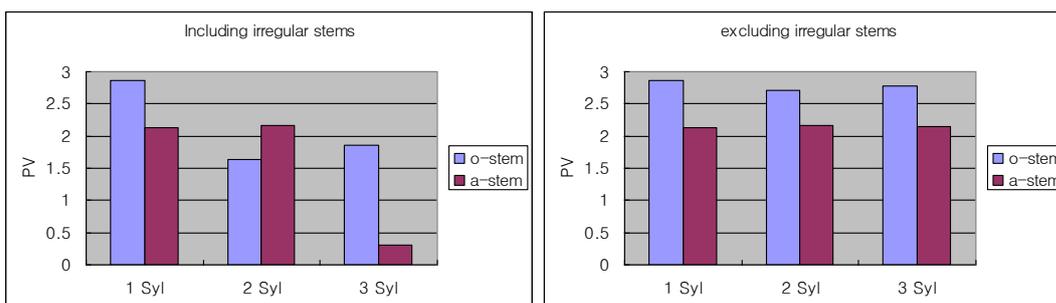

(18) Results : Significant difference ( $t(839) = 4.496, p < 0.001$ )

	Mean	N	Std. Deviation	Std. Error Mean
/o/	2.18	840	1.717	.059
/a/	1.78	840	1.763	.061

#### 3.4.2. Stem length

Unlike the prediction of hypothesis 2, there were no 'gradient' differences depending on the length of the stem. The PV's were in inverse proportion to the percentages of *p*-irregular stems. For example, monosyllabic and bisyllabic /a/-stems do not include any *p*-irregular stems, while trisyllabic /a/-stems have 50% of *p*-irregular stems. So I excluded *p*-irregular stems and got the averages, which are shown in the second chart. There were no significant differences among monosyllabic, bisyllabic, and trisyllabic stems (e.g., the averages for monosyllabic and bisyllabic stems were 2.43 and 2.40 ( $t(503) = 0.441, p = 0.660$ ). Therefore, hypothesis 2 in (16) is rejected.

(19) Results : No significant differences

Kim (2000) and Hong (2008) report that monosyllabic /o/-stems take [-ATR] suffix forms, while Kang (2002) finds some exceptions. The results of this experiments are consistent with Kang (2002)'s finding. The average is not 3, which means that at least some subjects think that some monosyllabic /o/-stems can also take [+ATR] suffix forms. Actually, 9 subjects gave a point lower than 3 to at least one of 9 one-syllable /o/-stems. To the subjects, one-syllable /o/-stems are no longer the last 'resistance' to the historical change of VH. However, before rejecting the hypothesis that there is no effect of stem length we should consider the fact that most long stems have two or more morphemes. Without eliminating this morphological effect, we cannot measure the stem length effect.

### 3.4.3. Target position

The target position, like the trigger vowel, produced significant differences. The results below indicate that the generalized [+ATR] vowel (-ɹ) is selected more often in sentence-final position than in the other positions. This confirms hypothesis 3 in (16).

(20) Result : Significant difference ( $t(447) = -7.599, p < 0.001$ )

	Mean	N	Std. Deviation	Std. Error Mean
Sentence-F	1.90	448	1.660	.078
Non-Sentence-F	2.35	448	1.379	.065

### 3.4.4. Frequency

The results indicate that frequency is not relevant, as shown in (21). The first table is the result of written frequency, the second is of spoken-stem frequency, and the third is of spoken-word frequency.

(21) Results : No significant differences

$t(447) = -1.160, p = 0.247$  (Low and Mid) &  $t(447) = 1.125, p = 0.261$  (Mid and High)

Group A	Mean	N	Std. Deviation	Std. Error Mean
Low F	2.16	448	1.528	.072
Mid F	2.27	448	1.440	.068
High F	2.17	448	1.508	.071

$t(279) = -1.012, p = 0.313$  (Low and Mid) &  $t(279) = 0.618, p = 0.537$  (Mid and High)

Group B	Mean	N	Std. Deviation	Std. Error Mean
Low F	1.95	280	1.731	.103
Mid F	2.03	280	1.702	.102
High F	1.94	280	1.666	.100

$t(391) = 1.737, p = 0.083$

Group C	Mean	N	Std. Deviation	Std. Error Mean
Low F	1.73	392	1.892	.096
Mid F	1.50	392	2.085	.105

Relatively low significance ( $p = 0.083$ ) in the results of spoken-word frequency implies that if frequency is relevant, the frequency would be based on the suffixed forms, not on the analyzed stem forms. In spite of this marginal relevance, the direction is the opposite to the prediction. To say, the mean for mid frequency words (1.50) is lower than that for low frequency words (1.73). So the hypothesis 4 in (16) is rejected.

The summary of the results is given in (22).

(22) Summary

A. Phonological factors

- i) Hypothesis I - Trigger Vowel √
- ii) Hypothesis II - Stem Length X
- Hypothesis II-1 - Monosyllabic /o/-stems X
- (But, valid for some participants.)
- iii) Hypothesis III - Target Position √

B. Non-phonological factors

- i) Hypothesis IV - Frequency X

In the following section, I will discuss how the results can be accounted for.

## 4. Discussion

### 4.1. Intervening consonant

Though the first phonological factor, intervening consonant, was not tested in the experiment, it is necessary to account for why this factor brings about a categorical difference. To repeat, with intervening consonant, both the harmonic and the disharmonic forms are possible (e.g., *tʰana-a/\*ʌ* ‘to leave’ vs. *metal-a/ʌ* ‘to hang’). At first glance, it seems that consonants block VH. But there are some reasons to doubt it. First, types or features of consonant do not seem relevant (Kang 2002: 16)<sup>9</sup>. Second, intervening consonants cannot block VH in case of (at least, some) monosyllabic /o/-stems. Therefore, we should ask not why consonants can block VH but why VH should always apply when there is no intervening consonant.

In many languages with VH, it is found that the influx of loanwords results in the weakening of VH (e.g., Mongolian, Svantesson 2005) and Korean is not an exception (Han 1996). This means that pure Korean words including verbal stems and suffixes exhibit a relatively strong tendency to maintain VH. Another difference between pure Korean and Sino-Korean words is that the former avoids VV sequences while the latter does not have any restriction on them. As a result, it is almost impossible to find disharmonic VV sequences (e.g., [aʌ] and [oʌ]) in pure Korean words. So I argue that there is no blocking effect of consonant in Korean VH, even though there seems to be. Instead other phonological constraints require VH on VV sequences.

#### 4.2. Trigger vowel

The results showed that /o/ triggers VH more often than /a/. In other words, /a/-stems are more likely to take the generalized [+ATR] suffix forms. According to the results, it seems that the leveling begins with /a/-stems first and then expands to /o/-stems.

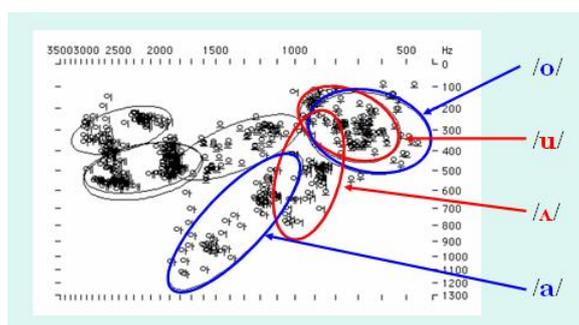

There might be two approaches to this problem. First, an articulation-based approach (Lindblom 1983) would argue that the harmony feature in mid vowels is realized in a more robust manner and, as a result, spreads more often than the harmony feature in other vowels. Alternatively, a perception-based approach (Kaun 1995) would argue that the harmonic feature in mid vowels is realized in a less robust manner and VH is required in order to enhance the perceptibility of the feature. I argue that the perception-based approach provides a better account for Korean VH. (23) shows the

<sup>9</sup> The proportions of disharmonic forms for each consonant type (Kang 2002: 16)

Type of C	lk	lm	th	kʰ	lh	n	p	m	nh	t	l	k	tʰ
Proportion	100	100	100	91.7	75	71	68.5	58.5	56.7	56.4	52.3	50	47

distributions of Korean monophthongs, based on F1 and F2 values. We can see that /o/ and /u/ share much of the formant space, which means that they could easily be confused. In contrast, /a/ and /ʌ/ seem sufficiently different from each other. This is why /o/-stems are more dependent on VH for their identification. This supports Kaun (1994: 86)'s argument that 'where a particular contrast is perceptually difficult, that difficulty has as its direct grammatical correlate a constraint of the "Bad vowel spreads" family.'

(23) The distributions of F1 and F2 of Korean monophthongs (Lee 1998)

#### 4.3. Stem length

The results confirmed that there is no 'gradient' effect of stem length. However, it is still true for many Korean speakers that monosyllabic /o/-stems do not allow the disharmonic forms, while polysyllabic stems do. So we need to account for why this is so (in other words, why the leveling of suffix forms spreads from long stems to short stems).

What makes monosyllabic stems exceptional? I argue that it is accounted for in the viewpoint of lexical access. Short stems have a comparatively small amount of phonological information and higher neighborhood density than long stems. This means that, sometimes, they cannot be identified easily by themselves. Here, harmonic suffixes could facilitate the lexical access of the stem. The examples in (24) show how they work.

(24) Minimal pairs

- |    |       |             |       |                |
|----|-------|-------------|-------|----------------|
| a. | tɕap- | 'to catch'  | tɕapa | 'Catch!'       |
| b. | tɕʌp- | 'to fold'   | tɕʌpa | 'Fold!'        |
| c. | koru- | 'to select' | kolla | 'Select!'      |
| d. | kuru- | 'to roll'   | kulla | 'Roll!'        |
| e. | po-   | 'to look'   | pwa   | 'Take a look!' |
| f. | pu?   | 'to pour'   | pwa   | 'Pour (it)!'   |

Without any suffix, the only difference in each pair is the stem vowel (/a/ and /ʌ/ in a and b, /o/ and /u/ in c and d). In suffixed forms, the distinction depends not only on the stem vowel, but also on suffix vowels, which makes them more different from each other. (24e) and (24f) exemplify an extreme case. In the suffixed form, it is not the stem vowel but the suffix vowel that signals the distinction between the two stems, because the stem vowels become glides before other vowels. More concrete evidence comes from neighborhood density. I sorted out stems with /a/ and /o/ as trigger vowels from the list of verbs and adjectives by NIKL and calculated the average numbers of neighbors whose difference is only the trigger vowels. For instance, the neighbors of *ka-* ‘to go’ are *ki-* ‘to crawl’, *ko-* ‘to boil’, *kɛ-* ‘to fold up’, and *kwɛ-* ‘to prop’. These numbers in (25) indicate that polysyllabic stems have, if any, few neighbors.

(25) Neighborhood density

a. Verbs

- i. One-syllable (89 stems) : 1.416
- ii. Two-syllable (165 stems) : 0.103
- iii. Three-syllable (490 stems) : 0

b. Adjectives

- i. One-syllable (26 stems) : 0.5
- ii. Two-syllable (73 stems) : 0
- iii. Three-syllable (132 stems) : 0

Trigger vowels in monosyllabic stems are word-initially positioned, while those in polysyllabic stems are not. If the word-initial position is ‘strong’ or ‘privileged’, the trigger vowel would be stronger in the first syllable than in the second or third syllable (Kim 2000). This may be an alternative to the ‘monosyllabic stem’ problem. However, this does not account for why monosyllabic /a/-stems are not different from polysyllabic /a/-stems.

#### 4.4. Target position

The results showed that the phonological feature of the suffix is also related to the acceptability of the disharmonic forms. The disharmonic target vowel, [ʌ], is more likely to appear when it is in the sentence-final position. Here, it is the perceptibility of the suffix, not of the stem, that should be enhanced, because the (sentence-final) position bears a significant information load in Korean, as shown in (26), where suffixes

signal the intent of the speaker, without changing other parts of the sentence<sup>10</sup>.

(26) The intentions expressed by the final syllable

tɕ <sup>h</sup> ʌlsu-ka	ʌtɕɛ	p <sup>h</sup> itɕa-rʉl	mʌk-ʌs'	-ta	declarative (neutral)
C.S.-Nom	yesterday	pizza-Acc	eat-Past	-ʌ	declarative (informal)
				-tɕi	declarative (confirmative)
				-ni	interrogative (informal)
				-nja	interrogative (insolent)

We have to relate the fact that the sentence-final position is informative to the tendency for the generalized suffix form to be selected more often at this position. I argue that it is required by positional faithfulness. In other words, an informative position requires that the element should be more faithful to the input form. So the input form /ʌ/, rather than harmonic form /a/, is preferred.

Now, another question rises: why should the input form be /ʌ/? The evidence comes from some cases when we have two or more harmony suffixes with one stem. In such cases, only the first suffix harmonizes with the trigger vowel of stem. The second suffix always has the [+ATR] form even if the trigger vowel of the stem and the harmonized target vowel of the first suffix are [-ATR] vowels. For instance, *po-as'*-ʌ/\*a 'to look-Past-Declarative' does not allow the second suffix -a, though the stem vowel and the first suffix vowel are all [-ATR] vowels. If we assume that a vowel other than /ʌ/ is the input form, we would not be able to explain this phenomenon.

We can think of another approach to this phenomenon. In Korean, the final syllable of the Accentual Phrase is lengthened (Jun 1993) and this lengthening is sometimes accompanied by raising of the vowel. But this happens only when the final vowel is [o]. Some examples are given in (27).

(27) Accentual Phrase final raising

- a. na-to → natu: 'me-too'
- b. iri-ro → illu: 'here-to'
- c. kʉriko → kʉriku: 'and'
- d. samtɕ<sup>h</sup>on → samtɕ<sup>h</sup>u:n 'uncle'

If final raising expands to the sentence-final suffix -a, it would be raised to -ʌ (*tɕapa* → *tɕapaʌ* 'Catch (it)!') However, this analysis has some problems. First, the

<sup>10</sup> Usually, they co-occur with different intonations.

domains are different. The domain of final raising is the accentual phrase, but the change from /a/ to /ʌ/ has as its domain a sentence. Second, the change from /a/ to /ʌ/ is applied only to the sentence-final suffix *-a/ʌ*. This change does not occur in other cases where a sentence ends with /a/ (*kata* → \**kataʌ* ‘to go’). In this respect, this is an allomorphic alternation, rather than a phonological process. However, the final raising is not restrictive to a specific morpheme, as in (27).

#### 4.5. Frequency

The experiment results showed that frequency does not predict the likelihood of VH violation. This is confirmed by the verb *ha-* ‘to do’. If high frequency forms are less susceptible to morpho-syntactic change (Bybee 2001: 34), the most frequent verb *ha-* is expected to be the most conservative with regard to VH, which means it should combine with harmonic suffix forms. But *ha-* behaves in opposition to the prediction: the verb is the first [-ATR] verb to lose VH. The harmonic form (e.g., *haya*) is found in literature published in the early 20th century, but in modern Korean, it is always used with the [+ATR] suffix forms (e.g. *hayʌ*) even though it has the [-ATR] trigger vowel [a].

To understand the behavior of this verb, we can appeal once again to perceptibility. As Hong (1997) notes, *ha-* does not seem to have any contribution to semantics, because the meaning of the verb comes from the noun which is an object of the main verb *ha-* (28b) or a noun to which the verbal suffix *-ha* attaches (28a). The meaning of (28b) is not different from that of (28a), though its syntactic structure is a little bit different. This means that the main verb *ha-* does not have any specific lexical meaning. It just fulfills a syntactic requirement. As a result, there is no need to enhance the perceptibility of the verb or verbal suffix *-ha*<sup>11</sup>.

(28) Two usages of *-ha*

a. Verbal suffix

Yengse-nun Cinhyey-lul	sarangha-yss-ta	‘Yengse loved Cinhyey.’
Yengse-Top Cinhyey-Acc	love(v)-Past-Dec	

---

<sup>11</sup> There is another approach to this phenomenon. San Duanmu (p.c.) pointed out that it is likely that the verb *-ha* is articulatorily weakened because it is not meaningful and it is used very frequently. Phonetically driven changes like vowel reduction take place more in high frequency words (Bybee 2001: 34). As a matter of fact, this verb is sometimes realized as [h□ □] a fully weakened form. A weakened vowel is less likely to spread its feature to adjacent vowels, but this approach leaves the problem of how to reconcile the fact that other high frequency verbal stems still require VH. In addition, we have to account for how this gradient weakening gives rise to a categorical change (non-harmonizing).

b. Main verb

Yengse-nun Cinhyey-lul	sarang-ul	<b>ha</b> -yss-ta
Yengse-Top Cinhyey-Acc	love(n)-Acc	do-Past-Dec

## 5. Summary and implications

We have seen that phonological factors like intervening consonant, trigger vowel, and target position play an important role in determining the spreading of the generalized form. Without an intervening consonant, the disharmonic forms are impossible (e.g., \**tɕa-a* ‘to sleep’ vs. *tɕap-a* ‘to catch’). I propose that this is due to a phonotactic constraint which prohibits disharmonic vowel sequences from occurring in pure Korean words, rather than to ‘consonant blocking’. The results of the experiment showed that /o/, one of the two [-ATR] vowels in Modern Korean, triggers the VH of suffixes more often than /a/, the other [-ATR] vowel. This is accounted for by the weak ‘perceptibility’ of /o/. Because /o/ has a weak contrastiveness with /u/, its [+ATR] pair, it needs the harmonic suffix form to enhance the perceptibility. Finally, the generalized suffix form is selected more often when the target vowel is at the sentence-final position than when it is not. I argue that sentence-final position, since it is an informative position in Korean discourse, requires more faithful output to its input. Opposed to the predictions of the exemplar model (Bybee 2001), frequency does not appear to play a role. This is consistent with Kiparsky (1995: 659)’s conclusion, “..., the language’s internal structure can channel its own evolution, giving rise to long-term tendencies of sound change”.

The results and analyses shed light on the motivation for VH. The trigger vowel factor shows that VH facilitates lexical access of the stems in Korean verbal conjugation. It is even more obvious when the two factors (trigger vowel and stem length) are combined: monosyllabic /o/-stems, which are the last stems to accept the disharmonic forms, because they are the most difficult to identify by themselves. In this respect, the Korean data support Kaun (1995)’s argument that VH should be viewed as a means of enhancing the perceptibility of the triggering element.

# Korean Palatalization as Coarticulation: Stroboscopic cine-MRI and acoustic data on gradual tongue movements

Hyunsoon Kim

Department of English, Hongik University  
Sangsoo-dong 72-1, Mapo-ku, Seoul 121-791, Korea  
hyunskim@hongik.ac.kr

## Abstract

The present study addresses the question of whether Korean palatalization is a categorical process or a coarticulatory effect. For this purpose, we conducted a stroboscopic cine-magnetic resonance imaging (MRI) experiment from two native speakers of the Seoul dialect and examined whether tongue raising and fronting is the same as in the vowel /i/ in two types of Korean palatalization: a) when consonants occur before /i/ within a morpheme and b) when the consonants /t, t<sup>h</sup>/ occur before /i/ across a morpheme boundary. The MRI results that the tongue gradually rises and advances throughout the target consonants are further confirmed by our acoustic data taken from ten Seoulites. Based on this, we propose that Korean palatalization is a phonetic coarticulatory effect.

**Keywords:** Korean palatalization, coarticulation, stroboscopic cine-MRI data, acoustic data, gradual tongue movements.

## 1. Introduction

Korean palatalization has been assumed to be phonological with two processes in the framework of lexical phonology (e.g., Ahn 1985; Sohn 1987; Y.-M. Cho 2005). In one process called postlexical palatalization, any consonants are assumed to automatically change into postalveolar before the vowel /i/ within a morpheme, as shown in (1a). The other process is the lexically derived palatalization whereby the alveolar plosive consonants /t, t<sup>h</sup>/ change into their postalvolar affricate counterparts across a morpheme boundary, that is, before derivational or inflectional suffixes beginning with the vowel /i/, as in (1b).

### (1) Korean palatalization

#### a. postlexical palatalization

/mati/ → [ma.d<sup>i</sup>] ‘knot’

/si/	→	[sʲi]	‘poem’
/katʃi/	→	[ka.dʒi]	‘egg plant’
/kʻini/	→	[kʻi.nʲi]	‘meal’
/pʻalli/	→	[pʻal.lʲi]	‘fast’

b. lexical palatalization

/mat+i/	→	[ma.dʒi]	‘first child’ (‘child’+Nominalizer)
/kat <sup>h</sup> +i/	→	[ka.tʃ <sup>h</sup> i]	‘together’(‘to be like’+Adverbializer)
/put <sup>h</sup> +i+ta/	→	[pu.tʃ <sup>h</sup> i.da]	‘to be attached’(‘to attach’+Causative)
/tat+hi+ta/	→	[ta.tʃ <sup>h</sup> i.da]	‘to be closed’(‘to close’+Passive)

In the account of the two types of palatalization, the tongue has been proposed to move front and rise high toward the hard palate as much as in the vowel /i/ and the change of the tongue position has been given a formal account as a feature-changing (Kiparsky 1993), a feature-filling (Iverson 1993), or a featural assimilation (Y.-M. Cho 2005) process, depending on whether a target consonant is specified for [+anterior, -high] or not when the process applies. For example, according to Kiparsky (1993), Korean postlexical palatalization “applies in feature-changing fashion” with the features [+anterior] and/or [-high] changing into [-anterior] and/or [+high]. In the postlexical palatalization of the fricative /s/, the features [+anterior, -high] of the original fricative change into [-anterior, +high], and in the case of the lenis affricate /tʃ/ which is assumed to be underlyingly specified for [-anterior, -high], only the feature [-high] changes into [+high] by virtue of postlexical palatalization. The phonological account of Korean palatalization accords with the phonetic view of palatalization in Ladefoged and Maddieson (1996:363) among others, according to whom palatalization is “the superimposition of a raising of the front of the tongue toward a position similar to that for /i/.” From this, we would expect palatalization to involve both tongue raising and fronting, as in the vowel /i/, in the phonetics.

In the present study, we raise the question of whether Korean palatalization is a phonological process such that the tongue rising and fronting of palatalized consonants is as much as those of the vowel /i/ within a morpheme and across a morpheme boundary. This question is motivated by recent studies showing that Korean affricates are not postalveolar, but alveolar just like the coronal plosives /t, t<sup>h</sup>, tʻ/ in support of Skaličková (1960) (Kim 2001b, 2004) and that the change of /t, t<sup>h</sup>/ into alveolar affricates before the vowel /i/ across a morpheme boundary in (1b) is the phonological process of assibilation (Kim 2001a). The

present study is also motivated by the fact that there have been no empirical studies on tongue movements in the two types of palatalization in the literature.

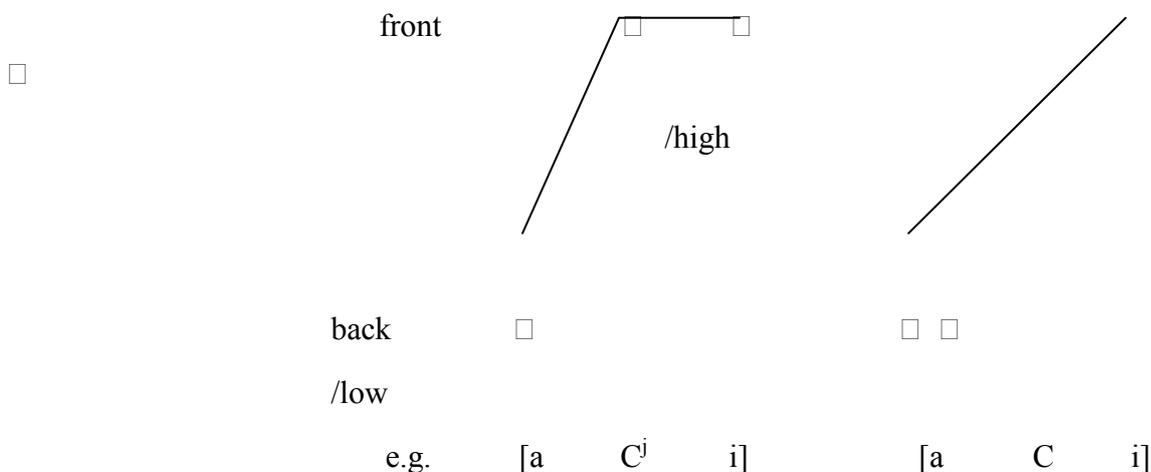

If a consonant in the context /a\_\_i/ is categorically palatalized across or within a morpheme in the phonology, it is specified for the feature [-back] for tongue fronting and for the feature [+high] for tongue raising in a standard feature theory (Chomsky and Halle 1968). Then in the target-interpolation model (e.g., Keating 1988a) as a model for the phonology-phonetics interface, a phonologically palatalized consonant is specified for the secondary vocalic features, as in the second segment in (2a i), when leaving the phonology, and phonetic targets are assigned as in (2a ii), along some scale for [-back] and for [+high]. These targets are then hooked up through interpolation, showing a fairly rapid transition between the neighboring back/low and front/high targets, that is, between the vowel /a/ and the following palatalized consonant. And the targets between the palatalized consonant and the following vowel /i/ form a plateau for the vocalic features [-back]/[+high], as in (2a iii).

On the other hand, if a consonant is not phonologically palatalized, it is unspecified for [-back] and also for [+high], as in (2b i), and only the first and last segments, which are already specified for the features [back] and [high] in phonology, receive phonetic targets, as shown in (2b ii). Hence, the intervocalic segment receives a transitional amount of the scale for the features from the phonetic context, showing gradual interpolation between the targets, as in (2b iii). As a result, the phonologically underspecified segment in (2b) has a continuously changing, transitional, quality from beginning to end that depends on context on either side. And the unspecified consonant is expected to be transparent to vowel-to-vowel transition in the sense of Öhman (1966).

iii. Phonetic Interpolation:

(B: [back], H:

[high])

In order to investigate whether the two types of Korean palatalization is phonological or phonetic in the sense of Öhman (1966) and Keating (1988a, b), we conducted a stroboscopic cine-MRI and an acoustic experiment, and examined tongue movements. The issue of whether a consonant preceding the vowel /i/ is phonologically palatalized or not would be empirically answered by the examination of neighboring vowels' F<sub>1</sub> and F<sub>2</sub> values in our acoustic data as well as of tongue raising and fronting from a target consonant to the following vowel /i/ in our stroboscopic-cine MRI data.

This paper is structured as follows. In the next two sections 2 and 3, stroboscopic cine-MRI and acoustic data on tongue movements in Korean palatalization are presented, respectively. In section 4, drawing on the experimental data, we discuss the nature of Korean palatalization as coarticulation. Section 5 is a brief conclusion.

## 2. Stroboscopic cine-MRI data

The MRI experiment was performed on a Shimadzu Marconi Eclipse Power Drive 250 (=1.5[T]) at Advanced Telecommunications Research Institute, Kyoto, Japan. Two middle-aged native speakers (one male and one female) speaking the Seoul dialect participated in the experiment. Each MRI image for midsagittal data of the two subjects' head and neck has a 256 mm x 256 mm field of view with a 10 mm slice thickness, mapped on to 256(x) x 256(y) pixels. Each trigger pulse signals the MRI controller to begin the field echo scans (TR=16.5 ms, TE=3 ms, NEX=1) repeated 52 times every 16.7 ms (60 frames/sec) for one of the 128 gradient magnetic field conditions which is maintained for each 1000 ms period and changed at each trigger pulse. During data acquisition, the subjects repeated 128 times

the seven test words in (3) and thus 128 MR scans for each of 52 sequential midsagittal frames were collected. The repetitions needed to be perfectly synchronized with MRI scanning in order to retain high quality motion imaging. To facilitate the synchronization, trigger generator software on a PC was used to output two types of signals: trigger pulses to initiate MRI scans and tone bursts for the subjects (see Masaki, et al., 1999). The obtained images were displayed on a computer screen with 8-bit gray-scale resolution for analysis.

- (3) a. /mat+i/ ‘first child’  
 b. /mati/ ‘knot’ /matsi/ (nonsense word)  
 /mat<sup>h</sup>i/ (nonsense word) /mats<sup>h</sup>i/ (nonsense word)  
 /mat<sup>ʔ</sup>i/ (nonsense word) /mats<sup>ʔ</sup>i/ (nonsense word)

As shown in Figure 1, we measured the distance between the highest part of the hard palate and the tongue body for tongue raising (a), and the distance between the tongue root and the pharyngeal wall for tongue fronting (b), as a function of time.

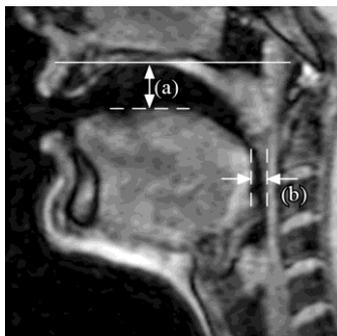

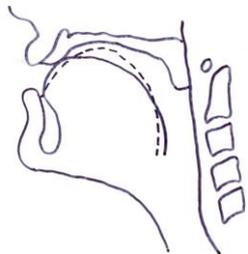

Figure 1. Measurements for tongue raising (a) and for tongue fronting (b).

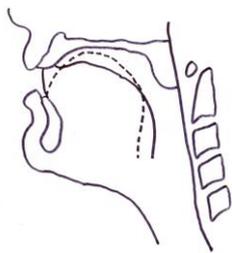

Figure 2 presents overlays of traced tongue contours of the lexically-derived affricate in /mat+i/ and the consonants /t, t<sup>h</sup>, t<sup>ʔ</sup>, ts, ts<sup>h</sup>, ts<sup>ʔ</sup>/ in /ma\_i/ at closure onset (marked with a solid line) and at the vowel /i/ (marked with a dotted line) from the female (i) and male (ii) subjects. In the examined contexts, we can note that, at the beginning of a target consonant, the tongue does not rise as high as in the following vowel /i/ and it does not move as front as in the vowel, either. For example, at the closure onset of the lexically-derived affricate in /mat+i/ (Figure 2a), the tongue has no configurations appropriate to the following vowel /i/, as in /mati/ and /matsi/ (Figure 2b, c), in the two subjects. This is also true of the other test words. Thus, regardless of a morpheme boundary, the tongue position at the

closure onset of the target consonants is not the same as in the following vowel /i/.

In order to more clearly see how the tongue rises and advances in the test words, we measured the distance for tongue raising, and for tongue fronting, as in Figure 1, from a closure of the consonants through a release onset to the vowel /i/ as a function of time. The result is in Figure 3.

a.

b.

pronounce \_\_\_' and the sentences were read four times at normal speed by ten speakers (five males and five females) including the two subjects in the above articulatory experiment, all of whom commanded the Seoul dialect. The test words were tape-recorded and the total 360 tokens (9 test words x 10 subjects x 4 repetitions) were then analyzed. In order to investigate whether or not the lexically-derived lenis affricate and the underlying consonants /t, ts/ before the vowel /i/ have tongue raising and fronting as much as the high front vowel, we investigated F<sub>1</sub> and F<sub>2</sub> frequency values of vowels adjacent to the target consonants. In order to measure F<sub>1</sub> and F<sub>2</sub> values, we put a cursor at the four points — (a) at the midpoint of the vocalic period in the first vowel, (b) at the end of the first vowel, (c) at the onset of the second vowel, (d) at the midpoint of the vocalic period for the second vowel — in wide-band spectrograms of the test words, as shown in Figure 4.

**4 kHz**

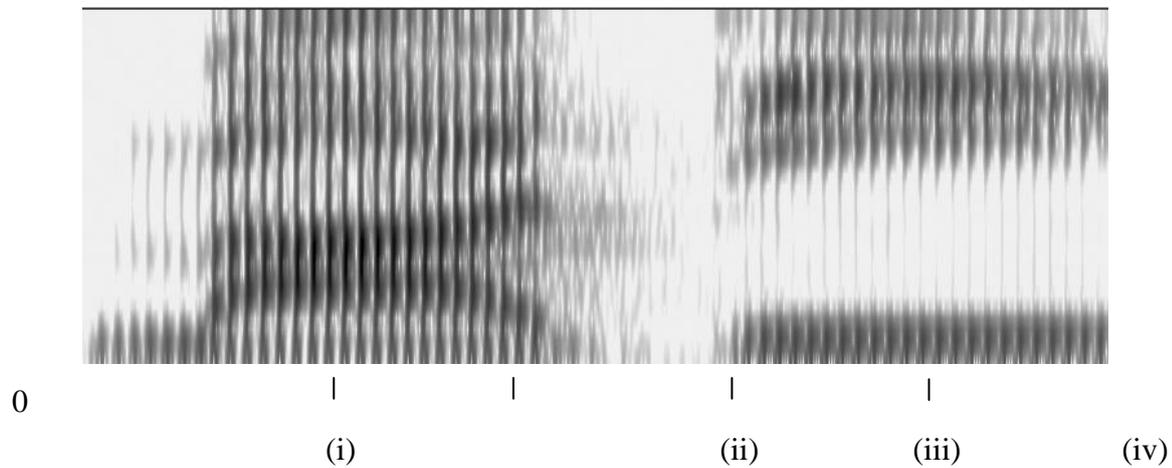

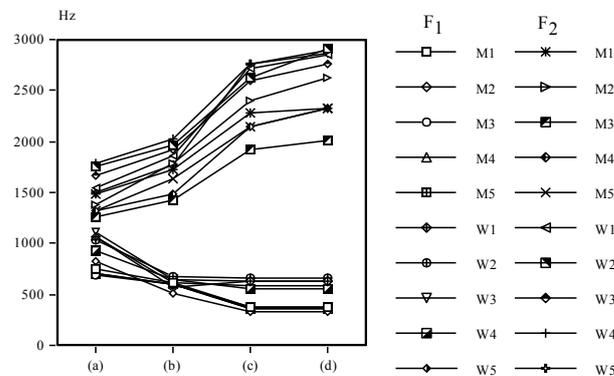

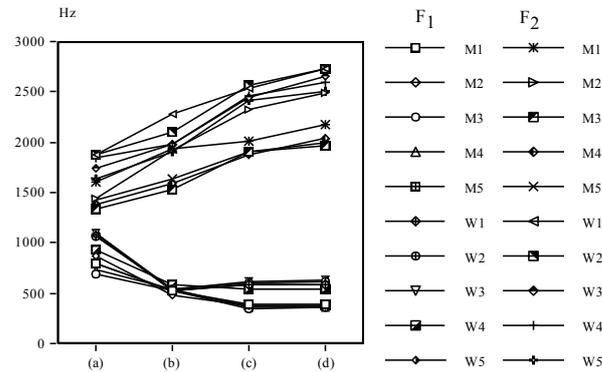

Figure 4. Cursor placements for an F<sub>1</sub> and F<sub>2</sub> transition analysis in /mati/ ‘knot’

Figure 5 shows the average of the F<sub>1</sub> and F<sub>2</sub> values at the four measured points in the four tokens of the test words /mati/ (a), /matsi/ (b) and /mat+i/ (c) spoken by ten subjects.

a.

b.

c.

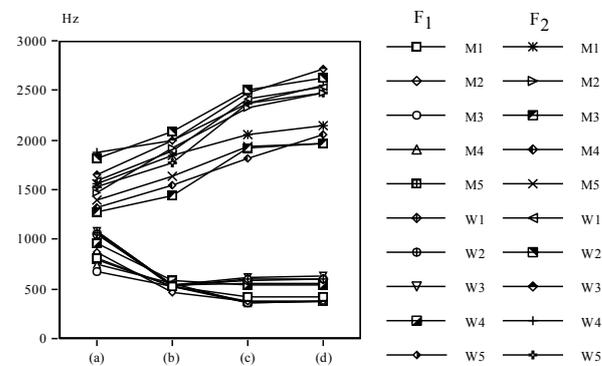

Figure 5. The transition of the average first and second formants at the four examined points in /mati/ (a), /matsi/ (b) and /mat+i/ (c).

We can note that the second formant goes up gradually from the first vowel /a/, throughout the intervening consonants, to the following vowel /i/ across the ten speakers. On the other hand, the first formant begins to fall down gradually in the first vowel and throughout the intervening consonants. This corresponds to the gradual tongue fronting and raising before and during the target consonants in the above articulatory data (Figures 2 and 3). In particular, when we compared the average of F<sub>1</sub> and F<sub>2</sub> value differences between in the middle and at the end of /a/ preceding the underlying affricate and the lexically-derived affricate in /matsi/ and /mat+i/, respectively, in Figure 5 (b, c), a paired samples two-tailed *t*-test revealed that it is not significant, across the ten subjects ( $t(9) < 1$  for F<sub>1</sub>;  $t(9) < 1$  for F<sub>2</sub>).

In addition, we examined whether a vowel preceding or following a target consonant would show transconsonantal vowel-to-vowel transition in the sense of Öhman (1966). The comparison of F<sub>1</sub> and F<sub>2</sub> value difference in the first vowel of the control condition /a\_a/ and the target condition /a\_(+)i/ reveals that the vowel /a/ in the latter is affected by the following vowel /i/ across the underlying plosive, affricate or the lexically-derived affricate. A paired samples two-tailed *t*-test showed that the average of F<sub>1</sub> and F<sub>2</sub> value differences between in the middle and at the end of /a/ preceding a target consonant is

significant, across the ten subjects, in the comparison of /mat+i/ and /matsa/ ( $t(9) = -10.6, p < .0001$  for  $F_1$ ;  $t(9) = 4.1, p < .05$  for  $F_2$ ), /matsi/ and /matsa/ ( $t(9) = -9, p < .0001$  for  $F_1$ ;  $t(9) = -5.9, p < .0005$  for  $F_2$ ), and also /mati/ and /mata/ ( $t(9) = -5.5, p < .0005$  for  $F_1$ ;  $t(9) = 5.6, p < .0005$  for  $F_2$ ).

A similar transition of the first and second formants is also observed in the vowel /a/ following the vowel /i/ across the underlying plosive and affricate in the test words /mita/ (a) and /mitsa/ (b), as shown in Figure 6. The second formant goes down from the vowel /i/, throughout the intervening consonants, to the following vowel /a/ across the ten speakers. As for the first formant, we can note that it rises gradually throughout the intervening consonants and goes up high toward the steady part of the vowel /a/.

a.

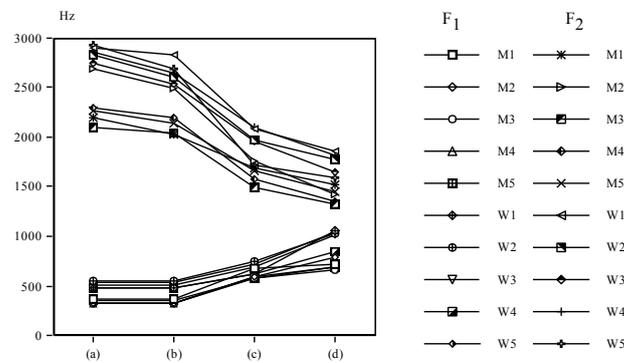

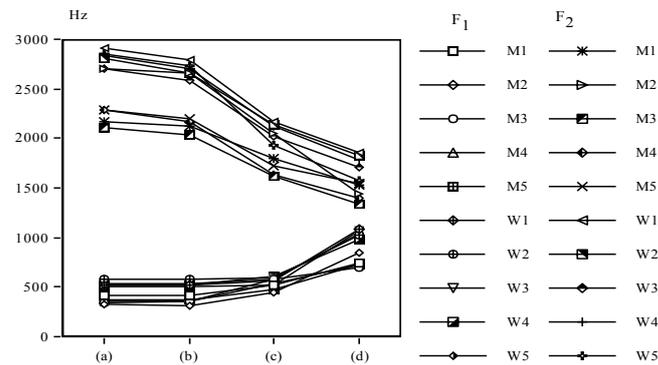

Figure 6. The transition of the first and second formants at the four examined points in /mita/ (a) and /mitsa/ (b)

b.

(Figure 6 continued)

The examination of the  $F_1$  and  $F_2$  values at the onset and in the steady part of the second vowel /a/ in /mitsa, matsa/ and /mita, mata/ reveals significant difference. A paired samples two-tailed  $t$ -test showed that  $F_1$  and  $F_2$  values at the points are statistically significant:  $t(9) = -5, p < .001$  for  $F_1$  and  $t(9) = -6, p < .0005$  for  $F_2$  in /mitsa/ and /matsa/;  $t(9) = -5.6, p < .0005$  for  $F_1$  and  $t(9) = -5.5, p < .0005$  for  $F_2$  in /mita/ and /mata/. The significant difference in  $F_1$  and  $F_2$  values both in /matsa/ vs. /mitsa/ and in /mata/ vs. /mita/ indicates that the second vowel /a/ is affected in tongue raising and fronting when preceded by the vowel /i/, no matter whether the intervening consonant is the plosive /t/ or the affricate /ts/.

In sum, we have examined neighboring vowels'  $F_1$  and  $F_2$  value differences between the steady part and the end of the vowel /a/ preceding the lexically-derived affricate in /mat+i/ and the tautomorphic consonants /t, ts/ in /ma\_(+)i, ma\_a/ and between the onset and the steady part of the vowel /a/ following the consonants /t, ts/ in /ma\_a, mi\_a/. The acoustic data have shown that the intervening consonants are transparent to vowel-to-vowel transition in /ma\_(+)i/ (vs. /ma\_a/) and /mi\_a/ (vs. /ma\_a/), regardless of the underlying lenis plosive, affricate or the lexically-derived lenis affricate. In the next section, we discuss the status of Korean palatalization, based on the above articulatory and acoustic data.

#### 4. Discussion

Given gradual tongue raising and fronting and transconsonantal vowel-to-vowel transition in the experimental data, we propose that Korean palatalization is a phonetic side-effect when the tongue moves toward the following vowel /i/, regardless of a morpheme boundary.

If a consonant is phonologically palatalized, a plateau throughout a consonant before the vowel /i/ in (2a iii) can be articulatorily correlated with the extension of the tongue-body movement for the vowel /i/ throughout the consonant. For example, according to Öhman (1966), in V<sub>1</sub>CV<sub>2</sub> (vowel-consonant-vowel) sequences, each vowel does not influence the transition into or out of the vowel on the other side of intervening palatalized consonants in Russian. This was attributed to the fact that Russian has a palatalized vs. nonpalatalized contrast for consonants in its sound system and Öhman (1966) suggested that because the position of the tongue body is used to distinguish these two sets of consonants, Russian speakers do not let the tongue body be manipulated by V<sub>2</sub> before the intervening palatalized consonant has had its chance to control tongue body position. The blocking of transition into or out of the vowel across the palatalized consonants in Russian can further be interpreted in the target-interpolation model (e.g., Keating 1988a, b) as a consequence of the phonological specification of the consonants for the secondary vocalic features [-back] and [+high], as in the intervening segment in (2a i).

However, this is not the case of Korean palatalization, as already shown in Figures 2, 3, 5, 6 and Tables 1 and 2. Gradual tongue raising and fronting before and during the intervening consonants in Figures 2, 3, 5 and the tables provide empirical evidence that the consonants are anticipatorily coarticulated with the tongue configurations of the following vowel /i/, regardless of a morpheme boundary. The anticipatory coarticulation is expected because the consonants are not phonologically contrastive in the tongue configurations such as tongue fronting and raising, thus being transparent to V-to-V transition. As shown in (5), Korean does not have a palatalized vs. nonpalatalized contrast for consonants. Rather Korean obstruents are phonologically contrastive in terms of the primary articulator (*labial, coronal, dorsal*), the manner of articulation (*continuant, strident*) and the laryngeal characterization (*lenis, aspirated* and *fortis*). For example, Korean coronal consonants are all alveolar and they are contrastive in the phonology by virtue of the manner of articulation and the laryngeal characterization.

(5) Korean obstruents

		<i>labial</i>	<i>coronal</i>	<i>dorsal</i>	
<i>noncontinuant</i>	┌ ├ └	<i>lenis</i>	p	t	k
<i>nonstrident</i>		<i>aspirated</i>	p <sup>h</sup>	t <sup>h</sup>	k <sup>h</sup>
		<i>fortis</i>	p'	t'	k'
<i>noncontinuant</i>	┌	<i>lenis</i>	ts		

<i>strident</i>		<i>aspirated</i>	ts <sup>h</sup>
	—	<i>fortis</i>	ts'
<i>continuant</i>	┌	<i>lenis</i>	s
<i>strident</i>	—	<i>fortis</i>	s'

Since the Korean coronal consonants are not phonologically specified for the feature [+high] for tongue raising and [-back] for tongue fronting, like labial and dorsal ones, we may assume that this is why gradual tongue movements before and during the consonants do occur, as shown in Figures 2, 3 and 5. And transconsonantal vowel-to-vowel transition is also expected, as shown in the above acoustic data.

Given the present proposal of Korean palatalization, the sound change of the plosives /t, t<sup>h</sup>/ into their affricate counterparts across a morpheme boundary in (1b) is a phonological assibilation, following Kim (2001a). That is, only the manner of articulation of the underlying coronal plosives changes into their counterpart affricates across a morpheme boundary with their place of articulation remaining the same as alveolar. According to Kim (2001b, 2004), the plosives /t, t<sup>h</sup>/ and their affricate counterparts are alveolar ([coronal]) with the specification for [-continuant] as stop consonants, and differentiated by the feature values [+/-strident]: the plosives are specified for [-strident] and the affricates /ts, ts<sup>h</sup>/ for [+strident]. In the feature representation of the consonants, then, the sound change in (1b) can be considered as resulting from the insertion of [+strident] in the phonological representation of the plosives /t/ and /t<sup>h</sup>/ in line with Kim (2001a).

## 5. Conclusion

In order to investigate whether the two types of Korean palatalization are a feature-changing phonological process, we have examined stroboscopic cine-MRI data on the coronal consonants /t, t<sup>h</sup>, t', ts, ts<sup>h</sup>, ts'/ in the context /ma\_i/ and /t/ in /ma\_+i/ and acoustic (i.e. F<sub>1</sub> and F<sub>2</sub> transitions in wide-band spectrograms) data on the coronal plosive /t/ and the lexically-derived and underlying affricates /ts/ in /ma\_a, ma\_(+)i, mi\_a, mi\_i/. From the MRI data, we have found that the tongue gradually rises and moves front throughout the consonants up to the following vowel /i/. The gradual tongue fronting and raising were confirmed in the acoustic data on F<sub>1</sub> and F<sub>2</sub> values, and transconsonantal vowel-to-vowel transition in the sense of Öhman (1966) was also observed.

Based on the present phonetic results, we propose that Korean palatalization is a phonetic coarticulatory effect of the following vowel /i/, regardless of a morpheme boundary, in Öhman's (1966) transconsonantal vowel-to-vowel transition model and Keating's (1988a) target-interpolation model. That is, a consonant before the vowel /i/ is phonologically unspecified for tongue raising ([+high]) and fronting ([-back]) which acoustically correlate with F<sub>1</sub> and F<sub>2</sub>, respectively, and remain unspecified for the features

throughout phonetic implementation, as in (2b). Due to the transparent consonant, gradual tongue movements and transconsonantal vowel-to-vowel transition take place, as shown in the present study. It is concluded that Korean palatalization is a phonetic coarticulation, not a phonological process with the division of lexical and postlexical palatalization.

## ACKNOWLEDGEMENTS

I would like to express my thanks to Shinji Maeda, Kiyoshi Honda and Shinobu Masaki at ATR, Kyoto, Japan and our subject Jinwon Kim for the present MRI experiment. An earlier version of the present study was presented at the 16<sup>th</sup> ICPhS at Saarbrücken, Germany in August, 2007 and also at the international workshop on coarticulation at Université Paul-Valéry – Montpellier 3 in December, 2007. Any errors remain my own. This work was supported by the 2008 Hongik University Research Fund.

# Paradox of Negative and Honorific Morphology in Korean

Inkie Chung

University of Seoul

13 Shirpdaegil Rd, Dongdaemun-gu, Seoul, 130-743, South Korea

inkiechung@uos.kr

## Abstract

The two roots with short-form negation and honorification suggest different morphological structures: [[Neg V] Hon] for *al-* ‘know’, *molu-* ‘not.know’, *a-si-* ‘know-HON’, *molu-si-* (\**an(i)-a-si-*) ‘NEG-know-HON’; [Neg [V Hon]] for *iss-* ‘exist’, *eps-* ‘not.exist’, *kyey-si-* ‘exist-HON’, *an(i)-kyey-si-* (\**eps-(u)-si-*) ‘NEG-exist-HON’. Predicate repetition constructions support the [[Neg V] Hon] structure. In this structure, however, the negation suppletion is blocked by the structurally farther honorific suffix. Since government is the only requirement of context allomorphy in Distributed Morphology and the [+hon] feature governs the root, the root can show honorific suppletive allomorphy in the first cycle across negation. Negation fusion occurs in the second cycle after vocabulary insertion of the root. Fusion must refer to vocabulary items, not abstract features, and is interleaved with vocabulary insertion. Therefore, the two distinct morphological operations for suppletion, i.e., fusion and contextual allomorphy, are necessary. The proposed analysis supports separation and late insertion as advanced in Distributed Morphology.

**Keywords:** negation, honorifics, suppletion, contextual allomorphy, fusion, blocking, vocabulary insertion, Distributed Morphology, Korean

## 1. Introduction

Two predicates in Korean show a suppletive negative form instead of the usual short-form negation construction, and three predicates show a suppletive honorific root form in the environment of the subject honorific suffix. This paper concerns a root morpheme meaning ‘exist’ (with exponents *iss-*, *eps-* and *kyey-*) that shows both negative suppletion and honorific suppletion, and deals with their interactions. Specifically, negation is considered to be closer to the root than honorification is, but the structurally inner negative suppletion is blocked by the outer honorific suffix. The paper provides an analysis of this paradoxical situation with different formal mechanisms for the two cases

of suppletion, identifying the proper morphological structure of conjugated predicates in Korean.

The theoretical framework adopted here is Distributed Morphology (Bobaljik 2000, Calabrese 2008, Embick and Noyer 2001, Halle and Marantz 1993, Harley and Noyer 1999, Marantz 1997, 2001, among others). Distributed Morphology assumes that syntax lacks phonological features and manipulates abstract nonphonological features only. This mechanism of separation allows syntax to be uniform between short-form negation and suppletive negation. The difference emerges in PF, that is, after (overt) syntax, where phonological information is provided through vocabulary insertion. Vocabulary insertion can interact with morphological operations.

Section 2 recapitulates the analysis of the suppletive short-form negation in Chung (2007a,b). The suppletion phenomenon is analyzed as fusion of the two morpho-syntactic nodes without phonological features (i.e., prior to vocabulary insertion). Section 3 introduces honorific suppletion and identifies the paradoxical situation arising from the interaction between negative suppletion and honorific suppletion. Then, section 4 provides an integrated solution recognizing different formal apparatuses for the two different cases of suppletion, supporting separation and late insertion. It identifies the morphological structure of fully inflected predicates in Korean. Section 5 concludes the paper.

## **2. A Distributed Morphology Analysis of Suppletive Negation**

This section briefly summarizes the Distributed Morphology analysis of suppletive short-form negation in Korean, found in Chung (2007a,b).

### *2.1. Short-form negation as syntactic negation*

Short-form negation in Korean places the negator *an(i)* before the predicate as in *an(i) ca-ss-ta* ‘not sleep-PAST-DECL’, *an(i) mak-nun-ta* ‘not block-PRES-DECL’ and *an(i) cak-ass-ta* ‘not small-PAST-DECL’. Without the responsible negator, the remaining verbal expression is affirmative. I argue, following H.-D. Ahn (1991), Han, Lidz and Musolino (2007) and J.-Y. Yoon (1990) among others, in favor of a syntactic view on short-form negation: the negator *an(i)* is the head of the functional category NegP.

Short-form negator *an(i)* is allowed before a negative prefix such as *pu(l)-*, *pi-* and *mi-*, as in *an(i) pul-kanungha-* ‘impossible’, *an(i) pi-kwahakcek-i-* ‘unscientific’ and

*an(i) mi-wanseng-i/toy-* ‘incomplete’, but not before another instance of *an(i)*: \**an(i) an(i) kanungha-*, \**an(i) an(i) kwahakcek-i-* and \**an(i) an(i) wanseng-i/toy-*. The ungrammaticality of stacking the negator before a predicate is well-contrasted to the restriction on the occurrence of the negative prefixes. The latter restriction is that a predicate can have only one of these prefixes, hence making forms such as \**pul-pul-A*, \**pi-pi-A*, \**pi-pul-A*, \**pul-mi-A*, \**mi-pi-A* ungrammatical. The similarity and the contrast between the negator and the prefixes show that they are different kinds. If *an(i)* were a prefix, its occurrence would not be explained without a special stipulation on it. On the other hand, if *an(i)* is not such a prefix, there will be no problem in having this negative element in addition to a negative prefix. This shows that *an(i)* is not a negative prefix.

One characteristic of syntactic negation (as opposed to negative prefixes) is scope interaction with respect to quantifiers. The negator *an(i)* shows a clear scope ambiguity effect with a quantifier as in the following examples. (See Chung 2007a for an extensive discussion in favor of the ‘hard-to-get’ Neg >  $\forall$  reading.)

- (1) a. *motun haksayng-i an(i) ka-ss-ta.*  
 all student-NOM NEG go-PAST-DECL  
 $\forall$  > Neg: ‘No student went.’  
 Neg >  $\forall$ : ‘It is not the case that all students went.’
- b. *wuli-ka motun chinkwu-lul an(i) manna-ss-ta.*  
 we-NOM all friend-ACC NEG meet-PAST-DECL  
 $\forall$  > Neg: ‘We met no friend.’  
 Neg >  $\forall$ : ‘It is not the case that we met all friends.’

On the other hand, the above scope ambiguity does not arise with a predicate with a negative prefix, as shown below.

- (2) a. *motun haksayng-i i an-ey pulchansengha-y-ess-ta.*  
 all student-NOM this plan-DAT disapprove-EG-PAST-DECL  
 $\forall$  > *pul-*: ‘All students disapproved this plan.’  
 \**pul-* >  $\forall$
- b. *wuli-ka motun an-ey pulchansengha-y-ess-ta.*  
 we-NOM all plan-DAT disapprove-EG-PAST-DECL  
 $\forall$  > *pul-*: ‘We disapproved all plans.’  
 \**pul-* >  $\forall$

The contrast between *an(i)* and the negative prefixes is a clear indication that *an(i)* is not a negative prefix, but syntactic negation.

Another piece of evidence in favor of the syntactic view of short-form negation

comes from licensing of negative polarity items. One typical and representative environment licensing a negative polarity item is a negative clause, which contains a syntactic (and semantic) negation element. In the following examples, negator *an(i)* serves as such a licenser.

- (3) a. *amu-to an(i) sengsilha-ta.*  
 any-NPI NEG sincere-DECL  
 ‘Nobody is sincere.’  
 b. *na-nun amu-to an(i) manna-ss-ta.*  
 I-TOP any-NPI NEG meet-PAST-DECL  
 ‘I didn’t meet anybody.’  
 c. *amu-to na-lul an(i) manna-ss-ta.*  
 any-NPI I-ACC NEG meet-PAST-DECL  
 ‘Nobody met me.’

The crucial point is that a sentence without *an(i)* or with a negative prefix cannot license a negative polarity item:

- (4) a. *\*amu-to (pul-)sengsilha-ta.*  
 any-NPI (in)sincere-DECL  
 (\*‘Anybody is (in)sincere.’)  
 b. *\*con-un amu pep-(ey)-to (pul-)pokconggha-y-ess-ta.*  
 John-TOP any law-DAT-NPI (dis)obey-EG-PAST-DECL  
 (\*‘John (dis)obeyed any law.’)  
 c. *\*amu-to i pep-ey (pul-)pokconggha-y-ess-ta.*  
 any-NPI this law-DAT (dis)obey-EG-PAST-DECL  
 (\*‘Anybody (dis)obeyed this law.’)

If *an(i)* were a prefix like *pul-*, it should not be able to license a negative polarity item. (See Chung 2007a for more supporting arguments.) This contrast between *an(i)* and negative prefixes is another indication that *an(i)* is a syntactic negator which licenses a negative polarity item.

## 2.2. Suppletive negation: *molu-* for ‘not.know’ and *eps-* for ‘not.exist’

This section looks into the two suppletive negative predicates. The affirmative roots are *al-* ‘know’ and *iss-* ‘exist’, and their negative counterparts are *molu-* ‘not.know’ and *eps-* ‘not.exit’, respectively. These suppletive forms behave like short-form syntactic negation with respect to the distribution of the negator, negative polarity item licensing and scope ambiguity.

The suppletive negative roots *molu-* and *eps-* pattern as if a syntactic negator were present in that *an(i)* cannot be placed before them: \**an(i) molu-* and \**an(i) eps-*. This suggests that these negative roots are a result of syntactic negation, usually done by *an(i)*.

Negative polarity items support the syntactic negation analysis of *molu-* and *eps-*. They license a negative polarity item without the negator *an(i)*.

- (5) a. na-nun *amu* tap-*to* **moll**-ass-ta.  
 I-TOP any answer-NPI not.know-PAST-DECL  
 ‘I didn’t know any answer.’  
 b. *amu-to* tap-ul **moll**-ass-ta.  
 any-NPI answer-ACC not.know-PAST-DECL  
 ‘Nobody knew the answer.’  
 (6) *amu-to* **eps**-ta.  
 any-NPI not.exist-DECL  
 ‘There is nobody.’

A quantifier in a sentence with *molu-* and *eps-* supports these roots’ status of syntactic negation. Consider the scope ambiguity between a quantifier and these suppletive negative predicates.

- (7) a. *motun* haksayng-i ku wuhwa-lul **molu**-n-ta.  
 all student-NOM the fable-ACC not.know-PRES-DECL  
 $\forall > \text{Neg}$ : ‘No student knows the fable.’  
 $\text{Neg} > \forall$ : ‘Not all students know the fable.’  
 b. ku haksayng-i *motun* wuhwa-lul **molu**-n-ta.  
 the student-NOM all fable-ACC not.know-PRES-DECL  
 $\forall > \text{Neg}$ : ‘The student knows no fable.’  
 $\text{Neg} > \forall$ : ‘The student doesn’t know all the fables.’  
 (8) *motun* haksayng-i **eps**-ta.  
 all student-NOM not.exist-DECL  
 $\forall > \text{Neg}$ : ‘There are no students.’  
 $\text{Neg} > \forall$ : ‘Not all students are present.’

This scope ambiguity is unique to syntactic negation and supports the syntactic negative status of the predicates *molu-* and *eps-*.<sup>1</sup>

Negation of *iss-*, however, does not always result in *eps-*. In other cases, the usual negation *an(i) iss-* is found as in (9)c.

---

<sup>1</sup>See Chung (2007a) for the parallelism between the usual short-form negation and the suppletive negation regarding the ‘hard-to-get’ reading.

- (9) a. Eysute-ka yeki-ey iss-ess-ta.  
 Esther-NOM here-LOC exist/stay-PAST-DECL  
 ‘Esther was here.’
- b. Eysute-ka yeki-ey **eps**-ess-ta.  
 Esther-NOM here-LOC not.exist-PAST-DECL  
 ‘Esther was not here.’
- c. Eysute-ka yeki-ey **an(i)** iss-ess-ta.  
 Esther-NOM here-LOC NEG be-PAST-DECL  
 ‘Esther was not/did not stay here.’

There is a semantic difference between two (negated) predicates. While *eps-* means nonexistence ‘do not exist’ or simple absence like ‘be not present, be lacking’, *an(i) iss-* involves intention and means ‘intentionally do not stay’. Also, the cases with *an(i) iss-* need an animate subject, which is an agent. In (9), both *eps-* and *an(i) iss-* are possible, because *iss-* is ambiguous between ‘exist, be present’ and ‘stay intentionally’ (See Chung 2007a and In press for more arguments).

### 2.3. A postsyntactic fusion analysis of suppletive negation

The uniformities between the regular syntactic short-form negation construction and the suppletive negative predicates suggest that there is only one uniform short-form negation construction in syntax (overt and covert) and that the difference arises in PF. This means that *molu-* and *eps-* show exactly the same configurations and properties in syntax and semantics as other predicates.

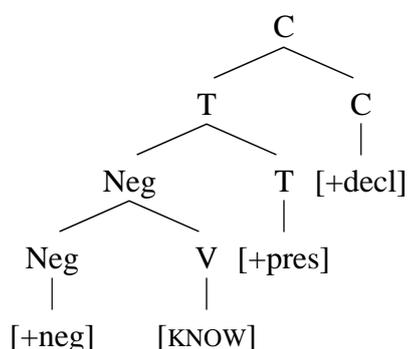

Sells (2001) writes that Korean has three different kinds of clausal negation: long-form negation, short-form negation and suppletive negation (i.e., “lexically negative verbs” in his term). However, this classification misses the fact that the affirmative predicates of those suppletive negative predicates do not have the expected short-form negation construction and that the long-form negation constructions do not have such suppletive cases.

This section presents a postsyntactic morphological fusion analysis in the Distributed Morphology framework.<sup>2</sup> The following structure is obtained for the verbal complex *molu-n-ta* ‘do not know’ at Spell-Out as a result of head movement in syntax or PF. (The ‘exist’ predicate *eps-ess-ta* has the parallel structure.)

---

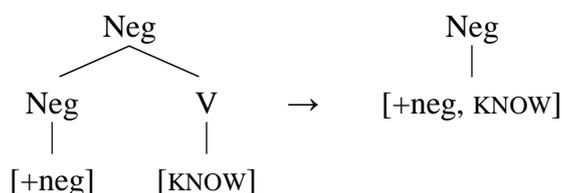

<sup>2</sup>See Chung (2007a) for arguments against a lexicalist approach to suppletive negative predicates including Kim (1999). See also Embick (2007), Embick and Marantz (2008), Embick and Noyer (2001) and Marantz (2001) for criticisms on the lexicalist treatments on blocking of a phrasal form by a lexical form.

(10) Structure for *molu-n-ta* at the end of overt syntax

The *v* head is not present here because ‘know’ is a state verb and does not require an agent argument. For the optionality of the *v*(P), see Bošković (1997), Chomsky (1995), Hale and Keyser (1993) (cf. Harley and Noyer 2000, Marantz 2001). This morphosyntactic structure lacks phonological features and undergoes fusion in PF. Fusion takes the two sister nodes, [KNOW] and [+neg], and turns them into a single terminal node. The resulting node contains all the original syntactico-semantic features, [+neg, KNOW], as shown below:

(11) Fusion of [+neg] and [KNOW] in PF

Subsequently, vocabulary insertion takes place with the following vocabulary items.

(12) a. [+neg, KNOW] ↔ /molu/

b. [KNOW] ↔ /al/

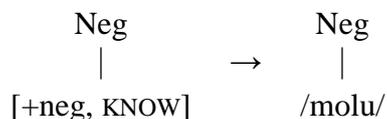

(13) a. [+neg, EXIST] ↔ /eps/

b. [EXIST] ↔ /iss/

(14) [+neg] ↔ /an(i)/

Because of underspecification, any of the vocabulary items in (12) could be inserted in the fused node in (11) (leading to competition). However, in such a situation, the vocabulary item that is most highly specified with the compatible features in the terminal node is chosen. Therefore, (12)a is chosen and the fused terminal node is provided with /molu/, resulting in:

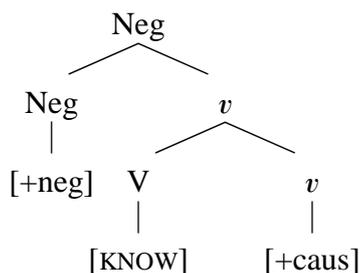

(15) Vocabulary insertion of /molu/ (into the fused node)

In a negative clause with other verbs showing the regular short-form negation, fusion does not occur, and the original V and Neg nodes proceed to vocabulary insertion separately. Hence fusion needs to refer to the syntactico-semantic features in the terminal node, as in (11), so that this process is limited to ‘know’ and ‘exist’.

If another element intervenes between Neg and V in the input structure, this operation will not take place as in the following derived causative of ‘know’ in the negative context.

(16) Structure for *an(i) al-li-* at the end of overt syntax

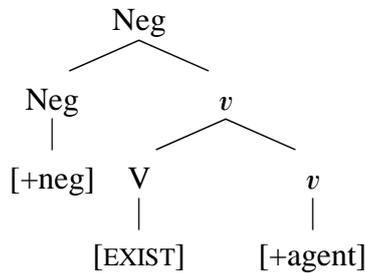

Neg and V are not sisters, and therefore fusion is inapplicable. Then, each terminal node separately undergoes vocabulary insertion, correctly yielding *an(i) al-li-* with the additional vocabulary item (17).

(17) [+caus] ↔ /li/

The case of the agentive, non-suppletive *iss-* ‘stay intentionally’ (whose negative form is *an(i) iss-*) behaves like other regular predicates. The present study recognizes only one root morpheme, which interacts with the *v(P)* projection according to agentivity/volitionality. The agentive *iss-* refers to staying intentionally and involves an agent argument. This property is granted by the additional *v(P)* projection between V(P) and Neg(P).

(18) Complex  $C^0$  after head movement of the agentive *iss-* in a negative clause (partial)

[+neg] and [EXIST] are not sister nodes, and hence fusion of them is inapplicable. Vocabulary insertion converts (18) to *an(i) iss-* with the zero exponent for [+agent].

(19) [+agent] ↔ ∅

This treatment relates the *al-* vs. *al-li-* case to the existential vs. agentive *iss-* case with respect to the agent argument and fusion blocking.

This section has presented how the Distributed Morphology framework explains the suppletive forms of ‘know’ and ‘exist’ in Korean. The morphological fusion operation is sensitive to the syntactico-semantic features of the terminal nodes to be fused (e.g., [KNOW] and [EXIST]). The structure is also critical: only sister nodes can be fused and a hierarchically intervening node blocks this operation. Finally, this operation occurs after syntax. The analysis of fusion of the negation node and the V root node in PF explains why the two non-long-form negation cases exhibit the same syntactic and semantic behaviors. It also explains why there is no independent negator in the two suppletive negation cases and why there is a single vocabulary item instead of the negation plus root sequence.<sup>3</sup>

### 3. Subject Honorification Suppletion and Negation Suppletion

This section turns to subject honorification. After surveying subject honorification and honorific suppletion, it identifies the morphological structure of the inflected predicates with subject honorification. The existential *iss-* is examined, which exhibits both honorific suppletion and negation suppletion. It is then contrasted to *al-* ‘know’ showing negative suppletion only. A paradoxical situation is highlighted resulting from the two

---

<sup>3</sup>See Chung (2007a) for more discussions of the present Distributed Morphology analysis and against lexicalist approaches to suppletive negation.

structures of these predicates.

### 3.1. Honorific root suppletion and blocking of negation suppletion

Subject honorification or subject exaltation is used when the subject of a sentence is honored or exalted by the speaker who is lower than, or inferior to, the subject. In this case, the predicate takes the honorific suffix *-si-* (with an epenthetic vowel *-u-* in phonological hiatus situations), and the subject takes an agreeing honorific nominative case suffix, as shown below:<sup>4</sup>

- (20) a. eysute-ka    nichey-lul    ilk-ess-ta.  
 Esther-NOM    Nietzsche-ACC    read-PAST-DECL  
 ‘Esther read Nietzsche (non-honorific).’  
 b. apeci-**kkeyse**    nichey-lul    ilk-u-**si**-ess-ta.  
 father-HON.NOM    Nietzsche-ACC    read-EV-HON-PAST-DECL  
 ‘(My) father read Nietzsche (honorific).’
- (21) a. eysute-ka    khu-ta.  
 Esther-NOM    big-DECL  
 ‘Esther is big (non-honorific).’  
 b. apeci-**kkeyse**    khu-**si**-ta.  
 father-HON.NOM    big-HON-DECL  
 ‘(My) father is big (honorific).’

There are a few predicates whose root form is, from the morphophonological point of view, radically different from the usual root form when the honorific suffix is attached to them. Hence, the root *mek-* ‘eat’ is realized as *capswu-* with the honorific suffix *-si-*, not as *\*mek-u-si-*; and the root *ca-* ‘sleep’ as *cwumu-si-*, not as *\*ca-si-*.

There arises an interesting situation when negation and honorification are put together for the predicate that has both a suppletive negative form and a suppletive honorific root form. The predicate *iss-* ‘exist/be.present’ (with the negative form *eps-* ‘not.exist/be.not.present’ and the honorific form *kyey-si-* ‘exist/be.present-HON’) is realized as *kyey-* in this situation: *an(i) kyey-si-*.

- (22) a. apeci-kkeyse    cha-ey    *an(i)*    *kyey-si*-ta.  
 father-HON.NOM    car-LOC    NEG    exist.HON-HON-DECL  
 ‘Father is not in the car (honorific).’

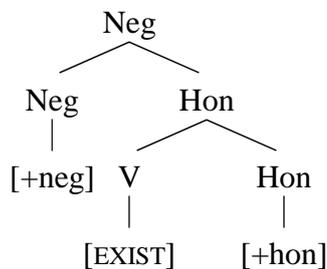

---

<sup>4</sup>H.-D. Ahn and H.-J. Yoon (1989), J.-W. Choe (2004), K. Choi (2003), S.-W. Kim (1996) and D.-W. Yang (1996) among others maintain a syntactic view of subject honorification, while S.-J. Chang (1996) and E.-Y. Cho (1994) maintain a pragmatic view. Bobaljik (2008) argues that the agreement features that have long been considered syntactic are in fact morphological, according to which view the problem of whether subject honorification is syntactic or not would disappear.

- b. \*apeci-kkeyse cha-ey eps-u-si-ta.  
 father-HON.NOM car-LOC not.exist-EV-HON-DECL

Vocabulary insertion takes place from root outward cyclically (Bobaljik 2000, Halle and Marantz 1993, Harley and Noyer 1999 among others). When a terminal node is provided with the phonological features at the given cycle, this vocabulary insertion may be sensitive to the morphosyntactic features at an outer cycle. In the following (partial) morphosyntactic structure for *an(i) kyey-si-ess-ta* ‘NEG exist.HON-HON-PAST-DECL’, the root node is first provided with phonological features.

(23) Morphosyntactic structure for [+neg]-[EXIST]-[+hon]-[+past]- (partial)

The [+hon] feature at the next outer cycle chooses /kyey/ for [EXIST]. Hence, with vocabulary items for [EXIST] and other relevant vocabulary items,

(24) Vocabulary items with feature [EXIST]

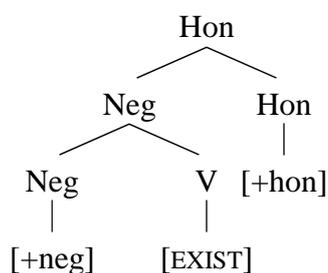

- a. [+neg, EXIST] ↔ /eps/  
 b. [EXIST] ↔ /kyey/ / \_\_\_\_ [+hon]  
 c. [EXIST] ↔ /iss/

(25) Vocabulary items with a functional category feature

- a. [+hon] ↔ /si/  
 b. [+neg] ↔ /an(i)/  
 c. [+past] ↔ /ess/

vocabulary insertion into the root cycle, providing /kyey/ for [EXIST] in the environment of [+hon] in (23), yields [[+neg] [/kyey/ [+hon]] [+past]]. To ensure the choice of /kyey/ in the environment of both negation and honorification, the structure of the inflected predicate is expected to be something like (23), rather than (26) below, in that the [+hon] node is to be structurally closer to the root than the [+neg] node is.

(26) Alternative for [+neg]-[EXIST]-[+hon]-[+past]- (partial)

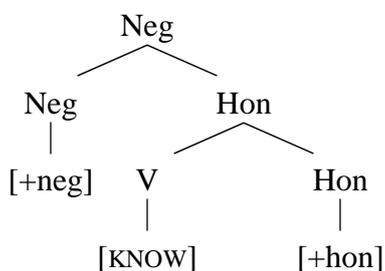

Furthermore, the structure (23) effectively blocks the suppletive negative exponent which would be caused by fusion. Vocabulary insertion converts (23) eventually to *an(i) kyey-si-ess-*, and not *\*eps-u-si-ess-*.

### 3.2. Honorific suppletion and negation suppletion: A paradox

A problem arises when the structure for [+neg]-[KNOW]-[+hon]- is considered. In the following structure identical to (23) except the root feature:

(27) Structure for [+neg]-[KNOW]-[+hon]- before vocabulary insertion

vocabulary insertion would take place separately and the result would be *\*an(i) al-si-* (which would further turn to *\*an(i) a-si-* due to the general phonological rule deleting [l] before a coronal consonant). However, the correct form is *molu-si-*. The problem is the failure of fusion because the root and the [+neg] node are not sisters in (27). Therefore, the suppletive behaviors of ‘exist’ and ‘know’ result in a paradoxical situation regarding which of [+neg] and [+hon] is closely structured with the root.

### 3.3. Predicate iteration constructions

Predicate iteration constructions show that negation is more closely structured with the root than honorification. Predicate iteration constructions include iterated rhe-

toric question, echoed verb construction, and *ha* focus construction.

(28) Iterated rhetoric question

- a. apeci-kkeyse    *an(i)*    po-**si**-ki-nun  
 father-HON.NOM    NEG    see-HON-NMLZ-FOC  
 nwukwu-lul    *an(i)*    po-**si**-ess-e?  
 who-ACC    NEG    see-HON-PAST-INF  
 ‘Father did see somebody, indeed (honorific).  
 (lit. Who on earth didn’t father see?)’
- b. \*apeci-kkeyse    *an(i)*    po-**si**-ki-nun    nwukwu-lul    po-**si**-ess-e?  
 c. \*apeci-kkeyse               po-**si**-ki-nun    nwukwu-lul    *an(i)*    po-**si**-ess-e?  
 d. ?apeci-kkeyse    *an(i)*    po-**si**-ki-nun    nwukwu-lul    *an(i)*    po-ass-e?  
 e. apeci-kkeyse    *an(i)*    po-ki-nun    nwukwu-lul    *an(i)*    po-**si**-ess-e?

(29) Echoed verb construction

- a. apeci-kkeyse    eysute-lul    *an(i)*    po-**si**-ki-nun    *an(i)*  
 father-HON.NOM    Esther-ACC    NEG    see-HON-NMLZ-FOC    NEG  
 po-**si**-ess-e.  
 see-HON-PAST-INF  
 ‘Father certainly did not see Esther.’
- b. \*apeci-kkeyse    eysute-lul    *an(i)*    po-**si**-ki-nun    po-**si**-ess-e.  
 c. \*apeci-kkeyse    eysute-lul            po-si-ki-nun    *an(i)*    po-**si**-ess-e.  
 d. ?apeci-kkeyse    eysute-lul    *an(i)*    po-**si**-ki-nun    *an(i)*    po-ass-e.  
 e. apeci-kkeyse    eysute-lul    *an(i)*    po-ki-nun    *an(i)*    po-**si**-ess-e.

(30) *Ha* focus construction

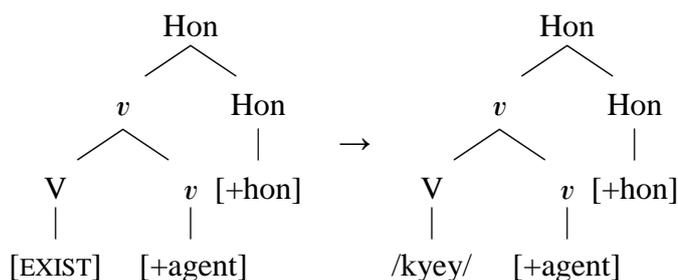

- a. apeci-kkeyse    eysute-lul    *an(i)*    po-si-ki-nun    ha-**si**-ess-e.  
 father-HON.NOM    Esther-ACC    NEG    see-HON-NMLZ-FOC    do-HON-PAST-INF  
 ‘Father certainly did not see Esther.’
- b. \*apeci-kkeyse    eysute-lul    *an(i)*    po-**si**-ki-nun    *an(i)*    ha-**si**-ess-e.  
 c. \*apeci-kkeyse    eysute-lul            po-**si**-ki-nun    *an(i)*    ha-**si**-ess-e.  
 d. \*apeci-kkeyse    eysute-lul            po-**si**-ki-nun            ha-**si**-ess-e.  
 e. apeci-kkeyse    eysute-lul    *an(i)*    po-**si**-ki-nun            ha-y-ess-e.  
 f. apeci-kkeyse    eysute-lul    *an(i)*    po-ki-nun            ha-**si**-ess-e.  
 g. \*apeci-kkeyse    eysute-lul    *an(i)*    po-ki-nun            ha-y-ess-e

These constructions show that negation and the root form a constituent in copying or replacing a certain part of the predicate. Negation is an obligatory part of the second copy or the replacement. On the other hand, the honorific suffix is not an obligatory part of the second copy or the replacement *ha-*. The minimal constituent of the copied or replaced predicate obligatorily includes the root and the negator. This contrast shows that negation is closer to the root than honorification is. This result is compatible with (26) and contrary to the discussions early in this section. (See Chung 2007b and In press for fuller discussions.)

### 3.4. Root suppletion with *v* and [+hon]

How suppletion works in (26) is in order. Consider the honorific agentive exponent *kyey-* from [EXIST]-[*v* +agent]-[+hon]. The *v*<sup>0</sup> node is transparent with respect to vocabulary insertion for [EXIST] when [+hon] is present outside of the *v*<sup>0</sup> node.

(31) Structure of [EXIST]-[*v* +agent]-[+hon]

The vocabulary item (24)b has to be revised as the following, adopting the government view of contextual allomorphy (Bobaljik 2000, Halle and Marantz 1993).

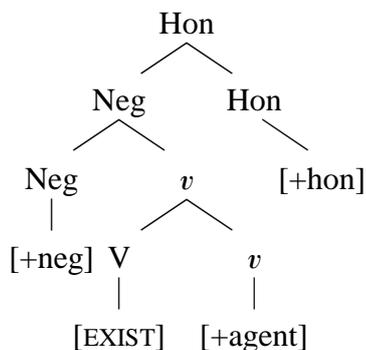

(32) Vocabulary item for [EXIST] (revision of (24)b)

[EXIST] ↔ /kyey/ / governed by [+hon]

Honorification in Korean shows that (outwards-sensitive) contextual allomorphy is not always strictly local (Bobaljik 2000, Embick and Noyer 2001, Halle and Marantz 1993; contra Allen 1978, Siegel 1977, Simpson and Withgott 1986).

Next, consider [+neg]-[EXIST]-[*v* +agent]-[+hon]-. The entire sequence is realized as *an(i) kyey-si-*, not as \**an(i) iss-u-si-*. If the structure [Neg [*v* V *v*]] from section 2.3 is maintained, [+neg]-[EXIST]-[*v* +agent]-[+hon] will have the following structure:

(33) [+neg]-[EXIST]-[*v* +agent]-[+hon]-

The intervening [+neg] is transparent with respect to the root suppletion in the environment of [+hon]. Honorific suppletion formulated as contextual allomorphy allows intermediate nodes between the allomorphic root and the governing allomorphy trigger.

#### 4. Allomorphy: Non-locality and Blocking of Inner Suppletion

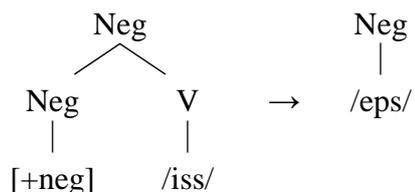

This section provides an integrated analysis of honorific suppletion and negative suppletion along with the government analysis of contextual allomorphy for honorific root suppletion. The status and formalism of negative suppletion fusion are reexamined.

##### 4.1. Blocking interaction of negative suppletion and honorific suppletion

The government approach solves the issue of locality between the root and [+hon]. Further, the Neg-V-Hon sequence should be structured correctly as [[Neg [V]] Hon] to allow the fusion process. This structure is not only necessary for fusion, but also maintainable if the outer [+hon] can trigger its root allomorphy under government.

Negative suppletion is more local, requiring a strict sisterhood configuration, while honorific suppletion simply requires a governing head. However, negative suppletion is blocked by honorific suppletion. The root can show suppletive allomorphy for honorification whether or not [+neg] or anything else intervenes, because [+hon] governs the root. On the other hand, fusion operates cyclically, thus interleaved with vocabulary insertion, and, crucially, is triggered by the higher head (i.e., the higher Neg node containing [+neg] and the root). Then, the blocking effect will follow automatically, if fusion makes reference to vocabulary items of the root node (post-insertion) as in (34) rather than abstract “morphemes” (pre-insertion).

(34) Fusion of [+neg] and /iss/ to /eps/ (revision of (11))

Vocabulary insertion has already applied in the inner cycle, and the root node must be stated as /iss/, not as [EXIST].

In the structure [[[+neg] [EXIST]] [+hon]] (26), the root is provided with /kyey/ because [+hon] governs this node. The choice of the root allomorph (honorific suppletion) is determined in the root cycle. The triggering morphosyntactic feature can “see” across negation. The governing [+hon] feature simply serves as the context of root allomorphy operating in the first cycle.

The negative suppletion, however, happens crucially in the second cycle with /iss/. Therefore, if the output of the first cycle is /kyey/ due to the outer [+hon] in (26) and (33), the negation fusion rule will not apply. When the [+hon] feature is not engaged in a given word, the fusion applies to [+neg] in the next outer cycle along with the root item /iss/ as in (34).

Then, the analysis presented in section 2.3 remains almost the same. In particular, if the fusion operation is restricted to sisters, a null *v* (giving the agentive *iss-* ‘stay intentionally’ in a negative clause as well) will still block the fusion rule. The only change in the new fusion rule is that the root is represented as the vocabulary item instead of the abstract morpheme, i.e., the non-phonological feature bundle [EXIST]. The rule finds its place accordingly. It does not apply before vocabulary insertion, but applies cyclically interleaved with vocabulary insertion. See Trommer (1999), Kandybowicz (2007) and Bobaljik and Thráinsson (1998) among others for different or alternative proposals as opposed to Halle and Marantz’s (1993) pre-insertion fusion.

#### 4.2. In support of late vocabulary insertion

The paradox between negative and honorific morphology can be resolved by employing two different apparatuses for negative suppletion and honorific suppletion. However, a crucial assumption needs to be made. In order for the vocabulary item (32) to be inserted in the structure (26) with [[[+neg] [EXIST]] [+hon]], the [+hon] feature should be present in the structure when vocabulary insertion applies to the root cycle.

In a lexicalist framework, the phonological features and the nonphonological features are added at the same time in each cycle. Such a more “traditional” morphophonological view of morpheme concatenation for [[[+neg] [EXIST]] [+hon]] would look like the following:

(35) Cyclic morpheme concatenation of [[[+neg] [EXIST]] [+hon]] in lexicalism		
	phonological	nonphonological
Cycle 1	iss-	[EXIST]
Cycle 2	eps-	[+neg, EXIST] (< [[+neg] [EXIST]])
Cycle 3	an(i) kyey-si-	[[[+neg] [EXIST]] [+hon]]

This undesirable and implausible derivation with radical exponent changes is unavoidable if the phonological features are provided at the same time as nonphonological features for each cycle.

On the other hand, if phonological features are available only after all the non-phonological features are provided for all the relevant morphological nodes in a certain domain such as word,<sup>5</sup> the entire morphophonological derivation will be coherent and consistent. Determining the correct phonological form of the root in one fell swoop is possible. Therefore, verbal suppletion in Korean provides a strong support for separation and late insertion as advanced in Distributed Morphology, as opposed to lexicalism.

To summarize this section, the suppletion interaction in Korean can be explained with two different mechanisms for the different suppletion types. Negative suppletion is characterized as fusion in (34), replacing the post-insertion root and the sister negation feature. This revised fusion formalism is interleaved with vocabulary insertion. Honorific suppletion is formalized as contextual allomorphy in the government configuration. Because honorific suppletion operates crucially in the root cycle, it blocks negative suppletion operating in the second cycle, resulting in *an(i) kyey-si-*. The discussions support the late vocabulary insertion as assumed in Distributed Morphology.

## 5. Conclusion

This paper has considered root suppletion in negation and honorification, and their interaction. Negative suppletion is blocked by honorific suppletion when both cases of suppletion are engaged in a single root (for [EXIST]). From these phenomena, a paradoxical situation has been identified between negation and honorification regarding which of the two is structurally closer to the root.

To replicate the paradox, different formalisms have been adopted for negative suppletion and honorific suppletion. Honorific suppletion has been analyzed as contextual allomorphy equipped with the government approach. Since the honorific feature serves as the non-local context governing the root, the negation feature can intervene between the root and the honorific feature. This non-local aspect of contextual allomorphy (Bobaljik 2000, Halle and Marantz 1993) for honorific suppletion leads to the revision of the fusion rule in such a way that the rule refers to the vocabulary item, i.e., the result of vocabulary insertion in the root cycle, and the negative feature.

# Opacity, Phonetics, and Frequency in Taiwanese Tone Sandhi

Jie Zhang, Yuwen Lai, and Craig Sailor

The University of Kansas  
1541 Lilac Lane, Blake Hall, Room 427  
Lawrence, KS 66044, USA  
zhang@ku.edu

## Abstract

A wug test study of tone sandhi patterns in Taiwanese indicates that sandhi productivity is affected by phonological opacity as well as the durational property and lexical frequency of the sandhi. Opacity outweighs phonetics and frequency as a global effect; frequency effects are evident for everyday users of the language; phonetic effects only surface for occasional users for whom the frequency effects have been weakened due to the lack of use of the language. The simultaneous underlearning of exceptionless opaque patterns, overlearning of phonetic effects, and proper learning of lexical statistics by Taiwanese speakers can be modeled by a Maximum Entropy grammar that encodes learning biases against lexical listing constraints and phonetically unmotivated patterns.

**Keywords:** tone sandhi, opacity, frequency, productivity, Maximum Entropy.

## 1. Introduction

The productivity of a linguistic process refers to its ability to apply to new items (Bybee 2001). The understanding of productivity is important to theoretical linguistics as it provides crucial evidence about the generalizations and cognitive abstractions that speakers make (Bybee 2001, Pierrehumbert 2003).

The productivity of a phonological process crucially depends on various properties of the process. Type frequency, which refers to the dictionary frequency of a pattern, and token frequency, which refers to the frequency of occurrence of a pattern in a corpus, have long been established to influence productivity (Bybee 1985, 2001, Moder 1992, Pierrehumbert 2003, 2006, among others). Recent research has also shown that both the phonetic grounding (Wilson 2003, 2006, Zhang and Lai 2006, Zuraw 2007) and phonological opacity (Hsieh 1970, Sanders 2001, Zhang and Lai 2008) of a pattern may have an effect on productivity. The goal of this research is to investigate

Interestingly, these frequency counts do not put the tones in the same order, which provides us with an opportunity to study which frequency count has the greatest effect on productivity. Furthermore, the effects of frequency may also be manifested differently for speakers in different environments; for example, speakers who speak the language daily may exhibit a stronger frequency effect than those who only speak it occasionally.

(2) Tone frequency counts in Taiwanese:

Syllable type frequency: 55 > 51 > 24 > 21 > 33

Morpheme type frequency: 55 > 24 > 51 > 33 > 21

Token frequency: 55 > 24 > 33 > 51 > 21

Previous research has shown that opacity, phonetics, and frequency all have an effect on the productivity of the sandhi pattern. Hsieh (1970) showed that the application rate of the entire Taiwanese tone sandhi pattern was as low as 10-30% in novel disyllabic words. Hsieh (1975), Wang (1993), and Zhang *et al.* (2006) all showed that the phonotactically transparent sandhi 24 → 33 had a higher application rate to novel words than opaque sandhis in the tone circle. Hsieh (1975) indicated that there might be a frequency effect, as the 55 → 33 sandhi, which has the highest counts for both type and token frequencies, had a higher application rate in novel words than other opaque sandhis in the tone circle. Finally, Zhang *et al.* (2006) reported that Taiwanese speakers tested at the University of Kansas showed a higher productivity for the duration reducing sandhi 33 → 21 than for the duration increasing sandhi 51 → 55. Our current study further quantifies the interaction among these effects. We also explicitly address the question of how these effects may differ for different speaker populations by comparing two groups of speakers — one from Taiwan, who uses the language in their daily functions; one from Kansas, US, who only uses the language occasionally.

### **3. Experimental methods**

#### *3.1. Stimuli and participants*

The basic method of our experiment was to present the subjects with two monosyllables and ask them to pronounce the syllables together as a true disyllabic

word in Taiwanese. Our analyses focused on the tone on the first syllable of the subjects' responses.

There are two within-subjects factors in the experiment. The first is Word Type. Following Hsieh (1970)'s experimental design, we constructed five types of disyllabic words in Taiwanese. The first type is real words, denoted by AO-AO (AO = actual occurring morpheme). These words served as the control for the experiment. The other four types are wug words: \*AO-AO, where both syllables are actual occurring morphemes, but the disyllable is non-occurring; AO-AG (AG = accidental gap), where the first syllable is actual occurring, but the second syllable is an accidental gap in the Taiwanese syllabary; AG-AO, where the first syllable is an accidental gap and the second syllable is actual occurring; and AG-AG, where both syllables are accidental gaps. The AGs were hand-picked by the second author, who is a native speaker of Taiwanese. In each AG, both the segmental composition and the tone of the syllable are legal, but the combination happens to be missing in Taiwanese. The second within-subject factor is Sandhi Type, which is determined by the tone on the first syllable of the disyllables. There are five different sandhi types, represented by the five tones in the tonal inventory on non-checked syllables — 24, 55, 33, 21, and 51. The tone on the second syllable was kept to a constant 33. Necessary frequency controls across the sandhi types were exercised using Tsay and Myers (2005). Eight words for each Word Type × Sandhi Type combination were used, making a total of 200 test words (8×5×5). We also used 160 filler words, which had tones other than 33 on the second syllable.

The experiment also has a between-subject factor, which is Speaker Group. We recruited 20 speakers from Taiwan (6 male, 14 female), who had an average age of 51.6 and all used Taiwanese in their daily functions, and 16 speakers from Kansas, US (6 males, 10 females), who had an average age of 31.3 and had been in the US for an average of 3.8 years — these speakers only spoke Taiwanese for an average of 45 minutes a week, usually in phone calls to their families in Taiwan. The Kansas speakers are also considerably younger than the Taiwan speakers, and sociolinguistic studies have shown that younger speakers use Taiwanese less often due to the increasing influence of Mandarin (Sandel 2003, Scott and Tiun 2007).

### *3.2. Experimental procedure*

The experiment was conducted with SuperLab (Cedrus) in the Phonetics and Psycholinguistics Laboratory at the University of Kansas for the Kansas speakers and in a quiet room for the Taiwan speakers. The stimuli were played through a headphone

worn by the subjects. Each stimulus consisted of two monosyllabic utterances read by the second author, separated by an 800ms interval. The subjects were instructed to put the two syllables together and pronounce them as a true disyllabic word in Taiwanese. Their response was collected by either a Sony PCM-M1 DAT recorder (in Kansas) or a Marantz solid state recorder PMD 671 (in Taiwan).

### 3.3. *Data analyses*

The sandhi tones on the first syllable of the test words were transcribed by the three authors — a native speaker of Taiwanese (Lai), a native speaker of Beijing Mandarin (Zhang), and a native speaker of American English (Sailor), all phonetically trained — using a 1-5 scale with the help of pitch tracks in Praat (Boersma and Weenink 2005). There was clear agreement for nearly all cases among the authors. In cases of disagreement, the judgment of the native Taiwanese author was taken. Based on the transcriptions, the correct response rates for the tone sandhis in each Word Type × Sandhi Type combination for each speaker were then calculated.

Mixed-design ANOVAs with Word Type and Sandhi Type as within-subject factors and Speaker Group as a between-subject factor were conducted for the correct response rates. Regression analyses with the durational property of the sandhis and the type and token frequencies of base tones as predictors for the correct application rates of the opaque sandhis in wug words (\*AO-AO, AO-AG, AG-AO, AG-AG) were also conducted for the two groups of speakers. All statistics were carried out in SPSS.

## 4. **Results and discussion**

The main effects of Speaker Group, Word Type, and Sandhi Type on the correct response rate from the ANOVA are plotted in Figure 1. The effect of Speaker Group is not significant:  $F(1, 34)=0.296, p=0.590$ . The effect of Word Type is significant:  $F(3.552, 120.766)=462.281, p<0.001$ . So is the effect of Sandhi Type:  $F(3.000, 102.012)=37.140, p<0.001$ . Post-hoc analyses with Bonferroni adjustments showed that real words AO-AO have a significantly higher correct response rate than all wug groups ( $p<0.001$  for all paired comparisons). The average correct response rate is 70.1% for real words, but only 16.9% for wug words. Post-hoc analyses also showed that the phonotactically transparent sandhi 24 → 33 has a significantly higher correct response

rate than all opaque sandhis ( $p < 0.001$  for all paired comparisons). The average correct response rate is 44.2% for  $24 \rightarrow 33$ , but only 23.3% for the opaque sandhis.

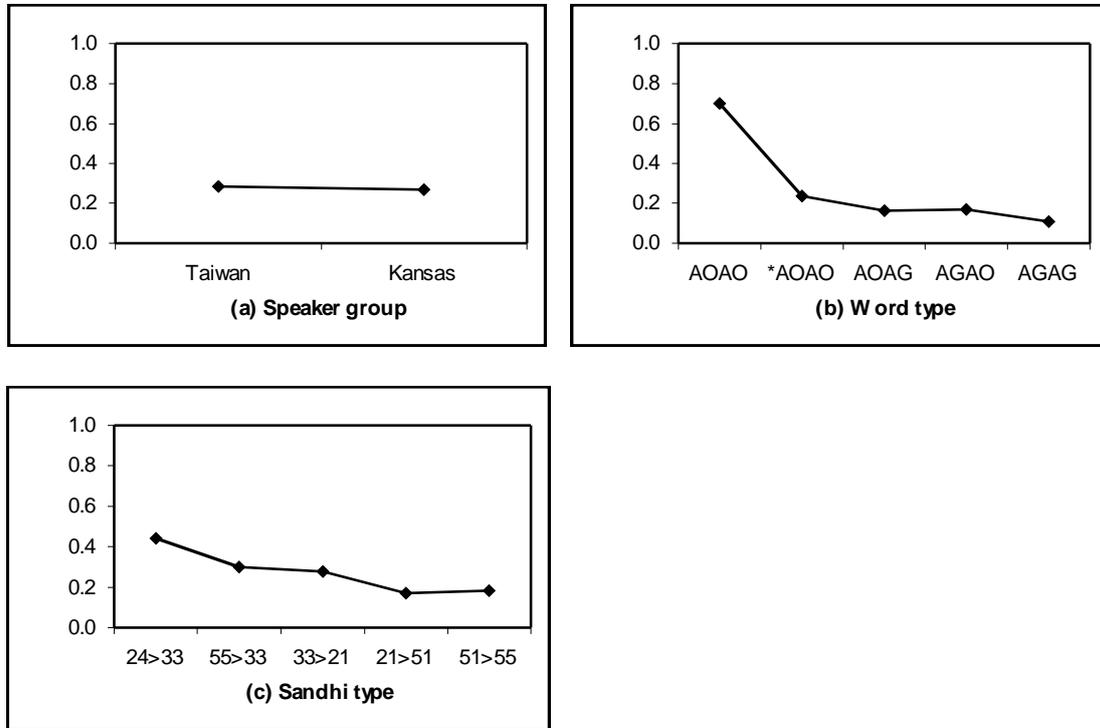

Figure 1: Effects of (a) Speaker Group, (b) Word Type, and (c) Sandhi Type on the correct response rates for tone sandhis in Taiwanese.

The interactions between the within-subject factors and the between-subject factor are plotted in Figure 2. The Word Type  $\times$  Speaker Group interaction just reached significance:  $F(3.552, 120.766) = 2.626, p = 0.044$ . The Sandhi Type  $\times$  Speaker Group interaction is also significant:  $F(3.000, 102.012) = 3.022, p = 0.033$ .

Two separate ANOVAs and subsequent post-hoc analyses on the two subject groups showed that for both Taiwan and Kansas speakers, real words AO-AO have a significantly higher correct response rate than all wug groups at the  $p < 0.001$  level; for Taiwan speakers, the phonotactically transparent sandhi  $24 \rightarrow 33$  has a significantly higher correct response rate than all the opaque sandhis in the tone circle at the  $p < 0.001$  level, and for Kansas speakers,  $24 \rightarrow 33$  has a significantly higher correct response rate than all opaque sandhis at the  $p < 0.05$  level except for  $33 \rightarrow 21$ . These results indicate that both groups of Taiwanese speakers had considerably more trouble in the application of tone sandhis to wug words and the application of opaque tone sandhis.

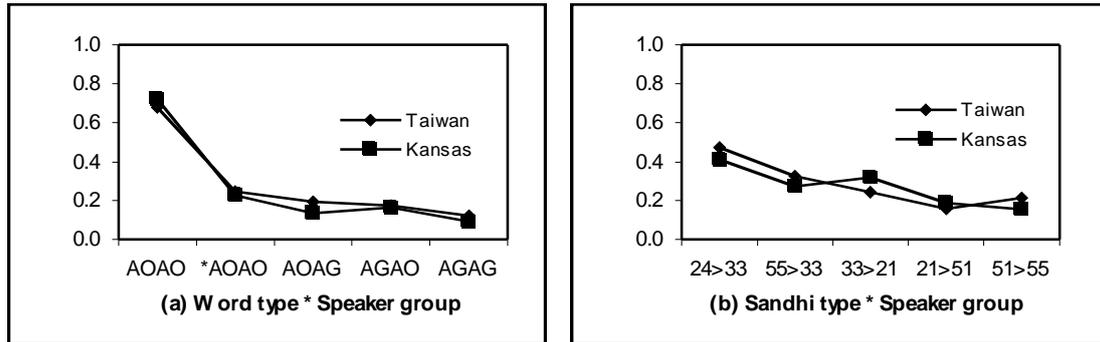

Figure 2: Interactions (a) between Word Type and Speaker Group and (b) between Sandhi Type and Speaker Group on the correct response rates for tone sandhis in Taiwanese.

To further compare the two groups of speakers on the potential effects of phonetics and frequency on sandhi productivity, we conducted an additional mixed-design ANOVA on only the correct response rates for opaque sandhis in wug words. The main effect of Word Type is still significant:  $F(3.000, 102.000)=23.896, p<0.001$ . So is the main effect of Sandhi Type:  $F(2.239, 76.132)=15.229, p<0.001$ . The interactions between the within-subject factors and the between-subject factor are graphed in Figure 3. The Word Type  $\times$  Speaker Group interaction is not significant:  $F(3.000, 102.000)=1.795, p=0.153$ . But the Sandhi Type  $\times$  Speaker Group interaction is significant:  $F(2.239, 76.132)=4.480, p=0.012$ .

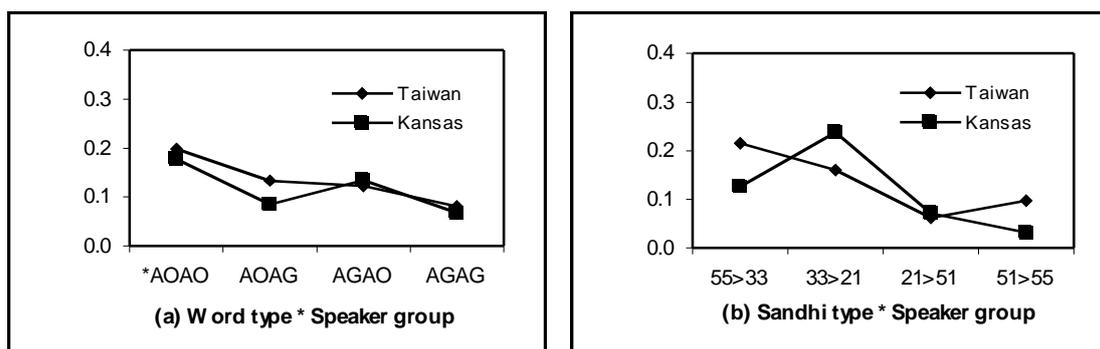

Figure 3: Interactions (a) between Word Type and Speaker Group and (b) between Sandhi Type and Speaker Group on the correct response rates for opaque tone sandhis in Taiwanese wug words.

The significant interaction between Sandhi Type and Speaker Group indicates that the two groups of speakers behaved differently in the application of opaque sandhis to wug words. Figure 3b shows that for Taiwan speakers, the highest productivity is found in the sandhi whose base tone has the highest frequency counts (55 → 33), and the lowest productivity is found in the sandhi whose base tone has the lowest morpheme type and token frequencies (21 → 51); for Kansas speakers, however, the sandhi with the greatest duration reduction (33 → 21) has the highest productivity, while the sandhi with the greatest duration increase (51 → 55) has the lowest productivity. These results indicate that Taiwan speakers' behavior may be closely related to frequencies, while Kansas speakers' behavior may be closely related to phonetic duration.

To further investigate the effects of frequencies and duration on sandhi productivity in the two speaker groups, we conducted a forward stepwise regression analysis for each speaker group with syllable type frequency, morpheme type frequency, and token frequency of the base tone and the amount of duration reduction of the sandhi as potential predictors for the productivity of opaque sandhis in wug words. The values for these predictors are given in Table 1. The frequency counts are from Tsay and Myers (2005) and have been *log*-transformed. The duration reduction data were deduced from the durations of the tones read in isolation reported in Lin (1988). A positive value indicates a duration decrease from the base tone to the sandhi tone, and a negative value indicates a duration increase.

	55 → 33	33 → 21	21 → 51	51 → 55
Syllable type frequency	2.499	2.391	2.407	2.467
Morpheme type frequency	2.872	2.715	2.687	2.736
Token frequency	5.085	5.058	4.972	5.020
Duration reduction (ms)	1	69	-9	-59

Table 1: Predictors for correct response rates for opaque tones sandhis in Taiwanese wug words used in regression analyses.

The regression model for the Taiwan speakers only included token frequency as a significant predictor ( $R^2=.502$ , adjusted  $R^2=.466$ ,  $\beta=.708$ ,  $p=.002$ ; syllable type frequency:  $p=.952$ ; morpheme type frequency:  $p=.664$ ; duration reduction:  $p=.843$ ). The model for the Kansas speakers, on the other hand, only included duration reduction as a significant predictor ( $R^2=.616$ , adjusted  $R^2=.589$ ,  $\beta=.785$ ,  $p<.001$ ; syllable type frequency:  $p=.491$ ; morpheme type frequency:  $p=.558$ ; token frequency:  $p=.348$ ).

In summary, our wug-test results showed a speaker-group independent opacity effect in support of our hypothesis. The opaque tone circle is largely unproductive, as indicated by its low correct response rates in wug words (12.6%). In addition, an analysis of the sandhi errors indicates that the vast majority of the errors are non-application errors (78.7%), which lends further support to the unproductive nature of these sandhis. The phonotactically transparent sandhi 24 → 33, on the other hand, is significantly more productive, as indicated by a higher correct response rate in wug words (34.5%). Moreover, the non-application rate of the sandhi in wug words is considerably lower (31.3%) than those of the opaque sandhis, indicating that even though the speakers might not know the exact outcome of the sandhi, they have effective knowledge of the phonotactic generation that “a rising tone 24 cannot occur in nonfinal positions.”

Our hypothesis that the effects of phonetics and frequency may be speaker-group dependent, in that Kansas speakers will be more strongly affected by duration, while Taiwan speakers will be more strongly affected by frequency counts, is also borne out by the regression analyses. To interpret the speaker-group dependent frequency effect, we assume that the Taiwan speakers exhibit a strong frequency effect due to their everyday usage of the language, and the Kansas speakers have stopped using the language regularly, causing the attrition of lexical strength of all words, which consequently causes the frequency effects to fall below a certain threshold. The age difference between our two groups of speakers, which also translates into usage differences, may have contributed to their difference in frequency effects as well. The difference in phonetic effects between the two speaker groups is correlated with their difference in frequency effects. Due to the incompatibility of the two effects (for instance, phonetic effects predict a high productivity of 33 → 21 and a low productivity of 51 → 55; but frequency effects predict a high productivity for 55 → 33 and a low productivity for 21 → 51), for Taiwan speakers, the phonetic effects may have simply been overridden by the strong frequency effects. But when the frequency effects weaken due to the lack of usage, as for our Kansas speakers, the phonetic effects surface. Therefore, failing to detect the phonetic effects for the Taiwan speakers does not necessarily entail that they do not exist.

We recognize that our experimental result on the speaker group effect may have two opposing interpretations. One interpretation is that it demonstrates the usage-based nature of phonology *à la* Bybee (1985, 2001), as it shows that the speakers' behavior is determined by the context of usage. But conversely, it could also be interpreted as demonstrating that the only true linguistic effects are those of opacity and phonetics, as

they are shared by all speakers; the effects of frequency are metalinguistic. Without committing ourselves to either of these extreme positions, in the following section, we propose an alternative that incorporates both processing and phonological factors to predict the observed behavior of both Taiwan and Kansas speakers. This echoes the position espoused in works such as Hayes and Londe (2006), Pierrehumbert (2003, 2006), Wilson (2006), Zuraw (2000, 2007), and Zhang and Lai (2008).

## 5. A theoretical model

To model Taiwanese speakers' tone sandhi behavior in the wug test, we are faced with the following challenges. First, the model needs to account for the fact that the speakers are exposed to exceptionless opaque patterns in the lexicon, but somehow do not internalize the patterns productively. We term this the underlearning challenge. Second, the model needs to ensure that the speakers have phonetic knowledge that affects productivity, even though the lexical statistics does not inform them of such knowledge. We term this the overlearning challenge. Lastly, the model also needs to capture the speakers' detailed knowledge gleaned from lexical statistics, which we term the proper-learning challenge.

### 5.1. The Maximum Entropy model

The Maximum Entropy model of phonology (Goldwater and Johnson 2003, Wilson 2006, Hayes and Wilson 2008, Jäger, to appear) is a model that is equipped to handle the challenges laid out above. As a variant of Optimality Theory, it is inspired by conditional random fields in information theory (Della Pietra *et al.* 1997, Lafferty *et al.* 2001) and closely related to Harmonic Grammar championed by Smolensky (1986) and Smolensky and Legendre (2006).

In lieu of ranking the constraints on a linear scale, the MaxEnt model assumes that each constraint  $C_i$  has a weight of  $w_i$ . For a candidate  $y$  of a given input  $x$ , if  $C_i(y|x)$  is the number of times  $y$  violates the constraint  $C_i$ , then the Harmonic Score of  $y$  given  $x$  is defined as  $e$  to the negative power of the weighted sum of the numbers of violations of all constraints, as shown in (3).

$$(3) \quad H(y | x) = \exp\left(-\sum_i w_i C_i(y | x)\right)$$

Given the Harmonic Score of  $y$ , the probability of  $y$  as the output to  $x$  is then the proportion of its Harmonic Score to the sum of all Harmonic Scores of  $x$ 's candidates, as shown in (4).

$$(4) \quad p(y|x) = \frac{H(y|x)}{\sum_{y \in \Omega} H(y|x)}, \Omega \text{ is the set of candidates for } x.$$

Given the constraint set, learning in a MaxEnt model from a set of training data  $D$  composed of input-output pairs is to determine the constraint weights that maximize the log probability of  $D$ , which equals to the log of the product of the probabilities of all input-output pairs in  $D$ , as in (5).

$$(5) \quad \log(p(D)) = \log\left(\prod_{y|x \in D} p(y|x)\right)$$

To prevent overfitting the training data, each weight is often considered to be associated with a regularizing Gaussian prior (Martin et al. 1999, among others). The prior specifies  $\mu$  as the default weight for a constraint, and  $\sigma^2$  as the determinant of how severe the penalty is if the weight deviates from the default — the smaller the  $\sigma^2$ , the greater the penalty. Learning, then, is to find the constraint weights that maximize the function combining  $\log(p(D))$  and the penalty, as shown in (6). Crucially, learning *biases* can be encoded as different  $\sigma^2$ s for different constraints, as we will see in §5.3.

$$(6) \quad \log\left(\prod_{y|x \in D} p(y|x)\right) - \sum_i \frac{(w_i - \mu_i)^2}{2\sigma_i^2}$$

## 5.2. Constraints

We turn to the necessary constraints for our analysis in this section. Further statistical analyses of the correct response rates reported above showed that for both Taiwan and Kansas speakers, there is a gradation in sandhi productivity from real words to wug words in which the first syllable is an actual occurring syllable (\*AO-AO, AO-AG) and to wug words in which the first syllable is an accidental gap (AG-AO, AG-AG). We hence represent the three types of words as AO, \*AO, and AG. All pairwise comparisons are significant at the  $p < .001$  level except for the difference between \*AO

and AG for Kansas speakers, which is at  $p < .05$ . This gradation in sandhi productivity from AO to \*AO to AG indicates that the theory needs to encode three different levels of listedness. First, the higher productivity of AO than \*AO requires the listing of disyllabic words in the lexicon, and we posit a group of USELISTED constraints (see Zuraw 2000) on disyllables that force the listed disyllables to be used, as in (7a). Second, \*AO's higher productivity than AG indicates that sandhi *allomorphs* of existing syllables are also listed, and we posit a second group of USELISTED constraints that forces the listed syllable allomorphs to be used in nonfinal sandhi positions, as in (7b). Finally, the modest productivity of the sandhi in AG words indicates that the *tonal* allomorphs independent of segmental contents are also listed in the grammar, and we posit a third group of USELISTED to force the use of such tonal allomorphs, as in (7c).

- (7) a. USELISTED( $\sigma 55$ - $\sigma$ ): Use the listed / $\sigma 33$ - $\sigma$ / for / $\sigma 55$ /+/ $\sigma$ /.  
*Mutatis mutandis* for USELISTED( $\sigma 33$ - $\sigma$ ), USELISTED( $\sigma 21$ - $\sigma$ ), USELISTED( $\sigma 51$ - $\sigma$ ), and USELISTED( $\sigma 24$ - $\sigma$ )
- b. USELISTED( $\sigma 55$ ): Use the listed allomorph / $\sigma 33$ / for / $\sigma 55$ / non-XP-finally.  
*Mutatis mutandis* for USELISTED( $\sigma 33$ ), USELISTED( $\sigma 21$ ), USELISTED( $\sigma 51$ ), and USELISTED( $\sigma 24$ )
- c. USELISTED(55): Use the listed tonal allomorph /33/ for /55/ non-XP-finally.  
*Mutatis mutandis* for USELISTED(33), USELISTED(21), USELISTED(51), and USELISTED(24)

The analysis also needs two other constraints, shown in (8). The markedness constraint \*24-NONFINAL expresses a phonotactically true generalization in Taiwanese. IDENT(Tone) discourages tone sandhi.

- (8) a. \*24-NONFINAL: Tone 24 cannot occur on non-XP-final syllables.  
 b. IDENT(Tone): The tones of the corresponding syllables in the input and the output must be identical.

### 5.3. Learning biases as $\sigma^2$ values

Wilson (2006) argued that learning biases can be encoded as different  $\sigma^2$  values of the Gaussian prior in a MaxEnt model. We capitalize on Wilson's claim to capture the underlearning and overlearning aspects of our Taiwanese speakers' behaviors here.

We assume that the default weight  $\mu$  for all constraints to be zero. The  $\sigma^2$  for \*24-NONFINAL and IDENT(Tone) is set to  $10^{-3}$ ; the  $\sigma^2$  values for USELISTED constraints, however, are  $10^{-3} \times B_{Listed} \times B_{Duration}$ , where  $B_{Listed}$  and  $B_{Duration}$  are two coefficients representing the biases based on listedness and phonetic duration, respectively.

For each type of USELISTED constraints (disyllabic words, monosyllabic allomorphs, tonal allomorphs), we posit  $B_{Listed}$  to be 10 to the negative power of a logistic function, where  $x$  represents the number of morphemes that the type of USELISTED constraints covers on average, as in (9a). As estimated from Tsay and Myers's corpus, the average number of monosyllabic homophones is 2.1, and the average number of morphemes that a lexical tone may denote is 585.4. These values represent the  $x$  values for the USELISTED constraints for monosyllabic allomorphs and tonal allomorphs, respectively. The  $x$  value for the USELISTED constraints for disyllabic words is naturally 1. We can then calculate the  $B_{Listed}$  values for these constraints accordingly, as in (9b). The intuition behind this bias coefficient is that if USELISTED is the learner's strategy to cope with exceptional patterns that cannot be captured by regular means, such as the MARKEDNESS » FAITHFULNESS ranking, then the learner is first of all cautious about positing exceptions, expressed in the model by assigning USELISTED constraints greater penalties if they deviate from the default ranking of 0; secondly, the learner is unwilling to treat massive amounts of data as exceptions, expressed in the model as greater penalties for USELISTED constraints that make generalizations.

(9) a.  $B_{Listed} = 10^{-\frac{1}{1+e^{2-2x}}}$ ,  $x$  = the number of morphemes that the type of

USELISTED constraints covers on average

	$x$	$B_{Listed}$
USELISTED( $\sigma\sigma$ )	1	$10^{-0.5} = .316$
USELISTED( $\sigma$ )	2.1	$10^{-0.9} = .126$
USELISTED(T)	585.4	$10^{-1} = .1$

The  $B_{Duration}$  coefficient expresses a substantive bias *à la* Wilson (2006). It biases against the duration increasing sandhi  $51 \rightarrow 55$  by having a value of .95, but encourages the duration reducing sandhi  $33 \rightarrow 21$  by having a value of 1.05. Duration neutral sandhis  $55 \rightarrow 33$ ,  $24 \rightarrow 33$ , and  $21 \rightarrow 51$  all have a  $B_{Duration}$  of 1.

The  $\sigma^2$  values for all constraints are summarized in Table 2.

Constraint	$\sigma^2$	Constraint	$\sigma^2$
UsLSTD( $\sigma$ 55- $\sigma$ )	.000316	UsLSTD( $\sigma$ 21)	.000126
UsLSTD( $\sigma$ 24- $\sigma$ )	.000316	UsLSTD(55)	.0001
UsLSTD( $\sigma$ 33- $\sigma$ )	.000332	UsLSTD(24)	.0001
UsLSTD( $\sigma$ 51- $\sigma$ )	.000300	UsLSTD(33)	.000105
UsLSTD( $\sigma$ 21- $\sigma$ )	.000316	UsLSTD(51)	.000095
UsLSTD( $\sigma$ 55)	.000126	UsLSTD(21)	.0001
UsLSTD( $\sigma$ 24)	.000126	*24-NONFINAL	.001
UsLSTD( $\sigma$ 33)	.000132	IDENT(Tone)	.001
UsLSTD( $\sigma$ 51)	.000120		

Table 2:  $\sigma^2$  values for all constraints.

#### 5.4. Modeling the speakers

We turn to the modeling of learning of our two groups of speakers in this section. Our modeling was conducted with the MaxEnt learner in OTSoft 2.2 (Hayes et al. 2005). To model the Taiwan speakers, we fed the MaxEnt learner a training dataset of AO-AO input-output pairs that approximates the token frequency distribution of the different sandhi patterns: 13,000 /55-33/→[33-33], 12,000 /24-33/→[33-33], 11,000 /33-33/→[21-33], 10,000 /51-33/→[55-33], and 9,000 /21-33/→[51-33]. To model the Kansas speakers, we simulated the lack of frequency effects by feeding the learner an equal number of AO-AO input-output pairs (10,000) for each sandhi pattern. For each input, we considered 25 candidates that represent all possible tonal combinations. The two grammars learned by the MaxEnt model are given in Table 3.

We can observe that for both groups of speakers, the USELISTED constraints for real disyllables have the greatest weights, followed by \*24-NONFINAL and IDENT(Tone). USELISTED for monosyllabic allomorphs and tonal allomorphs have lower weights, *even though they are never violated by any of the outputs in the training data*. Within each group of USELISTED constraints, for Taiwan speakers, the sandhi that has a higher token frequency has a greater weight, while for Kansas speakers, the sandhi that has a greater duration reduction has a greater weight; the only exception is that the constraints governing 24 → 33 have the lowest weights within the group, as \*24-NONFINAL is able to share some of the burden of enforcing the tone sandhi.

<b>Constraint</b>	<b>Weight (Taiwan)</b>	<b>Weight (Kansas)</b>	<b>Constraint</b>	<b>Weight (Taiwan)</b>	<b>Weight (Kansas)</b>
USLSTD( $\sigma$ 55- $\sigma$ )	2.958	2.782	USLSTD( $\sigma$ 51)	.875	.873
USLSTD( $\sigma$ 33- $\sigma$ )	2.878	2.815	USLSTD( $\sigma$ 21)	.866	.882
USLSTD( $\sigma$ 51- $\sigma$ )	2.745	2.747	USLSTD( $\sigma$ 24)	.755	.730
USLSTD( $\sigma$ 21- $\sigma$ )	2.708	2.782	USLSTD(55)	.736	.701
USLSTD( $\sigma$ 24- $\sigma$ )	2.675	2.556	USLSTD(33)	.721	.707
*24-NONFINAL	1.892	1.868	USLSTD(51)	.696	.694
IDENT(Tone)	1.755	1.740	USLSTD(21)	.688	.701
USLSTD( $\sigma$ 55)	.926	.882	USLSTD(24)	.600	.580
USLSTD( $\sigma$ 33)	.907	.890			

Table 3: Constraint weights for Taiwan and Kansas speakers learned by the MaxEnt model.

To compare the grammars' predictions with the speakers' wug test behavior, we calculated the correct response rates of AO, \*AO, and AG inputs based on each grammar and juxtaposed the predictions with the outcomes of the wug test for the two groups of speakers, as in Figure 4 and Figure 5.

For both groups of speakers, the model successfully captures the overall low productivity of the sandhis in wug words despite the exceptionless input to the learner; it also captures the higher productivity of 24  $\rightarrow$  33 than the opaque sandhis in the tone circle. Among the opaque sandhis, the predictions for both groups of speakers are also well matched with the wug test results: for the Taiwan speakers, the predicted order of productivity mirrors the order of token frequency, with 55  $\rightarrow$  33 being the highest and 21  $\rightarrow$  51 being the lowest; for the Kansas speakers, however, the predicted order of productivity follows a durational pattern, with the duration reduction sandhi 33  $\rightarrow$  21 being the most productive and the duration increasing sandhi 51  $\rightarrow$  55 being the least productive. The only prediction that the grammars fail to make is the magnitudes of the frequency and duration effects in Taiwan and Kansas speakers, respectively: the predicted effects are considerably smaller than the attested effects. However, regression analyses indicate that the grammars' predictions are significantly correlated with the experimental results. Taiwan speakers:  $R^2=.866$ , adjusted  $R^2=.855$ ,  $\beta=.930$ ,  $p<.001$ ; Kansas speakers:  $R^2=.879$ , adjusted  $R^2=.869$ ,  $\beta=.937$ ,  $p<.001$ .

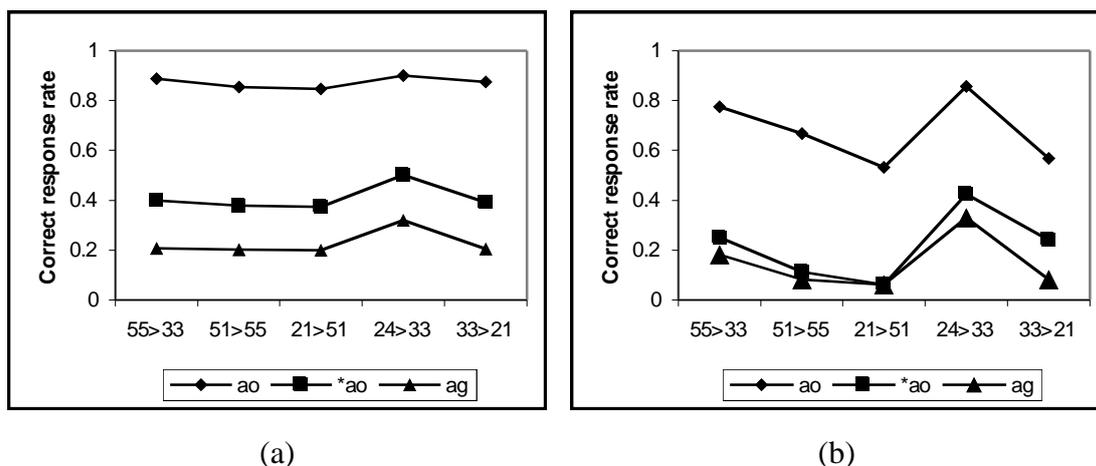

Figure 4: The grammar's predictions (a) and the wug test results (b) for the Taiwan speakers.

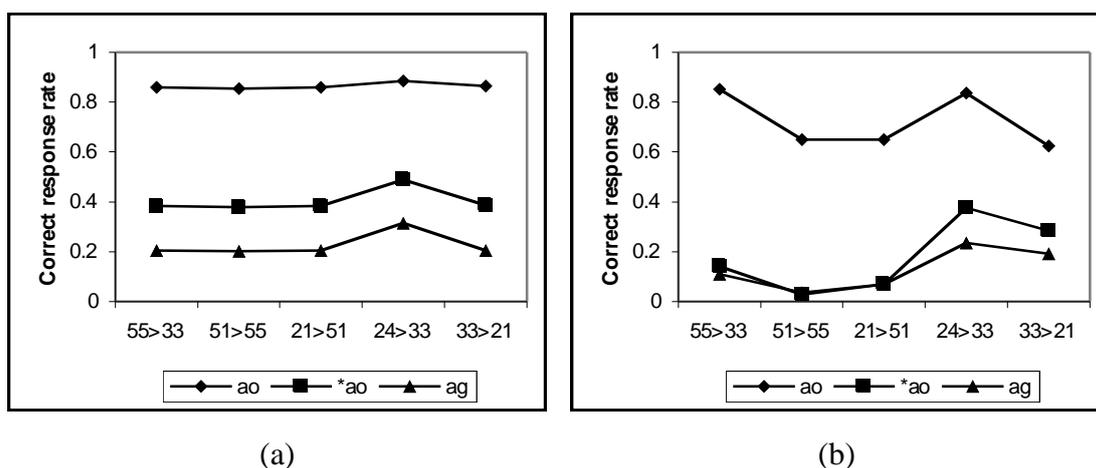

Figure 5: The grammar's predictions (a) and the wug test results (b) for the Kansas speakers.

### 5.5. Model summary

Our model sets out to take on the underlearning, overlearning, and proper learning challenges posed by the wug test data. The underlearning of exceptionless opaque sandhi patterns in the lexicon is achieved by deriving the opaque patterns via USELISTED constraints that directly state the input-output mappings of the sandhis and positing a learning bias against these constraints in the form of lower  $\sigma^2$ s. The magnitude of the effect predicted by the model is well matched with the experimental results. The overlearning of the phonetic knowledge despite the lack of information from lexical statistics is modeled by a substantive learning bias against phonetically

unmotivated patterns, again in the form of lower  $\sigma^2$ s, *à la* Wilson (2006). The model succeeds in predicting the existence of this effect, but the predicted effect size is small compared to the experimental results. The proper learning of lexical statistics happens naturally for the learner, as the MaxEnt model inherently encodes the frequency effects by letting more frequent patterns to have greater pulls on constraint weights. But the magnitude of the effect predicted by the model is again small compared to the experimental results.

The small size the phonetic effect in the model is a direct result of the small frequency effect. Since the model needs to ensure that for Taiwan speakers, the phonetic effect is overshadowed by the frequency effect, it is not able to assign greater substantive biases according the durational property of the sandhis; in particular, the substantive bias cannot be greater than the frequency effect derivable by the model from token frequency exposure. What the model crucially needs, then, is a mechanism that predicts not only the existence, but also the correct magnitude of the frequency effect observed from the wug test.

The lack of frequency effect for the Kansas speakers is captured in the model by feeding it learning data that provide no frequency differentiations among the different sandhis. We recognize that a more comprehensive model should also have an explicit mechanism that captures the attrition of the frequency effect due to lack of usage and the corresponding constraint weight adjustments in the grammar that reflect the usage change. We take the last two points of discussion here as directions of future effort to improve our model.

## **6. Conclusion**

Our wug test study on the tone sandhi patterns in Taiwanese showed that gradient factors such as phonetic duration and lexical frequency interact with formal factors such as opacity in meaningful ways in influencing the productivity of phonological processes. For Taiwanese tone sandhi *per se*, opacity outweighs phonetics and frequency as a global effect, while frequency and phonetic effects are dependent on the speakers' usage of the language in that frequency effects are evident for everyday users of the language, while phonetic effects only surface for occasional users for whom the frequency effects have been weakened due to the lack of use of the language. We have taken the position that a more fruitful approach to phonological grammar is to incorporate both processing and phonological factors to predict the observed behaviors of speakers with different

usage backgrounds, and we have shown that a Maximum Entropy grammar that encodes learning biases against lexical listing constraints and phonetically unmotivated patterns can model the simultaneous underlearning of exceptionless opaque patterns, overlearning of phonetic effects, and proper learning of lexical statistics by the two groups of Taiwanese speakers. Finally, an important methodological point also emerged from the study: in experimental phonology research, *where* the speaker comes from can have a significant impact on both the experimental result and its theoretical modeling, and we as researchers need to be aware of this potential effect and incorporate it in our analyses and modeling of phonology when appropriate.

## Loans and Language Contact Models in Algonquian and French Cree\*

Boštjan Dvořák & Patrick Steinkrüger

ZAS Berlin

[dvorak@zas.gwz-berlin.de](mailto:dvorak@zas.gwz-berlin.de) & [steinkrueger@zas.gwz-berlin.de](mailto:steinkrueger@zas.gwz-berlin.de)

When asked about some modern expressions taken from a European language, mainly English, like **computer**, **internet** or **plane**, **Ojibwe** speakers often hesitate, when interviewed in the experiments<sup>1</sup>, referring either to a standardized pretence, such words would not exist in their language, or presenting skilfully a big variety of the language's own corresponding words, like **mazinaabekiwebinigan**, **waazamoo-assab** or **bemissemagak**. The preference for such neologisms may be associated with a kind of national purism from a modern European point of view, but on the other hand it coincides with what we find in early statements made by Baraga and other authors about the language and its nature – characterising it as “being that rich and dynamic that it tended to express all things by own words and forms”<sup>2</sup>. This peculiarity seems to be true of many other Algonquian languages as well.

On the other side, there is the case of the **Michif**<sup>3</sup> language within the same linguistic and geographic context, showing an extreme opposite to the situation

---

\* The present contribution contains a synopsis of the data material presented in our talk held on January 20<sup>th</sup> at the 2007 International Conference on Linguistics in Korea; we would like to specially thank the ICLK organizers and the ZAS institute for the kind support of our presentation and research. Many thanks also to all of the participants for the constructive discussion of our theses.

<sup>1</sup> We mainly refer to lexical data collected by Dvořák from experiments with native speakers, compared with the material available in Nichols & Nyholm (1995) and Rhodes (1985).

<sup>2</sup> Friderik Baraga, letters to sister Amalija, August 1831.

<sup>3</sup> The names *French Cree* and *Michif* denote the same language and are used as synonymous terms in this publication.

above, in combining two typologically extremely different grammars consequently in one system, with the nominal part almost completely integrated from a non Algonquian language, French, representing therefore a striking contrast both to Algonquian and most other language contact cases in general. As to French, it is often involved into “normal” language contacts, from which several Creole languages<sup>4</sup> arose, as is also the case with many other Romance languages; thus it presents a good base for a typological comparison between what is supposed to be a **mixed** respectively a **creole** language. The comparative view of some detailed material reveals essential differences – and parallels – between these two types of languages resulting both from extreme language contact situations.

What is the concrete relation between language type and possibilities for loans and borrowings? This and further questions about contacts between European and Algonquian languages arise when we consider older statements, new opinions and own observations; most parts of gathered information seem to bring some evidence for the proposed or at least indicated (Rhodes, pc<sup>5</sup>) claim that Algonquian languages show a certain immunity from influences by other languages, based mainly on complexity and type of their morphological structure. It is likely to assume that loanwords should be rather rare<sup>6</sup>, therefore, when compared with other situations of contact between (more closely related) languages. The peculiarity described initially should therefore not surprise, according to some legal speculations about connections between language types and their contact behaviour.

---

<sup>4</sup> Data from comparative studies in several French-based *Creole languages* gathered and analysed by Steinkrüger are used for the systematic comparison between this type of language contact relations and that found in French Cree as a *mixed language* (sensu proprio) as described by Bakker (1997).

<sup>5</sup> This tendency was also mentioned and briefly commented at the 2006 Rara et Rarissima Conference in Leipzig after the talk about Ojibwe Morphology by Richard Rhodes, to whom I owe my thanks for patiently answering my numerous questions.

<sup>6</sup> This conclusion represents a further step though, as the above assumption is mainly expected to apply on the morphological structure itself, as being stable in the sense of “unchangeable”.

But how should the striking exception of Michif be interpreted in this context? Although being considered as a typological rarum, or – due to the sociolinguistic situation given at its origin – a systematically planned or constructed language<sup>7</sup>, this structure might be considered as an evidence for the assumed contact difficulties based on morphological structure rather than being in opposite to them; the present consideration attempts to associate Michif as a mixed language phenomenon with the tendencies found in general in the languages of the Algonquian family, when exposed to contact, with an account based on morphological structure and dominant parts of the grammar. With Michif and Algonquian morphology, some systematic differences between Creole and mixed languages arise, which can be compared in several aspects of grammar and language contact situations.

Admittedly, there are some points of view which can make it quite acceptable to assume that the strange observation mentioned initially is due to a purist attitude of the speakers towards new words. Coming from a foreign language, they may be viewed as a threat for the mother tongue, since they usually represent new concepts and may often be associated with formerly unknown elements of a new “way of life” and thus eventually considered as threatening the traditional life and heritage, to which the native language is naturally considered to belong. This may be considered as an impediment for new words to be overtaken in the native language, representing thus a big contrast to the creole languages and leading to the above phenomenon – but is it a real one in our case? Why not simply use the words coming from another language, as this is the most simple way and also represents the most usual behaviour in language contact situations? We are trying to explain.

Two other different kinds of behaviour towards the new expressions and concepts associated with them, can generally be observed, both of which seem also to be (at least partly) found among Ojibwe speakers: In the first case, new concepts are not necessarily overtaken into the own language together with the new words from another language, although the innovations are accepted and present in the everyday life; the speakers try

---

<sup>7</sup> This is but one of several hypotheses given and explained in Bakker, among which the components of the sociolinguistic situation (intermarriage, mixed identity, social delimitation) clearly prevail as bases for the explanation of its origin.

to systematically integrate the innovations by finding new expressions for them based on the material available in their own language, a widespread phenomenon observed by many languages from different families and types and especially well known in the European area, and this also seems to be the case in our example in Ojibwe. It should be mentioned, though, that this behaviour generally includes at least some influence by a systematic language policy – and the most speakers of the most languages are generally considered to be more likely to accept any foreign word for a new thing of a formerly unknown concept when being confronted with it, in spontaneous situations of language contact – which seems to be an important point for our latter argumentation. But once the way is indicated, the efforts of this “creative method” may result in new conceptualizations for the things as well as in concrete and “faithful” word-by-word translations and, not rarely, calques<sup>8</sup>. Several types and stages of such easily controlled and nationally oriented language purisms (neologisms) – combined with different degrees of loanword tolerances – are known for many European neighbouring and, mostly, related languages.

The other possibility is much less innovative – but not more preservative at all; it consists in restricting the field of use of the own language to commonly known traditional world areas, in that the speakers (consciously or unconsciously?) avoid talking about “the new things” in their own language and seemingly prefer to switch to the foreign language for that purpose – this can seriously endanger the language and may also lead to its death in a long-term view, especially if the foreign language is dominantly used in the same area, and most speakers are bilinguals. This kind of “interaction” is more typical for less related or very different languages. We suspect to have observed such tendencies among some Anishinabe populations as well, since several of the speakers confronted with word lists designating technical devices in English did not like

---

<sup>8</sup> There are huge amounts of example material like Breton *dada* “sweet” from French *bonbon* (“good-good”) or Slovenian *izlet* “trip” from German *Ausflug* (“out-fly”), to mention but two European examples. The Ojibwe word for “internet”, *waazamoo-assab*, partly represents this kind of translation, with *assab* (fishing net) and the prefix *wazamoo-* designating “electric” (< lightning), whereas *mazinaabekiwebinigan* “computer” is semantically a new invention, meaning a “picture up and down throwing machine”.

to talk about this item at all and even obviously thought we were making fun of them<sup>9</sup>. However, as quite some speakers in the same areas were able to spontaneously list (or find out by asking other speakers) a big amount of Ojibwe-own expressions for numerous modern technical devices including many details we did not even ask about (as eg. *computer-mouse, keyboard, mouse-pad* etc.) as well as other things pertaining to the context, we suppose that this kind of creative word-forming is well spread and generally productive in the language – and does not represent an exceptional purist attitude. Nevertheless, a kind of taboo-like behaviour can still be noticed from time to time when talking about things concerning the “modern way of life”<sup>10</sup>.

On the other hand, there is an obvious lack of loanwords in this respect, and this was the very starting-point for such tests and considerations – since this observation seems to correspond with both the neologism tendency on the one and the taboo-like attitude on the other side. Surprisingly, some evidence on this behaviour can also be noticed in modern works about Ojibwe and related Algonquian languages of several contemporary authors – but no clear statements or appropriate comments on these observations can be found, except some very short and rather accidental notices<sup>11</sup>. All these considerations as well as our own evidence seem to coincide amazingly with what the earlier authors told when writing their first descriptive works about Ojibwe and other

---

<sup>9</sup> Much time was needed initially to obtain the list of such expressions, as we started by full sentences containing them; the original idea was to check how loans from English would be integrated into the native context of morphology and syntax – and to look at phonological consequences. Technical devices were chosen, as it was likely to find many loans in this lexical area – and thus the latter systematic observation was somewhat accidental. I also often wondered if the modern concise dictionaries written by Nichols/Nyholm and Rhodes, containing extremely few loanwords, but huge amounts of indigenous neologisms in these fields, can really reflect the language reality; it came out that they mostly do.

<sup>10</sup> At this opportunity we would like to mention our belief that projects of language encouragement by supporting and popularizing traditional native activities are good and important, but should not be restricted to that; the only responsible and adequate method of language encouragement should cover all fields and levels of a language, without limiting it to a certain biotope.

<sup>11</sup> Rhodes, eg., notices in his 1985 dictionary, that Anishinabe people are more likely to spontaneously switch to English when talking about new concepts than accepting the word into the native speech.

Algonquian languages; Friderik Baraga (1797-1868), who worked as a missionary among the Anishinabe populations (Ojibwe and Ottawa) in the Great Lakes area since 1830 and was nominated “Indian Bishop” in 1852, writes in the letters addressed to his sister Amalija that Ojibwe tends to describe words from European languages in compound word constructions rather than borrowing them. It is amazing in this respect, that the same peculiarity can seemingly be observed in the modern Ojibwe 170 years later. Missing loanwords and borrowings could be an indication of a strong and dominant morphological structure. According to the requirements of this structure, it could be expected that creating new words within the inherited categories of (eg.) *animacy*, *transitivity*, *activity* and *obviation*, is somewhat easier than overtaking loans from other sources into the native language system. Admittedly, it is still difficult to exactly determine what kind of constraints there are or should be for a foreign word whether it can be integrated into the native language system or not, by sole observation that this is predominantly not the case; however, with strong and practically omnipresent categories as *animacy* and *reference tracking/ obviate* and *inverse morphology*<sup>12</sup> dominating the language system, it is to expect, that words taken from outside the system are simply ruled out by the very fact that they are not compatible with the existing categories, as they originally lack an adequate category in their source language. The essential point however seems to be the fact that the animacy constraint rules basic grammatical principles with respect to which types of verbs have to be used with a certain word as object or subject in a sentence, as shown in the following examples;

- |     |     |                           |                      |
|-----|-----|---------------------------|----------------------|
| (1) | a)  | <i>Memengwaan</i>         | <i>owaabamaan.</i>   |
|     |     | Butterfly (NA) <b>obv</b> | 3.see VTA <b>obv</b> |
|     |     | ‘(S)he sees a butterfly.’ |                      |
|     | a’) | <i>Memengwaa</i>          | <i>niwaabamaa.</i>   |
|     |     | Butterfly (NA)            | 1.see VTA            |
|     |     | ‘I see a butterfly.’      |                      |

---

<sup>12</sup> It is worth mentioning that the system of inverse morphology/ obviate marking is considered as unique by some authors in Algonquian languages; Wunderlich (2006, pc) even calls it “a genial invention”, on the base of which he argues against the universal rules of Chomsky’s syntax movement.

In (1a) a 3<sup>rd</sup> person subject sees an animate object, which therefore has to be marked (on both the noun and the transitive verb stem) by the *obviative* ending; the obviative category partly corresponds to the object-marking system known from European languages as Accusative case, but it is always used when more than 1 animate element (subject or object) occur in a sentence, whereas it does not apply to sentences with 1<sup>st</sup> or 2<sup>nd</sup> person

---

<sup>13</sup> *Bemisemagak* “plane” is an active participle to the verb *bimise* “to fly”.

<sup>14</sup> *Dekaag* “ice-cream” is a passive participle to the (vii) verb *dakaa* “be cool”.

subjects (a'). Additionally, another verb stem is used in (b) – applying for inanimate objects<sup>15</sup>, different from that for animate objects. In c) the object is animate again.

With *dekaag* “ice-cream”, we have an inanimate object in (2), with no further marking required (a, b); in (c) there is no object in the construction, and another verb is used therefore.

With those complex structures pertaining to both verbs and nouns at the same time in an obligatory relation, and, as already said, being omnipresent in the language system, it seems to be very difficult to suddenly adopt a foreign expression for a technical device like “computer” or “plane”, an abstract conception like “politics” or a professional term like “politician” – since the knowledge about animacy, associated with the use of different verbs, is inherited – in comparison to “simply” creating it by using the well known and compatible material, which the speakers are acquainted with. A further point has to be mentioned in this context, which can be made evident in (4): the fact that many verbs (at least partly) contain what would be obligatorily expressed by a separate noun in a European language; this characteristic, which can be considered as (at least partly) polysynthetic (with the semantic and the morphological meanings to be differentiated), may be an additionally hindering factor in overtaking loan words – and is obviously a facilitating circumstance for creating new words in Algonquian languages.

- (3) *Mazinaabekiwabiniganing*      *ozhibii`ige*.  
computer (NI) + **Loc**                      3.write VAI  
'(S)he writes on/with (a) computer.'
- (4) *Dibaakonige*.  
3.be in politics VAI  
'(S)he is politician/ is in politics.'

---

<sup>15</sup> This verb stem differs from that for animate objects in containing the *-nd-* element, which is a systematically productive morpheme; in some other cases animacy associates different lexical stems.

Since we have to deal with just the extreme opposite in French Cree, the famous mixed language combined (mainly) of Cree verbal and French nominal system, where nouns were systematically integrated into the language, it is worth considering how and whether we can find a systematic explanation for this contrast in a broader context of the observations made and somewhat typical for Algonquian languages. Even if it seems to be an absurd idea to connect these two extremes at the first glance, we would like to formulate the theoretical possibility to interpret them as belonging to the same phenomenal context, which we expect to be connected with what we called *dominant morphology*. The difficulties appearing in connection with adopting foreign words seem all to be caused predominantly by the complex structure of differentiated marking of animate and inanimate objects and different types of verbs connected with them in Algonquian languages – and there seem to exist two possibilities to consequently avoid them:

- 1.) A more or less strict inventive method including new creations and/or constructions corresponding to the foreign expressions by using inherited material compatible to the grammatical rules and excluding any foreign elements – as interpreted above, or
- 2.) A more or less complete integration of the foreign nominal system by overtaking it consequently as a whole, which enables the speakers to keep the inherited language structure widely intact – with adding the complete foreign system to it.

In the case of Michif, the option (2) has been chosen, leading to the most unusual language possible, with two grammatical systems coexisting and remaining (almost entirely) stable; this is possible, as the Cree verb system – representing the dominant grammatical element – remains mostly uninjured, as shown in the few examples;

- (5) *Li memaengwaen tukoushin*  
 DAMSNA VAI  
*daw li praentawn.*  
 Prep. DAMSN  
 ‘The butterfly appears in the spring.’

- (6) *Si boon la moor shioushtawhk.*  
 It is good DAMS love V to do.  
 ‘It is good to make love.’
- (7) *John ki-wapam-e-w aen šaen. (/ aen šaen-wa)*  
 John Perf-see-3Obv 1 dog (NA)  
 ‘John saw a dog.’

In (5), (6) and (7) the Cree verbs are underlined; the French nouns appear with definite (*li/la*) or indefinite (*aen*) articles, which are also used in the rare cases when words are of Algonquian origin (*li memaengwaen* < Ojibwe). This situation is opposed to that (mostly) found in creole languages, characterized by an extensive reducing and reorganising of the grammar, as evident on the few examples gained by Steinkrüger (2006) from Mauritius Creole;

- (8) *Eski ou kapav koz kreol avek mwa?*  
 Q you able speak creole with 1. non-subj  
 ‘Can you talk creole to me?’
- (9) *Fer enn lot pri pou mwa!*  
 make a other price for 1. non-subj.  
 ‘Make another price for me!’ (Faites un autre prix pour moi!)

On this comparison we see that Michif truly represents another language type, which is not to be confused with that of the creole languages; based on the observation of how the French elements are integrated in the respective system, we can conclude in underlining the following essential differences: whereas creole languages result from mainly *restructuring the whole system*, the *emergence of new categories* and a high degree of *simplification*, mixed languages like French Cree are built by *coexistence/combination of strategies*, *substitution of categories* and an increased *complexity of the system*.

In our short contribution we tried to interpret both the difficulties of nominal loanword acceptance observed in several Algonquian languages and the apparently op-

posed complete integration of the French noun system in Michif as two sides of the same phenomenon, based on the *dominant morphology* of the Algonquian<sup>20</sup> languages.

Katra, J & K, India-182 320  
amitabh.vikram@smvdu.ac.in

## **Abstract**

My aim in this paper is to work on the spatial cognition in Hindi. This paper finds its root in artificial intelligence. The basic inquiry that shapes in this work is: How can one produce and interpret locative expressions that are appropriate in a given context? This paper will present an analysis of the semantics of locative expressions. The paper will examine the possibility of constructing a computational model of comprehension and production in the spatial domain.

---

**Keywords:** Artificial intelligence, Cognition, Locative, Semantics, Computational model, etc.

## **1. Introduction**

Hindi is the name of the language spoken chiefly in north India. This region has states namely Rajasthan, Madhya Pradesh, Chattisgarh, Uttar Pradesh, Uttaranchal, and Bihar. The main aim of this paper is to demonstrate the play of locative expressions in Hindi. It is a SOV language and locative expressions occur post – positional. As in:

1. *pese ke upar katori: rakhi: he*  
coin PREP.SUF. on bowl placed is.AUX

“The bowl is on the coin.”

Here the interesting element is that “*ke upar*” (on) is made of two different locative lexicons but it gives the sense of one locative that is ‘on’ as translated into English. Contrary to SVO languages like English where a locative expression modifies the following phrase in Hindi a locative expression works as post – modifier. Keeping in mind how people can produce and interpret locative expressions that are appropriate in a given context, the data in the paper mainly focus on these questions:

- (i) How do people manage to produce and interpret locatives?
  - (i-a) Do the locative phrase, and the locative phrase in a sentence give the same interpretations, or they vary?
  - (i-b) Why do certain locative phrases come as a null phrase, and others get full expression?
- (ii) What is the possible syntax semantics interface in the construction of locatives?

## **2. Argument**

As we know in human language processing, our brain computes the performance which works out in a given context, and “the brain is viewed as an information processing system in which data can be stored and retrieved and operated on(Sanford,1987)” To prove the accountability of a given performance the question how the acquired knowledge is put to use is crucially important. A human compute system works on the following terms: How we take in the observe data, process it, and work out for actual use, given various contexts. Before giving an explanation to the problem: What are the relevant brain mechanisms for spatial cognition? It would be appropriate to suggest that in general conversation we are not aware of computation consciously<sup>1</sup>. This can be shown by giving a native speaker of Hindi the following sentences: For example:

2. *pen kita:b me he*  
pen book in.PREP is.AUX

“The pen is in the book.”

The speaker cognizes one situation-the book is closed, and the pen is inside the book. He cannot say that the book is open, and the pen is in it. For this interpretation he will use different locative expressions like ‘par’ and the sentence would become:

3. *pen kita:b par he.*  
Pen book on.PREP is.AUX

“The pen is on the book.”

The sentence 3 helps him to cognize two different situations:

- a. The book is closed and the pen is on the book.
- b. The book is open and the pen is on it.

This clarity has come out because locative expressions occur in the sentence. If they were used in the phrase:

4. *kita:b me pen.*  
Book in.PREP pen.

“The pen (is) in the book.”

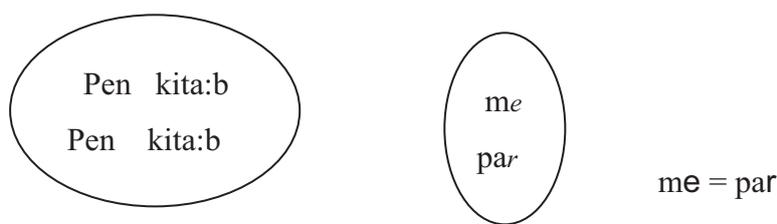

Or

5. *kita:b par pen.*  
Book on.PREP pen.

”The pen (is) on the book.”

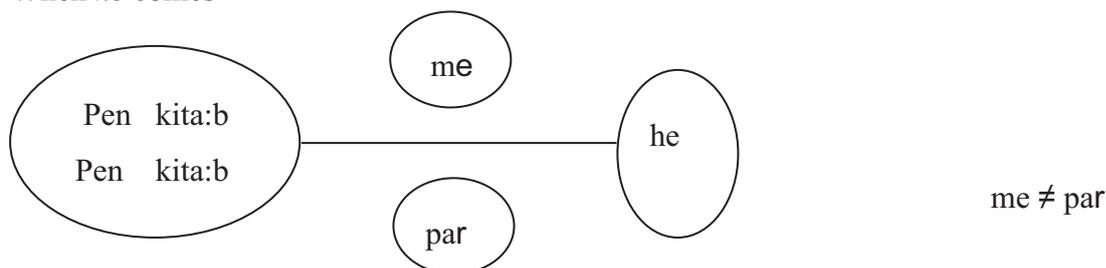

The native speaker is not able to comprehend the various interpretations”(undoubtedly all these embarrassing exaples reveal that the choice of different levels of abstraction in different languages constitutes a highly relevant lexical-

typological parameter(Peter Koch,2001)” if they were used in the phrases. This proves that locative expressions find their meaning in sentences. Though we acquire a language in phrases yet we comprehend it in sentences. Hence syntax finds its expression in pragmatics. From the above example an interesting fact comes into light that verbal element adds clarity to the sentence, and provides various interpretations. Lemke, in this context, argues that in all dynamical systems which show individual properties, we have a situation where “elementary units on any scale interact with many others so that collective properties emerge, we rapidly reach levels of complexity of compound units for which there can be individual identity, memory, and history(Lemke,1997)” Now the question arises whether verbal element entails the post positional meaning or post positions find their meaning itself in the sentence. Let’s take two examples:

**Diagram – I -** Post position without *he*.

When *he* comes

**Diagram – II –** Post position with *he*

## 2.1. Argument

We can say that both *me and par* locatives function like planets, and don't possess any light of their own but when the verbal element *he* comes like sun they start illuminating and showing their light. Then the logical question arises why do we not use full expression in our day to day conversation? The possible answer is: we have been attuned to the economy principle<sup>2</sup> since our childhood. Children expect from their adults to understand what they are intending to say with context by using minimal expressions, and for this reason social environment is important to children's development because it can accelerate or decelerate development(Vygotsky,1962).” For example, if a child says “mil” she may try to express:

- a. Milk, no milk
- b. Give me milk.
- c. I like milk
- d. I do not milk
- e. I have taken milk; and thousands of similar expressions

Now it is up to the mother to understand the minimal expression in the correct context. Similarly competent speakers want to use language minimally, and try to express maximal meaning. The inborn economy tendency in every human being gives rise to thus infinite expressions. Another possibility is that locative expressions show their dependency on other lexicon (noun, verb, etc.), when they come as post position and adverb. As for example:

6. *kamere se fal le a:o.*  
Room from.PREP fruits take come.

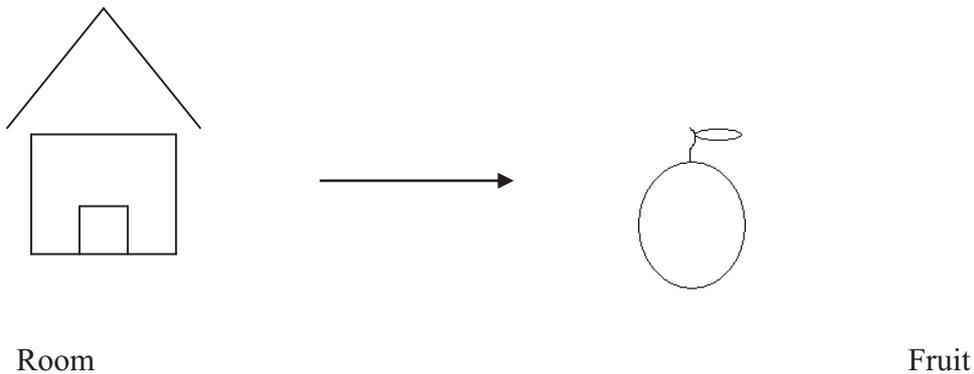

“Bring fruits from the room.”

And

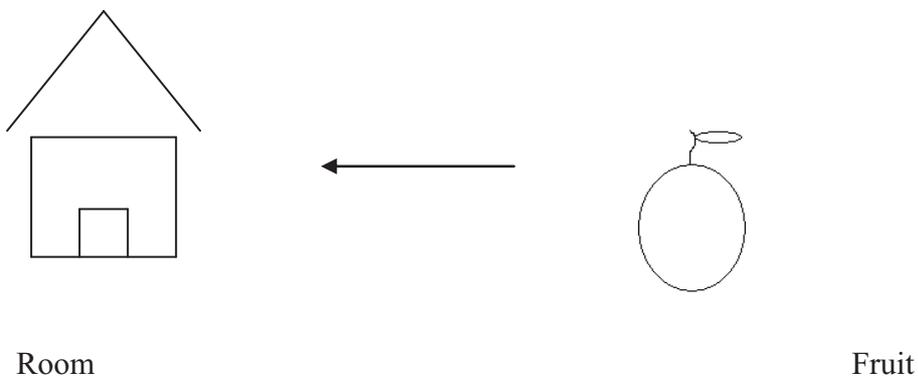

7. *kamera: me fal le a:o.*  
Room in.PREP fruit take come

“Bring fruits in the room.”

Here *se* and *me* represent certain spatial location and their meaning is inverted to one-another with reference to the movement of object and goal.

**Diagram – III** – Movement of object from location for *se*

**Diagram – IV** – Movement of object to location for *me*

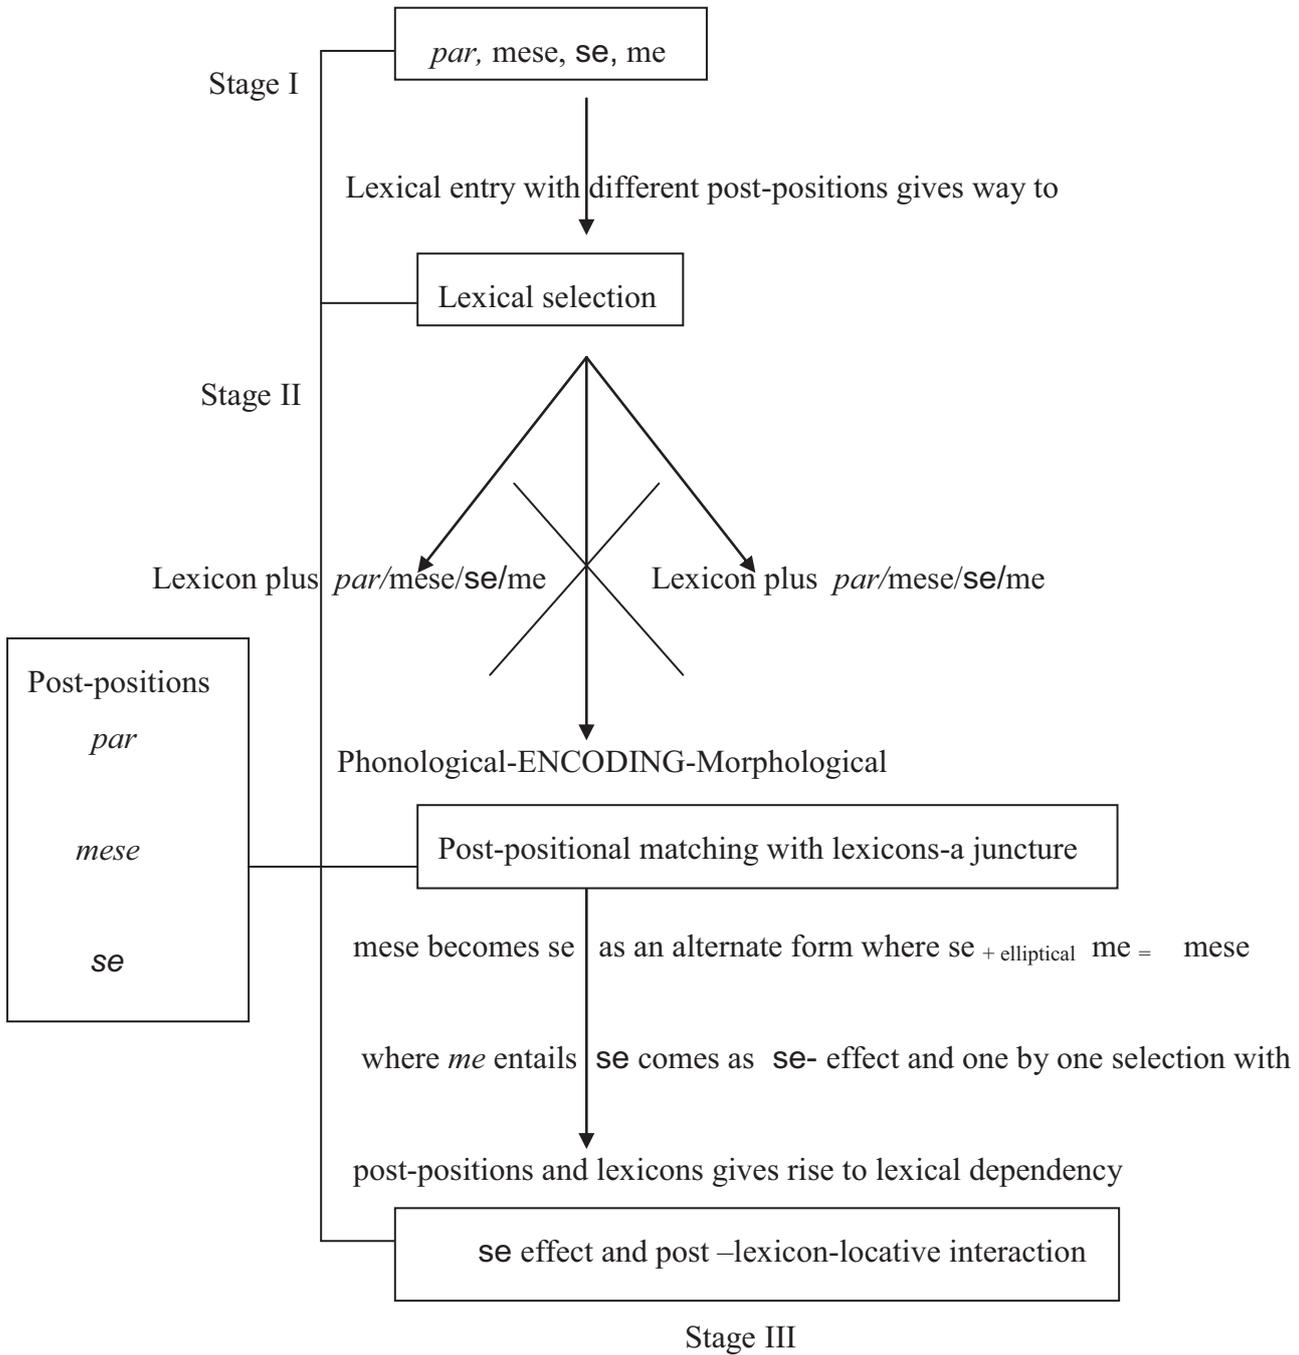

But interestingly there is a post position *mesa* i.e. made of *se* and *me* but gives the meaning of locative of *se*. The reason for this variation is explained as null hypothesis in the paper further. The evidence of null post position is also found in certain noun phrases. As in the question:

8. *ra:m kaha: he?*

Ram where is?

“Where is Ram?”

The possible answer would be *ghar pe or ghar me, kamre par or kamare me* “in home or at home, in the room”. Here *ghar* “home” and *kamre* “room” take both the post-positions *me* and *par* but there are certain lexicons like *i:sku:l(school)*, *ba:ja:r(market)*, *chok(juncture)*, etc. that come with only *me* post- position, and don’t allow the occurrence of *par*. But both of the above mentioned post-positions indicate aim, goal, and objective in the similar manner. The possible criteria for this post-positional selection for specific lexicons(‘morphological motivation’ insists on formal properties of words, whereas ‘semantic motivation’ highlights cognitive relations) can be understood and explained by the computational diagram because “models have been developed for aspects of memory, perception, problem-solving, language production and speech perception...step by step process models are not and can not be the whole concern of information processing theories(Sanford,1987).” This computational model tells us the reasons why certain lexicons come with the specific postpositions. So far the post lexicon locative is concerned the choice of the locatives with the lexicon behaves like a person who is on the road without zebra crossing, and wants to cross the road. The selection of that person for the right timing to proceed depends upon inbuilt calculations of nature that are far more complex and refined with that of advanced mathematics and physics. The competent language user of Hindi uses contextually correct and pragmatically congruous locatives because of null hypothesis and filtering hypotheses. The model below shows the selection procedure:

**Diagram – IV**–Computational model reflecting *se* effect and post lexicon locative interaction

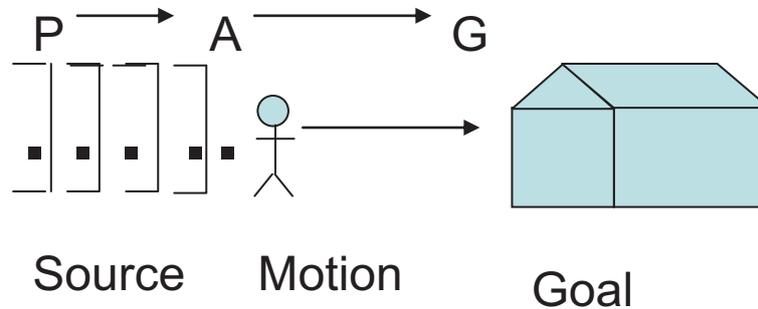

Before putting forward the hypothesis let's have a look over some sentences showing how do the verbal elements effect on the selection of post positions. For example:

- 9.a Ra:m ghar ja:ta: he  
Ram home go is.AUX  
'Ram goes to home'
- b. Ra:m ghar (*me*) ja:ta: he. (*me* = to)
- c. Ra:m gahr (*ne*) ja:ta: he. (*ne*= to)
- d. Ra:m ghar (*ke liye*) ja:ta: he. (*ke liye*= towards)
- e Ra:m ghar (*su:.*) ja:ta: he. (*su:*= from)

## 2.2. Argument

The given parenthesis (*me*), (*ne*), (*ke liye*), (*se*), are different postpositional choices which the speaker may or may not use in the conversation. To tell when a native speaker uses them is a matter of the electrical discharges in brain and nervous system. But we can give a general theoretical description for the above sentences because we can easily understand the workings of mechanical things...such things are substancial, and clear chains of causation(Sanford,1987).” We show:

There is a transfer of agent ‘A’ from any fixed or moving point ‘P’ and the goal is ‘G’ then, the whole process would be like:.

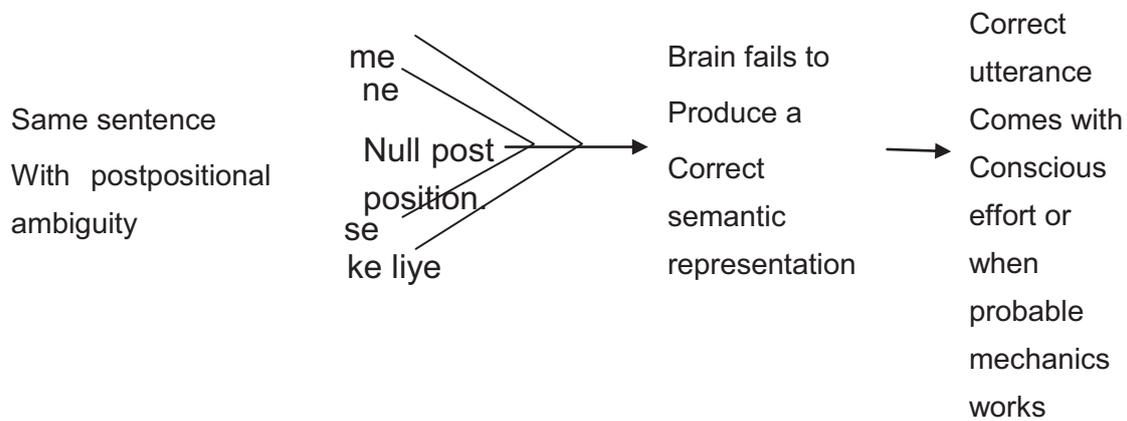

**Diagram-V:** Movement of an agent from the source to the location.

As we know that in any communication, speakers construct sentences which depict state(s) of affairs which the communicators wish to convey to their interlocutor(s). In Hindi, we have these prepositions (*me*), (*ne*), (*ke liye*), (*se*) in the sentences 9.b,c,d, and e, which give the similar sense (s) of 9 a. but the ambiguity among postpositions which the brain fails to compute can be defined through probability mechanics. All these postpositional to= (*nil prep*), (*me*), (*ne*), (*ke liye*), (*se*) expressions in Hindi have high randomness in the conversation. I will propose two hypotheses to show how this ambiguity can be solved in computers by monitoring some of its operations.

### 3. Null postposition hypothesis

My first hypothesis states that there is a null postposition in Hindi: which conserves all the other postpositions given in the parenthesis. In the sentence Ra:m ghar ja:ta: he (IIa), the elliptical gap between ghar and ja:ta: is filled by (*me*), (*ne*), (*ke liye*) or (*se*). We show this:

**Diagram-VI** The relationship between postpositional ambiguities, brains fallacy and probability mechanics

The speakers use the sentence 9a or they may use 9 b, c, d, and e. respectively. We suppose they use either 9 d or 9 e at random with equal probability, i.e. with probability of 1/2. But for 9 b and 9 c, there is also an internal probability of 2/3 for the null postpositional sentence; because the difference between (me) and (ne) is very minute for the speakers (some speakers prefer me instead of ne). We can then find the randomness for computation:

$$9 \quad a \quad = \quad 1/2 \times 2/3 = 2/6 = 1/3$$

This probability result has come out when we consider *me = ne*, and *ke liye:=se* in 9b, 9c, 9d and 9e. (as a native speaker of Hindi my tacit knowledge permits me to equal them and later on apply them in a context free sentence). Now we have three sentences, one is with null postposition, and the rest of the two are with either *me/ne* or *ke liye/se*, to disambiguate. In order to move from this postpositional ambiguity, we need a filtering device which can filter out the wrong expressions.

#### 4. Filtering hypothesis

Our awareness in the conversation shows that computation process is something we apply once we are speaking consciously, and not all the time—“ a set of conceptions being applied to a current situation which lead to a restricted set of terms through which the current situation can be understood or thought about (Sanford, 1987).” The brain’s fallacy and the probability mechanics shows this above. In natural language processing<sup>3</sup>, we require to have access to the syntactic analysis of the sentence as well as knowledge of the prior discourse to produce a correct semantic representation. This filtering device exists in human body as a prior discourse but in computers to get the desired outcome from the input data in language is still a big problem<sup>4</sup>. Our main work is to disambiguate the sentences.

Let us rewrite the sentence 9 with modification.

- 10 a. *ra:m ghar ja:ta: he [par nahi phuchta:]*  
*but neg. reach (trans)*  
b. *ra:m ghar (me) ja:ta: he [par nahi pahuchta:]*  
c. *ra:m ghar (ne) ja:ta: he [par nahi pahuchta:]*  
d. *ra:m ghar (ke liye) ja:ta: he [par nahi phuchta:]*  
e. *ra:m ghar (se) ja:ta: he [par nahi phuchta:]*

The additional phrases given in the brackets play a crucial role to disambiguate the postpositional differences. Earlier we have placed the null postposition as the store house of the other postposition i.e. *(me)*, *(ne)*, *(ke liye)* and *(se)*. But interestingly when we add the additional information to the previous sentences in 10b and 10c prove to be incorrect. This indicates an important factor which in term we codifies the postpositions. The phrase *par nahi phuchta*: ‘but doesn’t reach’ represents an unfulfilled goal which gives an oppositional sense relation to *(me)* and *(ne)*. The filtering device is a negative expression of the verb that deletes sentences 10b and 10c from the computational system. We show this in the following diagram:

FILTER

Ra:m ghar	Null locatives	→			Null locatives	
	(me)	→			* 10b	
	(ne)	→	nahi	ja:ta	*10c	he
	(ke liye)	→	phuhta;		→ ke liye 10d	
	(se)	→	(neg. filter Passes only 10d & 10e)		→ se 10e	

**Diagram-VII The filtering device shows the unacceptable sentences with “\*”**

Earlier we have seen in 9 that all the expressions give the same sense; and the usability criterion was on the random selection for computation.

In Diagram VII we have shown that with the help of filtering device we have not only cleared the half ambiguity but also the excessive probability. And similarly there are other verbs in Hindi which also behaves in the same manner. As we show:

Ra:m	Noun	[nil prep; me, se, ke liye etc.]	Verb he (is.AUX)	FILTERING
Ra:m	Noun-haath,	‘hand’	Verb- jalta: ‘to burn’ he	NEGATIVE SHOWS SAME BEHAVIOUR FOR THESE VERBS WITH THE RESPECTIVE POST- POSITIONS
Ra:m	Noun – Kursi	‘seat’	Verb- beithta: ‘to sit’ he	

**Diagram –VIII Generalized filter for the simple sentences**

## 5. Conclusion

Hence, we can say there is a knowledgeable neuron-functional mechanisms work in brain that “encodes subpatterns of feature values that occur in the environment. The different frequencies with which various such patterns occurring encoded in the set of strengths, of the atoms(Smolensky,1986b:215)” which often permits ambiguity in expressions, and interlocutors often decode the ambiguity by pragmatic fillers. But, at the same time the meta-linguistic system which monitors the correctness of the sentences (about to be produced), can be modified semantically to delete ambiguous representation. This device can solve half of the ambiguity of computation for certain Hindi postpositions.

I have presented here the relationship between computational problem-solving and comprehension. I have collected data showing that locative problems have a vague structure, which needs to be systematically dealt to infer disambiguation. I have also indicated that the comprehension of locatives expression is not a frame-based process, but rather is a constructive process through which the deep structure is built from the sentences. This computation process is done by means of computational model and generalized filter, which build the deep structure on the basis of the semantics of the logical forms of the sentences and on the deep structure under construction. These ideas are being applied to the construction of databases from natural language input, and further implemented to develop a translation machine with high degree of artificial intelligence for computers.

## 6. Notes

1. Icons dominate the language, and the mediation between what we mean and what matters to us is recognised by cultural and semiotic process that at times remains aloof from the immediate spatial and temporal environment.
2. Chomsky’s work on Minimalism focuses light on economy principle where he tries to pare down the linguistics rule like the law of physics.
3. By using this information processing approach of the process model we are equipped to think about thought in a concrete way.

4. Understanding that our intuitions are fallible will we make the effort to question ourselves and seek other's opinions.

# Linguistic Markers of Information Structure in Latvian

**Baiba Saulīte**

Institute of Mathematics and Computer Science,  
University of Latvia  
 Raiņa bulvāris 29, Rīga, LV-1459, Latvia  
baiba.saulite@lumii.lv

## **Abstract**

The article gives analysis of two levels of the information structure: the topic – focus structure and the givenness (given – new information) in literary-colloquial speech. Studying these levels attention has been drawn to formal indicators: nominal phrases explicitly expressing the category of definiteness, anaphoric pronouns as well as the indirect order of the subject, predicate and object.

Presuming that the topic is the starting point of an utterance, or that part of its meaning of which the message bears a certain idea, as well as the fact that it is usually before the focus, analysis is given as to what parts of a sentence can form the topic. The attention has also been drawn to how the topic – focus structure is influenced by the opposition given – new partition.

**Keywords:** topic, focus, given information, new information, definiteness.

The research on the information structure is essential in the analysis of the text structure and in identifying anaphoric references. This research will be useful for the development of the semi-automatic semantic analyzer of the Latvian language.

The aim of this report is to define three types of possible explicit indicators of information structure in Latvian. They are: possible indicators of opposition “definite – indefinite”, anaphoric expressions and peculiarities of the word order (mainly position of subject (S), predicate (P), and object (O)) in the context of information structure. The research aims to be one of the first attempts to analyze the information structure of an utterance in Latvian. Consequently, it will mark the main tasks in the analysis of the discourse structure and informative structure in the Latvian language.

The Latvian language together with Lithuanian belongs to the Baltic languages group of the Indo-European languages and is an inflective language, where the ending of the nominal expresses gender, number and case. There are no articles in Latvian.

Dialogues from newspaper articles reflecting literary colloquial speech have been

used as a language material. In comparison with a standardized formal text literary colloquial speech has a more unimpeded sentence structure – and more frequent use of pronouns.

The structure of the given sentences has been first analyzed by applying morphological and syntactic analyzer and manually. The syntactic parser<sup>1</sup> partially marks units related with anaphoric references. The sentences have been considered from the point of view of the information structure: firstly, whether the noun phrase subject or object has any indicator of definiteness/indefiniteness and, secondly, what is the position of the subject – predicate – object with respect to indirect SPO order with further analysis of reasons that influence the indirect order, i.e. – information structure and context or the sentence structure. The mentioned phenomena will not be viewed in parts of complex sentences – principal clauses and subordinate clauses as a linear organization is determined by the structure of a compound sentence in general. Indirect SPO position appears without a particular communicative function – in both clauses – principal and subordinate. Here the main attention will be paid to coordinate sentences with indirect word order and explicit indicators of the definiteness.

Unlike the Latvian linguistics there is plenty of research on information structure and communicative structure in the world linguistics. The functional sentence perspective (terms – “nucleus” and “focus”) contrary to its formal division – grammatical subject and grammatical object – was introduced by Vilem Mathesius (Mathesius 1967: 239) in the 20th century. He points out that this division is not only psychological but also grammatical. Moreover, this division shows that word order in languages with flexible word order is one of the most important indicators of the functional sentence perspective.

Speaking about organization of message, there are various approaches and different terminology. Both “thematic structure” and “information structure” are referred to almost the same phenomenon, but according to the tradition of Russian linguistics we speak about the “communicative organization” of sentence (Тестелец 2001). It demonstrates the relationship of the message with its context and sentence package. Information packaging indicates how information conveyed by linguistic means fits into the context or discourse (Vallduvi and Engdahl 1996: 460). Writing about the communicative structure, Russian linguists point out that its constituent parts are “theme” and “rheme” which partly overlap with the given and the new. Although the English terminology also mentions “theme” and “rheme”

---

<sup>1</sup> <http://www.semti-kamols.lv/analyze/analyze.php>

(Halliday 2004: 64), terms like “topic” and “comment/focus” are more frequent.

It is hard to find the most relevant position in the different approaches of discourse analysis as well as its terminology. Igor Mel’čuk points out that communicative structure specifies the manner in which the speaker wants his message to be organized: what should be presented first and what should be added later; what should be explicitly asserted and what can be only presupposed; what should be emphasized and what can be left in the background (Mel’čuk 2001: 58). As the first of the opposition pairs he offers the following communicative categories: thematicity and givenness.

As there is a strong tradition to call parts of the information structure “topic” (the starting point of an utterance; part of its meaning of what the message bears a certain idea) and “focus” (what is communicated about), these terms will be used in this article. I regard these terms as analogue for “theme” and “rheme” [VPSV 2007].

Without going into details, but keeping in mind that frequently the features of the topic, the given and the definite overlap and often the features of the focus, the new and the indefinite are the same, an attempt will be made to analyze the information structure of an indirectly placed object and the subject with explicit indicators of definiteness, by separating two levels – themacity and givenness.

Information status of a nominal is very important in information structure. In many languages a noun phrase may contain an element, whose sole or principal role is to indicate the definiteness or indefiniteness of the noun phrase. In Latvian there is no regular category of definiteness, thus formally it is more difficult to separate the given information from the new. However, there are some indicators which allow us to identify the phenomenon either as new, unknown and indefinite or, as mentioned before, definite and as referential in discourse – indefinite and definite adjectives, demonstrative pronouns in the function of an article, anaphoric pronouns and word order.

Definiteness of the noun phrases in Latvian can be revealed with an adjective as attribute. The adjective strictly demands the category of definiteness. Indefinite adjectives in Latvian are older. They were used in all situations including a noun phrase with two attributes – pronoun and adjective. However, in Latvian as well as in Lithuanian, the indefinite – definite position has developed gradually. The definite ending has formed by the adjective in a definite number, gender and case by adding a pronoun *jis\*/ji\** (he/she) in the corresponding gender, number and case (*labai* (good-F.DAT.SG.INDF) + *jai* (she-F.DAT.SG) > *labajai* > *labajai* (good-F.SG.DAT.DEF)). (Endzelīns 1907: 55) Certainly, not always the definite or indefinite ending of the

adjective possesses the function to indicate the definiteness.

Although not regularly, but definiteness can be indicated by a demonstrative pronoun in the function of an article (*šīs* (this-M.NOM.SG.), *šī* (this-F.NOM.SG)) which is the attribute of a noun. The use of the demonstrative pronouns in spoken Latvian shows that it is often necessary to express the definiteness of the certain object or phenomenon and the relationship with the prior utterance and context. Together with other indicators of definiteness the text will also deal with anaphoric pronouns (*tas*, *viņš*).

It is more complicated to distinguish indefiniteness as it is marked by the indefinite pronoun, the indefinite ending of an adjective or is expressed by word order. One of the possibilities to mark the nominal phrase as new, unknown before and indefinite, is to place the syntactic subject after the verb at the end of the sentence. It is vivid in fairytales rendered by children e.g., in (1), (2) and (3).

(1)

<i>Dzīvoja (PRED) meitenīte (SBJ)</i>
There lived a little girl
Focus
New information

The whole sentence is new information and the subject is also indefinite. Research on such structures in natural Latvian has still to be done, as there is similarity with sentences with indirect word order without subjective information, i.e. *Līst lietus – līst*(rain-PRS.3SG) *lietus* (rain-M.SG.NOM) – *It is raining*. It seems that in such sentences we should deal withthetic utterances. Although the first mentioned example could bethetic utterance, indirect word order indicates an indefinite noun.

(2)

<i>Viņai</i>	<i>bija (PRED)</i>	<i>pīrādziņi (SBJ)</i>
she-F.SG.DAT	have-PST,3	bacon buns-M.PL,NOM
Topic	Focus	
Given	New	
She had bacon buns		

(3)

<i>Viņa (SBJ)</i>	<i>tos (OBJ)</i>	<i>nesa (PRED)</i>	<i>vecmāmiņai (O)</i>
she-F.SG.DAT	them-M.PL.ACC	bring-PST.3	granny-F.SG.DAT
Topic	Focus		
Given		New	
She brought them to her granny			

In the sentence (4) the definite and the given information is expressed by the determinant at the beginning of this sentence while the subject is indefinite and new in the context.

Analyzing the information structure these indicators can be taken into account, thus identifying the common accessible information and the new first mentioned information for the hearer. The topic, the given and the definite certainly do not mean the same as the definite noun phrase can express also new information (Lyons 1999: 228). It still has to be admitted that in cases when the nominal phrase in Latvian is marked as definite (with its possible indicators of definiteness), this nominal phrase will be qualified as given information.

(4)

<i>Vecmāmiņai</i>	<i>bija (PRED)</i>	<i>vilks (SBJ)</i>
granny-F.SG.DAT.DEF	have-PST,3	wolf-M.SG.NOM.INDF
Topic	Focus	
Given	New	
The granny had a wolf		

Very often it is not possible to change the word order in a certain context in Latvian as this would change the information structure of sentence. On the contrary, changing the word order does not often change the syntactic relationship. The attribute has to be placed before the head of the phrase, while the position of other parts of the sentence is not strictly determined. There could be cases where the change of the position of the attribute changes its function. The attribute turns into semi-predicative component. (*Saule uzlēca sarkana* (semi-predicative component) – The sun rose red; *Sarkana* (attribute) *saule uzlēca* – Red sun rose.) Syntactic function of a modifier can change depending on its placement – whether it is a modifier or a situant. If the verb has several objects they are placed before and after the verb to have the most precise indication of the relationship between the verb and its objects, besides the traditional place of the direct object is immediately after the predicate while the indirect object can be placed either before or after the predicate. Particles and modifiers are very important in the thematic structure of the sentence; however, this report will deal only with the indirect placement of the SPO with emphasis on whether such indirect word order is expressive word order.

Nevertheless all six combinations are possible in colloquial Latvian, analyzing indirect SPO order, order SOP is dominant, and it seems like a neutral word order. Not only in spoken language (less – in literary colloquial speech) but also in newspaper texts there is a trend to start a sentence directly with new information, placing the object,

even indefinite and new, at the beginning of the sentence. However, it seems to be a typical thematic structure of newspapers texts.

In English the topic tends to be expressed by the subject. In the Latvian language, too, the subject is most often the topic while information is expressed in the following order: the topic/given/subject followed by the new/focus/predicate, objects. Analyzing the extract of a text we can see regularly expressed information:

(5)

<i>Šī grāmata (SBJ)</i>	<i>nav ne statistika, ne vispārējo tēžu kopsavilkums (PRED)</i>
Topic	Focus
Given	New
This book	is neither statistics, nor summary of general theses

(6)

<i>Tā (SBJ)</i>	<i>ir par dzīvjiem cilvēkiem (PRED)</i>
Topic	Focus
Given	New
It	is about human beings

(7)

<i>Tā (SBJ)</i>	<i>nav domāta (PRED) tikai juristiem (OBJ)</i>
Topic	Focus
Given	New
It	is not for lawyers only

(8)

<i>Bet arī juristi (SBJ)</i>	<i>tajā</i>	<i>varēs gūt (PRED)</i>	<i>ko noderīgu (OBJ)</i>
lawyers-M.PL.NOM	it-F.SG.LOC	can-FUT.3; find-INF	useful-M.SG.ACC
Topic	Focus		
Given	New		
But the lawyers too will find something useful in it			

(9)

<i>Tā (SBJ)</i>	<i>paredzēta(P)</i>	<i>plašam lasītāju lokam (OBJ)</i>
It	is meant	wide-M.SG.DAT;people-M.PL.GEN;circle-M.SG.DAT
Topic	Focus	
Given	New	
It is meant for a wide circle of people		

The first sentence (5) starts with given/topic/subject. The anaphoric pronoun *tas* 'it' is used in the sentences (6), (7), (8), and (9), giving the same subject. It has to be

mentioned that unit (8) shows, that the new information (*juristiem*) is at the end of the first utterance, but in the next unit it is the topic showing that the information is already given and definite.

Definite nominal phrase can be placed before or after the predicate. It can be expressed as subject and indirect or direct object. If a definite nominal phrase is at the beginning of the sentence it would be natural if it overlapped with the given and the topic. For example, in the following utterance (10), where the subject is not explicitly given.

(10)

<i>To visu (OBJ)</i>	<i>noteica (PRED)</i>	<i>Maskavā</i>
everything-M.SG.ACC	rule-pst.3	Moscow-F.SG.LOC
Topic	Focus	
Given	New	
Everything was ruled in Moscow		

However, if the sentence (11) with a predicate in the third person and without a subject is introduced by situant, the definite object forms the focus.

(11)

<i>Un toreiz</i>	<i>šo ideoloģiju (OBJ)</i>	<i>arī diezgan atklāti</i>	<i>pauda (PRED)</i>
and then	this ideology-F.SG.ACC	rather openly	expressed-PST,3
Topic	Focus		
Given		New	
And then this ideology was expressed rather openly			

It is interesting to observe the communicative structure in utterances (12), (13) where the definite direct object is placed between an anaphoric pronoun as a subject and predicate. Here the subject has the function of topic while the object is focus.

(12)

<i>Viņi (SBJ)</i>	<i>to ainu (OBJ)</i>	<i>zināja (PRED)</i>	<i>diezgan labi</i>
they	that picture-F.SG.ACC	know-PST.3	quite well
Topic	Focus		
Given		New	
They knew that picture very well			

(13)

<i>Bet tos dzejolīšus (OBJ)</i>	<i>man (OBJ)</i>	<i>neviens (SBJ)</i>	<i>nevar īsti atņemt (PRED)</i>
poems-M.PL.ACC	I-SG.DAT	nobody-M.SG.NOM	can't-PRS.3; take away-INF
Topic	Focus		
Given		New	
But nobody can take away those poems from me			

But in the sentence (13) the definite and nominal phrase has the function of the topic, because the given subject stands between the object and the predicate.

Topic can even be a part of the predicate.

(14)

<i>Un tieši</i>	<i>tādi (PRED)</i>	<i>ir</i>	<i>šie skaisti nopļautie lauki (SBJ)</i>
and exactly	such-M.PL.NOM	is-PRS.3	these beautifully mowed fields-M.PL.NOM
Topic	Focus		
Given			
And this is exactly how these beautifully mowed fields look like			

For example, utterance (14) contains only given information. Both nominal phrases are marked as definite. The formal features show that the pronoun *tādi* “such” replaces the mentioned adjective in the previous sentence. Besides, the nominal phrase is expressed by two indicators of definiteness. The adjective with a definite ending is obligatory in relation with the demonstrative pronoun and noun. The question is: what is the topic – focus structure of the utterance. The context tells that the topic is definite and given while focus is not expressed by a typical feature, as it is also definite and given. But it seems that in this sentence topic is expressed by nominal predicate and we cannot talk about sentence-initially focus.

Similar information structure has the sentence (15).

(15)

<i>Tā</i>	<i>manu turpmāko dzīvi (O)</i>	<i>ievirzīja (P)</i>	<i>šī saruna (S)</i>
so	my future life-F.SG.ACC	direct-PST,3	this conversation
Topic	Focus		
New			Given
This was how my future life was directed by this conversation			

Here definite nominal phrase – subject – seems as a final topic but the given (direct object) forms focus. But at the beginning of the sentence there is a situation that

forms topic, and both nominal phrases are parts of focus. The topic expressed by the situant can be seen also in the sentence (16).

(16)

<i>Un pēkšņi</i>	<i>zvana (PRED)</i>	<i>viņa mamma (SBJ)</i>
and suddenly	rings-PRS.3	his mother
Topic	Focus	
New		
And suddenly his mother rings		

## Conclusions

1. If a sentence begins with a subject, the subject is a topic, but if the subject stands at the end of the sentence and in the topic there is a determiner, the subject– nominal phrase – expresses the new information.
2. Preverbal object not necessarily express subjective information. It can be both part of topic (if it comes first), and focus (if the sentence begins with a situant or determiner). In word order SOP, object (even definite) is part of focus, because topic is formed subject.
3. If the sentence does not have a subject or there is only a verb in the 3<sup>rd</sup> person form, the object forms topic, but the verbal phrase – focus.
4. In a specific context topic can be formed also by situants, determinants and nominal predicates.
5. Latvian linguistics still needs profound discussion concerning the terminology of information structure and aspects of its research, as well as analyses of information structure in complex sentences. It would also be vitally important to analyze the sentence intonation, its logical emphasis and the structure of the rheme.

## Abstract

We consider the binding-theoretic status of the Korean long-distance anaphor *caki*. After examining competing analyses, including the cyclic head movement account for long-distance anaphors (Cole et al., 1990) and the treatment of *caki* as a pronoun, we argue that *caki* is a bound variable. We show how this bound variable account can unify local, long-distance, and discourse-bound instances of *caki*. Furthermore, we present the results of a corpus study, the findings of which are twofold. Firstly, we find support for our analysis in that the majority of instances of *caki* fit the bound variable account. Secondly, by broadening our analysis to find alternative means of binding *caki*, we are able to capture purported counterexamples within our bound variable analysis.

**Keywords:** Korean, long-distance anaphor, binding, topic, bound variable.

## 1. Introduction

It has been argued that the binding of long-distance anaphors can be reduced to a series of local dependencies by cyclic head movement of the anaphor to a matrix Infl position at LF (Chomsky, 1986; Cole et al., 1990; Cole and Sung, 1994). As a consequence, these anaphors are predicted to be subject-oriented. In Korean, however, the long-distance anaphor *caki* is not strictly subject oriented, and it is able to be bound by local and non-subject arguments, as in (1).

---

\* We thank the audience at CIL 18 for their insightful questions and comments. This work was supported by SSHRC Standard Research Grant 410-2007-2169 to Han.

- (1) John<sub>i</sub>-i Mary<sub>j</sub>-eykey [Tom<sub>k</sub>-i caki<sub>i,j,k</sub>-lul coaha-n-ta-ko]  
 John-NOM Mary-DAT Ton-NOM self-ACC like-PRES-DECL-COMP  
 malha-yess-ta.  
 say-PAST-DECL  
 ‘John told Mary that Tom likes self.’ (Sohng 2003, ex 11a)

Given that *caki* can be bound locally, as well as at a distance, the need for postulating LF movement is called into question. If *caki* can be bound locally, then an LF movement would violate economy constraints, in that such a movement would not be absolutely necessary to prevent the crashing of the sentence. In this paper, we present a bound variable analysis of *caki* which provides a single account for local and long-distance cases, be they subject-oriented or not.

This paper is organized as follows: in section 2, we show that the current literature suggests two different analyses for *caki*, either an anaphor binding treatment in line with the generative account for long-distance anaphors, or a treatment in which *caki* is considered to be a pronominal, falling under coreference rather than binding. Section 3 will comprise the argument for the treatment of *caki* as a bound variable, based upon a treatment of nominals as generalized quantifiers, and exploiting quantifier raising (QR) as a means of creating the necessary operator-variable structure. In section 4, we turn to corpus data, demonstrating that despite some initially challenging examples, the bound variable analysis does indeed capture all the observed facts. Finally, section 5 summarizes the arguments presented in this paper.

## 2. Anaphora vs. Coreference

### 2.1. Generative Account of Anaphora

In Cole et al. (1990), and further refined in Cole and Sung (1994), it is argued that long-distance anaphors are most adequately analyzed as undergoing movement to a local Infl head, and then undergoing cyclic head movement to the matrix Infl position. There, the anaphor is bound by the matrix subject, the only available c-commanding antecedent. This analysis thus predicts strict subject orientation, even though it is founded upon an otherwise unmotivated initial movement of the anaphor to Infl. Interestingly though, in their discussion of *caki*, Cole et al. conclude that *caki* is not a long-distance anaphor, but rather a pronominal.

This issue is taken up again in Sohng (2003), where it is argued that *caki* can be made compatible with the cyclic head movement account, bringing it in line with the account of other long-distance anaphors in neighbouring languages, such as Chinese and Japanese. Sohng first provides a modified version of this head-movement analysis, adding the possibility that the long-distance reflexive can be chain bound by any NP which binds one of the links in the movement chain up to the matrix Infl. Furthermore, there is an added parameter which states a preference for direct matrix subject binding over chain-binding by lower antecedents. Combined, these are argued to account for local and non-subject binding of *caki*, as in (1), within the cyclic head-movement analysis.

## 2.2. Evidence for Coreferentiality

Even though *caki* can be brought in line with the generative account for long-distance anaphors, there are still arguments which lead to the conclusion that *caki* is in fact a pronominal. As already discussed, *caki* can be bound locally, or long-distance. In fact, *caki* is even more versatile, not even requiring a c-commanding antecedent within the same sentence.

- (2) Na-nun Suni<sub>i</sub>-eykey chayk-ul pilye cwu-ess-ta.  
 I-TOP Suni-DAT book-ACC lend give-PAST-DECL.  
 Kulendey sasil ku chayk-un caki<sub>i</sub> oppa-ka  
 and yet in fact that book-TOP self elder brother-NOM  
 ceney nay-key pilye cwun kes ita.  
 before me-DAT lend give thing be  
 ‘I lent a book to Suni. But the fact is that self’s brother had lent it to me before.’ (Kim 2000, ex 2b)

In (2), *caki* is bound by *Suni* from the previous sentence. Assuming that c-command is a sentential relation, *caki* is not c-commanded by *Suni*, and no LF movement is available to resolve this problem. That *caki* can be bound in this manner has led to claims that it is discourse-bound.

Furthermore, *caki* can be bound by a non-c-commanding antecedent within the same sentence. For instance, in (3), although *caki* is not c-commanded by a genitive embedded in a DP, it is read as being coreferential with that genitive.

- (3) Suni<sub>i</sub>-uy sinpal-un caki<sub>i</sub>-uy pal-pota hwelssin kuta.

Suni-GEN shoes-TOP self-GEN foot-than a lot big  
'Suni's shoes are a lot bigger than self's feet.'

Because *caki* can have antecedents which do not c-command it within the same clause, this is seen to be an argument for treating it as a pronominal, rather than an anaphor.

Finally, there are exceptional cases where *caki* does not appear to require an antecedent at all, as in (4).

- (4) Caki-ka chakhay.  
you-NOM good  
'You all are good.' (Sohng 2003, ex 16a)

Sohng (2003) refers to this as inherent reference, wherein a *caki* without an antecedent is inherently 2<sup>nd</sup> person. This can also be used deictically, and two antecedentless instances of *caki* can be used to refer to different people given enough explicit pointing, as in (5).

- (5) Caki<sub>i</sub>-ka caki<sub>i/j</sub>-lul coaha-n-ta.  
self-NOM self-ACC like-PRES-DECL  
'You like yourself.'  
'You like you.' (Different addressees)

The sentence in (5) is actually ambiguous, with one reading being that the object *caki* is bound by the inherently-referential subject *caki*. The second reading indicated is the deictic usage, with each *caki* indicating a different 2<sup>nd</sup> person addressee. Without an antecedent, *caki* is also used as a term of intimate address. As these uses of *caki* are substantially different from the other cases, antecedentless 2<sup>nd</sup> person *caki* will not be analyzed further in this paper. However, the fact that such readings do obtain makes for a useful test. Because of this inherent 2<sup>nd</sup> person reference, no sentence containing a *caki* is judged as being technically ungrammatical; there is always a possible "last resort" meaning. While we are not concerned with the underlying nature of this meaning, it can be employed as a test for the presence of an antecedent. Given that a *caki* without an antecedent is interpreted as 2<sup>nd</sup> person, we can conclude that any *caki* which is not interpreted as 2<sup>nd</sup> person must at some level have an antecedent, either through coreference or binding, which obviates the inherent reading.

To summarize the facts presented so far, the example of *caki* being bound from a genitive, and from a prior sentence calls into question the requirement for a c-command relation between *caki* and its antecedent. Yet, in the face of this apparent contradictory data, *caki* is generally considered to be an anaphor, bound, and not a pronominal. In the next section, we provide support for a binding analysis, and advance a proposal which can account for all the counterexamples.

### 3. The Case for Binding

The data presented in the previous section appear to make a strong case for abandoning a treatment of *caki* as a bound form. However, some of that evidence can be discounted, and there is equally compelling evidence that *caki* must be bound. In this section, the facts supporting a bound variable analysis will be presented, leading into an implementation of such an analysis. The first argument in favour of a bound variable analysis comes from VP-ellipsis, as discussed in Cho (1996), and exemplified in (6).

- (6) John-<sub>i</sub>      caki-lul      kwasinhay-ss-ko,      Mary-to      kule-ha-yess-ta.  
 John-NOM self-ACC overtrust-PAST-and      Mary-also so-do-PAST-DECL  
 ‘John overtrusted himself, and Mary did too.’ (Cho 1996, ex 19a)  
 =Mary overtrusted Mary. (√ Sloppy)  
 =Mary overtrusted John. (\* Strict)

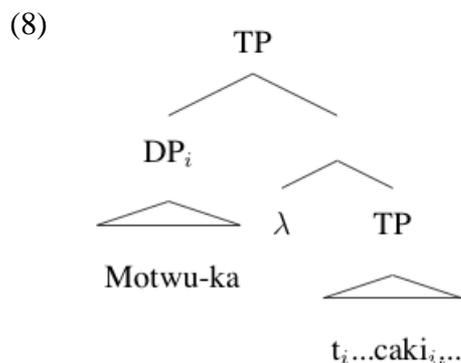

In this VP ellipsis construction, there is just one possible reading for the elided conjunct. Only the sloppy reading where Mary overtrusted Mary is possible, indicating that the elided *caki* is still locally bound within its conjunct. If *caki* really were coreferential, then the strict reading where Mary also overtrusted John should be available.

Perhaps the strongest argument against treating *caki* as coreferential comes from cases involving quantifiers, as in (7).

- (7) Motwu<sub>i</sub>-ka      caki<sub>i</sub>-lul      salang-ha-n-ta.  
 everyone-NOM self-ACC love-do-PRES-DECL  
 ‘Everyone loves self.’

Here, *caki* is bound by the quantifier *motwu* (everyone); the result is unquestionably

a bound variable reading. At LF, the underlying structure for (7) will be (8), the result of an application of QR and lambda-abstraction. This LF structure maps onto the semantic form in (9).

- (9) Every  $\lambda x[x \text{ loves } x]$   
 $= \lambda P.\forall y[\text{person}(y)][P(y)](\lambda x[x \text{ loves } x])$   
 $= \forall y[\text{person}(y)][y \text{ loves } y]$

This bound variable analysis for quantifier cases applies equally well for local and for long-distance cases, as illustrated in (10).

- (10) a. Motwu<sub>i</sub>-ka [John<sub>j</sub>-i caki<sub>i</sub>-lul salang-ha-n-tako]  
 everyone-NOM John-NOM self-ACC love-do-PRES-COMP  
 sayngkak-ha-n-ta.  
 think-do-PRES-DECL  
 ‘Everyone thinks John loves self.’ (Moon 1995, ex 3:93)
- b. Every  $\lambda x[x \text{ thinks } [\text{John loves } x]]$   
 $= \lambda P.\forall y[\text{person}(y)][P(y)](\lambda x[x \text{ thinks } [\text{John loves } x]])$   
 $= \forall y[\text{person}(y)][y \text{ thinks } [\text{John loves } y]]$

In discussion of this example, Moon (1995) is quite clear on the point that this can have a bound variable reading where *motwu* (everyone) binds *caki*. As QR and variable binding can account for this long-distance relationship without requiring any LF movement of *caki*, we propose that this bound variable analysis can be extended to all instances of *caki*.

If other nominals, such as proper nouns, are treated as generalized quantifiers, it then becomes possible to treat all cases of *caki* as bound variables. As generalized quantifiers, proper nouns would also undergo QR, yielding exactly the same operator-variable structure as in (10). In so doing, local and long-distance binding of *caki* can be unified under one analysis, as opposed to the long-distance case

requiring a special mechanism to raise *caki* at LF. On the surface, it may seem that this analysis is no less costly at LF, in that all antecedents now undergo LF movement, but this movement is independently motivated, and is not taking place solely for the benefit of *caki*. Regardless of *caki*, QR is a well-motivated phenomenon, making the current proposal more economical at LF.

The bound variable analysis also allows for an account of the genitive case from (3), where *caki*'s antecedent was embedded within a possessive DP. As shown in (11), this can also happen with quantifiers binding *caki*.

- (11) Motwu<sub>i</sub>-uy    sinpal-un    caki<sub>i</sub>-uy    pal-pota    hwelssin    kuta.  
 everyone-GEN shoes-TOP self-GEN    foot-than    a lot    big  
 'Everyone's shoes are a lot bigger than self's feet.'

The most reasonable conclusion to draw from this example is that QR allows the quantifier to escape the DP, and bind its variable. Thus, the generalized quantifier analysis provides an explanation for the genitive problem: the same instance of QR which accounts for (11) will also account for (3).

At this point, it is worth noting that while QR can, to some extent, allow *caki* to be bound by elements which do not c-command it on the surface, there are restrictions on the power of QR. One prediction is that *caki* should not be bound by a nominal that is within a subject clause island, a domain typically opaque to QR. As shown in (12), the prediction is borne out, as neither *Tom* nor *Mary* may bind *caki*. Instead, the inherent reference of antecedentless *caki* emerges.

- (12) [Tom<sub>i</sub>-i    Mary<sub>j</sub>-lul    salang-ha-n-ta-nun]    sasil-i    caki<sub>k</sub>-lul  
 Tom-NOM Mary-ACC love-do-PRES-DECL-ADNOM    fact-NOM    you-ACC  
 nollaykh-yess-ta.  
 surprise-PAST-DECL.  
 'The fact that Tom loves Mary surprised you.'

The sentence in (12) is ungrammatical under the reading where *caki* and *Mary* are coindexed or where *caki* and *Tom* are coindexed. At best, this sentence could be grammatical if *caki* took the inherent reference reading, but this would not be a case of binding. So while the QR analysis solves some problems through the postulation of LF movement, that movement is constrained enough to avoid overgenerating instances of binding.

To account for discourse binding of *caki*, Gil (1998) proposes that *caki* is not

necessarily subject oriented, but rather topic oriented. Gil argues that this approach also captures cases where *caki* is discourse-bound, with no antecedent within the sentence. To do this, she posits an empty topic operator which may serve as an antecedent for *caki*. This operator would itself be coreferential, getting its reference from prior discourse, but it would sit in an A' position similar to that occupied by a quantifier after QR. From this position, the operator would bind *caki*. This is illustrated in (13).

- (13) Ani, [Op<sub>*i*</sub>]<sub>Top</sub> caki<sub>*i*</sub>-ka kasse.  
 no self-NOM went.  
 'No, self went.' (Where 'self' is from prior context.)

In (13), the empty operator (Op), coreferential with something from prior discourse, binds *caki* within the sentence. By adopting this analysis, discourse binding cases can be reduced to sentence-local binding by a covert operator.

Gil further speculates that all instances of *caki* can be unified under the rubric of topic binding, a proposal which is not incompatible with the notion of treating *caki* as a bound variable; topicalization can simply be seen as a form of A' movement (possibly even covert), similar to QR. Under this analysis, the observed subject orientation becomes an epiphenomenal effect, merely the result of a general tendency for discourse topics to emerge as sentential subjects. As an A' phenomenon, topicalization creates the necessary operator-variable structure.

To summarize the proposal so far: *caki* is to be treated as a bound variable, and semantic operator can be posited to account for the discourse binding examples. With this proposal in place, local and long-distance binding of *caki* have been unified under one analysis, and all the data which appeared to support a coreferential analysis have been addressed. We now turn to our corpus study and provide further empirical support for the bound variable analysis of *caki*.

#### 4. Corpus Study

We automatically extracted 675 sentences containing *caki* from 550,000 word Sejong Colloquial Corpus, published by the National Korean Language Institute and the Department of Tourism and Culture in Korea ([www.sejong.or.kr](http://www.sejong.or.kr)). The corpus is a collection of transcribed recordings of radio/TV interviews, plays, soap operas, news and talk shows. Out of 675 tokens, 655 were analyzed: 623 contained 3<sup>rd</sup>

person *caki*, 23 contained 2nd person *caki* and 9 contained 1st person *caki*. 20 were unanalyzable as they were incomplete, garbled, or contained speech errors to the extent that they were incomprehensible. As stated above, instances of 3<sup>rd</sup> person *caki* are of particular interest, as they should only obtain when there this a 3<sup>rd</sup> person antecedent binding *caki*. For this reason, we only consider the 3<sup>rd</sup> person cases here.

Type	Number	Percent
C-commanding Antecedent	497	80%
Non-c-commanding Antecedent	26	4%
No Antecedent	100	16%

Table 1: Distribution of 3<sup>rd</sup> Person *caki* by Type of Antecedent

Breaking these down by the type of antecedent gives the distribution shown in Table 1. First, we discuss those cases where there was a c-commanding antecedent, then turn to the cases with a non-c-commanding antecedent, then turning finally to those with no antecedent.

#### 4.1. *Caki with C-commanding Antecedent*

The majority of tokens containing 3<sup>rd</sup> person *caki* had a c-commanding antecedent for *caki* (497 out of 623 tokens). The antecedent was in the form of a full referential noun phrase, null pronoun, or trace. The distribution is summarized in Table 2.

Type	Number	Percent
Full Noun Phrase	347	70%
Null Pronoun	129	26%
Trace	21	4%

Table 2: Distribution of C-commanding Antecedents

Examples from the corpus of *caki* with c-commanding antecedents are given in (14)-(16). In (14), the matrix subject *yengkam-tul-un* (old man-PL-TOP) c-commands and antecedes the embedded subject *caki-ka* (self-NOM). In (15), a null pronoun subject can be postulated that in turn c-commands and antecedes *caki* in the same clause, and in (16) a trace of an empty relative pronoun operator can be postulated in the subject

gap position of a relative clause, which in turn c-commands and antecedes *caki*.<sup>1</sup>

- (14) Yengkam-tul<sub>i</sub>-un selo [caki<sub>i</sub>-ka wonnim-uy apeci-lako]

 ‘Do you sometimes think the wife who<sub>i</sub> only tells self’s<sub>i</sub> view is heartless?’  
 [221;;090.txt]

All these examples containing *caki* with a c-commanding antecedent are consistent with bound variable analysis of *caki*. In all these cases, QR of the antecedent and subsequent binding of *caki* can be postulated.

#### 4.2. *Caki* with a Non-c-commanding Antecedent

In 26 tokens containing 3rd person *caki*, the antecedent of *caki* did not c-command it. This constitutes a direct challenge to our binding analysis, as an antecedent generally needs to c-command the element which it binds. In 22 of these examples, the antecedent of *caki* was a clear topic of the sentence, in 2 tokens, the antecedent of *caki* occurred in a genitive phrase, and in 2 tokens, the phrase containing *caki* has been displaced, undergoing movement over the antecedent. The distribution is summarized in Table 3.

---

<sup>1</sup> Each example from the corpus is annotated with a token id and the file it is from. For instance, (14) is annotated with [2;;001.txt]. 2 is the token id and 001.txt refers to the file name.

Type	Number	Percent
Topic Antecedent	22	84%
Genitive Antecedent	2	8%
Displaced <i>caki</i>	2	8%

Table 3: Distribution of Non-c-commanding Antecedents

Examples of *caki* whose antecedent is topical, but does not c-command it are given in (17) and (18). In (17), the antecedent was a subject with a topic marker in a clause conjoined to the clause containing *caki*, and the antecedent occurred in a topic introducing phrase such as *according to Yoshida* in (18).

- (17) Kyengsam<sub>i</sub>-un mayil pap-ul cie talak-ey nehe cwuko-n  
 Kyengsam-TOP everyday meal-ACC make attic-at put give-and  
 caki<sub>i</sub>-nun cwung-ul capule tany-ess-ta.  
 self-TOP monk-ACC catch go-PAST-DECL  
 ‘Kyengsam<sub>i</sub> made a meal and put it in the attic every day and self<sub>i</sub> went  
 around to catch the monk.’ [19;;008.txt]

- (18) Yoshida<sub>i</sub> yayki-incuk, caki<sub>i</sub>-ka ilcey ttay  
 Yoshida tell-according to self-NOM Japanese occupation time  
 Cwungkwuk pongchen-uy chongyengsa-lo iss-ess-nuntey  
 China Pongchen-GEN consulate general-as exist-PAST-and  
 ‘According to Yoshida<sub>i</sub>, during the Japanese occupation self<sub>i</sub> was the  
 consulate general of Pongchen in China and’ [23;;013.txt]

Despite their apparent status as counterexamples to the binding analysis, with closer inspection, it can be argued that all these examples can map onto an operator-variable structure and so are consistent with the bound variable analysis of *caki*. First, we saw in section 3 that *caki* can be bound by a discourse topic. Thus, the instances where the antecedent of *caki* is a topic of the sentence should be able to map onto a topic-operator-variable structure that binds *caki* in a similar way in which instances with a discourse topic map on to a topic-operator-variable structure that binds *caki*.

Sentence (19) contains an example of *caki* whose antecedent is marked with genitive case.

- (19) Ku<sub>i</sub>-uy chilyopep-un kuce caki<sub>i</sub>-ka sangkakna-nun  
 he-GEN treatment-TOP always self-NOM think-ADNOM  
 tay-lo chilyoha-nun saylo-wun pangpep-i-ci.  
 in accordance to treat-ADNOM new-ADNOM method-COP-DECL  
 ‘His<sub>i</sub> treatment method is a new method where self<sub>i</sub> always treats in  
 accordance to his thoughts.’ [18;;008.txt]

As was discussed in section 3, these structures are comparable to cases where *caki* is bound by a quantifier from a similar position, forming an operator-variable construction.

Finally, a case where *caki* has undergone movement is shown in (20).

- (20) [Caki<sub>i</sub> nalumtaylo nonlicekulo]<sub>j</sub> yay<sub>i</sub>-nun t<sub>j</sub> ihay-lul  
 self in one’s own way logically kid-TOP t<sub>j</sub> understanding-ACC  
 hakwu iss-eyo.  
 do be-DECL  
 ‘The kid<sub>i</sub> understands logically in self’s<sub>i</sub> own way. [547;;182.txt]

If the moved phrase undergoes reconstruction and is interpreted in the source position, a c-commanding relation between the antecedent and *caki* obtains. This reconstructed structure can then straightforwardly map onto an operator-variable structure where *caki* is bound by its antecedent.

#### 4.3. *Caki with no Antecedent*

We found 100 tokens with no overt antecedent for 3<sup>rd</sup> person *caki* in the same sentence. The absence of an antecedent also provides a challenge for our analysis, as bound forms generally require an antecedent. Recalling the cases of antecedentless *caki* in section 2.2, those emerged as 2<sup>nd</sup> person. That these examples are in the 3<sup>rd</sup> person suggests the presence of a covert antecedent, obviating the inherent 2<sup>nd</sup> person reading. Upon further investigation of these instances of antecedentless *caki*, we classified them into 5 categories, the distribution of which is summarized in Table 5.

Type	Number	Percent
Discourse Topic	34	34%
Generic	25	25%
Sentence Fragment	21	21%
Reportative Particle	13	13%
Compound Noun	7	7%

Table 3: Distribution of Non-c-commanding Antecedents

The first (and most numerous) type of antecedentless *caki* was that where the antecedent was discourse salient, as shown in (21).

- (21) A: Park Tongsil sensayng <Yelsaka>-nun nwuka ...?  
 Park Tongsil teacher Yelsaka-Top who ...  
 ‘Who (composed) Yelsaka that teacher Park Tongsil (sang)?’  
 B: Caki-ka mantul-ess-ciyo.  
 self-NOM make-PAST-DECL  
 ‘Self made it.’ [348;;118.txt]

In (21), *caki* refers to *Park Tongsil sensayng* (Park Tongsil teacher) mentioned in the previous discourse. While it may at first glance appear counterintuitive to be using a *wh*-question as a diagnostic for topicality, the “new” information, the identity of the composer, is already contained within the question. As *Park Tongsil sensayng* (Park Tongsil teacher) is salient in the discourse, it can function as the discourse topic binding *caki*. Gil (1998) herself uses similar question-answer sequences to motivate her treatment of *caki* as topic-bound.

An example of a generic sentences containing an antecedentless *caki* is given in (22). In this case, a generic operator can be postulated that binds *caki*, producing a generic reading in the familiar operator-variable configuration.

- (22) Caki swukcey-nun caki-ka ha-nun ke-ya.  
 self homework-TOP self-NOM do-ADNOM Fut-DECL  
 ‘In general, self should do self’s homework.’ [111;;053.txt]

Example (23) contains a case where *caki* occurred in a sentence fragment with an elided matrix clause that is part of a narrative. In (23), the speaker is describing the content of a letter he received from a student.

- (23) Context: The speaker is talking about a letter he received from a student.  
 Caki-nun yeksa sikan-i cham silh-ess-ta.  
 self-TOP history time-NOM very dislike-PAST-DECL  
 ‘(The student said) self disliked history very much.’ [210;;088.txt]

The sentence fragment in (23) is embedded in a quote context. If the quote context is spelled out (*the student said*), then it would be in the form of a matrix clause. With the recovered matrix clause, *caki* now has an antecedent that binds it: *the student*.

An example of *caki* occurring in a sentence with a reportative particle on the predicate is given in (24). The reportative particle such as *tay* or *lay* contributes the meaning component that contains the reporter of the proposition, the exact reference of which is determined by the discourse context, and a predicate of saying the proposition. In other words, the reportative particle can be seen as introducing an implicit argument that refers to the reporter (Bhatt and Pancheva, 2006). This implicit argument can then bind *caki*.

- (24) Enceyna caki-ka mac-tay.  
 always self-NOM correct-REPORT  
 ‘(Steve said) self is always correct.’ [8;;007.txt]

According to the discourse contexts, the reporter in (24) is *Steve*. Once recovered from context, this reporter binds *caki*.

Lastly, there are cases where *caki* appears in a compound noun, as exemplified in (25).

- (25) Kuken caki pyenmyeng-i-ko wiysen-i-ya.  
 that-TOP self excuse-COP-and hypocrisy-COP-DECL  
 ‘That is self-excuse and hypocrisy.’ [78;;044.txt]

We conclude that these should be treated as fixed expressions, similarly to *self-control* or *self-esteem* in English, and therefore should be exempt from having a binder.

## 5. Conclusion

In this paper, we have argued that the Korean long-distance anaphor *caki* is best

analyzed as a bound variable. Its antecedents bind *caki* from an A' position either via QR, or through topicalization. To account for discourse-bound *caki*, we have exploited a previously proposed empty topic operator. In sum, we are thus able to treat local and long-distance cases of *caki* under a single analysis without postulating any otherwise-unmotivated LF movement. This analysis allows us to account for apparent counter-examples to the generative anaphor-binding account, as well as data which is incompatible with a coreferential analysis of *caki*.

The results of our corpus study support the bound variable analysis as well. While new potential counter-examples, such as the data involving generics and reportative particles, were raised, we have shown how these too are compatible with our analysis.

## A dynamic approach to the semantics of *almost* and *barely*

Debra Ziegeler

National University of Singapore\*

### Abstract

The age-old debate on the semantic classification of proximative adverbs has tended more recently towards empirical investigation; e.g., Amaral (2007), Pons Bordería and Schwenter (2005), Ziegeler (2006). The present study continues such trends, examining the semantic analysis of the English proximative adverbs, *almost* and *barely*, from a dynamic perspective, and providing new results obtained from the evaluations of speakers of differing dialectal backgrounds. It is found that the responses vary significantly, as in earlier studies, according to the aspectual nature of the predicate, and slightly according to affective factors. The synchronic status of variation can now be positioned within a diachronic framework, revealing the negative inferences of *almost* as conventionalising implicatures, but the positive inferences of its polar counterpart, *barely*, as de-conventionalising entailments.

**Keywords:** proximative adverbs, entailments, implicatures, R- and Q-based inferences.

### 1. Introduction

The semantic status of the approximative adverbs in English, *almost* and *barely* ('proximatives' after the grammaticalisation tradition of Heine (1994) and his followers), has been the subject of an on-going debate which has been fraught with tension since Sadock (1981) first questioned the accepted doctrine of the time that the negative inferences arising from the use of *almost* were not entailments, but conversational implicatures. Atlas (1984; 2005), Anscombe and Ducrot (1983), and Hitzeman (1992) followed in Sadock's path of questioning, and more recent studies such as Sevi (1998), Ziegeler (2000a, henceforth, Study 1), Horn (2002), and Pons Bordería and Schwenter (2005), the last account introducing new insights from Spanish containing evidence of the expletive appearance of negation in contexts in which it had been thought to be only an implicit inference, and suggesting ambiguity between polar and proximal readings of the adverbs. A full chronological summary of the various earlier positions taken can be found in Horn (2002). Ziegeler (2006, henceforth, Study 2) investigated expletive uses in Chinese, and Amaral (2007) has now provided us with similar examples from European Portuguese. The studies conducted by Horn (2002), Pons Bordería and Schwenter (2005) and Amaral (2007) interpret the occurrence of expletive or pleonastic negation as an indication that the negative inferences contained in the meaning of the proximative when not expressed pleonastically are 'unasserted' entailments (after Horn (2002)), and that the so-called 'flip-flop' between polar and proximal readings means that the polar readings are in focus. However, few of the earlier studies have given any consideration to the understanding of

the semantics of *almost* and *barely* as a dynamic or changing phenomenon, with present-day uses representing merely a stage in a meaning shift over an enduring time period. The present study will therefore examine in greater detail evidence taken from speakers' interpretations of (constructed) *almost* sentences, in which the negative inferences were shown previously to vary quantitatively according to the aspectual environment of the predicate, and similar example sentences using *barely* will also be analysed. As well as this, the combined factors of both predicate aspect and evaluatively favoured or disfavoured predicate events will be considered in a sample of data from native speakers of English from various dialect backgrounds, and a new method of analysis will be used to investigate whether the polar inferences are entailments or conversational implicatures.

In the second section, some of the arguments on the status of *almost* will be discussed, and in section 3, the present-day distribution of *barely* will be reviewed. Section 4 will look at the historical development of present-day meanings, and section 5 presents intuitive data from different groups of native speakers. Section 6 will discuss the evidence from the point of view of variation shown in the data, as well as the position of the two adverbs from a diachronic pragmatic perspective.

## 2. Previous discussions

### 2.1 *Adversative conjuncts*

The volume of research that has increasingly been produced relating to the topic of proximatives crosslinguistically provides obvious testimony for the problems that are perceived in the definition of their meanings, and the intermediate functional positions they are likely to occupy. In many ways, the role of the proximative encroaches into the linguistic domain of fuzzy logic (as pointed out by Sadock (1981), in that, depending on one's point of view, it may be understood to refer to the existence of *P* and the non-existence of *P* at the same time. It is obviously within such understanding that earlier studies had proposed a conversational implicature account for the semantics of proximatives, in particular for those of *almost* and its synonyms. Sadock's (1981) first introduction of a scalar explanation, using the first Gricean maxim of Quantity, was based on the premises (i) that the implicature so generated was calculable as a generalised conversational implicature, (ii) the ability for the implicature to be cancelled without redundancy or contradiction, using *not only* (well-known as a diagnostic cancelling phrase to test for a scalar implicature – see, e.g., Levinson (2000: 81), and (iii) the cancellation of what has more recently been referred to by Amaral (2007) in an entailment analysis as the 'standard of comparison' – the maximal degree on the quantity scale to which the proximative sense is oriented, as in

- (1) Bill almost, but did not quite swim the English Channel.<sup>1</sup>

The cancellation is shown by the use of the adversative, or contrastive conjunct *but*, which in such cases serves to rule out the possibility of the swim including the whole of the

English Channel. This cancellation was referred to again in Study 1 and Study 2, in which the use of an adversative conjunctive clause was held to illustrate that it was the proximal meaning of orientation towards *P* that was cancelled. In what are known as Conjunctive Analyses (Horn 2002) - those which treat the proximal meaning of proximatives as distinct from the polar meanings - it may seem therefore, that the use of such conjunctions enables the polar meaning of negation to surface under the cancellation of the proximal meaning. However, in Studies 1 and 2, it was considered that the polar meaning and the proximal meaning were not distinct components of meaning, but merely two sides of the same pragmatic coin: the bipolar Quantity maxim, i.e., Horn's (1984) R-inferences vs. Q-inferences, the precedence of either inference depending very much on contextual indicators. In accordance with diachronic developments in the expression of modal verbs (e.g., Traugott 1989; Ziegeler 2000b; Traugott and Dasher 2002), it was found possible therefore to create counterfactual inferences from the cancellation of the R-inference by an adversative clause, so producing a Q-inference, and it was even suggested (Ziegeler 2006) that Q-inferences were only metonymically-derived, R-inferences being basic to most interpretations involving scales of Quantity. Crosslinguistic evidence, furthermore (e.g. Heine 1992, Kuteva 2001, Malchukov 2004, and Pustet 2008), showed that there was nothing redundant, rhetorical, or reinforcing about the use of *but*-adversative clauses with proximatives, as had been suggested, e.g., by Horn (2002). The contrast shown in examples like (1) was seen as holding between the R-inferred orientation of the modal or proximative meaning (predicting the event to which it approximated), and the aversion or interruption of the goal-directed event created by the information conveyed in the contrastive proposition in the *but*-clause. This analysis will be expanded further in 2.3.

## 2.2 Aspectual variation

The implicature analysis was taken up later by Atlas (1984) who claimed for an account based on the aspectual tendencies of the predicates with which the proximative adverb was combined – suggesting that only for Accomplishment and Achievement predicates does *almost P* entail  $\sim P$ . He illustrated the aspectual contrast by suggesting that the implicature explanation is quite adequate to account for the semantics of *almost* with stative predicates, such as,

- (2) Moore almost understood ‘material object’ and he understood it

and maintaining that there was no contradiction in the conjoined clause (note that (2) would be slightly odd, as noted above, with a *but* –conjunct instead). The only partial concession to an entailment explanation was considered to be due to the fact that *almost* is equivalent to *not quite*, and *not quite* with telic predicates is equivalent to *not*. Since such predicates presuppose a terminal boundary, it is possible to agree with him, though there may be some exceptions, as seen below. In order to come to terms with such proposals, it is sometimes necessary to equate partial completion of *P* with the event of *P* per se. Consider, for example:

(3) My balloon is almost inflated

One could not deny one state of balloon-inflation as incompatible with another state of inflation, in which the balloon was even more inflated than before – the balloon is inflated from the moment of the first puff. However, it would be wrong to suggest that

(4) My balloon is almost inflated and it is inflated

makes for any kind of logical contradiction. If anything, all it suggests is that the passive participle carries an inference, perhaps a presupposition, of an implicit terminal point, which *almost* may, under most circumstances, help to elucidate.<sup>2</sup> We shall see later in the study why this is so.

At the same time, Atlas highlighted an important point in regard to the use of proximatives, and that is that there is no restriction on their contextual distribution, at least for English. His aspectual account was taken up in Study 1 and Study 2, and across both English and Chinese native speaker samples, the aspectual categories taken into consideration being based upon Langacker's (1987) summary of the parallels between verbal and nominal aspect. The following three categorizations were investigated: (i) imperfective situations, including stative and activity verb predicates or progressive aspect predicates: for example *When I saw Sue she was almost running* and (ii) perfective events, e.g., *John almost fell off the bridge* since they indicate that the time span over which the event occurs is of too brief a duration to accommodate proximity. If anything, the proximity could only be supplied by the time-scale, not the semantic composition of the predicate itself (Ziegeler 2000a: 1766). It is for such reasons that only perfective events, expressing highly punctual duration, may be considered as relevant to counterfactual readings of *almost*. In such situations *P* becomes a predicted value, not an actual value, and hence with past time reference is easily rendered as hypothetical/counterfactual.

Another aspectual category investigated was (iii), that of interconnected entities/accomplishments. Interconnected entities is the term given by Langacker to refer to count nouns with compositional distribution over a collective of members; e.g. *team*, *constellation* and *alphabet*, and they were considered to express in nominal terms the same telicity expressed by Accomplishment predicates, as in *The dog almost crossed the road*. These were investigated as their internal composition was considered to provide the ambiguity between what is *P* and what is not *P* (so that even examples like *Sam is almost bald* could be argued to fall within such categories, *bald* having a terminal boundary). Thus the aspectual distribution of *almost* in the previous Studies 1 and 2 was taken into consideration as a synchronic factor determining the level of hypotheticality that could be derived from its use. Such aspectual distinctions will continue to be used in the present study as a semantic variable of investigation. It was found that there was quantitative variability where aspectual differences are concerned, with higher degrees of contradiction assessed for sentences with bounded, perfective predicates than those with unbounded, imperfective predicates. At the same time, there was no rejection of any aspectual environment as unacceptable. What was apparent in the use of *almost* with variable aspectual conditions is that the adverb casts a meronymic shadow over whatever falls

within its scope, whether or not that entity can, under other circumstances, be thought of as lexically decompositional in any way.

Another argument in favour of a decompositional analysis can be found in the use of *almost* with cumulative entailments, as shown in (5a) using an example similar to one used in Study 2, and taken from the *ICE-GB* (w2a-028):

- (5) a. He was almost underwater  
entailing b. He was not underwater  
entailing c. He was not even slightly underwater  
which contradicts, by transitivity:  
d. ?? He was almost underwater, but he was not even slightly underwater.

As discussed in Study 2, the use of minimisers rules out a number of cases where it would not be possible to use a proximative without some minimal sign of *P* being in evidence. It can thus be seen that *not underwater* is not a contradictory of *almost underwater*, as there are cases where both situations may prove false, leaving *slightly underwater* as a valid possibility. Also, the partial representation of *P* (*almost underwater*) cannot be expressed without entailing *slightly underwater*, in which case it cannot compatibly entail *not underwater* at the same time. That such examples are not uncommon in natural discourse may also be shown by the fact that (5a) is not a constructed example, and yet there is still no precise ‘standard of comparison’ supplied to accommodate the counterfactual needs of our ideal proximative.

However, the problem does not go away with the removal of *almost* altogether, and (5b) does not necessarily entail (5c), regardless of what it co-occurs with. (5a) may be uttered in all sincerity when the facts clearly indicate that the subject was indeed partially submerged beneath the surface of the water, hence underwater. What *almost* contributes to such meanings is to focus not so much on any compositional degree expressed by the predicate, but on the degree to which the subject is wholly affected. The proximity expressed in (5a), therefore, is not towards the surface of the water, but towards the complete immersion of the subject referent.

The use of equative examples such as (5a), then, presupposes a different analysis, in which the scope of *almost* actually extends leftward over the subject, rather than rightward over the predicate. It will be seen later that such scope variation may be simply a legacy of the historical stages through which the developing adverb has gone; in the meantime, it is also necessary to point out that the referential ambiguity that is revealed in such examples is an illustration of what Langacker (2002: 189) termed ‘active zones’; i.e., referential metonymies in which a whole entity may stand for a part, that part being the part most salient to the action concerned; e.g., *I stroked the cat* (‘the cat’s back’). In (5a), an understanding of *almost P* as *P* involves the use of such whole-part metonymies, so that *he was almost underwater*, and *he was underwater* are not contradictory. In such readings, *almost P* is compatible with *P* only insofar as the hearer understands a partial representation of *P* to be equivalent to *P* itself.

### 2.3 Orientational meanings

It should also be noted that compositionality, rather than gradability, is basic to the meaning of *almost*-predicates, since gradability (assuming also orientation), towards a definitive end-goal, is a secondary (R-based) inference primed from the meanings of proximity alone. There is nothing in the meaning of proximity to *P* to entail that whatever is proximate to *P* is also necessarily moving in the direction of *P*.<sup>3</sup> For this reason, it is logical to suggest that not only the negative polar component of meaning, but the positive proximal component of the so-called Conjunctive Analysis as well is itself a conversational implicature – an R-based implicature of Quantity in which the expression of mere proximity to *P* stands for orientation towards *P* itself. This means that the Conjunctive Analysis should be revised to account for two polar meanings: positive and negative, with a basic assumption that the only entailed and asserted component of meaning is ‘closeness’ to *P*, the proximal component from which the two polar readings are derived, as shown in Figure 1 (*X* representing the point of proximity to *P* and the crossed arrow representing the cancelled R-implicature):

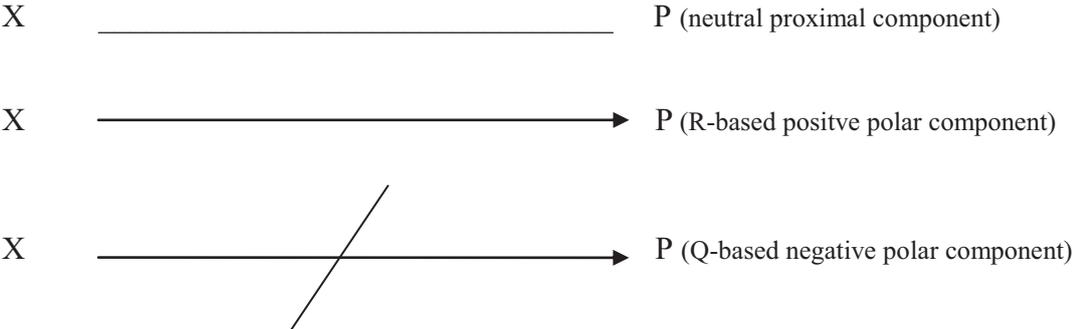

Figure 1. Diagrammatic representation suggesting a 3-part division in a revised Conjunctive Analysis.

*Not-P* appears thus no more an entailment of *almost P* than are *not-Q*, *not-R*, or *not-S*. There are infinite possible negative entailments derivable from *almost P*, and the only reason that *not-P* is raised as an inference of the proximate sense is due to the relevance of *P* as a target of orientation in the first place, derived by R-based implicatures. On the other hand if *not-P* presupposes that *P* is not part of the meaning of *almost P*, it could be argued that it may be difficult to reconcile an assertion (proximity to *P*) with an entailment suggesting that *P* is *not* part of its meaning. It is for this reason that the relationships between what is included and what is not included as part of the meaning of proximatives must be only pragmatic.

The R-based inferences of orientation are readily perceived in examples such as Horn (2008) describes, contrasting *almost* and *barely*:

- (6) The tank is almost half full – so {let’s drive on/#we’d better stop for gas}.
- (7) The tank is barely half full – so {we’d better stop for gas/#let’s drive on}.

The orientation towards *P* in (6) and towards  $\sim P$  in (7) is described as rhetorical; however, the connecting clauses suggest that the meaning is affected by nuances of desirability. In (6) the directional inferences in *almost* are conventionalised to the point at which the amount of petrol referred to may even be understood as increasing; hence the optimism of the speakers. In (7) the R-based orientation is towards the emptying of the tank, a more realistic, but less desirable situation. It will be seen in the empirical investigations to follow that the correlation of R-based inferences with desirable or undesirable situations can be readily assessed in elicitation tasks.

### 2.3.1 *Inverted readings*

The orientational approach may also supply evidence from the so-called ‘inverted’ readings of *almost*- and its counterparts in a number of other languages. Schwenter (2002) and Pons Bordería and Schwenter (2005) revealed that in Spanish, a form of pleonastic or expletive negation could occur in the case of the approximative adverbs *casi*, *por poco*, (‘almost’) and *apenas* (‘barely’) providing a sort of ‘double-negative’ in cases in which the predicated event was not likely to occur or undesirable; e.g. (2005: 263):

- (8) Por poco se mata  
‘She was almost killed’
- (9) Por poco no se mata  
‘She was almost killed’

In (9), the negated form is ambiguous between expressing the same as its positive counterpart in (8) and the meaning ‘almost-not’, or ‘barely’, which they describe as its canonical meaning. Pons Bordería and Schwenter (2005) show that the expletive use was more frequent at earlier times than after the 15<sup>th</sup> century, and that the patterns of pre-verbal negation found generally in Spanish at the time provided a parallel model for the use of such forms. The return of such uses in present-day Spanish they believe to be due to reasons of emphasis or to assert the underlying negative inferences which are held (in accordance with Horn 2002) to be (otherwise unasserted) entailments.

Further examples with expletive negation come from Chinese (see Zhu 1959; Li 1976; Peyraube 1979; Biq 1989); e.g. (L, 1976: 528):

- (10) Ta      cha yidiar      mei      zou  
he      miss-a-little      not      leave  
‘He almost left’  
‘He barely left’

In the Chinese cases, the explanations for anomalous expletive negation are similarly that the event complemented of the proximative was either unexpected or undesirable (e.g., Biq 1989). Given that the orientational meanings, as explained earlier, are R-based extensions of meaning in which proximity to *P* further implicates direction towards *P*, it would not be surprising, in the event that *P* referred to undesirable or unexpected events, to find that language users would wish to explicitly encode the avoidance of a misfortune or an

improbability, normally implicitly expressed using Q-based implicatures. The use of the negative, therefore, may be to reassure the hearer of the positive outcome of an otherwise implicitly unfavourable situation.

Pons Bordería and Schwenter (2005) arrive at the conclusion that the inverted readings they are obtaining from their historical and contemporary data from Spanish are due to the process of cryptanalysis (Croft 2000), a process whereby certain unmarked grammatical or semantic properties of a syntactic unit may be explicated in context with the use of an overt grammatical marker (similar, in fact, to the process of reinforcement in grammaticalisation (Lehmann 1995: 22)). However, although Croft uses cryptanalysis to explain the overt marking of negative entailments in context, there is nothing in his account that would prohibit implicatures from being subject to the same process, and therefore, if the explanation is to be convincing, it goes nowhere to proving that the inferences that are being assertively marked for their semantic value are always entailed. Croft's cryptanalysis may apply equally to a pragmatically implicit sense in the context (in fact, it would be much less likely to apply to an entailed one as if it did it would produce a tautological effect: we do not need to talk about *unmarried bachelors*, for example, and the entailment of being unmarried in the meaning of *bachelor* is equally unasserted). Thus, for the studies of pleonastic negation, we are left with the arguments that although an implicature definition of proximatives may not allow for the strength to support overt expression in context, there is also the counter-argument that an entailment analysis would, on the other hand, suggest that the negative inferences are being redundantly encoded (asserted or unasserted) and that there would be no need for their overt expression. It is doubtful, therefore, that such studies, though interesting, can *necessarily* support an entailment analysis of proximatives at all.

### 3. Distributional properties of *barely*

#### 3.1 *Adversative and causal conjuncts*

*Barely* has been credited with expressing the opposite semantics to *almost*, i.e., *almost-not*, and yet it has not received the same degree of attention that *almost* has (as shown in Horn 2002), probably because its semantics may seem, for some, a little less controversial. For Atlas (1997), at least, it is claimed that the inferences of the use of *hardly*, its synonymous counterpart, are clearly spelt out as entailments, regardless of whether the lexical aspectual character of the verbal predicate denotes Achievements, Accomplishments, or imperfective Processes. Perhaps the only controversy surrounding the use of *barely* is whether it can necessarily be described as a mirror-image of *almost*, as Sevi (1998) and Horn (2002) suggest. Amaral (2007) considers that it may not be assigned this status, but does not go into detail of why this should be so, apart from comparing the possibilities of cancellation between *barely* and *almost-not* (p. 11):

- (11) ??Bush barely won, but he got more votes in Ohio than he expected
- (12) Bush almost didn't win, but he got more votes in Ohio than he expected.

(12) explicates or asserts what is R-implicated in (11), but not yet a part of the semantics of *barely* (hence the oddity of (11)). Horn (2002) finds the Bush victory can readily be reasserted in such examples as:

(13) Bush barely won the presidential election, but win it he did

If the entailment analysis is to hold, the apparent redundancy of what may seem to be a reaffirming of the entailment in the first clause is not a redundancy at all, if it is considered instead that the adversative clause only reaffirms the entailment of Bush's winning in the face of the doubts created by its accompanying R-inferences, orientating the hearer's anticipations towards the non-achievements of Bush. The tug-of-war between the pragmatic prominence of the entailment (if it is an entailment) and that of the increasingly powerful R-inferences in the use of *barely*, it will be seen, is something that was not known at earlier historical periods, and is most likely a recent by-product of its use, especially with bounded predicates.

Although it may be argued that (13) is not completely unacceptable, it is marginally less acceptable than (12), in which the R-inferences associated with the use of *almost-not* can be cancelled. Sevi (1998: 33), however, finds problems with cancelling *barely* using an implicature diagnostic:

(14) ?? I barely caught the train this morning, in fact I didn't catch it

in which a perfective event is referred to, as in (11-13). He contrasts such examples with quantitative uses of *barely*, illustrating that they can co-occur felicitously with cancelling elements:

(15) I hardly/barely have any friends left, in fact I have none<sup>4</sup>

(15) illustrates that cancellation is less possible when *barely* is used as a modifier of actions or events: on this account it could be argued that the same diagnosis applies to *almost* which, as shown in Study 1 and 2, becomes more contradictory when speakers are attempting to read cancellations of perfective events. One normally knows whether or not one caught the train this morning, though there may be some doubts surrounding the relations one has with people one could call 'friends'. Thus, the coherence of an *in fact* clause in such instances is not entirely inconsistent, and it could be argued that if *barely* and *almost* are to be compared at all, then *almost* is a quantifying adverb with a pre-determiner function, which is developing into an anti-resultative marker in English, while *barely* is a manner adverb which may be developing into a quantifying, pre-determiner in English (depending on its frequency of co-occurrence with quantifiers and pre-determiners). The reasons for such arguments are shown below.

*Barely*, unlike *almost*, is not quantificational in functional origin, and unlike *almost*, originally a modifier for a quantifying determiner ('mostly all'), began life as a manner adverb, as seen below. *Almost* is not a manner adverb, but a measure adverb, describing

proximity to a point, which is consequently inferred to be a point of orientation via R-based implicatures. *Barely* describes the *way* in which an action was attained, i.e., with minimal sufficiency. It does not, unlike *almost*, contain as part of its inherent lexical meaning any sense of proximity, and does not require a gradable predicate with which to co-occur, so that if *P* barely occurred, *P* therefore did occur, but minimally. Although it may contain inferences of the difficulty of the attainment of *P*, *barely P* is always *P*, while *almost P* can be both *P* and *not-P* at the same time, depending on perceptions of predicate gradability (and even punctual events may be induced into demonstrating gradability within certain limits). The meaning of *P* in *barely P* thus appears to be an entailment, just as it is in any other manner adverb(ial), such as *easily P*, *smoothly P*, *heavily P*, *with difficulty P* and so on. The only difference between *barely P* and *almost P* is based on the precedence of scalar inferences: while *almost P* Q-implicates ‘not *P*’, while entailing ‘mostly *P*’, *barely P* R-implicates ‘not-*P*’, while (apparently) entailing *P*. The reason that the implicature-cancellation does not work in (14) is due to the fact that it is not correcting any R-based inference that the train was not caught, and therefore only reinforces the entailment in the *barely*-clause that the train was caught, suggesting instead a redundancy. It would seem, therefore, that we are looking not at mirror image adverbs of degree, but at one adverb of degree which can simply be synonymous in its negated form with a minimiser adverb.

#### 4. The historical distribution of *almost* and *barely*

##### 4.1 *Almost*

From the studies that have been conducted so far on the understanding and interpretation of *almost* in English, it could be argued that there is insufficient naturally-occurring data to provide a clear picture of whether the studies are examining actual uses or possible uses. Thus, it was considered necessary to investigate the distribution of *almost* in natural usage, starting from a historical perspective, in order to determine what factors in its early stages of development may have contributed to the meanings that are associated with it today, and whether the constructed sentences often used in empirical examples may correspond to actual usage.

In the *OED Online* (based on the 2<sup>nd</sup> edition, 1989) four senses are shown historically for the use of *almost*, the second composed of two parts and most closely corresponding to the present-day usage. The first sense provides the earliest citing of its use, at around 1000 CE, the function being that of a combined adverb + quantifier (‘mostly all’), often occurring with a nominal complement. This usage endures well into Early Modern English:

- (16) **1570** R. ASCHAM *Scholem*. II. (Arb.) 133:  
Thies giuers were almost Northmen.  
‘These givers were mostly all Northmen’

It is interesting that uses like (16) could appear at earlier times, and yet would not be acceptable today without invoking the sense that the entire group of men were transforming into Northmen (revealing the conventionalisation of R-based inferences); i.e., the present-day meanings reveal the fact that the orientation sense supplied by the R-based inference in the context has subsumed any previous lexical senses of quantificational proximity and the scope may no longer extend leftwards ('mostly all these givers'). The original, time-stable quantifier meaning of 'mostly all' has been lost to a certain extent as the adverb extends its uses to an increasing range of complements. The last usage of the original sense is cited as appearing in 1658.

It is an interesting observation that the semantic consequences of employing a proximative marker developed from a modified quantifying pre-determiner, as in the case of *almost*, are such that its distribution to modify verbal complements, even in present-day usage, may be relatively restricted, and therefore the 'counterfactual' uses often described for this adverb may be more illusory than at first appear in most of the studies which have focused on the co-occurrence of *almost* with perfective, bounded verb types. From the evidence of the *OED* it would appear that non-compositional predicates such as punctual, perfective lexical verb types (e.g., as in (12)) were the least prototypical of all the environments in which the adverb could occur. For this reason, a survey was conducted of the use of *almost* from the last Middle English section to the end of the Early Modern English section of the Helsinki Corpus, in order to investigate just how frequent such environments were historically.<sup>5</sup> The data produced only 7 examples of *almost* co-occurring with a bare preterite main verb form, out of 123 tokens in total (5.69%), in the period dating from 1420-1710.<sup>6</sup> The earliest is the following:

- (17) And I dowed the cony bytwene his eeris that almost I benamme his lyf from hym  
'and I struck the rabbit between his ears so that I almost took his life from him'

(1420-1500). Caxton, *The History of Reynard the Fox*  
(Ed. Blake, p. 58)

It is clear from such examples, and some of those above, that the use of *almost* initially with bare main verb forms could appear in pre-subject position with the scope extending over the entire proposition. Thus, it was not proximity to a specific action that was expressed so much as proximity to the possibility of the truth of a whole proposition, a more textual function. The likelihood of scope reduction with main verbal complements appears to become more prominent as time progresses, as shown in the last example found for the period surveyed:

- (18) and he had suffered so much in his Reputation, that he almost dispaired to recover it.

(1680) Burnet, Gilbert. *Some Passages of the Life and Death of the Right Honourable John, Earl of Rochester*. p. 13

The first example of the time period surveyed co-occurring with a cancelling *but*-clause appears in 1420 (this example was not included in the total count of 7, since it contains a participle predicate):

(19) I had almost spoke wyth Mestresse An Hault, but I dyd not.

(1420-1500). John Paston. *Letters*, p. 441.

The low frequency of lexical verbal predicates co-occurring with *almost* is continued into present-day usage: a survey of such uses in the *ICE-GB* reveals that of 264 tokens of *almost*, only 16 (or 6.06%) appeared with bare lexical (past or present) verbs (the count including auxiliaries accompanied by present participles, but not past participles as for the historical data); e.g.,

(20) They're almost doing a league now (s1a-079)

The earlier use of progressive participles in Study 1 (such as *almost running*) was criticized as a test sentence by Amaral (2007: 207) and yet such uses occur in natural discourse, as shown. In addition, three of the 16 examples co-occur with stative, perception verbs:

(21) ... popping their heads through curtains and uh little songs where you could almost hear Gilbert and Sullivan's patter songs coming through ... (s1b-044)

The use of a stative, imperfective verb similarly makes the standard of comparison (between *P* and  $\sim P$ ) somewhat vague, and it could be argued that (21) could not be uttered in all sincerity unless the subject could recognise at least some valid representation of the totality of *P*, i.e., Gilbert and Sullivan. While it is possible to use the adverb with such predicates, it may be questioned just how much counterfactuality is intended as part of the utterance. In (21) it seems that the speaker's intentions are not so much to report what is not happening, but what is close to happening.

It is for this reason that it may be possible to hypothesise that the use of *almost* as a counterfactual predicate marker, or focus adverb, has often been significantly exaggerated, and that much of its present-day usage reflects its source origins as a quantifying determiner over noun phrases, expressing nearly-complete quantities of entities or attributes, a function which is continued into present-day English to illustrate a majority of uses. The occurrence with main-verbal predicates appears to be a relatively extended use, and fairly limited in actual distribution today. For this reason, it is possible to suggest that as a quantifying adverb, it may be most prototypically used to express partial representations of complete states, or part-whole relationships, while not necessarily producing counterfactual inferences at the same time.

#### 4.2 *Barely*

The primary meaning of *barely*, according to the *OED Online*, is that of an adverb referring to nakedness, and they provide examples dating from 1483. However, earlier examples reveal a meaning which may appear to be extended from the meaning of nakedness, i.e., meaning ‘openly, without disguise or concealment, clearly, plainly’. These may refer to acts of speaking, as in:

- (22) **c950** *Lindisf. Gosp.* John xvi. 29 Nu..bærlice ðu spreces.  
‘Now ... you speak openly’

Such uses (which have also been observed by Traugott (2006)) appear to be restricted to verbs of communication in the *OED* data. It would seem likely that the meaning of physical nakedness would have preceded the extended meaning of nakedness in communication, a possible metaphor of its original meaning. Another meaning which appears derived from this carries the meaning of ‘unconditionally, without qualification or reserve, wholly, completely’, and a related sense: ‘merely, simply, only’ (see also Traugott’s (2006) more comprehensive summary of the semantic changes involved in *barely*):

- (23) **1682** NORRIS *Hierocles* 89 Goodness of action does not consist barely in not sinning.

The meaning of ‘simply’ overlaps with another sense, more closely related to its present day meanings: ‘only just’, ‘with difficulty’:

- (24) **1768** ELLIS in *Phil. Trans.* LVIII. 77 Some wax that was barely fluid.

This meaning is dated from 1494, indicating an overlap with other senses, but there are no clear unambiguous examples before (24). A more comprehensive and systematic search would be needed to discern the exact dates of the earliest examples of the different senses, but there appears to be, nonetheless, a distinct pathway of development (some of which is described already in the *OED Online*) from: *physical nakedness* > *abstract, verbal nakedness* > *absence of verbal condition or concealment* > *absence of verbal elaboration, with simplicity* > *minimally*, > *with difficulty*, i.e., the negatively polarised inferences are the result of a long and gradual semantic development over several centuries, in which related meanings may overlap. As an antonym of *almost*, meaning ‘almost not’, then, it can only be attributed that status in its latest, present-day uses.<sup>7</sup>

The *ICE-GB* lists very few – only 12 uses - in total in the entire corpus, suggesting that it may be competing with other forms such as *hardly*. The environments it appears in are: past participles (3), adjectives (3), one past participle used as an adjective, two main verbs, one past and one present tense, one noun phrase, and one quantifying pre-determiner used as a noun (*barely half*). There is no clear preference in this data for main verb uses and they are unlikely to feature prominently in natural discourse. However, the extent of the range of uses is well in evidence, suggesting it can be used in almost any environment as a minimizing adverb.

## 5. Empirical investigations

The historical evidence, though requiring of a much more comprehensive survey (which would be beyond the scope of the present study) does reveal, for the most part, what types of pragmatic developments may be possible in present-day analyses of the adverbs. As noted above for the studies of expletive negation in the use of proximatives in other languages, the use of explicit negation may indicate that the situation referred to in the predicate may be otherwise disfavoured or impossible within its context. Given the possibility, then, for factors of affective meaning to influence the usage of such forms, any disfavoured readings found to influence the interpretation of the proximative meanings would supply even more evidence against an entailment analysis of the canonical meanings, which should not be open to such interpretation. For this reason, a survey was designed in order to examine whether entailment readings could be resistant to the presence of a predicate expressing an unfavourable event when co-occurring with the proximative adverbs, *almost* and *barely*. The speakers selected were first year undergraduates of the National University of Singapore, whose L1 background was named as English. 38 students were surveyed, all with the use of an online questionnaire form. In addition, 25 non-students from various dialectal, age and educational backgrounds were surveyed by email as a control group.<sup>8</sup>

### 5.1 *The survey sentences*

The sentences used for analysis were the following:

1. Sam barely lost his wallet.
2. Sam almost lost his wallet.
3. The old lady barely fell over.
4. The old lady almost fell over.
5. The ship barely missed the dangerous rocks.
6. The ship almost missed the dangerous rocks.
7. The telephone barely rang.
8. The telephone almost rang.
9. Bob is barely bald.
10. Bob is almost bald.
11. It's barely raining.
12. It's almost raining.
13. The pristine rainforest was barely destroyed.
14. The pristine rainforest was almost destroyed.

The respondents were asked to evaluate each of the sentences according to whether they thought what had barely or almost happened actually did happen (in which case the response would yield a 'yes' answer), or whether it did not happen (when the response

would be ‘no’). Such responses were not intended to prove the implicature status of the inferences contained in the sentences, since there were no cancellation devices to test for such inferences. However, a case for entailment would be strongly supported by scores of close to 100% of ‘yes’ answers for *barely*-sentences and ‘no’ answers for *almost*-sentences. Given the *necessary* relation that exists in the entailment analysis of *almost P* and *not-P*, and *barely P* and *P*, any variation shown in the responses would weaken the definition of an entailment, which should hold in all possible worlds. For this reason, the first four sentences were selected for the fact that they refer to potentially unfavourable circumstances on the part of the subject. The plausibility of an entailment reading of the *barely* sentences 1 and 3 is thus at stake since they are polarized towards a negatively-evaluative event and there is a conflict between the logical entailment readings and the obviously disfavoured interpretations of such meaning. The situation is reversed in sentences 5 and 6, in which the use of a lexically negative predicate makes it preferred for both sentences to be interpreted with a positive ‘yes’ response in either case, the negative inferences associated with *almost* leading to a disfavoured reading in S6.

The next two sentences used were neutral as to evaluative nuances, and thus were intended as a control on the previous 6 sentences. However, they were also designed to investigate pragmatic plausibility when interpretation is unaffected by evaluative factors. The first eight sentences were also selected on the basis of their aspectual properties – all containing predicates referring to punctual and bounded (perfective) events. The second six sentences contained imperfective situations and passive participles as their predicates, in order to test whether the aspectual differences would create more variable interpretations of their truth values. Thus, if the responses to S1-8 were more closely in line with an entailment analysis (unanimous ‘yes’ answers for the *barely* sentences and unanimous ‘no’ answers for the *almost* ones), then the next eight sentences would determine whether such biases would hold through non-perfective and/or telic environments.

## 5.2 Results and discussion

The results of the responses to the sentences of the survey are as follows.

Table 1: *Almost* – evaluations of negative inferences in percentages, graded by environment  
Group 1 = Singaporean (N = 38); Group 2 = Non-Singaporean (N = 25).

Environment	Group 1	Group 2
Perfective events (S8)	94.7	92
Imperfectives (S12)	81.5	86
Perfective events (S2,4)	80.2av.	56av.
Perfective events (S6)	71	56
Accomplishments (S14)	63.1	48
Telic states (S10)	34.2	32

Table 2. *Barely* sentences: evaluations of positive inferences in percentages, graded by environment for Group 1 only. Group 1 = Singaporean group (N = 38, 37 for S1); Group 2 = Non-Singaporean group (N = 25)

Environment	Group 1	Group 2
Imperfectives (progressives: S11)	63.1	88
Perfective events (S5)	55.2	60
Perfective events (S7)	47.3	76
Accomplishments (S13)	47.3	40
Telic states (S9)	42.1	34
Perfective events (S1,3)	31.5av.	49av.

It can be seen in Table 2 from the percentage of positive responses to S1 and S3 (31.5%) that the Singaporean group (Group 1) was more likely to be influenced by the unfavourable or dispreferred nuances associated with the negatively evaluable predicates than the non-Singaporean group (Group 2) (49%), though both groups scored low for these sentences. In Table 1 the non-Singaporean group's negative answers to S6 (56%) was lower, though, than the Singaporean group at 71%. This may indicate that for *almost* there is a stronger tendency to evaluate unfavourable situations as occurring for Group 1 than for Group 2, and for *barely* there is a stronger tendency to evaluate predicates referring to unfavourable situations as not occurring for Group 1 than for Group 2. There is also a wide range of variation shown reflecting aspectual differences.

Given the definition of an entailment as a necessary relationship holding in every possible world, the results should be held against the hypothesis that for all *barely*-sentences, 100% 'yes' answers should obtain, and for all *almost*-sentences, 100% 'no' answers should obtain. However, we have seen that this is not the case, and therefore, the inferences derived are not entailments but variably conventionalizing implicatures, with the highest scores for both groups being for S8 (94.7% for Group 1 and 92% for Group 2) – an evaluatively-neutral example with a perfective predicate. A conventional implicature differs from an entailment in that it is peripheral to the main assertion of the proposition, or less crucial to its truth conditions (Abbott 2006: 11-13). The distinct difference has not always been clear in previous accounts: Grice's only (1975) example, *therefore* in *He is an Englishman, therefore he is brave*, lends itself to the interpretation that, although being brave is a consequence of the subject's being English, the relationship is not a necessary one and does not have to hold in all possible worlds. So it could be argued that one of the differences between an entailment and a conventional implicature is that entailments propose a necessary relationship between *p* and *q*, while conventional implicatures suggest only a sufficient, or possible relationship between *p* and *q*. This is why the data, distributed

in the way shown in Tables 1-2, suggest a likely conventional implicature analysis of *almost*.

The tendencies shown are thus graded with regard to environments, in descending order of implicature conventionalization. The expression of the data in this way suggests that the entailment analysis may not universally apply to all environments, and that if the meaning of *almost* is to be described in actual usage, then consideration must be given to its non-counterfactual meanings as well as its counterfactual ones. If there were entailments associated with every use of the proximatives, the data would incline more towards 100% in each environment. However, the data shown above are disparate and the differences reveal that this is not the case. The environmental distinctions may therefore provide instead an insight into the rate at which the implicatures in the proximatives are now conventionalizing to become entailments, and that it may take some time before such inferences are generalized to all environments.

In Table 1, it can be seen that the order of grading for each environment is the same for both groups, though the figures for negative inferences generally are much lower for Group 2, showing a certain degree of hesitancy in accommodating an entailment analysis of *almost*. However, the negative inferences are nearly categorical for both groups for perfective events that are neutral for evaluative influences (S8). For positively-evaluable perfective events (S2 and 4), though, the results show only a marginal preference for negative inferences for Group 2, which may be conventionalized at a lower level than for Group 1 (80.2: 56). For the control sentence (S6) the Singaporean group shows a lower preference for negative inferences (71%, ranked 4<sup>th</sup>) in a context in which they would be unfavourable; there is still a bias towards the canonical polar meaning. This could mean that the preferences for negative inferences for S2 and S4, then, are determined by factors other than evaluative factors (for Group 2 there is no difference where this is concerned (56% av. for S2, 4 and S6), thus it cannot be determined that there is any affective influence here at all). For accomplishments (S14), the ranking is lower for both groups, though the preference is still for negative inferences for Group 1 (63.1%) again as against only 48% for Group 2. The results almost agree for the environments of telic states (34.2: 32), suggesting that preferences for interpretations of the two aspectual environments at either end of the scale are almost the same across the two groups.

The grading for *barely* in Table 2 for the non-Singaporean group (Group 2) is more widely spread across nearly a 50% range, suggesting that there was less indecision about the polarization of the inferences than for Group 1, with only a 31.6% range. The highest scoring environment, imperfectives, matches the ranking of the Singaporean (Group 1) equivalent, though the score is higher (88: 63.1). The main difference in grading shown is in the perfective events. For the evaluatively-negative perfective events, S1 and S3, in the Singaporean group (1), the average score is only 31.5%, while for the non-Singaporean group (2), the score is 49%, with a 17.5% difference. Furthermore, it is not the lowest score available for the latter group. There is also a large margin of difference between the scores for evaluatively-neutral perfective events (S7): 76% for the Group 2 and only 47.3% for the Group 1 – nearly 30%. These data mean that the positive inferences (*barely*  $P \rightarrow P$ ) are much more conventionalized for the non-Singaporean group, and that in the absence of a decisive preference where *barely* is concerned, the Singaporean group may have been

influenced more strongly by evaluative influences, as shown in the differences between the two groups for the responses to S1 and 3, and also the 24% rise over S1 and 3 for Group 1 in preferences for positive inferences with the evaluatively-positive control sentence (S5). The control sentence (S5) though, shows little difference between the two groups (55: 60).

## 6. Conclusions

When the results of the two studies are compared, it is easily evident that the counterfactual inferences (or polar components of meaning) surrounding the use of *almost* and *barely* do not reflect any categorical tendencies for entailment readings to hold, whatever the environment. The distribution of the respondents' intuitions varies according to whether the predicate refers to a disfavoured event and also according to aspectual changes in the predicate. This indicates that the meanings are clearly reflective of an implicature which has the potential to be conventionalized in some environments (but not in others), making it indefeasible only in certain environments, i.e., bounded, perfective events neutral to affective interpretation.

The case for an entailment analysis for *almost* is thus little changed from what was predicted by Atlas (1984), in which he claimed that it held only for Achievements and Accomplishments. However, it might be possible to modify such restrictions to suggest, on the basis of the data above, that the entailment case of Accomplishments is not as sound as Atlas may have wanted it to be. The Achievement predicates shown in S2, 4, 6, and 8, described above as perfective events, certainly reflect for Group 1 the tendencies Atlas predicted, though not for Group 2. The data for the two environments of telic states and Accomplishments is not categorical in respect of the preferences for negative inferences for both groups, as shown in Table 1. The study therefore supports the claims of Ziegeler (2000a, 2006), that conventionalized implicatures are in evidence with many perfective or punctual event predicates, and for the other types, the conventionalization has not yet begun, since non-perfective predicates are taken to represent the partial representation of *P* at the same time as its non-representation.

The present study does not use any type of cancellation devices to determine if the intuitions expressed by the respondents are either entailments or implicatures. However, seen alongside the historical and present-day statistical patterns, the variation more clearly demonstrates the tendency for the gradual conventionalization of conversational implicatures over time. Thus, probably the most accurate interpretation of the inferences surrounding *almost* are that it can be described generally as a conventionalising implicature, in the sense that the entailment does not yet hold in every possible world.<sup>9</sup> This is also supported by the fact that, at least for *almost*, the environments most likely to produce counterfactual inferences (i.e., perfective events) are relatively infrequent historically and rarely-occurring in present-day corpus data. For *barely*, the number of uses is infrequent enough to suggest that the meanings associated with its functions as a proximative marker are only in their incipient stages. However, the hypothesis that *barely* expressed an entailment of its prejacent, discussed in 3, cannot hold for every instance in the face of the present data. It is more likely the case that the entailment which once held historically is

now weakening to accommodate the R-based inferences created by its own negatively-polarised senses of the minimalism of the predicate within its scope and may thus be devolving to the status of a conventional implicature as well. In this way, both the historical evidence as well as the variational data illustrate that the two adverbs cannot be regarded as mirror-images of one another and are describable only in terms of a dynamic pragmatic perspective, with meanings shifting gradually over time, across dialectal communities and linguistic environments at the same time.

\* Acknowledgements are due to the National University of Singapore Staff Research Support Scheme for conference support, and in particular, to Barbara Abbott, Laurence Horn, Aldo Sevi, and Alice ter Meulen for enlightening comments and suggestions. Any shortcomings, of course, are of my own responsibility.

<sup>1</sup> On the use of *quite*, it should be noted that the meaning intended is ‘wholly, completely’ rather than ‘partially’ or ‘rather’ as noted also by Atlas (1984: 350).

<sup>2</sup> Note, though, that it is not redundant to say: *My balloon is inflated to its maximum capacity*.

<sup>3</sup> In fact, Nouwen (2006) supplies adequate information to suggest contradictions between temporal orientation and the presumed polar orientation of *almost*, e.g., *Travis was almost on time* (p. 8), in which the usual relation between the polar orientation and the proximity point is reversed.

<sup>4</sup> *Hardly* is usually considered synonymous with *barely* but supports an ironic usage as well, as noted by Atlas (1997), marking it as polysemous. Further examination of its possibilities will be left to the broader scope of future research.

<sup>5</sup> The period selected was based on evidence from the *OED Online* that showed no (non-participial) verbal complements appearing before this time.

<sup>6</sup> The forms searched were taken from the range of forms shown in the *OED*, i.e., *allem-*, *alm-*, *amaist*, *a'most*, *almost*. The survey did not include examples in which the adverb co-occurred with a past participle or in the pluperfect.

<sup>7</sup> Traugott (2006) also notes that the entailment of *p* with *barely* has always been observed, and that the negative orientation is only a recent phenomenon.

<sup>8</sup> I am grateful to Keith Allan and Mark Newbrook for their help in distributing the online surveys of the second group to various students and colleagues in Britain and Australia, and also to the many Singaporean English Language undergraduate students from the National University of Singapore who patiently participated in the electronic surveys distributed on the student intranet for the data for Group 1.

<sup>9</sup> The stated relationship does not imply one that is *definitive* of conventional implicatures, which are notoriously difficult to describe in many accounts.

# Two Types of Case Alternation in Mongolian\*

Dolgor Guntsetseg & Udo Klein

Heilbronnerstraße 7, 70174 Stuttgart, Germany

dolgor.guntsetseg@ling.uni-stuttgart.de, udo.klein@ling.uni-stuttgart.de

## Abstract

In modern Mongolian there are two major case alternations involving the accusative suffix: direct objects as well as the subjects of (some) embedded clauses can occur either in the morphologically unmarked form (nominative) or in the accusative form. The first case alternation is well-known cross-linguistically as the phenomenon of “differential object marking”. The second alternation we will refer to as “differential embedded subject marking”, to avoid confusing it with the differential marking of matrix subjects. In this paper, we present the results of a questionnaire, which was conducted to investigate the conditions governing the case alternation on subjects in embedded object clauses, and propose that the accusative case in Mongolian has the function of distinguishing the argument to which it attaches from the matrix subject.

**Keywords:** case, case function, differential object marking, differential subject marking, Mongolian, Altaic.

## 1. Introduction

Modern Mongolian exhibits two types of case alternation: Differential Object Marking (DOM) and Differential Embedded Subject Marking (DeSM). DOM refers to the cross-linguistic phenomenon that some direct objects are accusative-marked whereas others are not, and DeSM refers to case alternations of subjects of embedded clauses. Here we will focus on the alternation between nominative versus accusative for

---

\* This research was supported by the German Science Foundation (DFG) via the project C2 *Case and referential context* in the SFB 732 *Incremental Specification in Context*. We would like to thank Jaklin Kornfilt, Reiko Vermeulen, and also the audience from the General Session at CIL 18 in Seoul / Korea for their helpful comments.

both DOM and DeSM (other alternations are also possible for DSM).

In this paper, we will discuss these case alternations from the perspective of the functions of case (cf. Comrie, 1989; de Hoop & Narasimhan, 2005, de Hoop and Malchukov, 2008). According to de Hoop and Malchukov (2008) “[t]he identifying strategy makes use of case morphology to encode specific semantic/pragmatic information about the nominal argument in question”, whereas “[t]he distinguishing strategy is a more specific strategy that is used for distinguishing between the two core arguments of a transitive clause, i.e. the subject and the object”.

Our proposal is that the function of the accusative case in Mongolian is clearly distinguishing; one could even say that it functions as a “non-(matrix-)subject-marker”. DOM in Mongolian indicates distinguishing function of the accusative case. This indication is supported by our data about DSM in Mongolian. Therefore, we assume that in Mongolian the accusative case distinguishes not only between two different arguments in the same clause but it also distinguishes between the two adjacent subjects across clause boundaries which also have similar features in terms of referentiality and animacy.

Section 2 introduces Mongolian as a language of the Altaic language family including its typological characteristics. In section 3, we will discuss each of the two case alternations. We will also derive our hypothesis about possible conditioning factors like adjacency and relative referentiality/animacy which trigger the accusative marking of embedded subjects. The experimental survey which we designed to test our hypotheses will be discussed with its results in section 4. Section 5 gives a summary and outlines the intended goals for further research.

## **2. Preface to Mongolian**

Modern Mongolian is spoken in Mongolia by its estimated 3 million habitants. It is also spoken, at least understood by other Mongolic minorities in Buryatia, western Mongolia and by the peoples in the autonomous province of Inner Mongolia in China. We will focus on Khalkha Mongolian, the general dialect of Mongolian and also the official language in Mongolia, which we will refer to in the present paper as “Mongolian”.

In the literature (Pope, 1951; Dörfer, 1966; Binnick, 1979), Mongolian is usually assigned to the Altaic language family, along with the Turkic and Manchu-Tungusic languages, because of its typological similarities even to Japanese and Korean. In spite

of the common typological characteristics among these languages, this genetic relation is still debatable. They are also often referred to as the Altaic Sprachbund because of their regional language contacts over a long period.

The typological characteristics of Mongolian, which it shares with other Altaic languages, are vowel harmony, agglutinated morphology, SOV-structure and the absence of a gender system. On the other hand, there are also some fine morpho-syntactic differences among the Altaic languages, e.g. subject-verb agreement which is absent in Mongolian, but present in Turkish.

### **3. Case alternations in Mongolian**

#### *3.1. Functions of case-marking*

It is broadly argued that there are two functions of case marking: **indexing and distinguishing** (Comrie, 1989; de Hoop & Narasimhan 2005, Malchukov, 2005). According to the indexing function, the overt case marking indicates some specific information about the thematic role of the arguments under consideration. For example, ergative case expresses agentivity, accusative case concerns patient, and so on. De Hoop & Narasimhan (2005) assume that overt case marking in its indexing function is associated with argument strength. That is, the strong arguments which are prototypical and highly prominent take case suffixes.

Another function of case marking is to distinguish between different arguments, e.g. between the agents and patients. Overt case marking on one of these arguments is sufficient for distinguishing them. If only patient-like arguments of transitive clauses are marked morphologically, while other arguments of transitive and intransitive clauses are morphologically unmarked, this results in a nominative-accusative case alignment. If on the other hand only patient-like arguments of transitive clauses are marked morphologically, while the other arguments of transitive and intransitive clauses are morphologically unmarked, this results in an ergative-absolutive case alignment. According to de Hoop & Narasimhan (2005), arguments are to be differentiated if they are close to each other in argument strength. That is, if both arguments show similar features in terms of their referentiality and animacy, they must be distinguished by overt case marking on one of these.

We will propose in this paper that the accusative case in Mongolian has clearly the distinguishing function. Moreover, while by DOM in Mongolian it is distinguished between the subjects and objects, our Mongolian data about case alternation of subjects

in embedded clauses show that overt case marking differentiates between two subjects in a complex clause and supports our assumption of a distinguishing function. This will be discussed in detail in the following sections.

### 3.2. Differential Object Marking<sup>2</sup>

In Mongolian, the direct objects in transitive clauses are marked differently morphologically. They can either take the accusative suffix *-(i)g* or occur in unmarked nominative, a form, which is morphologically zero. This phenomenon of DOM appears in many languages and some factors which trigger DOM cross-linguistically are pointed out in the literature (e.g. Bossong, 1985; Aissen, 2003 among others). According to these authors, DOM is triggered mainly by referentiality, animacy and topicality. DOM in Mongolian mainly patterns according to the Referentiality Scale in (1), which is suggested by Aissen (2003, p. 437).

(1) **pers. pro. > prop. names > def. NPs > indef. spec. NPs > indef. non-spec. NPs**

If the direct objects are realized by personal pronouns, proper names and definite noun phrases, the accusative marking is obligatory, whereas accusative marking on weak indefinite and incorporated<sup>3</sup> noun phrases is ungrammatical, as shown in (2) and (3).

(2) *Bi tuun\*(ig)/Tuya\*(-g)/ene uul\*(-ig) har-san.*  
 I 3.PS.ACC/Tuya-ACC / this mountain-ACC see-PST  
 “I saw him/her/Tuya/ this mountain.” **high in referentiality**

(3) *Bi zahia bich-sen.*  
 I letter.NOM write-PST  
 “I wrote a letter.” **low in referentiality**

Indefinite noun phrases show an interesting variation in Mongolian DOM. Some indefinite noun phrases can but do not have to be marked with the accusative case, in other words, it is optional. This optionality seems, at first glance, to depend on the specific feature of the direct objects, as illustrated in (4), similar to Turkish (Enç 1991,

---

<sup>2</sup> See Guntsetseg (to appear) for detailed descriptions about DOM In Mongolian.

<sup>3</sup> Incorporated noun phrases build a semantic unit together with the verb and do not introduce discourse referents. Cf. Dayal (2003) and Öztürk (2005) for detailed information.

von Heusinger & Kornfilt 2005).

- (4) a. *Bold neg ohin uns-sen.*  
Bold a girl.NOM kiss-PST  
“Bold kissed a girl.”  
b. *Bold neg ohin-ig uns-sen.*  
Bold a girl-ACC kiss-PST  
“Bold kissed a (certain) girl.”

In (4b), the accusative case requires a specific interpretation; it is a certain girl who is kissed by Bold, whereas in (4a) is unclear whether or not a specific girl is meant. In other words, in (4a) *neg ohin* can be interpreted either as specific or as non-specific. Since in both (4a) and (4b) the need for distinguishing the two arguments is the same, it the accusative case is less likely to be used to distinguish, and more likely to be used to index the specificity of the argument.

On the other hand, there are also cases where the accusative case on indefinite noun phrases with *neg* is hardly acceptable, despite having a specific reading, as illustrated in (5).

- (5) *Bold neg nom(\*<sup>2</sup>-ig) unsh-san.*  
Bold a book-ACC read-PST  
“Bold read a book.”

The ungrammaticality of accusative marking in (5) could be due either to the fact that there is no need to distinguish the arguments (the distinction is guaranteed by the fact that books cannot read, but can only be read), or to the fact that what the accusative indexes is only the specificity of human arguments.

Generally speaking, it is difficult to decide whether DOM in Mongolian has the indexing or distinguishing function, since the set of arguments which would be morphologically marked in each case would overlap considerably. Thus DOM appears to be compatible with both a distinguishing function of the accusative as well as with an indexing function. In order to find evidence for distinguishing more clearly the function of the accusative in Mongolian, we turn to the differential marking of subjects of embedded object clauses.

### 3.3. *Differential Embedded Subject Marking*

Another type of case alternation involving the accusative in Mongolian is that subjects of embedded clauses (further “embedded subject”, abbr. S<sub>E</sub>) are marked in different cases. This alternation depends on the type of the embedded clause. In relative clauses,

subjects can occur in nominative, genitive, and in few cases, even in ablative form, as illustrated in (6). Subjects of embedded temporal clauses are marked either with accusative case or they can occur morphologically unmarked (in nominative form), as shown in (7).

- (6) *Bi yerunhiilegch/-in/-uus bich-sen zahia-g unsh-san.*  
 I president.NOM/-GEN/-ABL write-PST letter-ACC read-PST  
 “I read the letter which the president wrote.”

- (7) *Bold/-ig ir-sn-ii daraa bi yav-na.*  
 Bold.NOM/-ACC come-PST-GEN after I go-FUT  
 “I will go after Bold comes.”

For our discussion in the present paper, we will focus on the case alternation of subjects in embedded object clauses. Before we begin with the investigation of the conditions underlying this alternation, we point out some important morphosyntactic features of embedded object clauses. Firstly, the object clauses are always suffixed with the accusative case.

- (8) *Bi ene oyutan haana amidar-dag-ig med-ne.*  
 I this student where live-HAB-ACC know-PRS  
 “I know where this student lives.”

Secondly, there are two possibilities where the embedded clause can occur within a complex clause. Since Mongolian is a verb final language, the embedded clause must occur before the main verb, but it can occur either after the subject of the main clause (further “matrix subject”, abbr. SM) or before it. These two possibilities are represented in (9). Sentence (8) has the structure (9a), and (8’) has the form (9b).

- (9) a. **SM [SE (OE) VE] VM**  
 b. **[SE (OE) VE] SM VM**  
 (8’) *Ene oyutan haana amidar-dag-ig bi med-ne.*  
 this student where live-HAB-ACC I know-PRS  
 “I know where this student lives.”

The subjects of the embedded object clauses can occur in nominative, accusative and also in genitive, as shown in our example (10). The case alternation is still present, when the whole clause has the form like in (9b).

- (10) a. *Bi ene oyutan haana amidar-dag-ig med-ne.*  
 I this student.**NOM** where live-HAB-ACC know-PRS  
 “I know where this student lives.”
- b. *Bi ene oyutn-ig haana amidar-dag-ig med-ne.*  
 I this student-**ACC** where live-HAB-ACC know-PRS  
 “I know where this student lives.”
- c. *Bi ene oyutn-i haana amidar-dag-ig med-ne.*  
 I this student-**GEN** where live-HAB-ACC know-PRS  
 “I know where this student lives.”

We will focus on the alternation between nominative and accusative because they seem to compete with each other, also in temporal clauses as in (6). The question here is: why is there an alternation and when do the embedded subjects take the accusative case?

At this point, we should mention that this kind of case alternation of subjects is much different from other types of differential subject marking, for example in ergative languages. In these languages the ergative cases express the agentivity and control feature of the subjects in a simple clause, possibly with an indexing function.

In Mongolian we propose that the accusative case attached to the embedded subjects has the function to distinguish it from the matrix subjects. When the whole complex clause has the form in (9a), both subjects are immediately in adjacent position, which might trigger accusative marking of the second noun phrase in order to signal: I am not the matrix subject, or I do not belong to the main clause.

Another factor would be the relationship of both subjects with respect to their position on the referentiality and animacy scales. From the perspective of distinguishing function, if the embedded subjects are higher in referentiality and animacy than the matrix subjects, then the accusative marking of embedded subjects is necessary.

Based on these observations, we have hypothesized the following factors for accusative marking on embedded subjects:

- **Hypothesis of adjacency:** If the matrix and embedded subjects are immediately adjacent like in (9a), then the second noun phrase should get the accusative case, in order to signal it is not the matrix subject.
- **Hypothesis of relative referentiality and animacy:** if embedded and matrix subjects differ in the referentiality and animacy features, such that the embedded subjects are higher on these scales, the accusative marking of embedded subjects is clearly preferred.

We tested our hypotheses with a web questionnaire, which will be discussed in detail in the next section.

## 4. Web Questionnaire

### 4.1. Design and method

The 156 participants were all native speakers of Mongolian, and most of them accessed the questionnaire website by means of an advertisement link placed on a popular Mongolian website (<http://www.medeel.com>). The 54 sentences were distributed over 6 questionnaires, so that each participant saw only 9 out of 54 conditions/items. The test sentences were mixed with an equal number of filler sentences in the questionnaires. We collected 26 judgements per item via a web questionnaire, using the WEBEXP2 software, where the participants had to choose 1 (very bad), 2, 3, or 4 (very good), as a response to how good the sentence displayed sounded.

The design of the questionnaire was as follows

**Dependent variable:** acceptability judgement

**Independent variable:**

- a. **Case:** nominative vs. accusative
- b. **Adjacency:**
  - 1: **SM SE** matrix and embedded subjects are immediately adjacent
  - 2: **SM Adv SE** matrix and embedded subjects are separated by an Adverb
  - 3: **SE...SM** matrix subject follows the embedded clause
- c. **Relative referentiality:**
  - 1: **SM > SE** matrix subject is higher on referentiality scale than embedded subject
  - 2: **SM = SE** matrix and embedded subjects have equal referentiality
  - 3: **SM < SE** matrix subject is lower on referentiality scale than embedded subject
- d. **Relative animacy:**
  - 1: **SM > SE** matrix subject is higher on animacy scale than embedded subject
  - 2: **SM = SE** matrix and embedded subjects have equal animacy
  - 3: **SM < SE** matrix subject is lower on animacy scale than embedded subject

Some of the test sentences used in the web questionnaire will be presented below. There were 54 (2x3x3x3) conditions and accordingly 54 test items, that is, one lexicalization per condition. The test items divided into 6 different questionnaires. Each subject saw 9 of them. The ratio between the test items and the control sentences was 1:1. There were 26 judgements per item.

#### 4.2. Results and interpretation

The data were analysed by means of a crossed 4-way between-subjects analysis of variance. We will discuss only selected results and have attached all results in the appendixes. The first result is about the interaction between the case and adjacency of both subjects, displayed in figure 1. In fact, there is significant effect of this interaction ( $F(2,1398)=10.2$ ;  $p<0,001$ ) in the sense of:

- If matrix and embedded subjects are adjacent, under 1 in the figure, then there is a significant preference for accusative marking of the embedded subject.
- If matrix and embedded subjects are NOT directly adjacent, under 2 and 3 in the figure, then there is NO preference for case marking of the embedded subject.

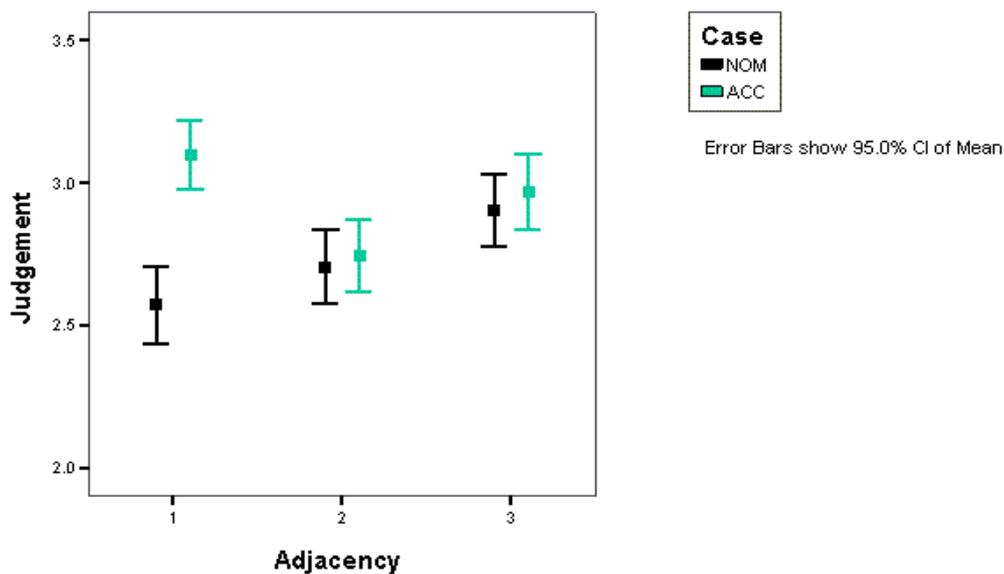

Figure 1. Interaction between case and adjacency of subjects

The test items for that are repeated in (11)-(13).

- (11) *Neg bagsh Tuya(-g) hicheel-d idevhtei orolz-oh-ig sanuul-av.*  
 a teacher Tuya-ACC lesson-DAT diligently participate-INF-ACC warn-PST  
 “A teacher warned that Tuya has to participate diligently at the lesson.”

- (12) *Neg bagsh unuudur Tuya(-g) hicheel-d idevhtei orolz-oh-ig*  
 a teacher today Tuya-ACC lesson-DAT diligently participate-INF-ACC  
 сануул-ав.  
 warn-PST  
 “Today a teacher warned that Tuya has to participate diligently at the lesson.”
- (13) *Tuya(-g) hicheel-d idevhtei orolz-oh-ig neg bagsh сануул-ав.*  
 Tuya-ACC lesson-DAT diligently participate-INF-ACC a teacher warn-PST  
 “A teacher warned that Tuya has to participate diligently at the lesson.”

The next 2 figures show the results about the hypothesis of referentiality and animacy, i.e. about the question whether there is an interaction between case and these features. Some of the test sentences where the subjects are adjacent but differ in relative referentiality are repeated below. Their results are shown in figure 2.

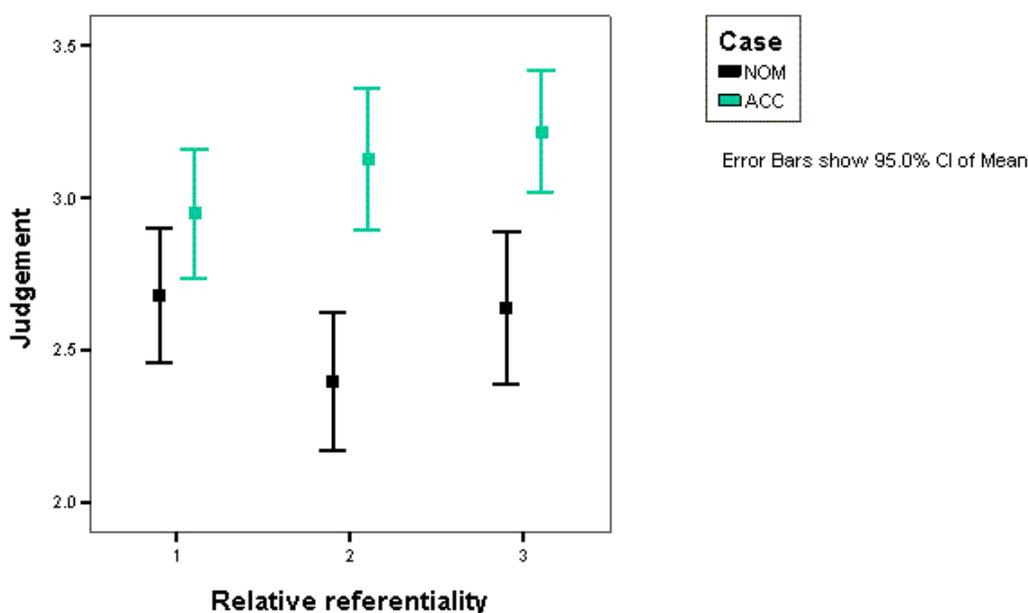

Figure 2. Interaction between case and relative referentiality of adjacent subjects

- (14) *Tuya neg shiree(-g) end bai-sn-ig har-san.*  
 Tuya a table-ACC here be-PST-ACC see-PST  
 “Tuya saw a table was here.”

(15) *Tsetsegee Bold(-ig) unuudur huduu-nuus ir-sn-ig sons-son.*  
 Tsetsegee Bold-ACC today country-ABL come-PST-ACC hear-PST  
 “Tsetsegee heard that Bold came today from the countryside.”

(16) *Neg zereg ene buu(-g) yaj ajilla-dag-ig nadad zaa-j ug-sun.*  
 a soldier this gun-ACC how work-HAB-ACC me show-CVB give-PST  
 “A soldier showed me how this gun functions.”

Figure 2 can be interpreted as follows. If the two subjects are adjacent, then accusative marked embedded subjects are significantly preferred to nominative embedded subjects only if they are equal to or higher than the matrix subject on the referentiality scale.

Finally, figure 3 shows the interaction between the case of embedded subjects and the relative animacy of both adjacent subjects. There is a significant preference for accusative marking of the embedded subjects adjacent to the matrix subjects if its animacy is equal to or higher than the animacy of the matrix subjects. Examples from the questionnaire are shown below.

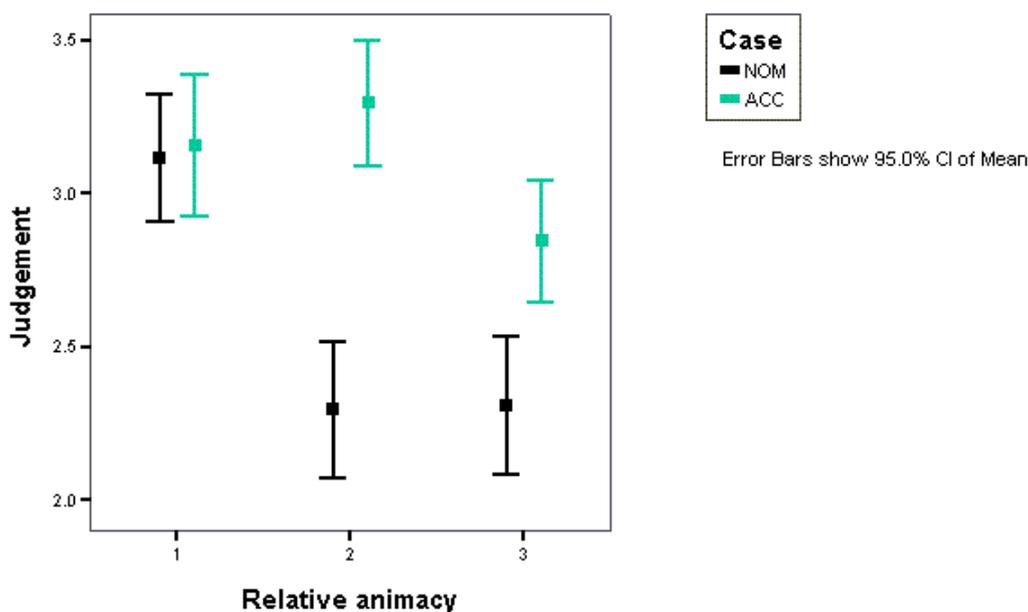

Figure 3. Interaction between case and relative animacy of adjacent subjects

(17) *Tuya neg shiree(-g) end bai-sn-ig har-san.*

Tuya a table-ACC here be-PST-ACC see-PST

“Tuya saw a table was here.”

(18) *Sarnai neg oyutan(-ig) end amidar-dag-ig med-ne.*

Sarnai a student-ACC here live-HAB-ACC know-PRS

“Sarnai knows that a student lives here.”

(19) *Ene GPS bagaj neg hun(-ig) haana bai-gaa-g todorhoil-dog.*

this GPS instrument a man-ACC where be-PRS-ACC determine-HAB

“This GPS instrument determines where a man is.”

To conclude, we see that the adjacency of subjects plays a role for accusative marking of embedded subjects, but only if the embedded subjects are equal to or higher in referentiality than the matrix subject, or if they have the same or higher animacy feature than matrix subjects. In other words, the accusative case occurs to distinguish between the two adjacent subjects provided that the matrix subject is lower than the embedded subject on the referentiality and/or animacy scale.

#### **4. Summary and further research**

The conditions for two major case alternations involving the accusative suffix in Mongolian indicate that it functions to distinguish not only between the two different arguments in the same clause (DOM), but also between the two adjacent subjects across clause boundaries. Put differently, the accusative case signals that the noun phrase to which it suffixes is not the matrix subject.

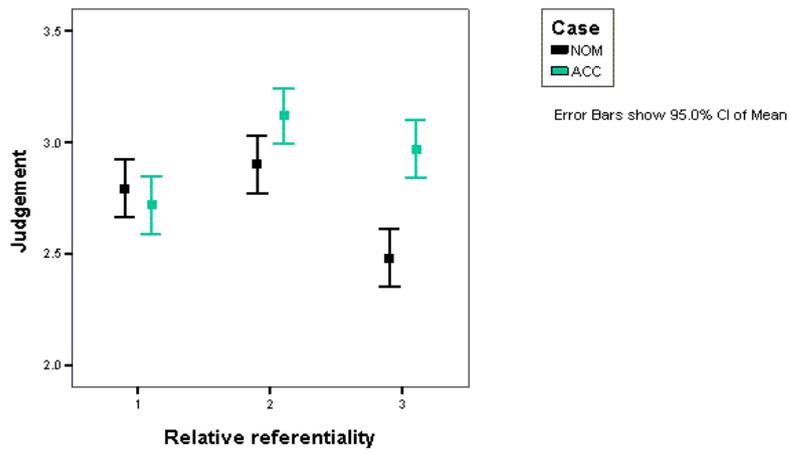

If the idea that the accusative case can also be used to distinguish arguments across clause boundaries, provided they are adjacent and the matrix subject is lower on referentiality and/or animacy scale, there is a reasonable expectation for this to be the case irrespective of the type of embedded clause. Since temporal subclauses also display a case alternation on the embedded subject involving the accusative, it would be interesting to find out whether this prediction is born out. This had to be left for future work.

# The Tonal Structures and the Locations of the Main Accent of Kyungsang Korean Words

Dongmyung Lee

Indiana University  
Department of Linguistics, Memorial Hall 322,  
Bloomington, IN 47405-7005  
[dl6@indiana.edu](mailto:dl6@indiana.edu)

## Abstract

This paper explicitly provides the experimental analyses for the fundamental arguments of Kyungsang (KS) tone. It provides the locations of the main accent in KS words and its basic tonal units. Furthermore through the results it ultimately contributes to the typological categorization of KS Korean tone. That is, the results of the current experimental analysis of the KS words provide us the evidences that KS Korean is a pitch-accent language. In KS Korean only one accent is assigned on a syllable and other syllables are predictable in terms of pitch. The accent type of South Kyungsang Korean is H\*+L with two register tones (H and L). North Kyungsang Korean has two types of accent L+H\* and H\*.

## 1. Introduction

Even though Korea is a small country, there exist several different dialects in the country. Among those dialects especially Southeastern dialects of Korean (South and North Kyungsang Koreans), unlike other dialects, show lexical contrast patterns based on pitch (f<sub>0</sub>). In this paper, therefore, we examine this tonal phenomenon in terms of the tone structures and the locations of the main (highest) High tone of the dialects and try to figure out what prosodic type this lexical contrast in tone patterns reflects.

Traditional works (Gim 1994, 1998, Lee 1997) claim that Kyungsang (KS) Korean is a tone language. They argue that KS Korean has three distinctive tones as High (H), Mid (M) and Low (L) and these tones are assigned on each syllable in a word. The height of non-high-toned syllables in KS Korean words is unpredictable. Therefore, they insist that KS Korean is a tone language. However, in a pitch-accent language like Japanese, an accent is assigned on only one syllable or mora in a word and the height of the other non-accented syllables is decided by rules (McCawley 1970, 1978). The primary purpose of this paper is to investigate the location of the main (highest) H in KS words and to decide whether the High tone in KS words function as in tone languages or as in pitch accent languages. The typological category of KS dialect is examined through the current experimental study.

Now let us consider some example words having multiple High tones. In KS Korean, some words have H tones in adjacent syllables. Both native and loanwords are assumed to have the same tonal characteristics (SKK: South Kyungsang Korean, NKK: North Kyungsang Korean).

(1) KS Words (N/A: not available tone patterns)

a. H H	b. H H L	c. H H H L	d. H H L L
SKK: əm.ma ‘mother’	mu.ɔ̃i.ke ‘rainbow’	in.ti.a.na ‘Indiana’	hal.a.pə.ɔ̃i ‘grandfather’
NKK: no.njən ‘old age’	ma.na.nim ‘madam’	-----N/A-----	hal.a.pə.ɔ̃i ‘grandfather’

(3) North Kyungsnag Korean (tones in parenthesis are tones of derivational nouns or compound words)

Disyllable	Trisyllable	Quadrisyllable
<b>HH</b>	<b>HHL</b>	<b>HHLL</b>
HL	HLL	LHLL
LH	LHL	(HLLL)
	LLH	(LLHL)
		(LLLH)

NKK also has words having multiple High tones like SKK but the actual tone patterns are a little bit different from SKK. In NKK trisyllabic words, there is no tone pattern like LHH of SKK, and in NKK quadrisyllabic words there are no tone patterns like HHHL, LHHL and LHHH of SKK. This dialectal difference in tone patterns of SKK and NKK also triggers our interests about conducting the current experimental study of these Southeastern dialects. Now let us examine the arguments of previous works that defines KS Korean as a tone language.

2.3. Previous argument of KS Korean Typology

In this part we introduce the arguments of traditional works categorizing KS Korean as a tone language (Lee 1997, Gim 1994, 1998). Among these, we summarize Lee's (1997) assumption about the different characteristics between tone languages and pitch-accent languages in (4) (see also McCawley 1970, 1978 for prosodic typology).

(4) Prosodic Typology (Lee 1997)

a. Tone languages

- Height of pitch has the function distinguishing the meanings of words.
- Distinctive heights are assigned on each syllable in words in the “phonological level” (Lexical level).
- The underlying tone that assigned in each syllable is not changed by sentence types (That is, they are not changed on the post-lexical level).
- Languages like Chinese, Igbo, Ganada, Mende, Tamang, Tswana, Otomi, and Huichol belong to this category.

b. Pitch-accent languages

- Accent is assigned on only one syllable or mora ( $\mu$ ) in a word and the height of the other non-accented syllables is decided by rules as shown in Japanese case:
  - 1) The moras following an accented mora is Low tone (pitch fall)
  - 2) The first mora is Low and the moras preceding an accented mora are High tone when the last mora is accented: LHH', LHHH',...etc.
  - 3) Unaccented words have Low tone in the first mora and High tone in the rest of the moras of the words: LHH, LHHH,...etc.
- The accent of each word is assigned at the “phonological level” (Lexical level).

Following Lee's (1997) assumption, we can simply describe the main difference between tone languages and pitch accent languages as below: First, in tone languages, each syllable in a word is assigned by a distinctive tone. However, in pitch-accent languages, only one tone is assigned on only one mora or a syllable in a word. Lee (1997) further argues that KS Korean has three distinctive tones as High (H), Mid (M) and Low (L) tone and these tones are assigned on each syllable at the “phonological (lexical) level”. Unlike Japanese, the height of non-high-toned syllables is not

predictable by rules in KS Korean. Therefore, he argues that KS Korean is a tone language. Throughout the current experimental study, we will argue against his claim and will show KS Korean is a pitch-accent language. That is, the height of the other non-accented syllables is somewhat predictable by rules similar to Japanese<sup>1</sup>.

### 3. Instrumental Study of Kyungsang Korean Tone Patterns

Before presenting the instrumental study, we show once again that some KS words have multiple High tones. The relevant tone patterns are shown in table (5) and (6).

#### (5) Multiple High Tone Patterns of SKK and NKK

	HH	HHL	HHLL	HHHL
SKK	əm.ma 'mother'	mu.ɕʒi.ke 'rainbow'	hal.a.pə.ɕʒi 'grand father'	in.ti.a.na 'Indiana'
NKK	no.njən 'old age'	ma.na.nim 'madam'	hal.a.pə.ɕʒi 'grand father'	N/A <sup>2</sup>

In the table (5), the tone patterns having multiple High tones are shown for both SKK and NKK dialects. In this table, both dialects have same tone patterns in di-, tri-, and quadrisyllabic words. In table (6), however, the tone patterns show a difference between SKK and NKK. As we mentioned previously, NKK words do not have all the tone patterns that SKK have. That is, even though SKK has LHH, LHHL, and LHHH tone patterns, NKK does not have these tone patterns. However, in spite of this mismatch, NKK has tone patterns like LLH, LLHL and LLLH. In this section, we will examine these NKK tone patterns to compare with the tone patterns of SKK LHH, LHHL and LHHH. We assume that this comparison may provide important information about the tone structure of both dialects.

#### (6) Difference in tone patterns between SKK and NKK (N/A: not available)

	LHH	LHHL	LHHH
SKK	non.t'u.rəŋ 'rice-field barrier'	men.t̚.ra.mi 'cockscorn'	pa.i.ol.lin 'violin'
NKK	N/A	N/A	N/A

(NKK has LLH, LLHL and LLLH instead of the counter parts of the SKK tones)

From the both tables, we can draw a question. Which of the High-toned syllables has the main accent in these multiply H toned words? The experimental data of the present paper will answer this question. In order to do this, the current study will examine the whole tone patterns of KS words and the characteristics of KS tone patterns. Then, we will be able to determine where the main accent is located. In the process of the analysis of the present data, we could show that KS Korean is a pitch-accent language and SKK and NKK show somewhat different patterns with respect to tonal structure. Now we provide the materials which are used for the current experimental study.

#### 3.1 Materials for recording

The materials for the current experiment study are provided in (7).

#### (7) Tokens of the Recording (σ: syllable)

Native	SKK		NKK	
	Tone Pattern	Number of Words	Tone pattern	Number of Words
2 σ	HH	3	HH	3
	HL	3	HL	3
	LH	3	LH	3

3 $\sigma$	HHL	3	HHL	3
	HLL	3	HLL	2
	LHL	3	LHL	3
	LHH	3	LLH	3
4 $\sigma$	HHLL	2	HHLL	2
	HLLL	3	HLLL	3
	LHLL	3	LHLL	3
	LHHL	3	LLHL	3
	LHHH	1	LLLH	0
<b>Loanwords</b>	<b>Tone Pattern</b>	<b>Number of Words</b>	<b>Tone Pattern</b>	<b>Number of Words</b>
2 $\sigma$	HH	3	HH	3
	HL	3	HL	3
	LH	3	LH	3
3 $\sigma$	HHL	3	HHL	3
	HLL	2	LHL	3
	LHH	3	LHL	0
	LHL	3	LLH	3
4 $\sigma$	HHHL	3		
	HHLL	1	HHLL	3
	HLLL	1	HLLL	1
	LHHH	3	LHLL	0
	LHHL	3	LLHL	3
	LHLL	1	LLLH	3
<b>Total Number</b>		65		59
124				

The words for current recording in each dialect are divided by the syllable number: di-, tri-, and quadrisyllabic words. In both SKK and NKK disyllabic words, HH, HL and LH words are recorded. In SKK trisyllabic words HHL, HLL, LHL and LHH words and in NKK HHL, HLL LHL, and LLH words are recorded. In SKK quadrisyllabic words, HHHL, HHLL, HLLL, LHLL, LHHL, and LHHH words and in NKK HHLL, HLLL, LHLL, LLHL, and LLLH words are recorded. We try to include all the tone patterns of each syllable composition except for the case without proper words for recording. The words are chosen from both native and loanwords. Each tone pattern has mostly three words but some tone patterns have less than that because of the difficulty of finding proper words for recording. The word list consists of 124 words. The subjects read each word five times. Thus, the total number of token for each subject is 620. The data set is then  $620 \times 5 = 3100$ , given an overall number of tokens.

#### 4. Methods and the Result of the Current Experiment

In this section, we show the experimental procedures briefly and the result of the current experiment. At first, we provide the conveyer sentence for the words reflecting each of the tone patterns. We also provide the f<sub>0</sub> pitch measurement procedures of the recorded data and the subject characteristics of the current recording. Second, we show the data result of the current experiment in graphs. These graphs will provide the basis for the analysis of the characteristics of KS tone patterns and the accent location of tone patterns having multiple High tones.

##### 4.1. Methods

##### 4.1.1 Conveyer Sentence

The conveyer sentence carrying the words reflecting each tone pattern words is \_\_\_ *i/ka* (nom. suffix) *itta* (there is). ‘*There is \_\_\_\_\_.*’ All the words are nouns and they are subjects of the sentence. The nominative suffixes are assumed not to have any tone so they do not affect the tone pattern of the target words.

#### 4.1.2. Measurement

The measurement procedures of f0 pitch of the recorded data are provided in (8).

##### (8) Measuring Procedure

- a. Four measuring points are set in one syllable<sup>3</sup>: beginning, two middle points and final points (1/4, 2/4, 3/4 and 4/4 time) and they are marked by alphabets and numbers (e.g. the first syllable has a1, a2, a3 and a4 and the second syllable has b1, b2, b3, and b4...etc).
- b. The distance between each point in a syllable is approximately proportional in terms of time (ms). If there are strong effects of consonants, however, the locations of the points are adjusted to avoid them.
- c. If the final point of the preceding syllable (e.g. a4) and the beginning point of the following syllable (e.g. b1) are not easy to distinguish in some data, the point is marked as a4 and it is interpreted as both final and beginning points of two adjacent syllables.

#### 4.1.3. Subjects

Five native speakers of each dialect were recorded for the current study. Four of the five SKK native speakers were born in the SK region and lived there for their whole life, and four of the five NKK native speakers were born in the NK region and lived their whole life there, too. The other speaker of each dialect was also born in the dialect speaking region and lived there at least 22 years (SKK) and 31 years (NKK). For the current paper, we analyze a portion of a larger study. That is, only three subjects of each dialect are analyzed here: one male and two female SKK native speakers and three female NKK native speakers. The age range of SKK speakers is from the mid thirties to the early fifties while the NKK speakers are all in their mid thirties.

#### 4.2. Data

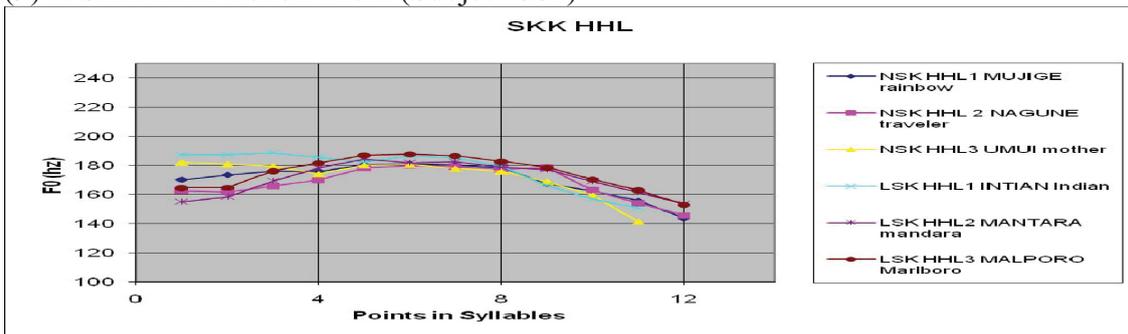

In this section we provide the statistic graphs of the measured data of KS Korean words. The accent types of KS Korean and other characteristics of KS Korean tone patterns will be discussed in section 5 on the basis of the present data analysis. The current paper provides only the data of trisyllabic words in both KS dialects that are crucially representing the characteristics of KS tone patterns.

##### 4.2.1. South Kyungsang Korean (SKK)

###### 4.2.1.1 SKK Trisyllabic Words

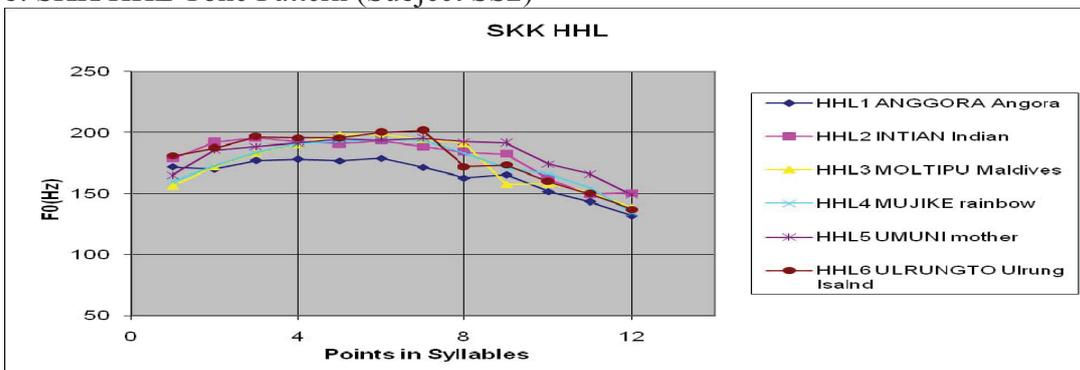

The first tone pattern in (9) is the HHL tone pattern of South Kyungsang Korean. There are graphs of three subjects for each tone pattern in both KS dialects in all the following data representation. Each tone pattern graph basically shows the f0 contour of six different words in most cases. Each syllable in every word has basically four measuring points of pitch (f0). For instance, the first syllable is from point one to point four and the second syllable is from point five to point eight and the last syllable is from point nine to point twelve in most data representation. The syllable deviation is represented by vertical grid lines inside the graphs.

(9) a. SKK HHL Tone Pattern (Subject SS1)<sup>4</sup>

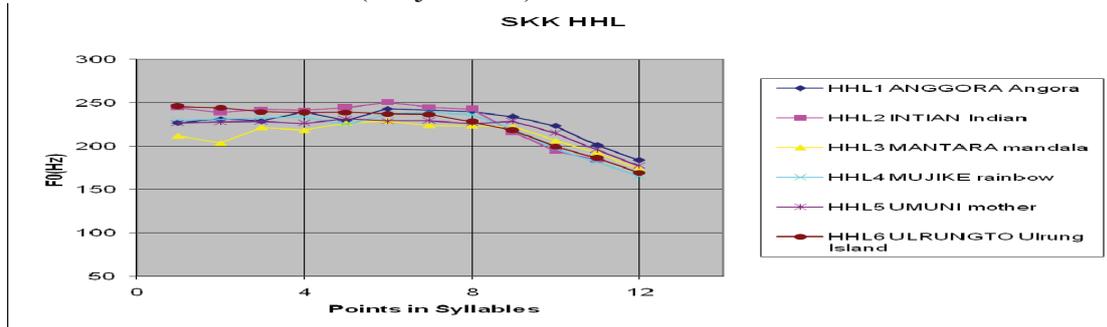

In graph (9a), each f0 contour trajectory is a single token of a word among 5 repetitions of a speaker. Each word in one tone pattern is marked by number e.g. HHL1, HHL2, HHL3,...etc. for the HHL tone pattern in trisyllabic words. The graph shows that the first syllables are lower than the second syllables except for the words starting with vowel (so called vowel effect). The following syllable of the accented tone (highest f0) is falling. The late peak can be seen. That is, the high pitch of the second syllable (accented syllable) remains in the beginning of the third syllable after the peak pitch. Therefore, the accent type of SKK HHL is H\*L on the second syllable. The first High tone is a register tone because the f0 transition from the first syllable to the second syllable is somewhat flat. This kind transition will be observed in the following SKK data. The height of the first syllables shows that the first H tone in the first syllable is a register tone. This register tone will be compared to the first syllable H tone on HHL words in NKK. Briefly speaking the first H tone in NKK words is somewhat different from the SKK initial H tone in terms of F0 transition to the following accented syllable (see graphs of (13) in section 4.2.2.1). The following two graphs of other two SKK subjects show similar patterns.

b. SKK HHL Tone Pattern (Subject SS2)

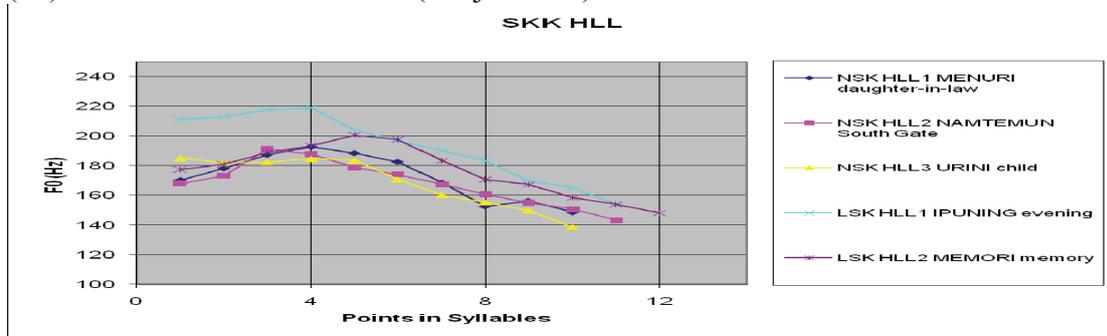

c. SKK HHL Tone Pattern (Subject SS3)

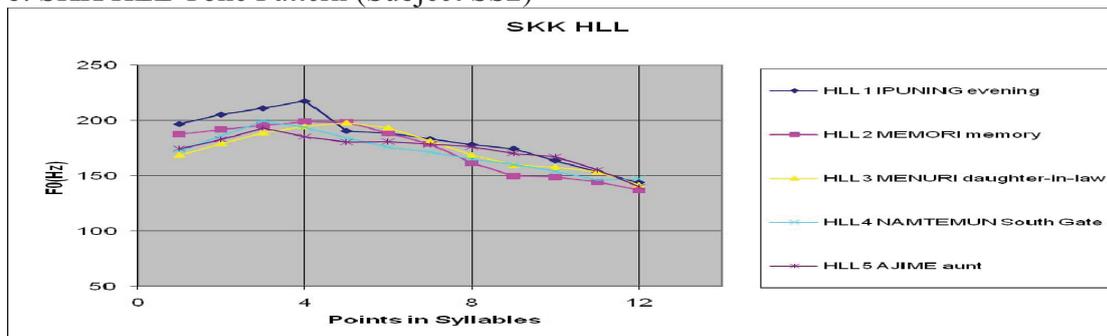

The second tone pattern in (10) is the HLL tone pattern of SKK. There are also graphs of three subjects for this tone pattern. Each graph of this tone pattern shows the tonal representation of five different words.

(10) a. SKK HLL Tone Pattern (Subject SS1)

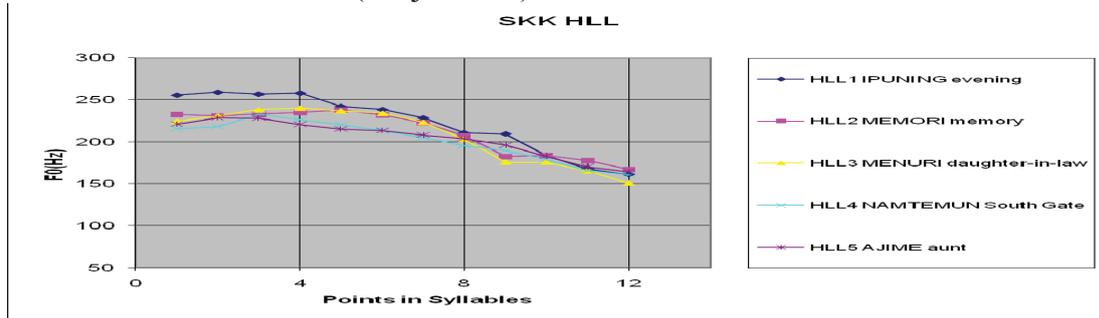

In graph (10a), the late peak is also observed. It is maintained after the pitch peak in the beginning of the second syllable. The accent type of the tone pattern is H\*L. You can also see the vowel (or consonant) effect. The effect showing the gap between the initial points in terms of f0 frequency is somewhat huge in between consonant initial words and vowel initial words. This may cause the misjudgment about the initial height of KS Korean words. That is, even though some words are in the same tone pattern like HLL, the initial tones are maybe misjudged as different tonal categories as H and M simply because of the vowel (or consonant) effect. The shape like a cap in these SKK words is the representative f0 contour shape of the Japanese HLL tone pattern. The following two graphs of other two SKK subjects show similar patterns except for the third subject (Subject SS3). In this subject's graph, the late peak after the pitch peak is somewhat not clearly represented in the beginning of the second syllable.

b. SKK HLL Tone Pattern (Subject SS2)

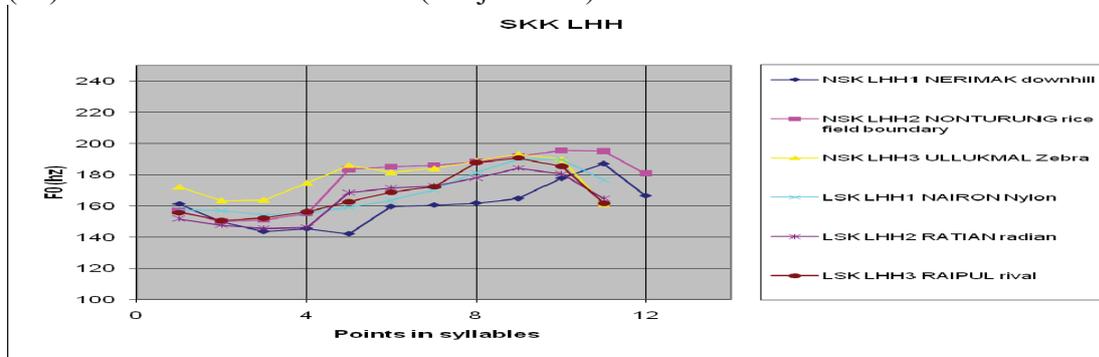

c. SKK HLL Tone Pattern (Subject SS3)

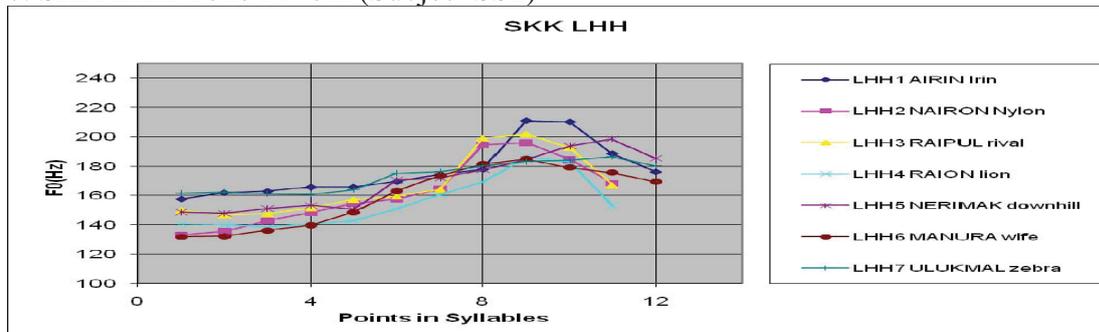

The third tone pattern that is shown in (11) is the LHH tone pattern of SKK. There are also graphs of three subjects for this tone pattern. Each graph of this tone pattern also shows the f0 contour of six different words.

(11) a. SKK LHH Tone Pattern (Subject SS1)

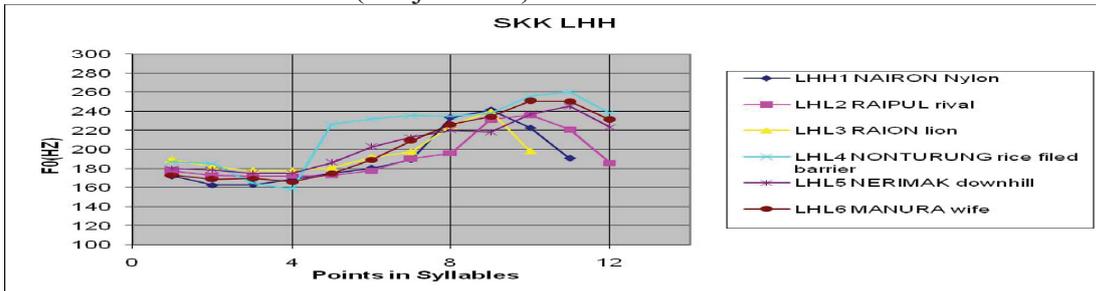

In graph (11a), the second syllable is higher than the first syllable and the third syllable is higher than the second syllable. The last part of the third syllable is falling. There is Low falling in the first syllables. Therefore, the tone type of the pattern is LHH\*(L) with initial Low register tone. The main accent is on the last syllable. We will see later, however, the graph shown here is different from the LLH tone pattern of NKK words. That is, here the second syllable sharply rises however in the LLH tone pattern of NKK, the L tone is sustained quite late before the rising part of the third syllable (so called late rising). The following two graphs of other two SKK subjects show similar patterns even though the height distinction between the first syllable and the second syllable in second subject (SS2) in (11b) is not dramatically distinguishable comparing to the first subject (SS1) in (11a).

b. SKK LHH Tone Pattern (Subject SS2)

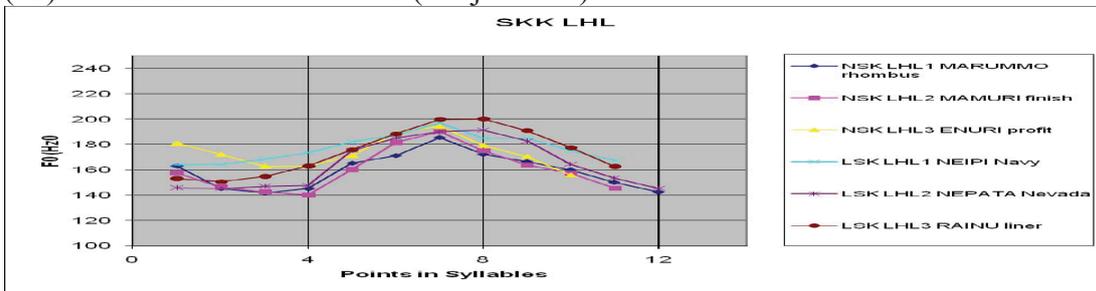

c. SKK LHH Tone Pattern (Subject SS3)

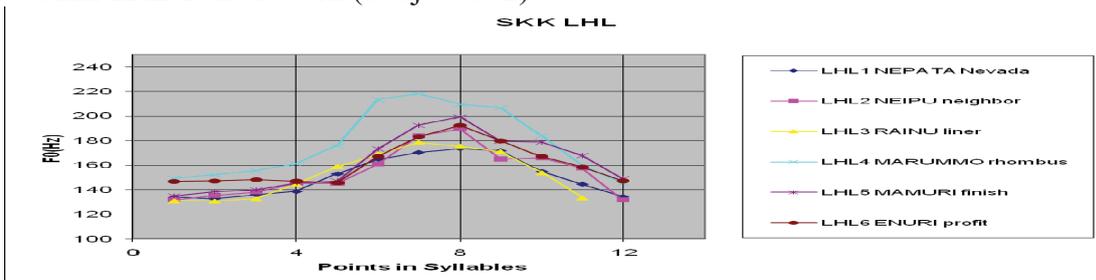

The last tone pattern in (12) is the LHL tone pattern of SKK. There are also graphs of three subjects for this tone pattern. Each graph of this tone pattern also shows the f0 contour of six different words.

(12) a. SKK LHL Tone Pattern (Subject SS1)

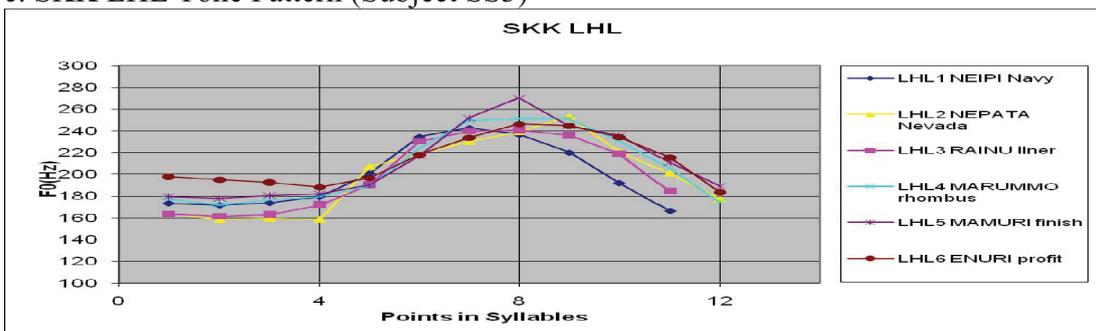

In graph (12a), the first syllable is Low (falling) and the second syllable is rising from the end of the first syllable. The final syllable is falling after a little late peak. Therefore, the accent type is H\*L with the initial Low register tone. The following two graphs of other two SK subjects show similar patterns even though the initial L falling is little weaker in the second subject (SS2) in (12b) comparing to other two subjects.

b. SKK LHL Tone Pattern (Subject SS2)

c. SKK LHL Tone Pattern (Subject SS3)

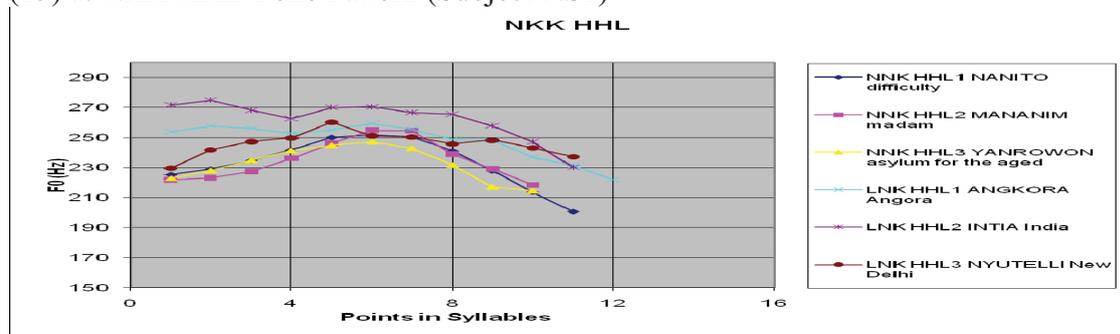

From the above data, we can summarize the general characteristics of SKK tone patterns as follows. The accent type of SKK H tone is H\*+L with two initial register tones (H and L). The accent type H\*+L shows the late peak as well as the falling after the peak pitch. The late peak exists in the beginning of the following syllable after the peak pitch. The Low register tone can be judged from the Low falling in the first syllable and the H register tone can be judged from the relatively high f0 frequency of the H tone in the first syllable comparing to the pitch peak. That is, unlike NKK initial H of the HHL tone pattern, SKK HHL tone pattern shows an almost level f0 trajectory in the first two H tones of the pattern. This is why we judge the register H tone in the first syllable rather than only one H\* on the second syllable (We will compare this case later to NKK patterns). The vowel effect shows that the initial syllables starting with vowels have higher f0 frequency than those with consonants. In the next part, we will see North Kyungsang Korean words. NKK shows somewhat different tone patterns from SKK.

#### 4.2.2. North Kyungsang Korean (NKK)

##### 4.2.2.1 NKK trisyllabic words

The first tone pattern in (13) is the HHL tone pattern of NKK. There are also graphs of three subjects for each tone pattern in this KS dialect in all the following data representation. Each tone pattern graph basically shows the f0 contour of six different words. Each syllable in every word has four measuring points. The syllable deviation is represented by the vertical grid lines in all the following graphs.

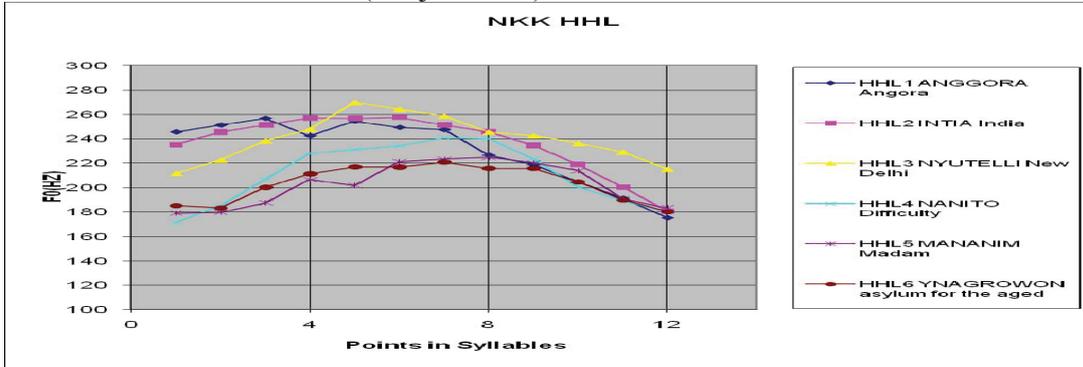

(13) a. NKK HHL Tone Pattern (Subject NS1)

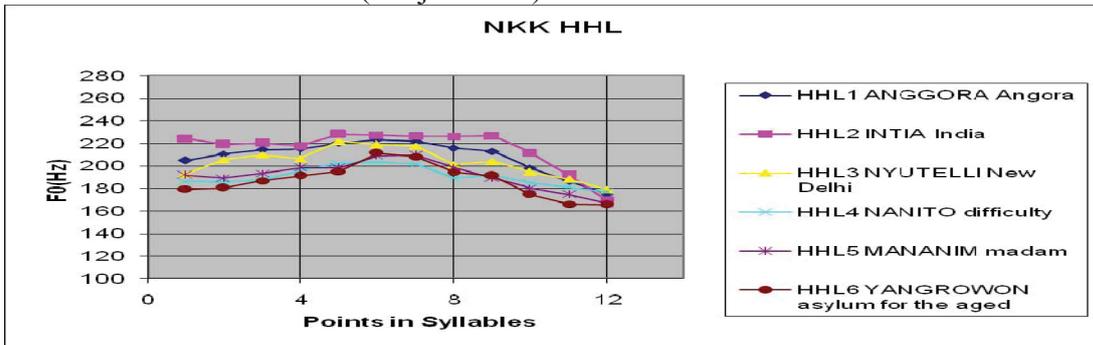

In graph (13a), the vowel (or consonant) effect is observed. The first points of two loanwords (ANGKORA [aŋ.ko.ra] ‘angora’ and INTIA [in.ti.a] ‘India’) are higher in the pitch than the consonant initial words like NYUTELI [nju.tel.li] ‘New Deli’. The second syllable is higher than the first syllable so the main accent is on the second syllable. The late peak remains in the beginning of the third syllable and the peak is interpolated to the final point. There is a difference between the native SKK HHL tone pattern in (9) and this graph. In (9) the transition from the first syllable to the second syllable pick is somewhat flat, but here the transition trajectory shows a slightly rising curve. Therefore, in SKK HHL tone pattern, the first H tone is interpreted as a register H. However, in NKK HHL tone pattern, the first H tone is not interpreted as a register H tone because of the rising transition from the first syllable to the second peak syllable. This means that the accent type of NKK HHL tone patterns is H\* on the

second syllable. The following two graphs of other two NKK subjects show similar patterns even though the rising curve from the first syllable to the second syllable in the third subject (NS3) in (13c) is not as enhance as in other two subjects.

b. NKK HHL Tone Pattern (Subject NS2)

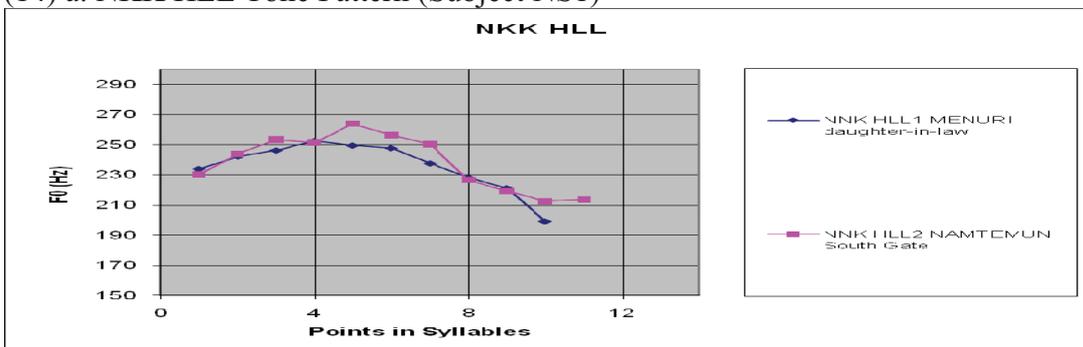

c. NKK HHL Tone Pattern (Subject NS3)

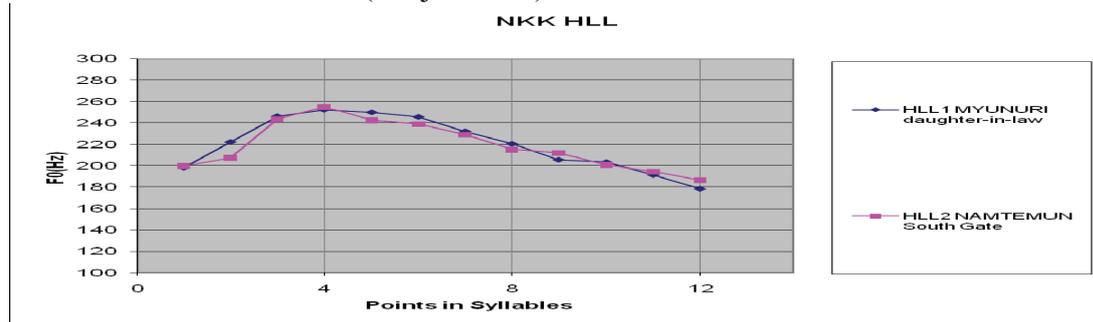

The second tone pattern in (14) is the HLL tone pattern of NKK. There are also graphs of three subjects for this tone pattern. Each graph of this tone pattern shows the tonal representation of two different words because of the lack of proper words for recording.

(14) a. NKK HLL Tone Pattern (Subject NS1)

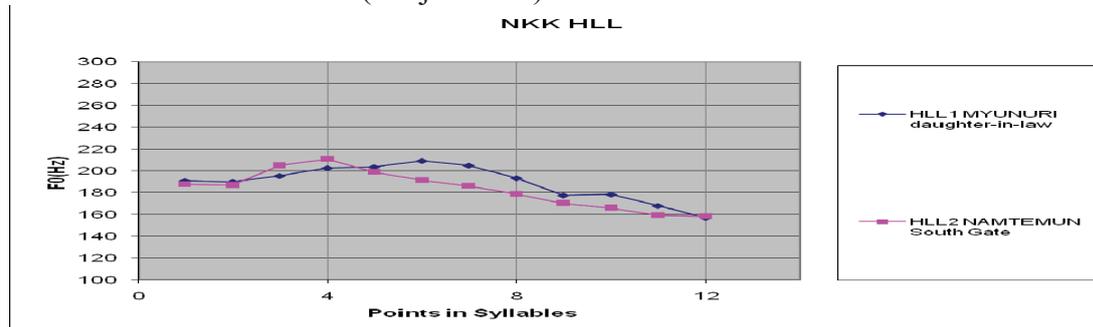

In graph (14a), the first syllable has an H tone. The late peak is shown in the beginning of the second syllable as in the SKK forms. The accent type is H\*. The following two graphs of other two NKK subjects show similar patterns even though the rising curve from the first syllable to the second syllable in the third subject (NS3) in (14c) is not as enhance as in other two subjects.

b. NKK HLL Tone Pattern (Subject NS2)

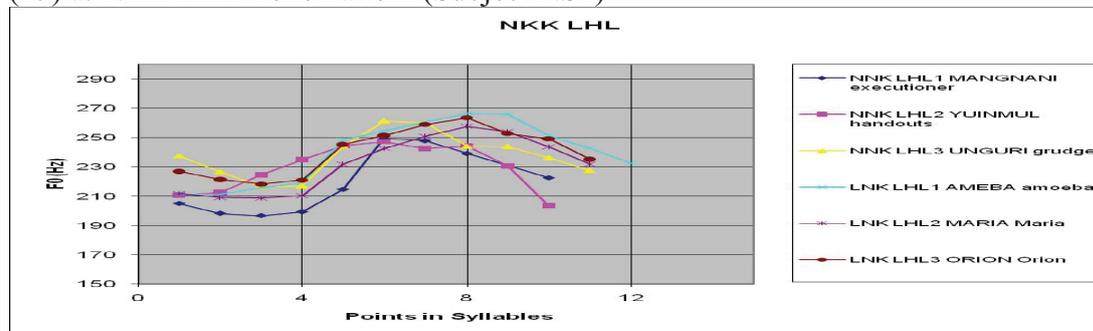

c. NKK HLL Tone Pattern (Subject NS3)

The third tone pattern shown in (15) is the LHL tone pattern of NKK. There are also graphs of three subjects for this tone pattern. Each graph of this tone pattern also shows the f<sub>0</sub> contour of six different words.

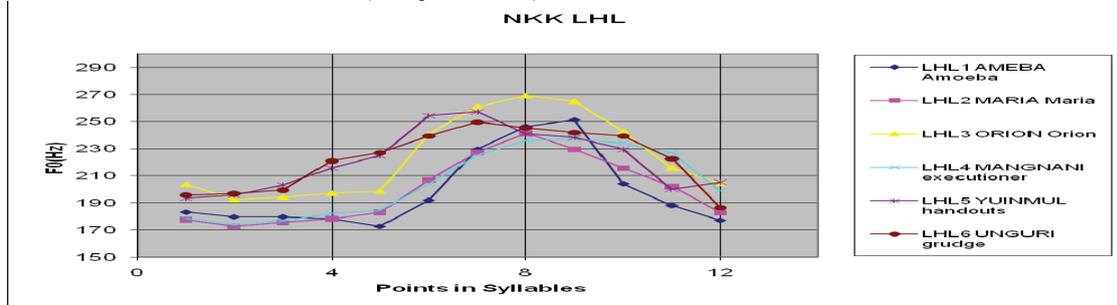

(15) a. NKK LHL Tone Pattern (Subject NS1)

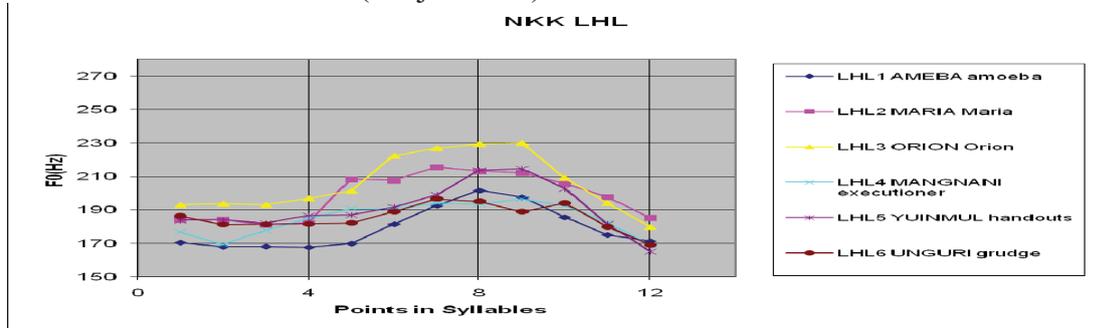

In graph (15a), the second syllable has an H tone. However, the L tone part preceding the accent is quite delayed to the beginning part of the second syllable before rising comparing to the native SKK LHL data in (12) (except for the word YUINMUL [ju.in.mul] ‘handouts’). Therefore, the accent type of NKK LHL tone pattern is L+H\*. This is somewhat surprising result because SKK has only one accent type (H\*+L) with two initial register tones (H and L) but NKK shows two different types of accent as H\* and L+H\*. The late peak effect is maintained for almost half of the last syllable in the words MARIA [ma.ri.a] ‘Maria’ and ORION [o.ri.on] ‘Orion’. There is no deep fall after the pitch accent L+H\* in the third syllable. This is a just interpolation from the peak to the last part of the words. The vowel effect is also observed. The following two graphs of other two NKK subjects show similar patterns even though the rising curve

from the first syllable to the second syllable in the third subject (NS3) in (15c) is not as enhance as in other two subjects.

b. NKK LHL Tone Pattern (Subject NS2)

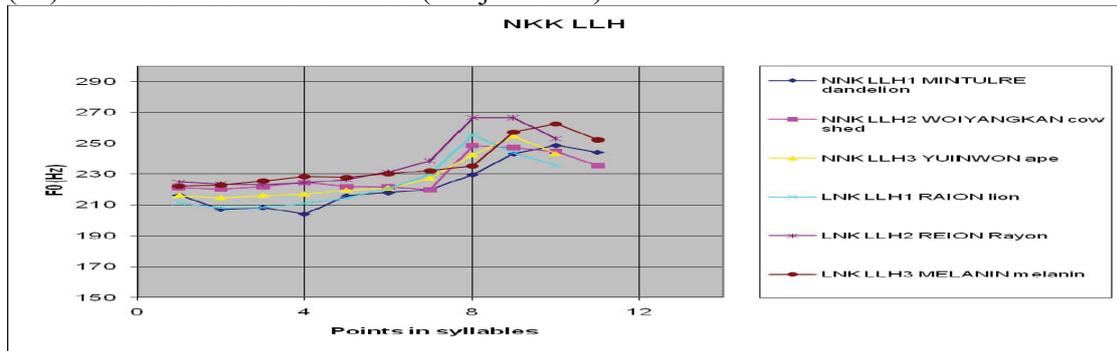

c. NNK LHL Tone Pattern (Subject NS3)

The last tone pattern in (16) is the LLH tone pattern of NKK. There are also graphs of three subjects for this tone pattern. Each graph of this tone pattern also shows the f0 contour of six different words. One thing to keep in mind for the analysis of the following graph (16a) is that most words end either at the tenth or at the eleventh point. This means that the second syllable of the words starts from either the sixth or at the seventh point, not from the eighth point.

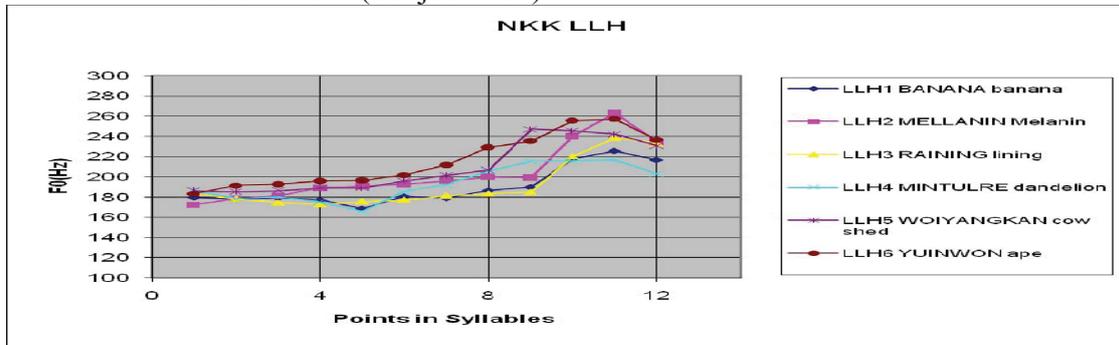

(16) a. NNK LLH Tone Pattern (Subject NS1)

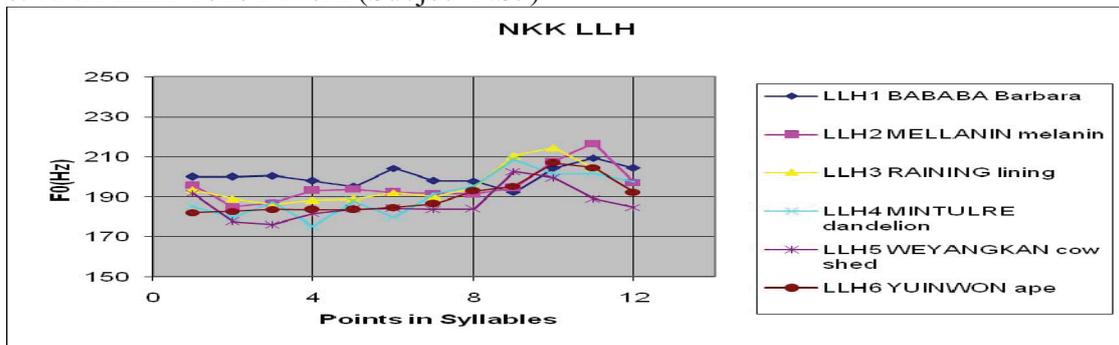

In graph (16a), unlike the LHH tone pattern in SKK, the second syllable is Low and the third syllable is a high tone. The High peak remains in the last part of the third syllable. The fall is not that deep in the last part of the final syllable compared to SKK LHH words in (12). There is a low plateau in the first two syllables and the rising is quite delayed. Therefore, the accent type is L+H\*. The observations from the above data show that the accent types of NKK are two different kinds: L+H\* and H\*.

it does not seem that there are register tones as High or Low in word initial position in NKK. The following two graphs of other two NKK subjects show similar patterns even though the rising from the second syllable to the third syllable in the third subject (NS3) in (16c) is not as enhance as in other two subjects.

b. NNK LLH Tone Pattern (Subject NS2)

c. NNK LLH Tone Pattern (Subject NS3)

From the above NKK data, we can summarize the general characteristics of the NKK tone patterns as follows: There are two accent types in NKK as H\* and L+H\*. The accent type H\* shows the late peak as well as the interpolation after the peak pitch. The late peak exists in the beginning of the following syllable after the peak pitch. The H tone before this accent H\* in the HHL tone pattern cannot be judged as a register H tone because there is rising transition from the first H to the following pitch peak H\*. This is different phenomenon from SKK HHL tone pattern as we saw before. That is, in SKK HHL tone pattern the first two H tones show a plateau thus the first H tone is judged as a register H tone. The initial L tone preceding the peak pitch in NKK LLH and LHL tone patterns, unlike SKK LHH and LHL, shows delay before rising to the following H tone. This delay of Low tone before rising to the pitch peak can be judged as the accent type L+H\* instead of the initial L register tone before an accent H\*. That is, unlike the SKK tone pattern, NKK shows two tone types without any initial register tone. The vowel effect shows that the vowel initial syllables have higher f0 frequency than consonant initial ones.

So far, we looked over the data result of SK tone patterns and we can see the constancy in tonal representation of each word in all the subjects of both KS Korean dialects. In the following section we will summarize the result and analyze the tone patterns in terms of typological categorization.

## 5. Analysis

In this section, we argue that KS Korean is a pitch accent language based on our experimental data result. First, we can summarize the overall accent type of the SKK words. Analyses for di- and quadrisyllabic words are also the same as trisyllabic words (We do not provide the analyzed data here).

(17) The Accent Pattern of SSK Tones ( $\sigma$ : Syllable)

			1 <sup>st</sup> $\sigma$ accent	2 <sup>nd</sup> $\sigma$ accent	3 <sup>rd</sup> $\sigma$ accent	4 <sup>th</sup> $\sigma$ accent
2 $\sigma$ words	Register tones	H		HH*(L)		
		L		LH*(L)		
	None		H*L			
3 $\sigma$ words	Register tones	H		HH*L		
		L		LH*L	LHH*(L)	
	None	None	H*LL			
4 $\sigma$ words	Register tones	H		H H*L L	HH H*L	
		L		L H*L L	LH H*L	LHH H*(L)
	None	None	H*L LL			

In table (17), the accent type of SKK is H\*L with two register tones: H and L. The height of the other syllables except for these accented syllables is somewhat predictable. In SKK, like Japanese, the syllable height right before the accented syllable is High: LHH\*(L). The syllable height after the accented syllable is Low: H\*LL, LH\*LL,... etc. And these additional tones can be gotten through interpolation.

This is against Lee's (1997) argument of the unpredictability of KS tones as mentioned in (4). From the careful examination of the current data result of both SK dialects, we can say that the typological category of SKK seems to fit a pitch-accent language rather than a tone language. That is, as we can see in the SKK data, like Japanese, the height of the non-accented syllables in SKK words is predictable. That is, the height of the syllables following the accented syllable is Low tone and that preceding the accented syllable is High tone.

As a consequence, this shows the syntagmatic movement of the accent (H\*+L) from the first syllable to the last syllable and a representative pattern of a pitch-accent language like Japanese. Therefore, we can claim that the South Kyungsang Korean is a pitch-accent language with two initial register High and Low tones. SKK tone patterns are similar to Kyoto (Kansai) Japanese that has register tones as well as accent tones. However, we will not discuss the comparison of the two languages here.

Now let us consider the accentual pattern in North Kyungsang Korean words.

(18) The Accent Pattern of NKK Tones ( $\sigma$ : Syllable)

		Accent Type	1 <sup>st</sup> $\sigma$ accent	2 <sup>nd</sup> $\sigma$ accent	3 <sup>rd</sup> $\sigma$ accent	4 <sup>th</sup> $\sigma$ accent
2 $\sigma$ word	H*		H*L	HH*		
	L+H*			L+H*		
3 $\sigma$ words	H*		H*LL	HH*L		
	L+H*			L+H*L	LL+H*	
4 $\sigma$ words	H*		H*LLL	H H*LL		
	L+H*			L+H*LL	LL+H*L	LLL+H*

In table (18), NKK has two types of accent patterns (H\* and L+H\*) and this also shows a syntagmatic movement of the accents from the first syllable to the last syllable in the

words. The tones following the pitch accent are Low tones and the preceding tones of the H\* accent type are High tones and those of the L+H\* accent type are Low tones. The height of the syllables other than an accented one is also predictable. Therefore, we can also claim that North Kyungsang Korean is a pitch-accent language with two types of accent: H\* and L+H\*.

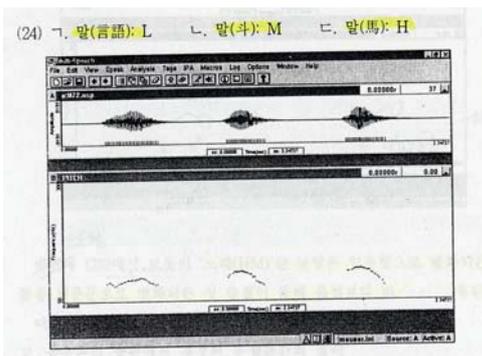

## 6. Other Considerations about KS Tone Patterns

In this section, we will discuss the typological issue of KS Korean regarding to the comparison of the traditional works and the present study. We argue that KS Korean is a pitch-accent language unlike the assumption of the previous works. Let us recall the previous arguments about this issue. Lee (1997) and Gim (1994, 1998) argue that KS Korean is a tone language. The reasons of the argument are mainly because, first, KS Korean has three distinctive tones as High (H), Mid (M) and Low (L). And second, each tone is assigned on each syllable in a word paradigmatically so the height of the syllables in a word is unpredictable unlike Japanese. Lee (1997) provides the f0 contour outcomes as the evidence of the existence of the M tone in KS Korean as shown in (19).

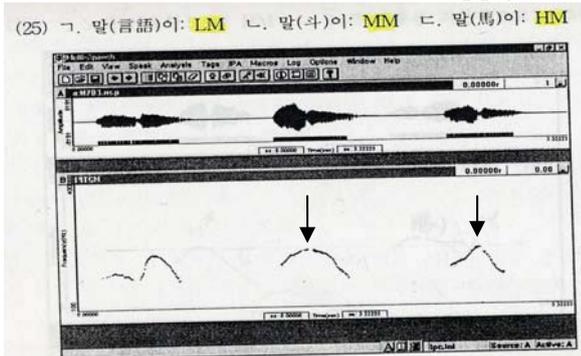

From now on we will argue two main reasons against the traditional assumption that KS Korean is a tone language typologically: First, the existence of M tone and second the unpredictability of non-high toned syllables. First, we discuss the three main reasons why we are against the argument of the M tone existence. First, let us examine the Lee's (1997) f0 contour data:

- (19) The Tone Patterns of South Kyungsang Korean (In the following two pictures, from left to right, the L tone word is [mal] 'language', the M tone word is [mal] 'a measuring unit' and the H tone word is [mal] 'horse' respectively. And both the pictures are a little bit tilted to the upper right side in the process of scanning).

a. F0 Contour of L, M, and H

b. F0 Contour with nom. suffix '-오' [i] (M tone)

Actually as we can see in the above two pictures (19a, b), there seems to be no difference in the peak height between the M tone and the H tone in the two pictures. The height difference between M and H tone in (19a) looks smaller than the difference between the initial consonant pitch and the initial vowel pitch that shown in the data result of the current experimental study.

Lee (1997) also argues when the words have suffix '-오' [i] as shown in (19b) the difference between the M and H tone becomes more distinguishable but there seems to be no clearly enhanced differences between them in (19b). For instance, the height of

M tone looks more similar with the height of H tone in **M+M** and **H+M** tone pattern even after the suffixation of [i]. That is, the height of M tone (represented as an arrow) in the word (**MM**) ‘**a measuring unit**+suffix [i]’ looks same as (or even higher than) the height of H tone (represented as an arrow) in the right most word (**HM**) ‘**a horse** +suffix [i]’. Therefore, we can assume that the M tone in the word “**a measuring unit**+suffix [i]’ (**MM**) is simply a High tone. Some KS native speakers may listen to the difference between M and H tone. However, this may happen because the difference of perceptual height of M and H may come from the relationship between the height of the preceding noun and the following suffix. For instance, in the prosodic word ‘a measurement unit (**M**)+suffix [i] (**M**)’, the height of the noun ‘a measurement unit’ [mal] and the suffix [i] is same (flat f0 contour) but in the word ‘horse (**H**)+suffix [i] (**M**)’, the height of the noun and that of the suffix are different (falling f0 contour). This difference may cause the perceptual differences (most Native KS speakers actually do not distinguish the difference between H and M tone in perception of quotation forms: Choi 1998, Kim 1991, 1994) between the heights of the two nouns with the suffix. However, this does not entail that the heights of the two nouns are actually in the different height category as lexical H and M tone. Therefore, we can argue that there is no M tone in KS Korean and this argument can be supported by the fact that the native speaker of KS Korean actually cannot distinguish the difference between the height of M and H tone in perception.

Second reason why we argue against the M tone existence comes from the data that Lee (1997) and Gim (1994, 1998) provides. They showed MH and LM tone words in their data, however, no LH tone pattern words are provided in their disyllabic word data. That is, only LM and MH but no LH tone pattern words are provided in the data. This shows the poverty of three way contrasts in disyllabic tone patterns. Therefore we can think that the M tone in their data is actually one of H or L tone. The possible output tone patterns would be ideally 27 different patterns with H, M and L three tone based analysis in the trisyllabic words ( $3 \times 3 \times 3 = 27$ ). However, the tone patterns of SKK trisyllabic words are only four in term of two tone, H and L, based analysis. Therefore, it is not easy to believe that the underlyingly specified tone patterns in SKK trisyllabic words may have 27 different types.

Third, let us consider the vowel (consonant) effect that we observed in our current data result. As we can see in the current data, it is a segment effect that may affect the perception of the tonal interpretation of a few very sensitive listeners. That is, the words with initial vowel sound mostly higher than the words with initial consonant do in terms of pitch (F0). Therefore, there is a possibility that the vowel initial words may be misjudged as M (or H) comparing to the consonant initial words (L or M). That is, the same LH tone pattern words may be heard as LM tone or MH tone patterns according to the initial segment effect of the words. The very important notation about the tonal perception and categorization is that the word initial segment may affect the perception of the pitch differences.

Now we argue against the second reason of the assumption that KS Korean is a tone language typologically, which is the unpredictability of tonal assignment in each syllable in KS Korean words (Lee 1997). Our current data shows that the highest KS pitch is an accent and the height of the other non-accented syllables is somewhat predictable unlike Lee’s (1997) argument. In SKK, the pitch accent is H\*+L and the height of syllables following the pitch accent is L and that of syllables preceding the

pitch accent is H except for the two initial register tones (L or H). Unlike Lee's (1997) claim, this shows that only one accent is assigned in only one syllable and the height of the other syllables than accented one is somewhat predictable in KS Korean words. The register tones are lexically specified so they are unpredictable (contrastive).

From this aspects, we can think that SKK is similar with the Kyoto (Kansai) Japanese (Western Japanese dialect) in terms of the existence of the initial register tones and the syntagmatic movement of the pitch accent H\*+L (see McCawely 1970 for Kansai Japanese cases). And NKK is typologically similar with the Tokyo (Kanto) Japanese (Eastern Japanese dialect) in terms of the pitch accents without the initial register tones. However, NKK is also similar with Swedish in terms of the two different accents and positional contrastive accents.

The prosodic typology of the KS Korean, therefore, can be summarized as in (20):

(20) Prosodic Typology of KS Korean (c.f. de Jong, 2006)

	With Tone	Without Tone
Accent-position contrast (Lexical contrast)	Swedish <b>North Kyungsang Korean</b> <b>South Kyungsang Korean,</b> Kyoto (Western) Japanese	English Tokyo (Eastern) Japanese
Accent non-position contrast (No lexical contrast)	Cherokee	Hungarian
Non-accent language	Chinese	<b>Seoul Korean</b>

In table (20), the accent-positional contrast tone languages have accents as H\*+L, L+H\* or H\* as well as initial register tones as H or L. The accent-positional contrast no tone languages have only one tone (H\*+L) like Tokyo Japanese or no lexical tone like English. The accent non-positional contrast languages have predictable accent positions, that is, the accents are not lexically specified but fixed: Cherokee has two tones (H and L) and a predictable penultimate H accent as LH, LHL,...etc. and Hungarian has only an initial pitch accent. The non-accent no tone languages have no tonal prominence in word (lexical) level like Seoul Korean.

## 7. Conclusion

In this paper, we argued the three main points through the experimental data analysis of KS Korean tone patterns. First, the main accent position of KS Korean words that have two high tones in series. Second, the accentual structure and the characteristics of the tone patterns of KS Korean words, and third the typology of the KS Korean tone system. From the analyzed data, we could draw a conclusion that South Kyungsang Korean is a pitch accent language that has two word initial register tones (H and L) and a pitch accent (H\*+L). The location of the main accent shows a syntagmatic movement and the height of the other non-accented syllables is somewhat predictable. North Kyungsang Korean is also a pitch accent language. However, unlike the Southern dialect, it does not have register tones but has two different types of accent: L+H\* and H\*. However, it still shows the syntagmatic movement of the pitch accents in the words and the height of non-accented syllables is also predictable. Finally, we also came to know that the main accent of the KS Korean words having multiple H tones lies on the second H toned syllables.

For future research we would like to examine the segment (vowel or consonant) effects and the height effect of neighboring syllables including affixes in tonal perception of both native and non-native KS Korean speakers. And we also would like to examine whether the M tone really exists in the perception and production domain of native and non-native speakers of KS Korean.

## Notes

1. Tokyo Japanese and Kyoto Japanese actually show somewhat different characteristics. We will not discuss this here. Briefly, South Kyungsang Korean is similar to Kyoto (Kansai) Japanese rather than Tokyo Japanese.
2. There are actually variations in this tone pattern in NKK. However we do not discuss this here.
3. Only vowels and sonorants are measured for f0 contour.
4. In all the following graphs, NSK and LSK mean SK native and loanwords, and NNK and LNK mean NK native and loanwords.

## **Abstract**

Situated to the south-west of the German-speaking domain, the dialectal area of Alsace-Lorraine (Elsass-Lothringen) is distinguished by its variety: the extreme north-west is for instance « Luxemburgish » and the extreme south « Swiss », that is to say Mosel Franconian respectively High Alemannic. In order to delimitate dialect boundaries we only need to study the auxiliaries SEIN and HABEN (to BE and to HAVE) because they are omnipresent and above all the most frequent verbs of our language. Even if we know that dialect zones are never clearly definable by reason of the high dependence on the selected criteria, we can say that Middle Alsace is simultaneously Lower and Upper Alsace, but also a specific area. This article describes geographical, historical and cultural characteristics of this region and then concentrates on the dynamic forces illustrated by a systemic approach of all forms of SEIN and HABEN (SI and HA) as well as the development of the vowels and consonants, the formation of diminutives, syntactical and lexical peculiarities, morphology and use of the subjunctives and conditionals, prosody...

## **Professor Marthe Philipp**

First I have to pay tribute to Marthe Philipp, my colleague and friend, master and mentor. Because the fate decided to put the date of my presentation on the 24<sup>th</sup> of July 2008, I feel obliged to dedicate it to her. The reason is that Prof. Philipp would have been 86 years old on that day. Unfortunately she died one year ago, on July 15<sup>th</sup>, so that this great linguist could not cooperate in my present paper. Be that as it may, I seize the opportunity to remember who she was.

As a daughter of Alsace, her own destiny is a quite Alsatian one, particularly of a certain generation. So she had in 1940 to leave her country because of the French evacuation. The same year, the German-speaking pupil passed the « Baccalauréat » in the Normandie. In 1941 Marthe Philipp went back to Alsace which was now part of the third Reich. As an apolitical student, she used the situation to pass in her language the « Abitur ». One year later she inscribed at the « Reichsuniversität Strassburg » in order to study English, German, French and Italian. In 1944 the war made it impossible to keep on studying so that she had to wait till 1947 before she could begin new studies in the same town, but this time at a university which was now administrated by the French. Nevertheless the German language together with its dialects was and remained her passion.

In phonology she started from the « infinitely small », « Le système phonologique du parler de Blaesheim » (1965)<sup>1</sup>, to end up in the « infinitely great » in the German-speaking domain, namely « Phonologie de l'allemand » (1970)<sup>2</sup> which she translated four years later : « Phonologie des Deutschen »<sup>3</sup>.

The same year 1974 she published her meanwhile famous « *Que sais-je ? Grammaire de l'allemand* », revised and completed in 1980<sup>4</sup>.

Already co-author and in charge of the « Atlas linguistique et ethnographique de la Lorraine germanophone » (1977)<sup>5</sup>, she brought to completion the second Alsatian atlas « Atlas linguistique et ethnographique de l'Alsace »<sup>6</sup> – to which I contributed too – that came out in 1984 (year of birth of my daughter).

Well, all these works were « prematurely » systemic even though Marthe Philipp did not yet use this word. On the other hand, her last important book was it openly : « Semantik des Deutschen » (1998)<sup>7</sup>, what she explains at the beginning of the second chapter whose subtitle was just « Semantik und Systemik » (p. 57).

Therefore I can say that I was very lucky to meet this « Lady » 36 years ago at the University of Strasbourg, a Lady who was to supervise my master degree<sup>8</sup> (1981) and my thesis<sup>9</sup> (1988) in German dialectology.

## **Middle Alsace**

The subject of this article is another fruit of our 36 years old cooperation whose « crowning achievement » - she told it to a colleague - was the publication of « Sein und Haben im elsass-lothringischen Mundartraum. Ein organisiertes Chaos » (2002)<sup>10</sup>.

You can see on the map « Mundarttypen » (types of dialects) where Middle Alsace (Mittelsass) with its Middle Alsatian (Mittelsässisch) lies. At first sight it seems to be a transitional zone between « Unterelsässisch » (Low Alsatian) and « Oberelsässisch » (Upper Alsatian), an average of both. Or is it rather an original region with characteristic features ?<sup>11,12</sup>

Well, it depends on the angle, perspective, attitude, reference point, viewpoint and point of view of the observer, in short on the selected criteria. So the chosen premises are decisive – because only a moving approach is conceivable to apprehend dialects.

Thus, the Lower Alsatian from the Lower Rhine, Marthe Philipp, did not share the point of view, the field of vision, of the Upper Alsatian from Upper Rhine who writes these lines. They have gone naturally and (fuzzy) logically different ways which led to various perceptions about their meeting point « Middle Alsace » where they were regularly joining together. Indeed, this plot of ground separates as well as it puts together, it is a kind of midfield, therefore difficult to delimit and to define.

A look at the map shows us among other things the wasp-waist of a slender region, a slim territory. That the most characteristic feature of the dialects in Middle Alsace is the loss of final –n seems to illustrate pertinently the « morpho-geographical reduction ». Is then Middle Alsace a neither-nor or an as-well-as ? A sort of  $67^{1/2}$  ? - 67 is the number that represents the administrative entity « département du Bas-Rhin (Basse Alsace) », 68 the « département du Haut-Rhin (Haute Alsace) ». Opinions are divided on that matter.

However, only field work can give us an answer, if at all. Already a look at the relief puts us on the right track because the first answer is geological. Originally there was here in the middle of Alsace the « Landgraben », a ditch with a stream, the « Eckersbach ». It was a marshland, that means hardly conducive to settlement. This unfriendly territory already separated the Germanic Triboker from the Celtic tribes about 2000 years ago, then the former Nordgau from the Sundgau, that is the north from the south, the diocese of Strassburg from that of Basle, the early counties of Lower from Upper Alsace, the « Bezirke » of the « Reichsland » before being confirmed by the current limits of the « départements ». So we have in the middle of Middle Alsace a very old (fold) natural boundary.

## **Middle Alsace : land of culture**

Heart, lung, core, we are not lacking in metaphors to designate this Rhenish fringe, memory of the eternal Alsace.

Let us remember the renowned Convent of the Odilienberg, situated in the north-west of our area, a world-famous place of Christian pilgrimage, dedicated to Otilie, the patron saint of Alsace.

A little further into the south, right in the middle of the plain stands the proud old town Schlettstadt, the heart of the Rhenish humanism in the 16<sup>th</sup> century where the humanist library of Beatus Rhenanus is to visit. Schlettstadt is also the country of three great humanists named Johannes Mentelin – the printer of the first Bible in German - , Martin Bucer, the reformer, Jakob Wimpheling, the historian and « praeceptor » of the German Nation of that time (das Heilige Römische Reich Deutscher Nation, the Holy Roman Empire).

However, the most famous son of this region is born a bit deeper into the south, namely in Kaysersberg in 1875. I mean the Protestant theologian, musicologist, organist specialist of Johann Sebastian Bach, philosopher and doctor, Albert Schweitzer, Nobel prize-winner for Freedom in 1952; he died in 1965.

## **Middle Alsatian and systemics**

The vernacular language is a real jewel. As a core of the popular memory it is quite tough and not easy to grasp. So I think that the only productive approach has to be systemic. By the way, what do I mean by « systemic »? Well, we all know that any natural linguistic system can only be open, complex, in a situation of homeostatic balance, based on an autoregulating continuum, taking part in different networks, linked one another in constant interrelations so that the observance of the researcher(s) is automatically plural and holistic. For in science(s) just like in life, all factors are connected : ebb and flow (yin and yang), input(s), throughput(s), output(s) elude each attempt and temptation of static analysis because the taken directions are generally unforeseeable. As for the influence of the observer on the so-called observed facts, it is too often underestimated. According to the postulated premises, to the adopted posture, it is obvious that the results will differ: undeniable facts which seriously relativize the allegedly scientific pretensions – and this in all sciences.

So in our area, the « Bewusstseinsgrenzen », that means the subjectively perceived boundaries which the speakers are conscious of, play an important part. For instance, we can ask ourselves from where onwards, referring to which criteria, basing upon which impressions, a North-Alsatian will feel « Mittelelsässisch » as something specific, different, even as « Oberelsässisch », that is to say « South-Alsatian » ? From where a « Low Rhiner » does think he is hearing Swiss German in his own country ? From where a « South-Alsatian » will regard his compatriot of Middle Alsace as someone who speaks strangely and oddly like those of the north ? When will he peremptorily baptizes him *Bäägser*? « Bäägser » is a typical nickname with which Alsatians tease one another, but only northwards. Therefore Mülhauser call Strassburger « Bääägser » because of a different lengthening of the stem vowels which sound in « southern ears » heavily overstressed, even ridiculous. But Strassburger use this « nice label » too when they deride their neighbours of north-west, the Lothringer, the latter keeping this epithet for the Luxemburger. So we have here to do with a symptomatic change of referent which goes for once in only one direction.

But « Alsatian », what is it actually ?

Certainly not South Rhine Franconian (Südrheinfränkisch) – see the map – the dialect spoken in the extreme north-east of Alsace in the region of Weissenburg (Weisseburich) and Selz with its « Bavarian » diphthongs unknown in Alemannic. Nevertheless, the natives claim to speak « Alsatian » even if some « real » Alsatians do assert : *S'isch ke Elsassisch, s'isch Ditsch !* (It's not Alsatian, it's German !)

And in this respect our Middle Alsace is complex, awfully complex.

About thirty years ago, a dialect band, « D'Stüdànte », natives of Ebersheim near Schlettstadt were called *Ewerländer* (« Upperlander », « Southern people ») respectively *Bäägser* depending on whether they were singing some kilometres further northwards or southwards.

No, really, our residents of the south of the « département du Bas-Rhin 67 » and of the north of the « département du Haut-Rhin 68 », our Middle (average) Alsatians are quite difficult to place, all the more so since there is no problem of linguistic intercomprehension, but a natural continuum. Let us go back now to the « hard » science:

## Linguistic analysis

For a long time, dialectologists have favoured traditional analysis which allowed from well-defined criteria, mainly the Second Sound Shift with its Rhenish Fan (Zweite Lautverschiebung und Rheinischer Fächer) and the New High German Monophthongization to draw clearly visible areas.

This method is not to devalue because it still gives rise to good results, in our case to a certain extent for what we named « Unterelsässisch » (Low Alsatian), a relatively homogeneous subdivision.

On the other hand, in Middle Alsace, a turbulent zone par excellence, we have to refine the reference system if we want to have a clear understanding of what occurs here. Therefore is the systemic approach, though more demanding, the only one which renders possible a certain organization of an apparent chaos – this is what we attempted to put into practice in our book of 2002<sup>10</sup>.

This time, we took our data again, but concentrated on Middle Alsace in order to locate the dynamic of the « flowing » of « Sein und Haben ».

How far may we say that we have to do with a transitional zone (Übergangslandschaft)? First, we note that the simple forms are replaced by doublet forms:

- 1) For both verbs: In the infinitive  
                                  In the first person singular  
                                  In the three persons plural
- 2) For « Sein » only: In the past participle

So the system hesitates, chaos sets in, at least seemingly, intermediate forms are used until, further in the south – when we come from the north – the paradigm is reorganised.

For our two verbs « Sein » (to be) and « Haben » (to have), *si(n)*, *hå(n)*, we notice that the influence of the north is not stronger than that of the south, according to the data collected in our 38 points of investigation situated in the middle of Middle Alsace. Only at the foot of the Vogesen and along the Rhine a few preferences may be detected. However, certain forms indicate sometimes different directions. For instance (*ich*) *håpp* (*ich* habe, I have) and (*mir*) *hånn* (*wir* haben, we have) are northern forms, whereas (*ich*) *hå(nn)* and (*mir*) *hann* are southern.

On the other hand, the forms without final *-n* are expressly Middle Alsatian (Mittellelsässisch): Infinitive *si, hå*

First person singular *bi, hå*

Plural *si, ha*

Past participle *gsi*

Only slowly, about twenty up to thirty km further southerly, Middle Alsace gives way to Upper Alsace with its Upper Alsatian (Oberelsässisch). The past participle of « Haben » (gehabt) *ghet* is replaced with *ghå*, an outstanding and striking isogloss which roughly coincides with the appearance of the first subjunctives I (present): *hai(k) hei(k)* (habe), *sei(k)* (sei).

So the last « buttresses » of the zone of influence of Strassburg are disappearing. We are going imperceptively (in continuity) from a system to another without any abrupt change.

Compared with Baden, the opposite region on the other side of the Rhine, Alsace is dialectally a little more « dynamic » on account of a left side which was much more frequented for centuries so that the (northern) Franconian influence penetrated deeper on this side of the Rhine, what caused a dialectal asymmetry between west and east with the linguistic consequence that Middle Alsace has a much more northern aspect than Middle Baden (« Rheinstaffelung », Rhine terrace-formation).

Of course, the dialectal continuum which we baptized « Mittellelsässisch » is not limited to a study of the most frequent verbs of our language. Therefore, before closing this paper, I would like to mention some peculiarities that demonstrate the abundance and luxury of this intermediate Alsatian, this original « go-between ».

### Other perspectives and views, other cases

As I already wrote it above, these dialects sound rapidly « southern » to speakers of the north of Alsace. One of the reasons is the development of vowels and consonants, first of all the final *-e* becoming nearly *-a*:

*måche* > *måcha* « machen » to make

*schlofe* > *schlofa* « schlafen » to sleep

Another reason is the lengthening of the open syllable:

*Nawwel* > *Naawel* « Nebel » mist

*redde* > *reedda* « reden » to speak

The change of the half-consonant *j* to the voiceless plosive *g*:

*Raaja* > *Raaga* « Regen » rain

*Mååja* > *Mååga* « Magen » stomach

Development of long vowels into diphthongs:

*klaan* > *klään* > *klein* > *klain* > *klai* with loss of final **-n**

Points of articulation of diphthongs differing:

*Frau* > *Fröu* > *Froi*

Transition of the palatal fricative « Ich-Laut » to velar « Ach-Laut » in all positions:

*Strich* > *Strich [x]* « Zitzen » teats

*Büch* > *Büch [x]* « Bauch » belly

Suffix with or without consonant or with another one:  
*glücklich* > *glickli* > *glicklig* « glücklich » happy  
*rumpflich* > *rumpfli* > *rumpfig* « runzelig » wrinkled

Just like for « Sein » and « Haben », the final *-n* has been gradually lost by all short verbs in the infinitive:

*sähn* > *sah* « sehen » to see  
*gehn* > *geh* « gehen » to go  
*lonn* > *lo* « lassen » to let  
*gänn* > *ga* « geben » to give

as well as by an increasing number of lexemes from north to south :

*Bein* > *Bai* « Bein » leg  
*Win* > *Wi* « Wein » wine

In grammatical morphology, the formation of the diminutives evolves too from north to south:

*Maidl, Meidl* (plural *Maidle*) > *Maidla* (plural *Maidler* in Colmar).

Further in the south, there is an only form for singular and plural (like in New High German « Mädchen, Mä(g)dlein ») girl :

*Maidla* (*Maidli* along the Rhine)

The synthetic subjunctive II (imperfect, preterite) occurs very often. In order to express the conditional, it frequently « carries » a redundant morphem *ikt*.<sup>9</sup>

*hatt* > *hattikt* « hätte » would have  
*wisst* > *wisstikt* « wüsste » would know  
*sott* > *sottikt* « sollte » should  
*kam(t)* > *kamtikt* « käme » would come

Typical of this area is in the same context the analytic phrase with *gat*, coming from subjunctive II of *ga* (see above) « geben »:

*Ich gat garn assa* (ich würde gern essen, I would like to eat) which corresponds in Mosel Franconian of Lothringen and Luxemburg to *ech géif gär iessen*, whereas the rest of Alsace together with practically the whole south of the German-speaking countries uses only *täte* (from « tun » to do):

*I tat garn assa.*

A propos South-Germany, it is in Middle Alsace too that speakers begin not to differentiate the infinitive from the past participle of the modal auxiliaries (preterite-present verbs):

*Des het'r gewellt* Low Alsatian and Northern Middle Alsatian « das hat er gewollt » he has wanted it (he wanted it) > *dås het'r wella* Southern Middle Alsatian and Upper Alsatian.

Finally, it is also in Middle Alsace that appears the reduplicating of an infinitive in order to insist on the movement and the intention:

*Ar kummt geh fähra* « er kommt fahrend » he is coming riding

*Ar geht geh schâffa* « er geht arbeiten, will arbeiten gehen » he is going to work. This sort of Alemannic phrases are widespread in South Alsace and Switzerland, not only with « gehen », but also with « kommen » (*s'kunnt ku ragna*) and « lassen » (*lâ(ss) mi lâ mâche !* Swiss German). They are not easy to translate.

## Epilog

I cannot bring this paper to an end before having shown how a child – torn between the north and the south – can be inventive. Starting from the perfect with past participle of the Low Rhine *ich hâb's ghet* « ich hab's gehabt » (I have had it, I had it), this four years old girl had added the past participle of the Upper Rhine *ghâ* in order to form a real grammatical hapax which was quite ingenious because it allowed to rig up an original distinctive pluperfect *ich hâb's ghet ghâ* instead of an agrammatical repetition:

*\*ich hâb's ghet ghet, \*ich hâ's ghâ ghâ* « ich hab's gehabt gehabt, ich hatte es gehabt) I had had it - another repetition (syncretic form) which is correct in English.

She simply generalized by drawing an analogy with the « normal » pluperfects (double perfects) like:

*Ich hâb's gemacht ghet* from her mother and

*Ich hâ's gmâcht ghâ* from her father

for « ich hab's gemacht gehabt, ich hatte es gemacht », I had made it.

This smart person was my daughter. As symbiosis of the Middle (Central) Alsace, the neat and dainty Elfi Weider was already 20 years ago putting in the centre of my reflections an imaginary and real dialectal zone which is so fascinating.

## Abstract

This paper examines the syntactic behavior of two omnisyndetic coordinations (also called *correlative coordinations*), i.e. the disjunctive and the conjunctive types in Romanian, by explaining its data in a Romance perspective. Major issue has been whether these structures have symmetric or asymmetric structures. If all these Romance languages share a symmetric analysis for the disjunctive type Conj...Conj, it is not the case for the conjunctive type. Our aim is to show that the postulation of a conjunctive status for the Romanian structure *și...și* ('both...and'), which is the most widespread view in Romanian grammars, is inadequate for the Romanian data.

**Keywords:** simple / omnisyndetic / asyndetic coordination, disjunction, conjunction, Romance.

## 1. Introduction

In the literature on coordination phenomenon (see Haspelmath (2000), Huddleston and Pullum (2002), among others), one may find three main types of coordinate structures, with regard to the presence / the lack of the coordinator: i) *simple coordination*, when the coordinator appears with the last (or first, for head-final languages) conjunct, and optionally with the other conjuncts (except the first one), cf. (1a-b); ii) *omnisyndetic* or *correlative coordination*, in which the coordinator seems to appear on each conjunct, cf. (2a-b), and, finally, iii) *asyndetic coordination*, when it is not overtly marked by a coordinator, but it is achieved by means of juxtaposition, cf. (3a-b).

- (1) a. *Paul a appris [l'espagnol **et** le français].* (French)  
b. *Paul has learnt [Spanish **and** French].* (English)
- (2) a. *Paul a appris [**et** l'espagnol **et** le français].* (French)

- b. *Paul has learnt [both Spanish and French].* (English)
- (3) a. *Paul parle [l'espagnol, le français, l'anglais].* (French)  
 “Paul speaks Spanish, French, English”  
 b. *John invited [all his colleagues, all his students].* (English)

In this paper, we focus on the second type, the omnisyndetic structures, which a priori are more constrained than simple coordinations (cf. Mouret (2007), Mouret *et al.* (2008)). The restrictions operating on correlative coordinations include almost all levels of linguistic analysis: they concern syntactic, semantic, discursive and prosodic aspects. At the syntactic level, they are restricted with respect to the categories they conjoin, i.e. they conjoin maximal projections, but not words. From a semantic point of view, they accept only a Boolean reading. Let's take two examples in French (a priori available for other languages, too). If there is a conjunction of propositions, the conjunction *et* ('and') is ambiguous between a collective or distributive reading in simple coordination (4a), while it has only distributive reading in omnisyndetic structures (4b). We observe the same difference in the case of the disjunction of propositions: the conjunction *ou* ('or') has an inclusive or exclusive reading in simple coordination (5a), whereas in correlative structures, only the exclusive interpretation is available (5b).

- (4) a. *Paul et Marie se sont mariés.*  
 “Paul and Mary married (together or not)”  
 b. *Et Paul et Marie se sont mariés.*  
 “Both Paul and Mary married (not together)”
- (5) a. *Paul ou Marie viendront / viendra à la fête.*  
 Paul or Mary come.3pl/sg.FUT to the party  
 “Paul or Mary will come to the party”  
 b. *Ou Paul ou Marie viendra à la fête.*  
 Either Paul or Mary come.3sg.FUT to the party  
 “Either Paul or Mary will come to the party”

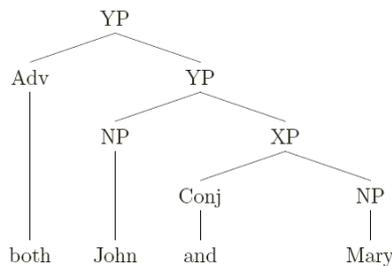

Finally, omnisyndetic coordination obeys a prosodic and discourse-related constraint, each conjunct being emphasized and forming an intonational phrase. These structures are compatible with focus and topic, but the relation involved by the doubled constituent obligatorily receives a contrastive interpretation.

Representative pairs we are concerned with in this study are the disjunction *either...or* and the conjunctive type *both...and*.<sup>1</sup> Cross-linguistically, there are two main structures proposed in the literature:

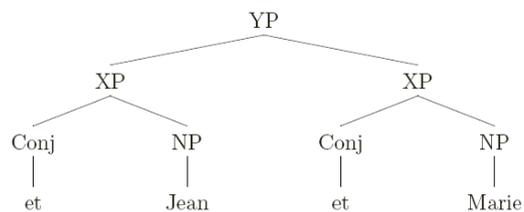

a. an asymmetric structure A (cf. (6a)), available for Germanic languages (such as English, German or Norwegian) (cf. Johannessen (2005), Hendriks (2004), Hofmeister (2008)), where the initial element of the structure is a Focus Particle (with relatively free distribution, restrictions by focus and intonation, scopal effects), modifying the whole coordination, thus the term *initial coordination*.

b. a symmetric structure B (cf. (6b)), available for French (cf. Piot (2000), Mouret (2005) and Mouret (2007)) and for Romance languages more generally (and a priori for Japanese and Korean), where all coordinators represent the same conjunctions combining with each conjunct, hence the term *conjunction doubling*.

(6) a. Asymmetric Structure A

b. Symmetric Structure B

Some languages use both structure A and structure B; for example, French has two different structures for the additive coordination: an asymmetric structure *à la fois...et* (7a) and a symmetric construction *et...et* (7b).

(7) a. *Jean lit [à la fois [en français et an anglais]].*

“John reads both in French and in English”

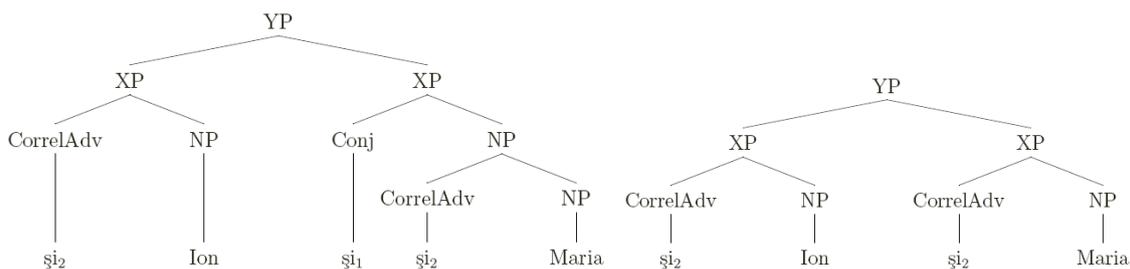

b. *Jean lit [[et en français] [et en anglais]].*

“John reads both in French and in English”

A superficial Romance overview may suggest a common analysis for all Romance languages, i.e. a symmetric structure. Romanian data show that we have to handle a hybrid case: a symmetric structure B for the disjunction type (cf. table 1), whereas for the ‘additive coordination’ we have two possibilities: an asymmetric structure with conjunction (C<sub>1</sub>, cf. (8a)) or a symmetric one without conjunction (C<sub>2</sub>, cf. (8b)), in both cases the correlative elements behaving like adverbials.

(8) a. Correlative Structure C<sub>1</sub>

b. Correlative Structure C<sub>2</sub>

The paper is structured as follows: In Section 2, we briefly mention the main distributional properties in Romance languages, and contrast French and Italian vs. Spanish and Romanian. In Section 3, we argue that, contrary to most Romanian grammars, Romanian elements *și...și* ('both...and') are (correlative) adverbs, rather than conjunctions. At the end of this section, we propose a revisited analysis of correlative coordination in the four Romance languages.

## 2. Main properties of the correlative coordination in Romance

### 2.1. Forms of the coordinators

**Table 1. Correlative coordinators of four Romance languages**

	<b>French</b>	<b>Italian</b>	<b>Spanish</b>	<b>Romanian</b>
<b>Disjunction Type</b>	<i>ou...ou</i> <i>ou bien...ou bien</i> <i>soit...soit<sub>c</sub></i> <i>soit que...soit que<sub>c</sub></i>	<i>o...o</i>	<i>o...o</i>	<i>sau...sau</i> <i>ori...ori</i> <i>fie...fie<sub>c</sub></i>
<b>Conjunctive Type</b>	<i>et...et</i> <i>à la fois...et</i>	<i>sia...sia<sub>c</sub></i> <i>sia...che<sub>c</sub></i>	<i>*y...y</i> <i>a la vez...y</i>	<i>și...și</i>

The index c in the left indicates that the form is always used in correlative structures.

A quick look at the table 1 shows that Spanish seems special, since it lacks the correlative pair *\*y...y* (9d).<sup>2</sup> A superficial examination of (9) would conclude that Romanian resembles French and Italian, but not Spanish.

- (9) a. *Et Jean et Marie sont venus à la fête.* (French)  
 b. *Sia Gianni sia Maria sono venuti alla festa.* (Italian)  
 c. *Și Ion, și Maria au venit la petrecere.* (Romanian)  
 d. *\*Y Juan y Marìa han venido a la fiesta.* (Spanish)

“Both John and Mary came to the party.”

Nevertheless, the structure *și...și* significantly differs from its counterparts, as shown by the empirical arguments mentioned in the section 3.

## 2.2. Properties of the coordinators<sup>3</sup>

If we look at the distribution of correlative items in these four languages, we observe at least three common properties. First of all, correlative items join phrasal categories such as NP (10-11-12-13a), PP (10-11-12-13b) or AP (10-11-12-13c) in all these languages.

(10) F a. *J'ai vu {soit / et} Jean {soit / et} Marie.*

“I saw {either / both} John {or / and} Mary”

b. *Je vais {soit / et} en Corée {soit / et} au Japon.*

“I’m going {either / both} to Korea {or / and} to Japan”

c. *Il est {soit / et} beau {soit / et} intelligent.*

“He is {either / both} beautiful {or / and} smart”

(11) I a. *(Io) ho visto {o / sia} Gianni {o / che} Maria.*

“I saw {either / both} John {or / and} Mary”

b. *(Io) vado {o / sia} in Corea {o / sia} in Giappone.*

“I’m going {either / both} to Korea {or / and} to Japan”

c. *(Lui) e {o / sia} bello {o / che} intelligente.*

“He is {either / both} beautiful {or / and} smart”

(12) S a. *(Yo) he visto o a Juan o a María.*

“I saw {either / both} John {or / and} Mary”

b. *(Yo) voy o a Corea o a Japón.*

“I’m going {either / both} to Korea {or / and} to Japan”

c. *(Él) es o guapo o inteligente.*

“He is {either / both} beautiful {or / and} smart”

(13) R a. *Maria adoră {fie / și} proza, {fie / și} poezia.*

“Maria adores {either / both} prose {or / and} poetry”

b. *(Eu) voi merge {fie / și} în Coreea, {fie / și} în Japonia.*

“I will go {either / both} to Korea {or / and} to Japan”

c. *(El) este {fie / și} frumos, {fie / și} inteligent.*

“He’s {either / both} beautiful {or / and} smart”

As an additional remark, one may say that, inside the VP, the correlative coordination is more complicated, since the distributions of correlative items and speakers’

acceptability vary cross-linguistically.<sup>4</sup>

Secondly, examples (14-15-16-17) show that such correlative items can also join embedded clauses:

(14) F a. *Paul s' imagine soit que Jean n'est pas là soit que Marie le cache.*

“Paul thinks either that John is not here or that Mary hides him”

b. *Raconte-moi soit ce que tu as lu à la maison, soit ce que tu as appris à l'école.*

“Tell-me either what you read at home or what you learnt at school”

c. *Je propose et que Jean vienne et que Marie le cache.*

“I propose both that John come and that Mary hide him”

(15) I a. *Paolo pensa o che Gianni non c'è o che Maria lo nasconde.*

“Paul thinks either that John is not here or that Mary hides him”

b. *Raccontami o quello che (tu) hai letto a casa o quello che (tu) hai imparato a scuola.*

“Tell-me either what you read at home or what you learnt at school”

c. *(Io) propongo sia che Gianni venga sia che Maria lo nasconda.*

“I suggest both that John come and that Mary hide him”

(16) S a. *Pablo se imaginaba o que Juan no estaba allí o que María lo escondía.*

“Pablo thought either that John was not there or that Mary hid him”

b. *Cuéntame o lo que (tù) has leído en casa o lo que (tù) has aprendido en el colegio.*

“Tell-me either what you read at home or what you learnt at school”

(17) R a. *Paula își imaginează fie că Ion nu e aici, fie că Maria îl ascunde.*

“Paul thinks either that John is not here or that Mary hides him”

b. *Povestește-mi fie ce ai citit (tu) acasă, fie ce ai învățat la școală.*

“Tell-me either what you read at home, or what you learnt at school”

c. *(Eu) propun și ca Ion să vină și ca Maria să-l ascundă.*

“I suggest both that John come and that Mary hide him”

However, these coordinators are more constrained with root clauses. On the one hand, the disjunction type seems less constrained than the conjunctive one (in French or Italian), as examples in (18-19-20-21) show;<sup>5</sup> on the other hand, declarative sentences are less constrained than imperative or interrogative clauses, as we observe in (22-23-24-25).

(18) F a. *Soit il fera beau soit il fera mauvais.*

Either it be.FUT fine or it be.FUT bad

“Either the weather will be fine or the weather will be bad.”

b. %*En ce moment, et ses élèves le fatiguent et ses collègues l’agacent.*

“At the moment, both his students are wearing him out, and his colleagues are annoying him”

(19) I a. *O il presidente guarisce entro domani, o la riunione verrà annullata.*

“Either the president gets better until tomorrow, or the meeting will be cancelled”

b. \**In questo momento, sia i suoi studenti lo stancano sia\che i suoi colleghi lo innervosiscono.*

“At the moment, both his students are wearing him out, and his colleagues are annoying him”

(20) S *O el presidente se pone bueno antes de mañana, o la reunión tendrá que ser suspendida.*

“Either the president gets better until tomorrow, or the meeting will be cancelled”

(21) R a. *Fie președintele se va însănătoși până mâine, fie reuniunea va fi anulată.*

“Either the president will get better until tomorrow, or the meeting will be cancelled”

b. *Și gazul se scumpește, și vremea se răcește.*

“Both the gas is getting expensive, and the weather is getting bad”

(22) F a. *Soit tu manges, soit tu prépares tes devoirs.*

Either you eat.IND, or you do.IND your homework.pl

b. \**Soit mange, soit prépare tes devoirs!*

Either eat.2sg.IMPERAT, or do.2sg.IMPERAT your homework.pl

c. \**Soit qui viendra soit où on ira?*

Either who come.3sg.FUT or where we go.1pl.FUT

(23) I a. *O mangi, o fai i compiti.*

Either eat.2sg.IND, or do.2sg.IND the homework.pl

b. \**O mangia, o fa i compiti!*

Either eat.2sg.IMPERAT, or do.2sg.IMPERAT the homework.pl

c. \**O chi verrà o dove andremo?*

Either who come.3sg.FUT or where go.1pl.FUT

(24) S a. *O comes, o haces los deberes.*

Either eat.2sg.IND, or do.2sg.IND the homework.pl

b. \**O come, o haz los deberes, ¡decídet!*

Either eat.2sg.IMPERAT, or do.2sg.IMPERAT the homework.pl

c. \**O quien vendrá o dónde iremos?*

Either who come.3sg.FUT or where go.1pl.FUT

(25) R a. *Fie mănânci, fie citești.*

Either eat.2sg.IND, or read.2sg.IND

b. \**Fie mănâncă, fie citește, decide-te!*

Either eat.2sg.IMPERAT, or read.2sg.IMPERAT, decide yourself

c. \**Fie cine a venit fie unde mergem?*

Either who come.3sg.FUT or where go.1pl.FUT

This restriction on main (declarative) clauses can be explained by the Boolean interpretation of omnisyndetic coordination (interpreted as conjoining propositions), assuming Ginzburg and Sag (2000)'s hypothesis that only declarative clauses have a propositional content. If interrogatives and imperatives do not have a propositional content, when embedded clauses are coordinated, one can interpret the coordination as scoping over the matrix clauses as well.

### 3. More on Romanian data

We give arguments for assigning structure B (given in (6b)) to Romanian disjunctive *sau / ori / fie...sau / ori / fie* ('either...or') and for assigning structures C (given in (8a-b)) to Romanian *și...și* ('both...and').

#### 3.1. Correlative disjunction

Unlike English focus particles (e.g. *either*, cf. (26a)), 'initial' elements such as *sau / ori / fie* cannot float outside the coordination (26b-c).

(26) a. *John either ate [rice or beans].*

b. *Ion a mâncat [fie orez, fie fasole].*

"John ate [either rice or beans]"

c. \**Ion fie a mâncat [orez, fie fasole].*

"John either ate [rice or beans]"

Unlike English *either* or *both* occurring only before the first term, Romanian correlative items can be iterated:

(27) *Maria ar vrea să învețe fie engleza, fie franceza, fie german, fie japoneza.*

“Mary would wish to learn either English, or French, or German, or Japanese”

Therefore, we consider that the symmetric structure B (proposed for French doubled conjunctions, cf. Mouret (2005) and Mouret (2007)) is appropriate for Romanian disjunctive structure *sau / ori / fie...sau / ori / fie* (‘either...or’).

### 3.2. Arguments against the conjunctive status of *și...și*<sup>6</sup>

Romanian grammars (e.g. GALR (2005)) distinguish between the conjunction *și*<sub>1</sub> (‘and’) and the homonymous form behaving like an adverb (*și*<sub>2</sub>):

(28) a. *Ion și<sub>1</sub> Maria vorbesc franceza.*

“John and Mary speak French”

b. *Și<sub>2</sub> Ion vorbește franceza.*

“Also John speaks French”

c. *Ion vorbește și<sub>2</sub> franceza.*

“John speaks also French”

As for the correlative occurrences of the element *și* (e.g. *și...și* ‘both...and’), the widespread view is that this distribution is restricted to adverbial items, which by ‘repetition’ lose their meaning, inheriting conjunctive properties (cf. GALR I (2005: 644)). Furthermore, the *și* occurrences in correlative pairs (*și...și*) are analyzed as conjunctions, without any empirical evidence.

In this sub-section, we give some arguments against the conjunctive status of *și...și*, arguing for an adverbial interpretation of *și* in correlative environments.

First, *și* can be preceded by a coordinating conjunction which exclusively realizes the coordination relation: it can combine with conjunctions like *și* ‘and’ or *dar* ‘but’ (29a). Even if the first correlative item is absent, a conjunction can occur before the second conjunct (29b).

(29) a. *Manolescu scrie și poezie {și / dar} și proză.*

Manolescu writes *și* poetry {and / but} *și* prose

“Manolescu writes both poetry and prose”

b. *La petrecere va veni Paul, {și / dar} și Mircea.*

to the party will come Paul, {and / but} **also** Mircea

“Paul will come to the party, and Mircea too”

As already mentioned, this item can occur outside coordination, in independent sentences, having a commonly accepted adverbial status: *și* ('too' / 'also') (see table 5):

- (30) a. *La petrecere, vor veni și prietenii, și colegii lui Ion.*  
to the party, will come **și** friends, **și** colleagues of John  
"Both John's friends and his colleagues will come to the party"
- b. *La petrecere, vor veni și {prietenii / colegii} lui Ion.*  
to the party, will come **also** {friends / colleagues} of Ion  
"Ion's friends / colleagues will come to the party, too"

Generally, the phrase composed by modifiers like *cam* 'rather', *chiar* 'even', *doar*, *numai* 'only', *și* 'also', *nici* 'neither', etc. (called semiadverbs in traditional grammars) and their host always bears 'emphatic' or contrastive stress, and that is exactly what we observe with the modifier *și*: prosodically, the constituent modified by *și* becomes stressed (receiving a special intonation).<sup>7</sup>

- (31) a. [Chiar Ion] a venit.                      b. (Eu) am [doar trei copii].  
"Even John came"                                      "I have only three children"
- c. [Și Ion] a picat examenul.                      d. [[Și Ion] [și Maria]] au venit.  
"Also John failed the exam"                      "Both John and Mary came"

An additional argument concerns the fact that the correlative conjunction (*fie...fie* 'either...or') always precedes each conjunct, whereas the adverbial *și* can occur inside the conjunct, following the subjunctive marker *să* 'that' (32a) or modifying a NP inside a coordinated VP (33a).

- (32) a. *Paul adoră [să și cânte la pian], [să și danseze].*  
Paul adores [Subj și play piano], [Subj și dance]  
"Paul adores both playing piano and dancing"
- b. \**Paul adoră [să fie cânte la pian], [să fie danseze].*  
Paul adores [Subj fie play piano], [Subj fie dance]  
"Paul adores either playing piano, or dancing"
- (33) a. *Maria [și-a făcut și patul], [a scris și tema la matematică].*  
Maria [made și her bed], [wrote și the-homework for maths]  
Maria both made her bed, and wrote the homework for the maths class"
- b. \**Maria [și-a făcut fie patul], [a scris fie tema la matematică].*

Maria [made *fie* her bed], [wrote *fie* the-homework for maths]

“Maria either made her bed, or wrote the homework for the maths class”

Another piece of evidence distinguishing between correlative conjunctions and the correlative *și* is related to the insertion of an incidental phrase. A significant difference between correlative conjunctions and adverbs is that one can insert an incidental element (like *poate* ‘perhaps’, *pare-se* ‘it seems’) after the conjunction *fie*, but not after the correlative *și*:

(34) a. *Ion vine fie azi fie {poate / pare-se} mâine.*

“John comes either today or {perhaps / it-seems} tomorrow”

b. \**Ion vine și azi, și poate mâine.*

John comes *și* today, *și* perhaps tomorrow

“John comes both today and perhaps tomorrow”

b'. *Ion vine și azi, (dar) {poate / pare-se} și mâine.*

John comes *și* today, (but) {perhaps / it-seems} *și* tomorrow

“John comes both today and perhaps tomorrow”

Moreover, there are some adverbs (*chiar* ‘even’) that can modify the adverbial *și*:

(35) a. *La petrecere, va veni (chiar) și primarul satului.*<sup>8</sup>

to party, will come even *și* the-major of-the-village

“Even the major of the village will come to the party”

b. *La petrecere, va veni Băsescu și chiar și fostul președinte.*

to party, will-come John and even *și* the ex-president

“Băsescu and even the ex-president will come to the party”

The distributional behavior of the adverbial *și* is not singular in Romanian. There is a class of adverbs (the so-called ‘intensifiers’) that has the same distribution as *și* (and *nici*, cf. Ciompec (1985)). Inside this special adverbial class, Barbu (1999) and (2004) distinguishes between lexical intensifiers (= adverbs<sub>1</sub>) and affixes (= adverbs<sub>2</sub>). Elements of the first sub-set (adverbs<sub>1</sub>) would be items like: *nici* (‘neither’, ‘nor’), *abia* (‘hardly’), *aproape* (‘almost’), *chiar* (‘even’), *doar*, *măcar*, *numai* (‘only’), *încă* (‘still’), *și* (‘also’, ‘already’), while the second sub-class (adverbs<sub>2</sub>) contain: *și* (‘also’, ‘already’), *cam* (‘rather’), *mai* (‘nearly’, ‘still’, ‘again’), *prea* (‘too’), *tot* (‘still’, ‘repeatedly’). In table 2, one may see the general precedence order rule for both adverbial classes.

**Table 2. General precedence order rule**

(PO) <b>adv</b> <sub>1</sub> <i>să nu</i> pron aux <b>adv</b> <sub>2</sub> vb
---

<p><i>să</i> = subjunctive marker (see <i>que</i> in French)  <i>nu</i> = negation  pron = weak pronouns  aux = auxiliaries  adv = monosyllabic adverbs (<i>cam, prea, mai, și, tot</i>)  vb = lexical verb</p>
---

**Table 3. Precedence order rule for the adverbial *și***

(PO)	( <i>și</i> )	<i>să</i>	<i>nu</i>	pron	aux	( <i>și</i> )	vb
------	---------------	-----------	-----------	------	-----	---------------	----

As the table 3 shows, the adverbial *și* can have both distributions, either at the edge of the verb cluster (= adverb<sub>1</sub>), or inside, between the auxiliary and the lexical verb (= adverb<sub>2</sub>).<sup>9</sup> We observe some variations related to the verbal mood or tense: with the subjunctive, both distributions are available (36); with the past tense, for example, it can occur only between the auxiliary and the past participle (37).

(36) a. *Maria vrea [**și** să citească], [**și** să deseneze].*

Maria wants [*și* Subj read], [*și* Subj draw]

b. *Maria vrea [să **și** citească], [să **și** deseneze].*

Maria wants [Subj *și* read], [Subj *și* draw]

“Maria wants both to read and to draw”

(37) a. *Astăzi, [**am și** băut], [**am și** mâncat].*

today [Aux *și* Vb] [Aux *și* Vb]

b. \**Astăzi, [**și** am băut], [**și** am mâncat].*

today [*și* Aux Vb] [*și* Aux Vb]

“Today I have both drunk and eaten”

To sum up this section, we can say that the Conj...Conj structure is available only for the disjunction type in Romanian (like in Spanish). With correlative adverbs (*și...și*), what we have is in fact simple coordination, or asyndetic coordination: **Adv...{Conj / ∅} Adv**.<sup>10</sup>

As for the Romance perspective, the four Romance languages have one common correlative structure, i.e. the Conj...Conj structure, as the new analysis of Romance shows in table 4.

**Table 4. Analysis of Correlative coordination in 4 Romance languages**

#### 4. Conclusion

Assuming three main types of coordinate structures (simplex, omnisyndetic and asyndetic), in this paper we have focused on omnisyndetic constructions, the disjunctive *either...or* and the conjunctive *both...and* in four Romance languages (French, Italian, Spanish and Romanian). First, we have mentioned some of their common distributional properties in Romance and, then, we showed the hybrid case of Romanian, by a detailed analysis of the correlative *și...și*. We have provided some empirical evidence for analysing the *și...și* ('both...and') structure as asyndetic with the element *și* as an adverbial, by showing the double status of the element *și* (conjunction or adverbial). A more precise analysis of the distribution of correlative coordinations (e.g. Why is the omnisyndetic structure allowed for disjunction and not for conjunction in French and Italian? Why declarative sentences are less constrained than imperative or interrogative clauses), as well as an extension to other omnisyndetic coordinations (e.g. the negative type *nici...nici* 'neither...nor', which a priori has the same syntactic analysis as *și...și* 'both...and') still need to be provided.

#### 5. Notes

<sup>1</sup> We leave aside the negative pair *neither...nor* which generally behaves as the conjunctive type *both...and* (at least, in Romanian). We use these terms (disjunction type, conjunctive type) for the sake of simplicity.

<sup>2</sup> Its equivalent would be *tanto...como*, rarely used (in political discourse), or the adverbial *a la vez*, corresponding to the French *à la fois...et* (which follows the structure A, given in (6)):

(i) a. Voy (\*y) a Corea y a Japón.

go.1sg.IND CORREL to Korea and to Japan

b. Voy **a la vez** a Corea y a Japón.

go.1sg.IND both to Korea and to Japan

“I’m going both to Korea and to Japan”

<sup>3</sup> For Spanish examples, we retain only the pair *o...o* (see the footnote number 2).

<sup>4</sup> A priori, one can obtain a similarity between French and Italian on the one side, and Spanish and Romanian on the other side, according to at least two facts: first, the coordinator can freely combine with non-finite verbal categories in French or Italian, but this possibility is limited in Spanish and unavailable in Romanian; secondly, disjunctive coordinators combine with finite verbal categories (even if our data study shows some speakers’ variation), while conjunctive ones are more constrained in French and Italian. We need further work in order to check these hypotheses.

<sup>5</sup> % notes speakers’ variation.

<sup>6</sup>The same observations hold for the pair *nici...nici* ‘neither...nor’ (cf. Bilbiie (2006)).

<sup>7</sup>*Semiadverbs* (cf. Ciompec 1985) behave differently from circumstantial adverbs, since they have modal or aspectual meaning (=intensifiers, so that they always need a head to modify), they can modify almost everything, they have relatively rigid order, in the immediate neighbourhood of the selected element. Barbu 2004 makes a distinction inside this class between lexical adverbs and affixal adverbs (the latter mentioned only occurring inside the verbal complex, next to the lexical verb).

<sup>8</sup>The adverbial item *chiar* (‘even’) marks the idea of surprise, an unexpected event (“The major of the village was the one least expected to come to the party”).

<sup>9</sup>The different distributions of the element *și* correspond to a different syntactic (and semantic) status, i.e. the occurrence of *și* as adverb<sub>2</sub> could be interpreted as an affix.

# **Interactional Aspects of Sharedness of Information in Korean Conversation**

**Haeyeon Kim**

Department of English, Chung-Ang University  
Huksukdong 221, Dongjak-gu, Seoul, Korea [156-756]  
haeykim@cau.ac.kr

## **Abstract**

In conversation, speakers' knowledge about the referents being talked about is reflected in shaping sequential structures in conversation. This research is to explore how the sequential structures are realized in shaping sequential structures in conversation. After reviewing prior research on information status, turn- constructional practice, and repair, this study examines the constructions in which knowledge status is of concern: (i) elliptical constructions, (ii) constructions with pronominal elements, and (iii) constructions with an overt NP with a broad or ambiguous category. After that, I discuss types of sequential structures in the following two terms: (i) turn extensions and unattached elements, and (ii) repair sequences. Based on the discussion, this study deals with the motivations for occurrence of incremental TCUs and repair sequences: (i) recipient design, (ii) invitation for uptake from the recipient, (iii) solving problems in understanding the prior talk, and (iv) request for more specific and clear information. The study shows that these motivations are major interacting factors which are responsible for shaping turns in the processes of sharing information between speaker and hearer. In summary, this research shows an interactive nature of conversation in sharing information between speaker and hearer.

**Keywords:** knowledge status, turn increments, lack of recipient uptake, recipient design, repair, ellipsis.

## **1. Introduction**

"Language use is a form of joint action" (Clark 1996), and conversation is basically a process of exchanging information between speaker and hearer. Thus, speakers monitor each other's speech in the course of producing utterances, constantly negotiating among participants in sharing information, regularly revising, elaborating, or specifying preceding turns according to the status of the information being delivered. In recent years, a great amount of research on turn-construction practice has been carried out in conversation analysis, characterizing turn-constructional units (TCUs), transition-relevance places (TRPs), co-construction, repair, prosody, projectability, and so on

(Ford and Thompson 1996, Ford, Fox and Thompson 2002, Ono and Thompson 1995, 1996, Schegloff 1996, 2000, Schegloff et al. 1977, Tanaka 1999, among others).

However, little research has been carried out on the question of how the interlocutors' knowledge about the referents being talked is reflected in shaping sequential structures in conversation. The purpose of this research is to explore how the sequential structures are realized when the current speaker's assumption about the shared knowledge fails. Here, assumed knowledge means that the current speaker assumes that the hearer assumes, "knows," or can infer a particular thing (Clark 1996, Clark and Haviland 1977, cf. Chafe 1976, Prince 1981). Based upon this definition, this research will explore some aspects of sequential structures realized as turn extension or increments (Ford et al. 2002, Kim 2001, Schegloff 2000) or second-turn repair sequences which are adopted as devices for seeking more information among participants (Schegloff 1997, Schegloff et al. 1977), when the current speaker faces the problem of failure of assumed knowledge.

In this research, first I will discuss previous studies of information status, particularly, assumed knowledge, the speaker's turn-constructional practice, and repair as foundations for the exploration of the relationship between knowledge status and sequential structures. Second, I will examine constructions in which knowledge status is of concern in the following terms: (i) elliptical constructions, (ii) constructions with pronominal elements, and (iii) constructions with an overt NP with a broad or ambiguous category, among others. Third, I will examine types of sequential structures with respect to the knowledge status of the referent being talked about, in the following two broad terms: (i) turn extensions and unattached elements (Ford et al. 2002, Kim 2001, Ono and Suzuki 1992, Ono and Thompson 1994, Schegloff 2000), and (ii) repair sequences. The former case is related to the situation in which the current speaker provides additional information after the completion point of the host TCU as turn extensions or unattached elements. The latter case deals with the situation in which the next speaker produces an utterance which functions as a next-turn repair initiator (NTRI), and then the current speaker produces a second- or third turn with a more informative TCU.

After discussing types and sequential structures of constructions which are sensitive to the knowledge status of the referents, this study will explore interactional motivations for constructing such interactional sequences. It will discuss occurrence of incremental TCUs and repair sequences in the following four terms: (i) invitation for uptake from the recipient (Ford et al. 2002, K. Kim 2001, Schegloff 2000), and (ii) recipient design (Sacks and Schegloff 1979), (iii) indication of problems in

understanding the prior talk, and (iv) request for more specific and clear information. This study will show that these motivations are major interacting factors which are responsible for shaping turns in the negotiating processes of seeking more information between speaker and hearer.

In summary, this paper will show that speakers, depending on the knowledge status of the referents being talked about, are actively engaged in the process of negotiation by adding specific types of turn components or indicating the need for more information. Based on the analysis of Korean conversational data, this research will discuss the current speaker's turn expansion and third-turn repair as information-sharing strategies in the process of exchanging information. The research shows an interactive nature of conversation manifested in the use of incremental TCUs in securing and providing information according to the interactants' need for seeking more information in communication.

## **2. Previous Studies of Information Status and Sequence Organization**

In doing this research, I will first discuss information/knowledge status, particularly, assumed knowledge, the speaker's turn-constructive practice, and repair as foundations for the exploration of the relationship between knowledge status and the sequential structures.

In functional linguistics and discourse analysis, a great amount of research has been carried out on the information status of referents, information flow, and the taxonomy of information states from textual and cognitive perspectives (Kuno 1972, 1978, Halliday 1967, Halliday & Hasan 1976, Chafe 1976, 1980, 1987, 1994, Prince 1981, 1992, Gundel et al. 1993, among others). In such research, terms such as given/old-new information, shared or assumed information, news-worthiness, theme, topic, afterthought, emphasis, and contrast have been proposed to explain knowledge status of the referents in information flow. In making a distinction between new and old information, terms such as recoverability, predictability, saliency, shared knowledge, and familiarity have been proposed. A number of researchers have proposed taxonomies of the status of information/knowledge of referents in two-, three-, or multiple ways. That is, Kuno, Halliday, Halliday and Hasan proposed taxonomies of a two-way distinction (i.e., given vs. new information), Chafe (1987) and Prince (1992) those of a three way distinction (i.e., active, semiactive, and inactive), and Prince (1981) and Gundel (1993) those of multiple-way distinctions. These studies have shown that

speakers are sensitive to the information status of the referents being talked about in producing utterances. They have focused on the information status of nominal expressions, but little research has been carried out on information status with respect to the sequential structures in conversation.

Since the research on turn-taking carried out by Sacks et al. (1974), interaction-based research has provided a new way of examining turn constructions in conversation in terms of interactional needs and motivations (Ford, Fox and Thompson 2002, Kim 2001, Ono and Suzuki 1992, Schegloff 2000, Schegloff et al. 1977). Among many topics discussed in conversation analysis and interactional linguistics, Ford et al. (2002), Kim (2001), and Schegloff (2000) show that variability of turn constructions can be explained in terms of turn extensions or increments. They claim that turn increments are closely related with interactional contingencies, including lack of recipient uptake.

In conversation analysis, repair is one of the most widely discussed topics in conversation. Schegloff et al. (1977) and Schegloff (1997: 503) define repair as "practices for dealing with problems or troubles in speaking, hearing, and understanding the talk in conversation." Such a definition provides a new way of examining repair phenomena in conversation in terms of interactional needs and motivations (Jefferson 1974, Schegloff 1979, 1997 Schegloff et al. 1977, among others). Beginning with research on repair in conversation by Jefferson (1974) and Schegloff et al. (1977), many studies have characterized repair phenomena in conversation from a conversation-analytic, interactional perspective (Schegloff 1979, Fox, Hayashi, and Jasperson 1996). Furthermore, Banno (1998) and H. Kim (2006) discuss types of elaboration repair, as a particular type of non-error self-repair. These studies show how repair is shaped by the syntactic practices of the speakers of a language, and the ways in which repair shapes those practices.

As discussed above, interaction-based research has provided a way of exploring how forms and types of turn-constructive units (TCUs) are interactionally determined by the negotiation between participants in talk-in-interaction. However, little research has been done on the question how turns are shaped according to the information status between speaker and hearer. In this regard, it is necessary to examine instances of variability of turn constructions in their sequential and interactional contexts as a way of characterizing the nature of TCUs.

### 3. Database and Methodology

In exploring the interactional nature of retroactive elaboration in conversation, it is imperative that one should look at naturally occurring data to perform an empirically-grounded micro-analysis of turn-constructive practices. In carrying out the research on knowledge status and sequential aspects of variability of turn constructions, I used four audio-taped face-to-face conversations in Korean. Each of the conversation is about 13 to 30 minutes long, totaling approximately one hour and forty minutes. Among the data, two are multi-party conversations among graduate students, the other two are dialogues between two acquaintances. The topics of the conversations are school life, learning/teaching English, and job experiences, among others. Based on these four conversations, this research will explore the contexts in which instances of variability of turn constructions are produced. In the present data, a total of 96 instances of variability of turn constructions were found. Based on these statistics, this research will characterize variability of turn shapes in terms of turn-constructive practice.

The conversations in the database were collected and transcribed by adopting the transcription convention proposed by Du Bois et al. (1993). The transcription convention in the data takes an intonation unit as a basic unit of spoken language, each line representing one IU. Bearing this in mind, let us consider an excerpt which involves ellipsis and turn increments.

(1) [Graduate students are talking about a phonetic analysis of voices.]

1 Y: kunkka Yumi enni-ka cham kulehkey kkaykkusha-tay-yo ikey <—A  
that:is Yumi Sister-NM well such clear-QUOT-HON this  
'That is, Sister Yumi's is clear, this.'

2 S: uuum.  
'uh-huh.'

3 Y: moksoli cachey-ka <—B  
voice itself-NM  
'the voice itself.'  
(3 intonation units deleted)

4 J: tutki-ey-nun an nangnangha-ntey.  
hearing-LOC-TM not clear-CIRCUM  
'as for hearing, (it's) not clear?'

5 Y: ø nangnangh-ay, <—C  
clear-IE

‘(It’s) clear,’  
 6     *tutki-ey-to*  
       hearing-LOC-too  
       ‘even for hearing.’  
 7     *nangnangha-cyo*       *Yumi-enni*     *moksoli*                                     ←—D  
       lear-COMM:HON        *Yumi-Sister*    *voice*  
       ‘(It’s) clear, Sister Yumi’s voice.’

In (1), Speaker Y produces the NP *Yumi enni* 'Sister Yumi('s voice)' first, the pronominal *ike* 'this', and then the NP *moksoli* 'voice'. As this example shows, the current speaker first produces an elliptical phrase, and then she revises her utterance in an escalating manner, resulting in turn increments. In Line 5, she produces a TCU in an elliptical construction with no subject. And in Line 7, she produces a full sentential TCU with inversion. As this excerpt shows, speakers produce TCUs in elliptical constructions, pronominals, and turn increments, particularly with respect to knowledge status of the referents being talked about. In conversation, such constructions take a variety of sequential structures, depending on the status and sharedness of information. In this research, I will examine instances of constructions with ellipsis or pronominals and turn increments which are sensitive to the information status of the referents being talked about. In the next section, I will discuss types of constructions with respect to information status in the database.

#### 4. Types of Knowledge-Status Sensitive Constructions

##### 4.1. Knowledge Status in Discourse and Grammar

In this section, let us discuss types of some constructions which are sensitive to the status of knowledge of the referents being talked about. As discussed above, interaction-based research has provided a way of exploring how forms and types of turn-constructive units (TCUs) are interactionally determined by the negotiation between participants in talk-in-interaction. In this regard, it is necessary to examine instances of variability of turn constructions in their sequential and interactional contexts as a way of characterizing the nature of TCUs. Here, I will examine constructions in which knowledge status is of concern in the following terms: (i) elliptical constructions which involves zero anaphora, (ii) constructions with pronominal elements, (iii) constructions

with lexical full NPs of broad or ambiguous categories, and (iv) non-constituents of the host TCU, especially unattached NPs, among others. As is well known, the Korean language has many elliptical constructions, resulting from the current speaker's assumption of shared knowledge about the referent. As a second case, the current speaker often produces an utterance with an overt pronominal, based on the assumption that the referent is shared by the hearer. As a third case, the current speaker sometimes produces a broad, ambiguous overt NP, which needs to be specified with an additional TCU. Based on an examination of these constructions, I will classify added segments in the following subcategories: (i) overt constituent NPs of the preceding elliptical constructions, (ii) replaced lexical full NPs of the pronominals, (iii) elaborated, specified lexical full NPs, and (iv) expanded elements, such as unattached NPs.

In producing these constructions, speakers are sensitive to the knowledge status of the referents being talked about, and such sensitivity is reflected in the practice of constructing turn shapes. As has been discussed, conversation is basically a process of exchanging information between speaker and hearer, and they constantly negotiate with each other in sharing information. Let us take a look at Excerpt (2):

- (2) S: .. akka malssumhasi-n ku yehaksayng-yo,  
           before mention-ATTR that girl:student-HON  
 .. kayey myec haknyen-i-eyo?                    ←—A  
           that:girl what grade-be-HON  
           '(As for) the girl student who you mentioned before,  
           what grade is she in?'
- P: .. etten yehaksayng malssumhasi-na-yo?       ←—B  
           which girl:student mention-Q-HON  
           'Which girl student are you talking about?'
- S: .. onul saylo onta-nun haksayng,           ←—C  
           today newly come-ATTR student,  
           'the student you who (you said) is coming today,'
- P: a:,  
       'oh,'  
       ce: ... ø kotunghakkyo 2 haknyen toy-nipta.  
       welll ø high:school 2 grade become-HON  
       'oh, well, (she) is a second-year high school student.'

As shown in (2), the current speaker sometimes produces a turn, assuming that the next

speaker shares information about the referent which (s)he is talking about (marked A). However, such an assumption does not hold, and the next speaker produces a turn which signals that (s)he does not share the information (marked B). In such a context, the current speaker provides additional, specific information in the next turn (marked C). As this excerpt shows, the current speakers' assumption about the sharedness of the knowledge about the referent is reflected in the shaping turn constructions. In this respect, there is a need to pay attention to the knowledge status of the referents and the sequential structures.

In Section 2, we have seen that Prince (1992) proposes a taxonomy of information status in terms of two distinct divisions: discourse-old/discourse-new and hearer-old/ hearer-old. Among the four theoretically possible information statuses, of which only three are possible in the analysis of discourse. Schiffrin (1987:268), on the other hand, proposes a taxonomy of meta-knowledge of speaker/hearer shared knowledge based on the sharedness of information about the referent between speaker and hearer.

Figure 1. Meta-knowledge about speaker/hearer shared knowledge (Schiffrin 1987)

Does speaker know of hearer's knowledge?	Yes	No
Does hearer know of X?	Yes (a)	(b)
	No (c)	(d)

As shown in Figure 1, according to Schiffrin, the hearer knows the background information and the speaker knows that; in (b) the hearer knows the background information and the speaker does not know that; in (c), the hearer does not know the background information and the speaker knows that; in (d), the hearer does not know the background information and the speaker does not know that.

In conversation, it is not always the case that the current speaker knows whether a speaker shares knowledge about the speaker's topic of talk because one cannot be in the mind of the other. The speaker only assumes that the hearer also has the background knowledge. Then, the question is whether the current speaker's assumption about the shared knowledge will hold or fail. If the current speaker's assumption holds, then the conversation keeps going. But when the assumption fails, there arise sequences of repair. In this respect, I will classify interaction sequences into two broad categories: (i) self-repair sequences, and (ii) next-turn repair sequences. According to the sharedness of the background knowledge, speakers makes negotiation with each other about the knowledge status of the referent being talked about, and such a practice of negotiation is

waiting for her thesis supervisor in the office, talking with other graduate students in the department office. She suddenly produces a sentential TCU without a subject NP, assuming that the information about the referent is being shared. However, Y, the next speaker, provides a candidate NP for the missing subject, which gets an affirmative response from Speaker S. As these excerpts show, the turns marked as A and B are produced as incremental TCUs to provide or secure more specific information about the referents being talked about.

As shown above, the use of zero anaphora is prevalent in Korean conversation. When such elliptical constructions are produced, speakers are sensitive to the status of information about the referents being talked about. In (3i), the current speaker produces an incremental TCU to provide more information retroactively. In (3ii), on the other hand, the next speaker's response functions as a try marker or a next turn repair initiator (NTRI), which functions as a request for more information. This fact suggests that speakers are sensitive to the status of information about the referents, and turn shapes are negotiated to get enough information to keep the conversation going. This usage shows that incremental TCUs and NTRIs are used as devices which function as devices for providing and seeking more specific information in Korean conversation in which the use of zero anaphora is prevalent.

#### *4.3. Pronominal Constructions*

As a second type of knowledge-sensitive constructions, the use of pronominal expressions is often sensitive to the knowledge status of the referents being talked about, especially when speakers use pronominal expressions without antecedents in the prior discourse. In Korean, pronouns are rarely used and the usage is limited to certain limited contexts. In discourse, it is common and natural for speakers to produce antecedents in the form of full lexical NPs, and use pronominals in the next mention to refer back to them. However, in conversation, speakers sometimes, though not frequently, produce a pronominal expression in the first mention in the host TCU upon the assumption that the information about the referent is shared with the addressee. In certain cases, such an assumption does not hold. In such a case, the current speaker provides the 'antecedent' in the form of a full lexical NP retroactively.

- (4) J: .. ani,  
no,  
(0) cepen cwu-ey,

last week-LOC  
 . yeki o-ass-ess-ketun-yo, <—A  
 here come-PST-PST-RETRO-HON  
 'Well, no, (he) came here,'  
 Y: (0) ung.  
 'Yeah.'  
 J: kkwasa-ey. <—B  
 dept.:office-LOC  
 'the department office.'  
 Y: ung.  
 'Yeah.'

As shown in (4), in conversation, speakers sometimes use pronominal elements first, then they backtrack to the repairable pronominals and replace them with full lexical NPs. That is, in (4), Speaker J, talking about a fellow graduate student, produces a deictic expression *yeki* 'here' first, and then she replaces it with a full lexical NP *kkwasa* 'department office'.

As a second case of the use of pronominals, the next speaker produces an NTRI which seeks more specific information about the referent expressed in the form of a pronominal.

(5) a. B: (6 intonation units omitted)  
 .. enni way kuke isschanha. <—A  
 'Sister, well, (you know) (there goes) that thing.'  
 A: ... (1.5) ku key mwey-a, <—B  
 that thing what-IE  
 'what is that thing?'  
 B: ... ai.  
 'well.'  
 A: (2.0) [wethe suphulei?] <—C  
 'water spray?'  
 B: [suphulei] <—D  
 'spray.'  
 b. M: .. nay-ka maynnal tayhakkyo-ttay,  
 I-NM every:day college-time  
 .. kulen kes-man ccochatany-ess-ketun. <—A

such thing-only chase:after-PST-RETRO

'When I was at college, I always chased after such things.'

S: ... (0.7) *kulen ke*, <—B  
           *such thing*,  
 .. *kangcwa tutnun ke?* <—C  
           *lecture attend thing*  
           'such things, attending (English) classes?'

M: .. *ung*,  
       'Yeah,'

In (5), we can see examples of next turn repair. That is, in (5a), two women are talking about a cosmetic. Speaker A produces a TCU with the pronominal *kuke* 'that (thing)' (marked C) based on the assumption that the knowledge about the referent is being shared with the hearer. But such an assumption is challenged by the next speaker. After that, turns which seek more information follow. In (5b), two speakers are talking about attending English classes during the summer vacation. In this context, Speaker M uses a pronominal element *kelen kes* 'such things' (marked C) in referring to attending English classes, assuming that the information expressed in the pronominal form is shared with the addressee. This assumption fails, and thus, Speaker S, after a 0.7 second pause, first produces the NTRI *kelen ke* 'such a thing' (marked E). Immediately after that, she produces the phrase *kangcwa tutnun ke* 'attending (English) classes' (marked F) as a candidate referent for the pronominal, which gets an affirmative response in the next turn. These excerpts shows that speakers are sensitive to knowledge status of the referents being talked about in the use of pronominals, and turns are shaped according to the degree of the sharedness of the knowledge in conversation.

#### 4.4. Constructions with Broad/Ambiguous NPs

Knowledge status is of concern in the use of NPs with broad or ambiguous categories. In conversation, the current speaker sometimes produces vague or ambiguous expressions based on the assumption that speaker and hearer share the knowledge about the referents being talked about, but sometimes such an assumption does not hold. In such a context, the current speaker produces an incremental TCU to make reformulation repair, or the next speaker produces a TCU which seeks more specific information about the referent. First let us consider some excerpts which involve incremental TCUs.

- (6) a. M: ... (0.7) ku=,  
that  
.. *hakkyo-eyse hanun ehak phulokulaym kulen ke iss-canha.* <—A  
Campus-LOC do language program such thing be-IE  
.. *ehakwen,* <—B  
language:institute  
.. *kekise ha-nun ke-ya.*  
there do-ATTR thing-IE  
‘that, there are language programs on campus, (you know),  
the language institute, they provide (the programs).’
- b. M: .. *kulay kaciko,*  
such that  
.. *wenlay kekise sensayngnim-i-ess-tay-yo,*  
originally there teacher-be-PST-HEAR-IE  
.. *sayngmwul sensayngnim-i-nci.* <—C  
biology teacher-be-maybe  
‘And (she) was a teacher there, maybe a biology teacher.’

Excerpts in (6) illustrate instances of incremental TCUs which occur after the host TCU as a way of providing more specific information. In (6a), Speaker M, in her talk about the summer English program on campus, produces the vague term *hakkyo* ‘school’ in her first mention. After that, she produces an incremental TCU, *ehakwen* ‘language learning center’, which is more specific and narrow in scope. Likewise, in (6b), Speaker M talks about a newly employed foreigner at the university career information center. In this excerpt, M first says that the referent was a *sensayngnim* ‘teacher’, which is a rather broad and vague term. Then, she reformulates the problem spot by adding *sayngmwul* (*sensayngnim*) ‘biology (teacher)’, which results in a more specific term. As these excerpts clearly show, speakers produce incremental TCUs as a reformulation repair device to provide more specific information to the interlocutor.

As a second type of the use of broad or ambiguous NPs, the next speaker produces an NTRI which functions as a device for seeking more specific information.

- (6) P: [twu si pan-kkaci-]  
two o'clock half-by  
‘by two and half (o'clock),  
S: [wencwu],

	wencwu haksayng.	<—A
	Wonjoo student	
	'Wonjoo, Wonjoo student,'	
P:	(0) wencwu?	<—B
	'Wonjoo?'	
S:	wencwu-eyse isa on haksayng,	<—C
	Wonjoo-from move come student	
	'(the) student moved from Wonjoo.'	

In (6), two teachers are talking about a student. Speaker S produces the NP *wencwu*, which is ambiguous, and then he repeats the NP because of the turn is overlapped with P's turn. In such a context, P repeat the NP with rising intonation, which functions as an NTRI. Then, S provides a modified NP which provides more specific information.

As the discussion above shows, when the current speaker produces a TCU with ambiguous or vague NPs, we can see there are two sequential organizations: (i) speakers produce incremental TCUs as a reformulation repair device to provide more specific information to the addressee, and (ii) the next speaker produces an NTRI to make a request for more specific information.

So far, we have examined four types of constructions in which knowledge status is of concern: (i) elliptical constructions which involves zero anaphora, (ii) constructions with pronominal elements, and (iii) constructions with lexical full NPs of broad or ambiguous categories. As has been shown, in producing these constructions, speakers are sensitive the knowledge status of the referents being talked about, and such sensitivity is reflected in the practice of constructing turn shapes. The discussion so far has shown that repair sequences or the current speaker's turn increments are used as information sharing strategies in the process of exchanging information.

## 5. Motivations in Turn-Construction Practice in Sharing Information

So far, we have seen some types of constructions which are sensitive to the knowledge status of the referents. The discussion has shown that the status of information is an object of active negotiation throughout the course of exchanging information among interactants, which is reflected in the sequential structures of turn taking. In this section, let us explore interactional motivations for constructing such interactional sequences.

'Chung-Ang Herald,'

In (8), the participants in the conversation are talking about *The Chung-Ang Herald*, the University English magazine. In this excerpt, Speaker S first produces the NP *Herald* (marked A), assuming that the next speaker shares with her the information about the referent. However, she receives a backchanneling response only from the next speaker. So she revises her utterance into a more specific NP with a pre-modifying clause (marked B) and a partial repeat of the preceding utterance. But still the next speaker does not take a turn. So, with a short pause, S provides another additional information in the form of an NP. After that, she gets another response in the form of an address term. Then, she provides a proper name of the magazine, specifying what she said before. As this excerpt shows, the current speaker revises or reformulates what (s)he said before to make it understood by the recipient.

Third, occurrence of incremental turns in the next IU used for retroactive elaboration is related to the turn-constructural practice of inviting recipient uptake in the process of sharing information among participants (Ford et al. 2002, K. Kim 2001, Schegloff 2000). Ford et al. (2002) state that speakers add segments which occur after a possible completion point in the absence of recipient uptake to provide a renewed possible TRP. Such an act to invite uptake from the recipient can be understood as an act of sharing information among participants.

- (9) B: ... ku ttay 235 kulaym-i-ess-na?  
that time 235 gram-be-PST-IE  
... onsu-i-ess-na?  
ounce-be-PST-IE  
.. 235 onsu-i-ess-na?  
235 ounce-be-PST-IE?  
'At that time, did it contain 235 grams? Or was it in ounce?  
Or did it contain 235 ounces?'
- A: ... al swu-ka eps-ci.  
know way-NM not-COMM  
'(We) cannot know (or I have no idea).'

In (9), two speakers are talking about a cosmetic. When B was wondering about the weight of the cosmetic, she first produces an utterance of whether it contained 235 grams or not. But she does not receive a response from the hearer. Then, she revises the

measurement units from *gram* to *ounce*. But still she does not get a response. Then, she partially revises and repeats what she said, and then she gets a response from the next speaker. As this excerpt shows, added segments which function as devices for creating a renewed TRP are used to share information about the referents being talked about among participants (Ford et al. 2002, K. Kim 2001, Schegloff 2000).

Fourth, the occurrence of next-turn repair initiators in the next-turn position signals problems in understanding the prior talk. NTRIs function as devices for seeking more specific and clear information. As has been discussed, the notion *repair* is defined broadly as "practices for dealing with problems or troubles in speaking, hearing, and understanding the talk in conversation." Such a definition involves not only 'error' correction but also problems in understanding the talk caused by insufficient amount of information about the referents being talked about.

(10) (Excerpt (5) repeated here)

B: (6 intonation units omitted)

.. enni way kuke isschanha. <—A

'Sister, well, (you know) (there goes) that thing.'

A: ... (1.5) ku key mwey-a, <—B

that thing what-IE

'what is that thing?'

B: ... ai.

'well.'

A: (2.0) [wethe suphulei?] <—C

'water spray?'

B: [suphulei] <—D

'spray.'

As shown in (10), when the current speaker produces an utterance with a pronoun based upon the assumption that the information about the referent is shared, the next speaker produces an NTRI, which seeks clear, specific information. Still she cannot get more information she produces an NP as a candidate answer for the referent. As this excerpt shows, speakers produce NTRIs not only to signal problems in understanding the prior talk but also to seek more specific and clear information.

As we have seen, speakers actively negotiate with each other in the course of exchanging information, which is realized as turn increments and repair sequences. In this regard, we have explored interactional motivations for constructing such

interactional sequences in the following terms: (i) recipient design, (ii) invitation for uptake from the recipient to share information, (iii) indication of problems in understanding the prior talk, and (iv) requesting for more specific and clear information.

## **6. Summary and Conclusions**

So far, we have discussed the question of how the interlocutors' knowledge about the referents being talked about is reflected in shaping sequential structures in conversation. This research has explored aspects of sequential structures realized as turn extension or increments. It has also dealt with repair sequences which are used as devices for seeking information among participants, when the current speaker's assumption about the sharedness of information about the referents being talked about.

To characterize sequential structures constructed according to the knowledge status, this research has reviewed previous studies which deal with information status, the speaker's turn-constructive practice, and repair as foundations for the present study. After that, I have examined the constructions in which knowledge status is of concern: (i) elliptical constructions, (ii) constructions with pronominal elements, and (iii) constructions with an overt NP with a broad or ambiguous category. Through an examination of these constructions, I have discussed types of sequential structures in the following two terms: (i) turn extensions and unattached elements, and (ii) repair sequences. Examination has shown that in conversation speakers use the constructions discussed above based on the assumption that the information being delivered is shared between speaker and hearer. However, when such an assumption fails or when the current speaker feels the need to provide more explicit information, (s)he produces incremental turns, or replaces the pronominal elements or ambiguous expressions with more informative expressions.

After discussing types and sequential structures of constructions which are sensitive to the knowledge status of the referents, this research has discussed interactional motivations for constructing such interactional sequences. It has dealt with the motivations for occurrence of incremental TCUs and repair sequences in the following four terms: (i) recipient design (Sacks and Schegloff 1979), (ii) invitation for uptake from the recipient (Ford et al. 2002, K. Kim 2001, Schegloff 2000), (iii) solving problems in understanding the prior talk, and (iv) request for more specific and clear information. The study has shown that these motivations are major interacting factors which are responsible for shaping turns in the processes of sharing information between

speaker and hearer.

In summary, this research has shown that speakers are actively engaged in the process of negotiation by the means of incremental TCUs and repair mechanisms for seeking more specific, clear information. The research has shown an interactive nature of conversation in sharing information between speaker and hearer.

## **Abstract**

In Japanese (J) and Korean (K), many words are borrowed from English into each language, and they form part of their lexicons. Many English loanwords are assimilated into J and K, and some of them undergo change in meanings and forms from the original English words. This research examines types of abbreviations in English loanwords and to explore linguistic motivations responsible for the formation of loanword abbreviations in Japanese English (JE) and KE (Korean English). This research will examine abbreviations in JE and KE and classify them into three types: (i) initialism/acronyms, (ii) clipping, and (iii) blending. Based on the examination of types and word formation rules of abbreviations in JE and KE, this study explores linguistic motivations responsible for the formation of abbreviations in JE and KE. It shows that economy and distinctiveness/contrastiveness are the most important motivations which are involved in the formation of abbreviations in JE and KE.

**Keywords:** morphology, loanwords, Japalish, Konglish, abbreviation, acronym, initialism, clipping, blending, economic motivation, distinctiveness, contrastiveness.

## **1. Introduction**

In Japanese (J) and Korean (K), many words are borrowed from English into each language, and they form part of their lexicons. In Japanese and Korean, words and phrases loaned or coined from English are often treated as non-standard, incorrect or bad language, termed Japlish (Japanese English: JE) and Konglish (Korean English: KE). So far, JE and KE have been treated as

examples of corrupted English, and many English educators have pointed out problems of JE and KE from a pedagogical perspective. However, little research has been done on the formation of abbreviated expressions in JE and KE from a cognitive perspective. The purposes of this research are to examine types of abbreviations in English loanwords and to explore linguistic motivations responsible for the formation of loanword abbreviations in JE and KE.

When considered in terms of phonology, morphology, and semantics, loanwords can be divided into a variety of types. Some loanwords are fairly faithful to their original pronunciation and meanings as in *tennis* and *ice*. Some are 'false cognates' which have completely different meanings from the original English words, as in *cider* 'soda pop' and *bond* 'glue'. Some are abbreviated or curtailed expressions of the original English words: *terebi* 'television', *super* 'supermarket', *biru* (JE) 'building' and *wa pro* (JE) 'word processor'. Some words are coined or fabricated according to the cognitive perception of the native speakers of Japanese and/or Korean, as in *American coffee* 'black coffee' and *open car* 'convertible'. Among these types of loanwords, this research will focus on abbreviated or curtailed expressions. As is well known, Japanese and Korean are notorious for abbreviating rather long English words into short forms, resulting in loanword abbreviations in JE and KE.

This research will examine abbreviations in JE and KE and classify them into four types. In English morphology, abbreviations are usually classified into the following three categories: (i) initialism/acronyms, (ii) clipping, and (iii) blending (Quirk et al. 1985, O'Grady and Archibald 2004). Abbreviation in language is a universal phenomenon found in the formation and use of words, and thus the processes of abbreviation are also found in the formation of loanwords from English in JE and KE, as shown in (1).

- (1) (i) khonto (condo) <-- condominium,  
aphatu (apa(r)t) <-- apartment (cf. Apt.)  
(ii) eyekhon (aircon) <-- air conditioner  
(iii) limokhon (remocon) <-- remote control  
(iv) aissi (IC) <-- interchange, tissi (DC) <-- discount

In (1), we can see examples of clipping ((1i, ii), blending (1iii), and initialism

(liv) in JE and KE. Bearing this classification in mind, we will examine what morphological rules apply for the formation of abbreviated loanwords in JE and KE. Examination will show that the morphological rules which apply language in general also apply to the formation of abbreviated expressions in JE and KE. In examining examples of abbreviation, we will compare similarities and differences in the formation of loanwords in JE and KE (e.g., *apart* 'apartment' and *super* 'supermarket' for JE and KE, but *pers com* 'personal computer' and *wa(word) pro* 'word processor' for JE only). Based on the examination of types and word formation rules of abbreviations in JE and KE, we will explore linguistic motivations responsible for the formation of abbreviations in JE and KE. In this study, we will take the economy and distinctiveness/ contrastiveness as the most important motivations involved in the formation of abbreviations in JE and KE (Zipf 1935, Haiman 1983, 1985, Croft 1990, Radden and Panther 2004).

In sum, this paper explores linguistic motivations for the formation of abbreviations by examining types of loanwords and linguistic motivations in the formation of diverse types of lexical expressions in JE and KE. Based on the examination of abbreviations in JE and KE, this research proposes that the linguistic motivations of economy and distinctiveness are the most important motivations which govern the formation of abbreviations in JE and KE. This study shows that these cognitive motivations apply not only to the processes of word formation of natural language in general but also to the formation of abbreviations in JE and KE.

## **2. Context of the Research: Abbreviations, Loanwords, and Linguistic Motivations**

In morphology, topics such as inflection, derivation, and compounding have been three major areas of research. However, little attention has been paid to abbreviations, although abbreviations are a topic in morphology (Bauer 1983, Quirk et al. 1985, O'Grady and Archibald 2004, Huddleston and Pullum 2002). In English, abbreviations are usually classified broadly into three types: (i) acronym, (ii) initialism, and (iii) clipping. In addition to these three types, consonantal abbreviations and blending are also treated as types of abbreviations. First, consonantal abbreviations refer to cases in which vowels of the word is deleted but only some 'prominent' consonants remain as in *Mr.*,

*Mrs.*, *km* (<--kilometer), PhD, and so on. Traditionally, commas have been added for the consonantal abbreviations, but nowadays, particularly in British English, commas are often deleted. Second, initialism refers to the cases in which the initial letters of each word in a compound are taken to form an abbreviation. One can find a great number of this type of abbreviations, as shown in ABC, BBC, FBI, FTA, UK, and so on. In this type, you should read each initial letter by their name, and thus you should not read UCLA as [juklə]. Third, acronym refers to a type of abbreviation in which the initial letter of each word in a compound noun forms a new word, and it is pronounced just like a common word, as shown in radar['reida:r], NATO ['neitou], NASA ['næsə]. Fourth, clipping refers to the case in which part of a rather long word is deleted/clipped, as in *Bros.* from *Brothers*, *champ* from *champion*, *Sun.* from *Sunday*, *Jan.* from *January*, and so on. In clipping, the latter part of the word is often deleted, but some other part may also be deleted. Fifth, parts of more than two words are often combined into one, forming blends. For examples, the three words *Belgium*, *the Netherlands*, and *Luxemburg* are combined into *BeneLux*, and *camera recorder* into *camcorder*. As we have seen, in English, five types of abbreviation can be found in shortening rather long words or phrases. Bearing these types in mind, let us consider how loanwords and coined English expressions are abbreviated in Japanese and Korean.

Through contact with English-speaking countries, Korean and Japanese have borrowed and integrated many English words into their language systems. Many words and phrases are used just as in English, but still many of them are 'transformed' according to the phonological and morphological rules of Korean and Japanese. For example, words such as *test*, *disk*, *airport*, *tennis*, *ice*, and so on retain their 'original forms' in representing them in Korean and Japanese. However, in a strict sense, they are not exact representations of the original words. That is, in Korean, the /i/ sound is inserted in words such as *test* [tesiti], *disk* [disiki], and *ice* [aisi], and in Japanese the /u/ sound is inserted, as in *test* [tesuto], *disk* [disuku], and *ice* [aisu] to conform with the Japanese syllable structures. Likewise, many abbreviated words are borrowed and used exactly as in English. For example, in Korean and Japanese words such as *Mr.*, *CIA*, *WHO*, *YMCA*, *DNA*, *radar*, *champ*, and *memo* are used almost exactly the same as in English.

A great number of English words have been borrowed and used as they are

in English. But many of the borrowed are 'transformed' or changed by observing the phonological and morphological rules. In addition, many words have been coined in response to the need of the speakers of Korean and Japanese. Such transformed and coined words are often called 'Konglish' and 'Japlish' words. Furthermore, some Japlish words have been borrowed into Korean and such words become part of Konglish vocabulary. So far, little attention has been paid to formation of Konglish and Japlish words (Kim 2007). In this respect, there's a need to examine Konglish and Japlish words and classify them into some limited types. Among the types, this research will examine types of abbreviations of Konglish and Japlish words in terms of initialism, clipping, blending and acronym.

In discussing abbreviations, it is necessary to examine linguistic motivation which is responsible for the formation of abbreviations. In linguistics, there had been a number of studies of linguistic motivations in the formation, development, changes of words (Zipf 1935, Haiman 1980, 1983, 1985, Croft 1992, among others). In recent years, Radden and Panther (2004, 2005) provide a comprehensive overview of linguistic motivations in terms of the relationship between forms and contents. According to them, contents sometimes determine forms as in the examples of signs, imagic iconicity, many of Chinese characters, onomatopoeic expressions, and so on. On the other hand, abbreviations are examples of where forms determine contents. Among many linguistic motivation, abbreviations are closely related to the motivation of economy. In this respect, there is a need to discuss formation of abbreviations in terms of linguistic motivation.

We have briefly discussed abbreviations in terms of their types and linguistic motivations in the formation. Bearing this in mind, this research will examine types of abbreviations of English loanwords in Japanese and Korean. In doing this research, I used the *Essence Japanese-Korean Dictionary* published by Minjungserim (2001), 2nd edition. The dictionary carries more than 115,000 entries, including not only current Japanese words but also old words, slangs, professional words, and foreign words. Among these, I found about 327 abbreviated English loanwords. The dictionary takes a conservative view in treating words as abbreviations, only entering words which are widely accepted 'standard' words as abbreviations. As is understandable, the standard policy is to transcribe loanwords as exactly as possible to the original words, common people tend to abbreviate rather long

and complex words and phrases as short as possible. In spite of the general tendency, the dictionary carries only 'fixed standard' words, not excluding many instances of words which are currently used in everyday life. In this respect, this research has some limitations in the sense that it does not include abbreviations which are currently used in everyday life.

### 3. Types of Abbreviations of English Words in Japanese and Korean

As we have seen in Section 2, abbreviations in English are classified into five types: (i) consonantal abbreviations, (ii) acronym, (iii) initialism, (iv) clipping, and (v) blending. Based on this classification in mind, let us examine types of abbreviations found in Korean and Japanese.

#### 3.1. Consonantal Abbreviations in Japanese and Korean

Consonantal abbreviations are widely used in Korean and English, being used almost exactly as in English. Borrowed consonantal abbreviations are address terms or measurement units in most cases, as shown in (2).

(2)	English	Korean	Japanese
	Mr.	mistə	misuta-
	cm	sentimetə	senchimeta-
	km	kirometə	kirometa-
	kg	kirogram	kirogramu
	No.	nəmbə	naNba-
	page	peizi	pe-zi-

As shown above, most of the consonantal abbreviations borrowed from English are used almost exactly as in English. Of course, there are some limited changes in pronouncing the words. That is, the final /r/ sound is not pronounced as in British English, and in Japanese, the syllables are transformed into CV(CV) to conform with Japanese syllable structures.

#### 3.2. Acronyms in Korean and Japanese

Acronyms are also found in Korean and Japanese in the case when they are directly borrowed from English. However, the number of acronyms is limited, as in English. Even in English abbreviations in the form of acronym is

limited because they should observe the English syllable structures.

(3) a.	English	Korean	Japanese
	AIDS	eiz i	eizu
	LAN	ræn	ran
	MODEM	modem	modemu
	NAFTA	napta	nahuta
	NASA	nasa	nasa
	NASDAQ	nas i dak	nasudaku
	NATO	nato	nato
	OPEC	opek	opeku
	PROLOG	pi rollog i	puro-ro-gu
	RIMPAC	rimpæk	rimpaku
	ROM	rom	romu
	UNICEF	junisep i	junisepu
	UNESCO	junesko	junesuko
	WASP	waspi	wasupu
b.	laser	leizə	le-za-
	radar/RADAR	reida	re-da-
	scuba	skuba	skuba

As shown in (3), acronyms, just like consonantal abbreviations, borrowed from English are used almost exactly as in English. We can also notice that there are some limited changes in the pronunciation of the acronyms, as discussed above.

### 3.3. Initialism in KE and JE

Initialism is one of the most typical methods of abbreviating long words or phrases. Initialism is prevalent not only in academic writings but also in spoken and written discourse such as television reports and newspapers in everyday life. In Korean and Japanese, a great number of initialisms are directly borrowed from English, and many of them are used almost exactly as in English, as shown in (4).

(4)	English	Korean	Japanese
-----	---------	--------	----------

ABC	eibisi	e-bi-si
CCTV	sisitibi	sisite-bi
EU	iyu	i-yu
GNP	ciempi	zi-enupi
ICBM	aisibiem	aisibiemu
LNG	elenci	eruenzi
MP	empi	emupi
NGO	encio	enzio
OECD	oisidi	oisidi-
PKO	pikeio	pike-o
USA	juesei	yu-esue-

As initialism is one of the most effective ways of abbreviating long words or phrases, it is widely used Japanese English, as shown in (5).

(5) a. Initialism	Japanese	Japanese English
BG	bizi	background, business girl
BS	biesu	bus stop, balance sheet
CATV	si-e-ti-bi	cable TV
CD	si-di-	compact disk, cash dispenser
CF	siehu	commercial film
CM	siemu	commercial message
DK	di-ke-	dining kitchen
DL	di-eru	diesel locomotive
DM	di-emu	direct mail
FA	ehue-	factory automation
FF	ehuehu	front engine, front drive
FR	ehua-ru	front engine, rear drive
HE	eichii-	human engineering
JR	ze-arū	Japan Railways
KK	kabushiki kaisha	Company limited.
LDK	erudi-ke-	living dining and kitchen
LK	eruke-	living kitchen
LL	erueru	language laboratory
LS	eruesu	longshot
MT	emu-tei-	magnetic tape

NG	enuzi-	no good
NHK	enu Eichike-	Nippon Hoso Kyokai
OG	o-zi-	office girl, old girl
OL	o-eru	office lady
OB	o-bi-	old boy
PC	pi-si-	precast concrete
pk	pi-ke-	penalty kick
pt	pi-tei-	physical therapist
SL	esueru	steam locomotive
TB	tei-bi-	Tuberkulose
TPO	teipio-	time, place, occasion
(cf. PB	puraiba-toburando	private brand,
PD	purodyu-sa-	producer)

As shown in (5), Japanese has coined a number of initial words by adopting the method of initialism. In the present data, 57 (i.e., 17.4%) out of the total 327 instances of abbreviations are initialisms. The initial words and the base words illustrated in (5) are not used in English, and thus they are often cited as examples of Japlish vocabulary.

In Korean English, the use of initialism is limited, compared to a rather frequent use of initialism in Japanese English. In Korean, only a limited number of initialisms are found, as shown in (6).

- (6) A/S (<-- After Service) 'after-purchase service, warranty'  
D/C 'Discount' (cf. Direct Current)  
IC 'Interchange' (cf. Integrated circuit)  
CC 'campus couple' (cf. carbon copy)  
OT 'orientation'  
MT 'membership training'  
[cf. PC, TV]  
PB 'private brand'  
PD 'producer'

In Japanese English, some of the initial words cooccur with another nouns. In that case, the initialism functions as a modifying element, as shown in (7).

(7) Initial words	Japanese	Japanese English
G-mark	zi-ma-ku	good design mark
DK group	di-ke- guru-pu	don't know group
D-cock	di-koku	drain cock
EE camera	i-i-kamera	electric eye camera
M size	emusaizu	middle size
QC circle	kyu-si-sa-kuru	quality control circle
SB spot	esubi-spotto	station break spot (ad, news)

As we have seen, in Japanese and Korean, initialisms which are directly borrowed from English are widely used almost exactly as in English. However, Japanese has made a variety of initialisms based on Japanese English, and the number of Japlish initialisms outnumbers Konglish ones.

### 3.4. Clipping in JE and KE

Clipping refers to a process which shortens a polysyllabic word or compound nouns by deleting part of the syllables or components. For example, in English compounds, *phys-ed* came from *physical education*, *poli-sci* from *political science*, *zoo* from *zoological garden*. Likewise in JE and KE, a great number of clipped expressions are found, showing the frequency of 190 (58.1%) out of the total 327 instances of abbreviations. In the Japanese data, we can find a variety of clipped words or phrases, as shown in (8).

(8) clipped words	Japanese	English
dia	daiya	diamond
handkerchi	hankachi, hankechi	handkerchief
infra	inhura	infrastructure
mime	maimu	pantomime
pave	pe-bu[mento]	pavement
perma	pa-ma[nento we-bu]	permanent [wave]
pain	pain[appuru]	pineapple
form	[puratto]ho-mu	platform
pitch	pitchi[ngu]	pitching
posi	pozi[tibu]	positive (film)
pro	puro	production, professional, program, propaganda

regi	rezi[sta-]	register
rehabili	rihabiri	rehabilitation
televi	terebi(zyon)	television
nish	(wa)nisu	varnish
sabo	sabo(ta-zyo)	sabotage

As shown in (8), one or more syllables of polysyllabic English words are clipped, resulting in short forms. Some words such as *sakusu* (sax) from *saxophone*, *pon* (phone) from *telephone*, *maiku* (mic) from *microphone*, *memo* from *memorandum*, *poppu* (pop) from *popular* (music), *purehabu* (prefab) observe the English morphological rules in forming clipped expressions. However, most of the examples illustrated in (8) do not observe the morphological rules of English, resulting in Japlish words.

In Japanese English, part of compound nouns is also deleted, resulting in clipped expressions, as shown in (9).

(9)	clipped words Japanese	(Japanese) English	
a.	ibuningu	ibuningko-to, ibuningudoresu	evening coat, dress
	mataniti-	mataniti- doresu	maternity dress
	maikuro	maikuro basu, maikro firumu	microbus, microfilm
	mini	miniska-to	miniskirt
	missyon	missyon skuru- (mission school)	'Christian school'
	naita-	naitage-mu nighter (game)	night/evening game
	pikku	aisu pikku	ice pick
	randamu	randamu (sampuringu)	random sampling
	rire-	rire-re-su	relay race
	seru	serumo-ta-	cell motor
	saido	saidobure-ki- (side brake)	emergency brake
	su-pa-	su-pa- makettko	supermarket,
			superimpose, superheterodyne
b.	nippa-	uestonippa-	westnipper
	zyoki	diskujzyoki DJ	disk jockey

In (9), in Japanese English, N2 of the compound nouns made of [N1+N2], which is the base of the compound nouns, is frequently clipped, but N1 is

retained as shown in examples in (9a). Only a limited number of compound nouns retain N2 instead of N1, as shown in (9b).

In Korean English, the use of clipped expressions is not that frequent as in Japanese English, but still similar processes of clipping is at work, as in (10).

(10) Clipped words	Korean	English	
a.	anno	ana	'announcer'
	apart	apat i	'apartment' (cf. Apt.)
	ama	ama	'amateur'
	accel	aksel	'accelerator'
	coordi	kodi	'coordinator'
	sign	sain	'signature (autograph)'
	synthe	sindi	'synthesizer'
	classic	clasik	'classical'
	trans	trans i	'transformer'
	porno	por i no	'pornography (--> porn)'
	condo	kondo	'condominium' (<-- a timeshare resort)
	pro	pi ro	'professional'
	mic	maik i	'microphone'
b.	auto	oto	'automatic transmission'
	super	supə	'super-market'
	punc	pnk i	'a punctured/flat [tire]'
	perm	pama	'permanent (wave)' (perm)
	driver	draibə	'screw driver'
	maker	meikə	'famous maker/brand name'
	tele-com	telikom	'tele-communication'
	ero [movie]	ero [mubi]	'erotic movie (soft porn movie)'

As shown in (10), Korean English also has the same process of clipping as found in Japanese English. That is, in (10a), polysyllabic words are clipped into two or three syllable words, abbreviating the long expressions into shorter forms. In (10b), compound nouns are shortened into single words, mostly deleting the base nouns. In (10), words such as 'ama', 'pro', 'classic', 'sign', 'trans', 'mic', 'telecom', 'punc' 'perma' among others were borrowed into Korean from Japanese English, not directly from English. In that respect, these words are also found in Japanese English or Japllish.

### 3.5. Blends in JE and KE

Blends are words which are made from non-morphemic parts of two already existing words, as in *brunch* from *breakfast* and *lunch*, *smog* from *smoke* and *fog*, *aerobicise* from *aerobics* and *exercise* (O'Grady et al. 1996:158). In KE and JE, we can see a number of blends, being made by combining parts of two English words. In particular, Japanese shows a wide variety of blends, as shown in (11). Examination shows that 56 (17.1%) out of the total 327 instances are found In the present data.

(11)	Blends	English Words
a.	ensuto	engine+stop
	hansto	hunger strike
	maikuroke	mic(rophone)+location (JE)
	metaku	meter+taxi
	no-to pasu kon	note(book) personal computer
	omuraisu	omelet+(on) rice (JE)
	re-kido-za-	rake+bulldozer
	tekkusmekkusu	Tex-Mex, Texas+Mexican
	teremetari	television+documentary
	terekura	telephone+club (JE)
	tereshoppu	television shopping
	biniron	vinyl+nylon
	yotteru	yacht+hotel (JE)
b.	hamusando	ham+sandwich
	minchikatsu	mince+cutlet (JE)
	minisu-pa-	mini supermarket
	no-daun	no down payment
	ohuisu-biru	office building
	purahobi-	plastic+hobby (JE)
	poribaketsu	poly(ethylene)+bucket
	resipuro enzin	reciprocating engine
	rokesetto	location+set (JE)
	ruporaita-	reportage +writer
	talentoana	talent announcer (JE)
	ta-minaru depa-to	terminal department store

terebigemu            television game

As shown in (11a), blends in JE are formed from the first part of the modifying noun and the final part of the second (and third) one(s). In (11b), either parts of either the first or second noun is deleted. Some blends are directly borrowed from English, as in the cases of *ekobizinesu* (eco business) from *ecology+business*, *mukku* (mook) from *magazine+book*, *heripo-to* (heliport) from *helicopter+airport*, and *haiteku* (high-tech) from *high + technology*. However, the blends in (11) are created by observing the Japanese morphological rules, resulting in Japlish words.

Korean also has a few blends, as shown in (12). However, the number of blends in Korean is limited, when compared the number with JE blends.

(12) Blends	English Words
otobai	'auto-bicycle (motor cycle)'
bolpen	'ball-point pen'
bihugas	'beef cutlet'
crepas	crayon+pastel' (JE trademark)
elec gita	'electric guitar'
interphone	'intercommunication telephone' (trademark)
masscom	'mass communication'
rimocon	'remote (control)'
remicon	'ready-mixed concrete'
karerais (<--curryrice)	'curry with/on rice'
omurais (<--ome(lette) rice)	'omelette over rice'

(12) illustrates a few examples of blends which are rather widely used in everyday language. However, words such as *karerais*, *omurais*, *bihugas*, *remicon*, *rimocon* and so on came from Japanese English, and they are also found in JE, though the present dictionary does not carry them.

### 3.6 KE Words Borrowed from JE Words

As is well known, Korean borrowed many English words not directly from English but through Japanese. During the Japanese colonial period, Korean borrowed many Japanese English words in the early and mid 20th century. After the normalization of the relationship between Japan and Korea in the

1960s, many JE words, particularly in food names and technology-related terms were introduced through Japanese, rather than directly from English. The examples in (13) illustrate some of the most frequently used words both in Japanese and Korean.

(13)	Abbreviations	JE	KE	English	
(i)	CF	siehu-	siep i	commercial film	
	CM	siemu	siem	commercial message	
	HE	eichii-	eichii-	human engineering	
	NG	enuzi-	enzi	no good	
	PD	purodyu-sa-	p i rodjusə	producer	
(ii) a.	apart	apato	apat i	apartment (cf. Apt.)	
	ama	ama	ama	amateur	
	condo	kondo	kondo	condominium	
	coordi	kodi	kodi	coordinator	
	classic	kurasiku	k i rasik	classical	
	infra	inhura	inp i ra	infrastructure	
	perma	pa-ma	pama	permanent [wave]	
	form	ho-mu	hom	platform	
	pro	puro	p i ro	program, professional	
	televi	terebe	terebe	television	
	nish	nisu	nis i	varnish	
	b.	driver	doraiba-	d i raibə	screw driver'
		mini	mini	mini	miniskirt
punc		pangku	pənk i	a punctured/flat [tire]'	
perm		pama	pama	permanent (wave)' (perm)	
super		su-pa-	supə	super-market	
(iii)	tele-com	terekomu	telekom	tele-communication	
	autobi	otobai	otobai	auto-bicycle (motor cycle)	
	ballpen	borupen	bolpen	ball-point pen	
	beef cut	bihugasu	bihugas i	beef cutlet	
	curryrice	kareraisu	karerais i	curry with/on rice	
	masscom	masukomu	mæs i kom	mass communication	
	rimocon	rimokon	rimokon	remote (control)	
	om(elete) rice	omuraisu	omurais i	omelette over rice	
remicon	remikon	remikon	ready-mixed concrete		

As shown in (13), many abbreviations based on English are shared between Japanese and Korean. For example, in (13a) initial words made in Japanese are directly borrowed, in (13bi) and (13bii) clipped words were also directly borrowed into Korean. Furthermore, as shown in (13iii), blends were also borrowed from JE into KE. The prominent difference between KE and JE is that JE and KE words observe the phonological rules and syllable structures of Japanese and Korean, respectively.

#### 4. Linguistic Motivations and Context of the Use of Abbreviations

So far, we have seen the types of abbreviations in KE and JE. Examination has shown that initialism, clipping, and blending are typical processes of producing abbreviated expressions in English loanwords in Korean and Japanese.

Here, let us first discuss problems of formation of Japlish and Konglish words in abbreviation. As we have seen, there is certain differences between JE and KE words because Korean and Japanese have different phonological inventory and phonological and morphological rules. Such differences can be broadly schematized as in the following:

English Words==> English Phonological/Morphological Rules==>  
 English Abbreviations  
 English Words==> Korean Phonological/Morphological Rules==>KE  
 Abbreviations  
 English Words==> Japanese Phonological/Morphological Rules==>JE  
 Abbreviations

<Figure 1>. Formation of English/KE/JE Abbreviations

As shown in Figure 1, when Japanese and Korean phonological and morphological rules apply to borrowed English words, the abbreviated expressions result in different forms from English words. Because of such differences, English loanwords in Japanese and Korean result in Japlish and Konglish words, respectively. As is well known, Japanese has a small number of phonemes and syllabary but Korean has a much more richer phonological inventory in representing English loanwords.

Second, As has been discussed in Section 2, formation of abbreviations is closely related to the economic motivation. Zipf (1935:29), who first discussed economic motivation in language, claims that "high frequency is the cause of small magnitude." Haiman (1980, 1983, 1985) discussed extensively on economic motivation and iconic motivation, illustrating how such motivations are at work in the formation of words, phrases, and structures. According to Haiman (1980, 1985), linguistic motivation is defined as "a structural resemblance of language to conceived reality." The iconic motivation is at work to make an expression more clearly by making the form bigger and longer, but the economic motivation to make an expression as simple and short as possible, leading to zero or minimal expressions. As has been discussed above, there has been much discussion on linguistic motivations which determines the relationship between form and content in language. When considered in terms of linguistic motivation, abbreviations are a typical example which is closely related to the economic motivation. Bearing this in mind let us examine how the economic motivation applies to the formation of abbreviations in English loanwords in Korean and Japanese.

The economic motivation can be stated like this: "abbreviate as much as possible." In the use of language, expressions tend to be as short as possible. If you are supposed to repeat expressions such as 'acquired immune deficiency syndrome' and 'permanent wave' every time, it would require too much energy and effort for memorizing and pronouncing. Thus, to lessen the burden of memorizing and pronouncing long words or phrases, one try to abbreviate them as short as possible. Thus, short forms such as 'AIDS' and 'perm' are almost always preferred to the long expressions.

If one applies the economic motivation too much, there occurs a problem of confusion and ambiguity. To avoid such a problem, the economy principle should be modified: "abbreviate as much as possible to the extent of avoiding ambiguity". In this respect, words such as 'infrastructure', 'condominium', and 'mass communication' are abbreviated into 'infra', 'condo', and 'mass com', respectively. As another example, in casual Korean speech, 'stainless steel' is frequently abbreviated into 'sten (stain)' contrary to the intended original meaning (stain-less).

Third, although abbreviation is an economic way of referring to an object, event, or state, the use of abbreviation tends to increase opaqueness of the

referent being talked about. In this respect, the use of abbreviation assumes sharedness of the information of the referent with which the abbreviation is associated. When the information about the abbreviation is not sufficient for the addressee to identify the referent, the current speaker should provide enough information about the referent. In this respect, the use of the abbreviation is closely related to the sharedness of the information about the referent being talked about.

## **5. Summary and Conclusions**

So far, we have discussed types of abbreviation in English loanwords in Korean and Japanese in terms of morphology and linguistic motivations. In Korean and Japanese, many borrowed English words are abbreviated, often resulting in Japlish and Konglish words. This research has shown that formation of Konglish and Japlish words in abbreviation results from the application of Japanese and Korean phonological and morphological rules instead of English rules. Because of the differences in phonological inventories and syllable structures, application of the rules results in JE and KE abbreviations.

Second, this research has shown similarities and differences between Korean and English abbreviations. Above all, Japanese has more diverse expressions of abbreviation in initialisms, clipped expressions, and blends. Examination of the present data shows that JE has more abbreviated expressions than in KE. Such a wide use of abbreviations is related to the limited number of phonemes and simple syllable structures (mostly CV(CV)) of Japanese. Korean, on the other hand, has a relatively rich inventory of phonemes and complex syllable structures (CV, CVC, CVCC, etc.), facing fewer problems in representing English words in their original forms.

Third, this study has discussed linguistic motivations responsible for the formation of loanword abbreviations in JE and KE. This research has shown that economic motivation is the principal motivation for use of abbreviations (Zipf 1935, Haiman 1983, 1985, Croft 1990, Radden and Panther 2004). On the contrary, the motivation of distinctiveness/contrastiveness is also at work to decrease the opaqueness resulting from the use of abbreviation.

Fourth, this research has shown that the use of abbreviation assumes sharedness of the information of the referent with which the abbreviation is

associated. When the information about the abbreviation should be sufficient for the use of abbreviation, in establishing common ground for the communication between speakers. In this respect, this study has claimed that the use of the abbreviation is closely related to the sharedness of the information about the referent being talked about.

In sum, this paper has explored types of abbreviations and linguistic motivations for the formation of abbreviations in terms of morphology and linguistic motivations. Based on the examination of abbreviations in JE and KE, this research has shown that initialism, clipping, and blending are the most important morphological processes. Furthermore, this study has proposed that the linguistic motivations of economy and distinctiveness are the most important motivations which govern the formation of abbreviations in JE and KE.

Dept. of English, Sungkyunkwan University, Seoul 110-745, Korea  
hanjung@skku.edu

## Abstract

This paper examines the effects of focus types on case ellipsis in Korean. A number of previous studies have suggested that accusative case markers in Korean and Japanese cannot be dropped when the object they mark is contrastively focused (Masunaga 1988; Yatabe 1999; Ko 2000; D. Lee 2002). Using experimental evidence, we argue against the view that case ellipsis in Korean is sensitive to the distinction between contrastive vs. non-contrastive focus. An alternative analysis is proposed which accounts for the phenomenon of variable case marking in terms of the interaction between the contrastive strength and the discourse accessibility of focused object NPs. By viewing patterns of case ellipsis as the result of balancing between these two forces, such an analysis can correctly predict the gradient pattern of case ellipsis shown by the three types of focused objects tested in the experiment (contrastive replacing focus, contrastive selecting focus and non-contrastive, informational focus), while at the same time offering an explanation for why subtypes of focus exert distinct influences on case ellipsis.

**Keywords:** case marking, case ellipsis, focus types, contrastiveness, accessibility.

## 1. Introduction

Korean has been described as a language in which all subjects and objects are case-marked, though case marking is optional in colloquial speech. An example of ellipsis of case markers is given in (1):

- (1) a. Ecey            Minswu-ka    chinkwu-lul    manna-ss-ta.  
         yesterday    Minsoo-Nom friend-Acc    meet-Pst-Indic  
         ‘Minsoo met his friend yesterday.’

- b. Ecey        Minswu-ka    chinkwu        manna-ss-ta.  
           yesterday Minsoo-Nom friend(-Acc) meet-Pst-Indic  
 ‘Minsoo met his friend yesterday.’

In (1b), the object *chinkwu* ‘friend’ appears without the following accusative case marker *-lul*, which would normally indicate the object of the verb. While (1a) and (1b) are semantically equivalent, i.e., in both cases the actor is *Minswu* and the theme is *chinkwu* ‘friend’, they may differ in contextually determined meanings, pragmatic functions, attitudes of interlocuters.

This paper examines the effects of the focus type of object NPs on the choice between case-marked and case-ellipsed objects in colloquial Korean. In a number of previous studies, the notion of contrastive focus has been claimed to be an important factor affecting case ellipsis in Japanese and Korean (Tsutsui 1984; Masunaga 1988; Ko 2000; D. Lee 2002, among others). For instance, Ko (2000) has suggested that the accusative case marker *-(l)ul* in Korean cannot be dropped when the object it mark is contrastively focused, i.e., when it is interpreted as contrasting with some other object(s) of the same type. More recently, D. Lee (2002) has analyzed the function of particle ellipsis in Japanese as ‘absolute specification’ i.e., referring to an entity without implying the existence of some alternative.

Using evidence from an elicitation experiment, we argue against the view that the naturalness of object case ellipsis in Korean can be explained in terms of the distinction between contrastive and non-contrastive focus. Instead, we show that patterns of object case ellipsis are sensitive to a more fine-grained distinction between focus types. We propose an alternative analysis which accounts for the phenomenon of variable case marking in terms of the interaction between the contrastive strength and the discourse accessibility of focused object NPs.

## 2. Focus, Contrastiveness and Case Ellipsis

Focus can be defined as the portion of the sentence that the speaker assumes is not known to the hearer. Contrastiveness is the state in which there is a set of entities that is mutually known (a contrast set) and one member is chosen from that set to the exclusion of the other members. Contrastive focus represents a subset of the set of contextually or situationally given elements for which the predicate phrase can potentially hold, whereas non-contrastive, informational focus only conveys new, non-presupposed information. These properties of contrastive focus—the availability of a limited set of

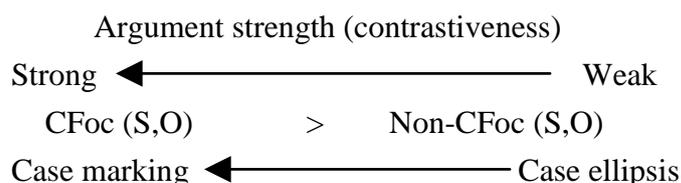

contextually given alternatives and exhaustiveness—contextualize the interpretation of contrastively focused elements and hence make them highly prominent as compared to non-contrastive focus (Choi 1999; Cowles 2003).

In a number of previous studies, the notion of contrastive focus has been claimed to be one of the strongest factors affecting case ellipsis in Japanese and Korean (Tsutsui 1984; Masunaga 1988; Ko 2000; D. Lee 2002, among others). Recently, Lee (2006b) has presented evidence of new factors on case ellipsis in Korean which have been unexplored in previous studies. Her data, drawn from the CallFriend Korean(CFK) corpus (LDC 1996), show that the animacy and definiteness of objects are significantly correlated with the choice of case-marked and unmarked forms of subjects and objects: the relative frequency of unmarked forms over case-marked forms was found to increase with subjects high in animacy and definiteness and objects low in those dimensions, and to decrease with subjects low in animacy and definiteness and objects high in the same dimensions.

Why is it that it is the contrastively focused arguments that tend to resist case ellipsis, and not the ones that are not contrastively focused? In Lee (2006a), we have argued that the effects of focus type and of animacy and definiteness are a reflection of the different functions of case marking. One motivation for case marking the subject or object of a transitive clause is to disambiguate arguments in terms of their function in the clause, especially where these are most likely to be confused (Dixon 1972, 1979; Comrie 1978; van Valin 1992). This function of case marking is known as the ‘distinguishing’ function of case. Another widely attested function of case marking is to mark high-prominent arguments. This function of case marking is referred to as the ‘identifying’ function of case.

De Hoop and Narasimhan (2008) argue that in its identifying function case-marking identifies arguments that are strong or prominent subjects or objects in order to distinguish between more prominent subjects and objects and less prominent ones (CFoc indicates subjects and objects that are contrastively focused, and Non-CFoc the ones that are not contrastively focused):

(2) The identifying function of case

Thus for Korean the identifying function predicts more prominent or stronger focus type, i.e., contrastive focus to be more frequently case-marked than weaker focus type, i.e., non-contrastive focus. Hence the identifying function explains the tendency observed in the experiment that objects left unmarked more frequently when they are low-prominent in the dimension of focus (i.e., non-contrastive focus) than when they are more prominent (i.e., contrastive focus).

Interestingly, the distinguishing function predicts the same pattern of case variation for objects: in the case of objects, the high-prominence ones in animacy and definiteness (e.g. human definite objects) are the ones that are more likely to be confused with subjects and are therefore potential candidates for case-marking on the basis of distinguishability. Thus, overt case should be assigned to objects that are more marked (or more subject-like) and case ellipsis should be more frequently applied to objects that are less prominent and hence are less marked. This prediction is confirmed by the results of our earlier corpus study and experiment reported in Lee (2006b) and Lee (2006a), respectively.

### (3) Distinguishing function

#### a. Argument strength (Animacy/Definiteness)

Strong ←————— Weak  
 Animate, definite S > Inanimate, indefinite S

Case ellipsis ←————— Case marking

#### b. Argument strength (Animacy/Definiteness)

Strong ←————— Weak  
 Animate, definite O > Inanimate, indefinite O

Case marking ←————— Case ellipsis

It must be noted that with respect to *subject* marking, the two explanations make the opposite predictions: the identification function marks the *prominent* or *strong* argument (i.e., contrastive focus), while the distinguishing function marks the argument that is more marked as the grammatical role of subject and hence confusable with objects (i.e., *low-prominence* subjects such as inanimate or indefinite subjects). In this paper, however, we are only concerned with object case ellipsis, leaving the question whether these predictions about subject marking are indeed the case for future research.

Before closing this section, we will discuss an important methodological limitation of our earlier experimental study, which has to do with the design of the experiment. As is well known, there are several different types of contrastive focus (Dik

et al. 1981; Dik 1989), which all assume a contextually or situationally given set of alternatives. But our experiment tested just one subtype of contrastive focus referred to as ‘replacing focus’. This type of contrastive focus explicitly contradicts a stated alternative and is considered the clearest instance of contrastiveness in some pragmatic approaches to contrastiveness (Lambrecht 1994; C. Lee 2007):

- (4) A: Jinmi-ka      computer(-lul)      sa-ss-e.  
      Jinmi-Nom      computer(-Acc)      bought  
      ‘Jinmi bought a computer.’  
      B: Aniya, hywutaephon(-ul)      sa-ss-e.  
      No,      cell phone(-Acc)      bought.  
      ‘No, (she) bought a cell phone.’

The fact that the design of the experiment was not balanced for subtypes of contrastive focus is an important issue because as not all types of contrastive focus may behave in the same way with respect to their formal realization, and hence choice of particular subtype of contrastive focus could have a considerable impact on experimental results.

S. Lee (2006) notes that in certain cases ellipsis of the accusative case marker is favored even though the object it marks is contrastively focused. Consider the following example in (5), taken from Lee (2006a: 333):

- (5) A: Jinmi-ka      computer(-lul)      sa-ss-e,      hywutaephon(-ul)  
      Jinmi-Nom      computer(-Acc)      bought,      cell phone(-Acc)  
      sa-ss-e?  
      bought  
      ‘Did Jinmi buy a computer or a cell phone?’  
      B: computer(-lul) sa-ss-e.  
      ‘(She) bought a computer.’

In B's reply, ‘computer’ is an example of what Dik et al. (1981) refers to as ‘selecting contrastive focus’. Unlike replacing focus, this type of contrastive focus does not involve any explicit contradiction of some other previously stated alternative. As in B's reply in (5), the speaker simply picks out one of the two candidates presented in a disjunctive question uttered by A. What's interesting about the formal expression of selecting focus objects is that they seem to favor case ellipsis over explicit accusative

marking. All Korean speakers we have consulted agree that the version with case-ellipsed selecting focus is more natural than that with the case-marked counterpart, while both versions are grammatically well-formed. One of the goals of the experiment, which will be presented in section 4, will be to examine whether and how two subtypes of contrastive focus (replacing vs. selecting focus) exert distinct influences on variable case marking in Korean.

### **3. Contrastive Strength, Accessibility and Case Ellipsis**

Recall that in its identifying function, case marking identifies strong arguments to distinguish more prominent subjects and objects from less prominent ones. Thus an account of case marking based on argument strength would predict that contrastively focused arguments to be more frequently case-marked than arguments that are not contrastively focused. This account further predicts stronger subtypes of contrastive focus to be more frequently case-marked than weaker ones. Of the two subtypes of contrastive focus tested in this experiment, which one is stronger than the other in terms of contrastiveness? Let us consider main sources of contrastiveness to clarify this question. The most important criteria that have been discussed in the literature in connection with the definition of contrastiveness are listed below:

- (6) a. Membership in a set
  - b. Limited set of alternatives
  - c. Exhaustiveness
  - d. Explicit contradiction of alternatives

The basic requirement for contrastiveness is membership in a set, namely that we can generate a set of alternatives for the focused constituent (Jackendoff 1972; Rooth 1985; Krifka 1993; Vallduví and Vilckuna 1998). Rooth (1985) and Krifka (1993) claim that a focus always evokes a set of alternatives. According to this view there is no contrastive focus to be separated from the ordinary, informational focus. Instead, focus is viewed as uniformly conveying a contrast between the actual element in focus and the potential alternatives. In fact, informational focus may involve membership in a contextually or lexically evoked set, though it does not require the existence of a contrast set. This is illustrated in (7):

(7) A: Did you finish packing what you need?

B: Yes, I packed toothpaste and a hair-drier. But I forgot my toothbrush.

*Toothpaste* and *a hair-drier* can trigger a set of travel items in the context of (7) (due to the previous mention of *packing*), and these items can provide the contrast needed for the focused *toothpaste* and *a hair-drier*.

In many approaches to focus, however, membership in a set is narrowed down to the requirement of a *closed* set. The decisive criterion for contrastiveness is thus, according to Halliday (1967), Chafe (1976) and Rooth (1992), the availability of a limited number of candidates. When the set of possibilities is unlimited (or not contextually restricted), the sentence supplies only new information and fails to be contrastive. Contrastiveness adds the requirement of exhaustiveness (Chafe 1976; Kiss 1998). Thus based on the two decisive criteria for contrastiveness (the limited number of candidates and exhaustiveness), we can define contrastive focus as follows: a contrastively focused constituent refers to alternatives in a contextually limited set where the alternatives are known to the participants of the discourse and identifies one element exclusively out of that set.

A further criterion of contrastiveness is explicit contradiction of some previously stated alternative(s). Halliday (1967) defined contrast to mean something that is contrary to a previously stated or predicted alternative. However, while it is the case that contrastiveness often has this corrective reading as in the case of replacing focus (example (4)), it does not require it, as shown in (5) above.

The criteria of contrastiveness mentioned above lead to the following distinction between foci:

(8) Distinction between foci according to contrastive properties

	Informational focus	Selecting focus	Replacing focus
Membership in a set	✓	✓	✓
Limited set of alternatives	X	✓	✓
Exhaustiveness	X	✓	✓
Explicit contradiction of alternatives	X	X	✓

On the basis of this distinction, we can also derive the following scale of contrastiveness where higher positions correspond to greater contrastive strength:

(9) Scale of contrastive strength:

Replacing focus > Selecting focus > Informational focus

Informational focus is the least clear or weaker instance of contrastiveness because it meets only the most basic requirement for contrastiveness, namely that of membership in a set. In addition to this, selecting focus meets two other criteria for contrastiveness, i.e., the limited number of candidates and exhaustiveness, and replacing focus meets the additional requirement of explicit contradiction of stated alternatives. Thus informational focus can be considered the least clear or weakest instance of contrastiveness, while replacing focus is the strongest instance of contrastiveness having the greatest number of crucial factors of contrastiveness.

The account of case marking based on contrastive strength would predict that of the three subtypes of focused objects, overt case applies most frequently to replacing focus objects and least frequently to informational focus objects, in line with the degree of contrastive strength:

(10) Prediction of contrastive strength:

Overt case-marking  $\longrightarrow$  Case ellipsis  
Replacing focus > Selecting focus > Informational focus

An alternative account of the phenomenon of variable case marking that is conceivable is to focus on the function of *case ellipsis* rather than on the (identifying) function of *case marking*. Why do speakers sometimes omit elements of syntactic structure that are normally obligatory? The short answer to this question is that speakers exploit ellipsis “for reasons of economy or style” (Crystal 1997: 134). The first function, economy of expression is, as the philosopher H.P. Grice observed, one of the fundamental principles underlying how speakers communicate with one another. Speakers strive to be only “as informative as required” and to “avoid unnecessary prolixity” (Grice 1975). From this perspective, ellipsis can be viewed as a mechanism by which speakers achieve more efficient communication (Nariyama 2000). However, ellipsis is not merely a tool for compressing utterances. Speakers often exploit ellipsis in order to convey aspects of the ‘packaging’ of their message. Hawkins (2004) argues that economy of expression is tied to the accessibility or cognitive status of a referent, i.e., the degree of activation of a referent in a mental representation: the more accessible entities are referred to by shorter and more reduced forms.

The accessibility of a referent is affected by three main factors: recency of mention,

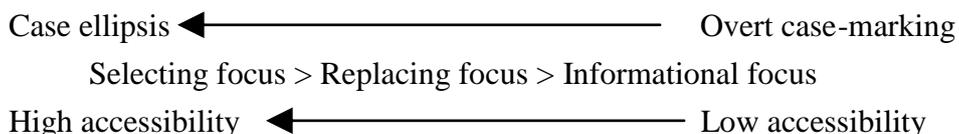

explicit mention, and unity—whether the previous mention of the referent is in the same or previous sentence, or in the same or previous paragraph. Entities that have been recently mentioned are more accessible than those mentioned further back in time (Prince 1981; Ariel 1990). Entities that have been mentioned explicitly are also more accessible than those whose existence is derived by an associative or bridging inference or by a general knowledge frame (Clark and Haviland 1977; Hawkins 1978; Matsui 2000). Entities are more accessible when they are mentioned in the same or previous sentence than when they are not (Arnold 1998; Almor 1999).

Coming back to the problem of the morphosyntactic encoding of focus accessibility, focus is not generally associated with high accessibility of its referent. But it is not the case that the referent of focus is always inaccessible. While focused referents do not consistently encode highly accessible referents, empirical work on the processing of focus shows that both topic and contrastive focus cause an increase in referent accessibility that leads to a preference for pronominal co-reference (Arnold 1998; Almor 1999; Cowles 2003). Cowles (2003) argues that this similarity between topics and contrastive foci with respect to referent accessibility is attributable to their shared property of presupposition of existence. As discussed earlier, in order for a sentence containing a contrastive focus to be felicitous, elements that are within the scope of that focus are presumed to exist prior to the utterance, even when they are not previously given in the discourse. Topics also necessarily presuppose the existence of their referent (Lambrecht 1994). These studies thus provide evidence in favor of the higher accessibility of contrastive focus compared to non-contrastive focus.

Of the two subtypes of contrastive focus tested in the current experiment, selecting focus can be considered most accessible than replacing focus in terms of givenness and unity. The referent of the selecting focus is often explicitly mentioned in a disjunctive question uttered by the previous speaker, whereas replacing focus does not have to take up a previously mentioned referent. Unlike replacing focus, selecting focus does not involve any explicit contradiction of some other previously stated alternative and satisfies the previous speaker's expectation or presupposition that his or her question will be answered with one disjunct (C. Lee 2007), thus leading to more predictable continuation of the discourse. This unity in turn may result in higher activation for the representation of the referent of the selecting focus.

Since more accessible entities are preferentially referred to by shorter or less complex forms, selecting focus objects are expected to be case-ellipsed more frequently than objects that represent other kinds of focus that are less accessible than selecting focus:

(11) Prediction of accessibility:

#### 4. Effects of Contrastive Strength and Accessibility: Experimental Study

##### 4.1. Methods

**Participants:** 98 students from Sungkyunkwan University, ages 20-26, participated in this experiment. The time to complete the experiment was approximately 15-20 minutes. All participants were native speakers of Korean, defined as having learned Korean before age five.

**Procedures:** Each participant was asked to fill in a questionnaire, which contained short conversations between two speakers, providing contexts for the choice of case-marked and case-ellipsed forms of an object. The participants had to choose as spontaneously as possible between the two object forms in the given contexts.

**Conditions and Stimuli:** An example of the stimuli used in the experiment is given below in (12). There were 20 items per condition, 60 items altogether.

(12) Example stimuli

Condition	Stimuli
Contrastive- Replacing focus	A: Jinmi-ka     computer(-lul)   sa-ss-e. Jinmi-Nom   computer(-Acc) bought ‘Jinmi bought a computer.’ B: Aniya, <u>hywutaephon-ul/∅</u> sa-ss-e. No,     cell phone-Acc/∅     bought. ‘No, (she) bought a cell phone.’
Contrastive- Selecting focus	A: Jinmi-ka     computer(-lul)   sa-ss-e,   TV(-lul) Jinmi-Nom   computer(-Acc) bought,   TV(-Acc) sa-ss-e? bought ‘Did Jinmi buy a computer or a TV?’ B: <u>computer-lul/∅</u> sa-ss-e. ‘(She) bought a computer.’

Non-contrastive- Informational focus	A: Ecey        mwuel        sa-ss-e? yesterday what.Acc bought 'What did you buy yesterday?'
	B: hwuka    cwung ilk-u-lyeko <u>chayk-ul/∅</u> sa-ss-e. break during read-to        book-Acc/∅ bought '(I) bought books to read over the break.'

#### 4.2. Results

Figure 1 below shows the relative frequency of case-marked and case- ellipsed objects according to the three types of focus tested. We can see that case-ellipsed forms are most frequent in the selecting focus condition (65%) and least frequent in the replacing focus condition (35%). By contrast, accusative-marked forms are most frequent in the replacing focus condition (65%) and least frequent in the selecting focus condition (35%). These results are significant at the 0.05 level ( $\chi^2=9.66$ ,  $df=2$ ).

(13) Figure 1. Relative frequency of case-marking vs. case ellipsis for three types of focused objects

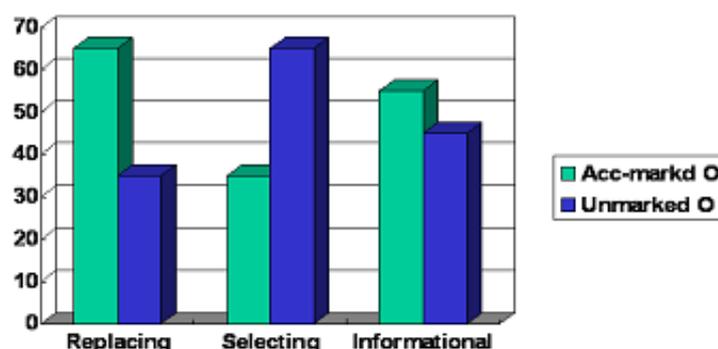

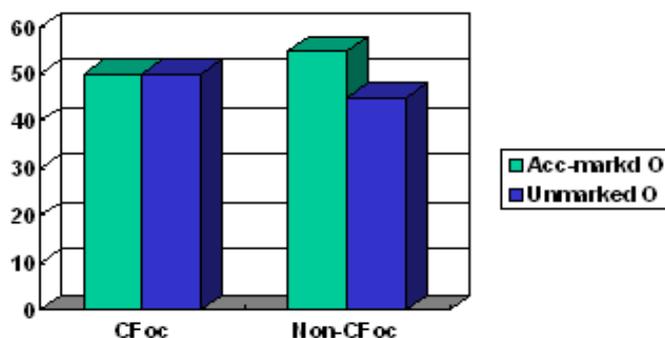

Figure 1 further shows that case-ellipsed forms are more frequent only in the selecting focus condition, while in the other two conditions, accusative-marked forms are more frequent.

When collapsing replacing focus and selecting focus into a single category of contrastive focus and considering how the two object forms are distributed in the two conditions, the following picture emerges. As shown in Figure 2, non-contrastive, informational focus objects show higher rate of overt case marking (55%) than contrastively focused objects (50%). The table further reveals that the rate of case ellipsis for contrastively focused objects (50%) is higher than the rate for informational

focus objects (45%), but the difference is not significant ( $\chi^2=0.5$ ,  $df=2$ ).

(14) Figure 2. Relative frequency of case-marking vs. case ellipsis for contrastively focused objects and informational focus objects

These results show that the dichotomous distinction between contrastive vs. non-contrastive focus is insufficient to account for the gradient pattern of case ellipsis for focused objects. Moreover, the results are not consistent with prior claims regarding the influence of contrastiveness on case ellipsis in Korean, calling into question the categorical generalization offered in previous studies that accusative case markers cannot be dropped when the object they mark is contrastively focused.

### 4.3. Discussion

#### 4.3.1. Accounts based on contrastive strength

As discussed in section 3, according to the account of case marking based on argument strength (e.g., Lee 2006a), the rate of case marking for argument NPs is sensitive to their relative strength in contrastiveness. If this is the case, replacing focus objects should show higher rate of case marking than the other two kinds of focused objects, in line with the degree of contrastive strength: replacing focus > selecting focus > informational focus. The experiment presented in section 4.2 provides support for this account as well as showing some results that it does not predict. Support for this account is found in the highest rate of case marking on replacing focus objects. However, the experiment also showed that informational focus objects are overtly case-marked by the accusative case marker more often than selecting focus objects. This finding is not consistent with the prediction of the account based on contrastive strength and cannot be accounted for in an account that takes into account contrastiveness as a sole factor triggering case marking.

#### 4.3.2. *Accessibility-based accounts*

The highest rate of case ellipsis on selecting focus objects confirms the prediction of an accessibility-based account that rate of case ellipsis is sensitive to the degree of the accessibility of argument NPs. The difference between selecting focus objects and replacing focus objects with respect to the rate of case ellipsis is attributable to the higher accessibility of the referent of selectively focused constituents. While offering a good account of the difference between selecting focus objects and replacing focus objects, the accessibility-based account offers no account of why informational focus objects, which are least accessible among the three subtypes of focused objects tested, show higher rate of case ellipsis than replacing focus objects. This suggests that an account which attempts to explain case variation solely in terms of the accessibility of arguments but does not take their contrastive strength into account would be inadequate.

### **5. The Balance between Form Minimization and Identification of Strong Arguments: A Proposal**

Why should accessibility be such an important factor that results in form minimization. Levinson (2000) and Hawkins (2004) suggest that what underlies form minimization is processing enrichment, that is inferences of various sorts which make use of linguistic or contextual clues. Levinson (2000) discusses an important truth about the exploitation of such clues, namely ‘Inference is cheap’: these inferences take place anyway, and it is inefficient to undertake additional processing of forms and properties when the relevant properties are already inferable contextually or are readily accessible for other reasons. Hawkins (2004) formulates a similar idea as the principle of Minimize Forms (MiF):

- (15) *Minimize Forms* (MiF): The human processor prefers to minimize the formal complexity of each linguistic form F and the number of forms with unique conventionalized property assignments, thereby assigning more properties to fewer forms. These minimizations apply in proportion to the ease with which a given property P can be assigned in processing to a given F. (Hawkins 2004: 38)

The principle of MiF predicts that the processor prefers minimizations in unique form-property pairings. Both formal units and unique property assignments can be minimized by using morphologically simple forms for frequently used elements and for properties that are inferable contextually or through inferences or real-world knowledge.

Pragmatic studies of reference within linguistics and psycholinguistics have identified several factors that facilitate form reductions and processing enrichment. They include (Hawkins 2004: 44-45):

- (16) a. High accessibility for the entities and events in the current discourse
- b. High frequency of property assignments in previous discourse
- c. Default or stereotypic correlation between a property (P1) and a second property P2, permitting P1 to be inferred from P2.
- d. Relevance or enrichment implicatures based on real-world knowledge

Having discussed the general principle of MiF as the ultimate basis of the relevance of accessibility to case ellipsis, we will now address the question of what this principle predicts about the gradient pattern of case ellipsis shown by the three subtypes of focused objects tested. First, let us consider what processing efficiency predicts about the realization of selecting focus. The strong preference of selecting focus for case ellipsis follows naturally from MiF: it is because of the high accessibility of the referent of selecting focus that it has priority for a simpler form, i.e., zero-marking. Although minimizing forms and assigning properties through on-line processing enrichments reduce overall processing effort in many cases, one cannot minimize everything and assign all properties through on-line inference. There has to be a balance in human languages between conventionalized forms and their linguistic properties on the one hand, and on-line inference on the other.

This balance is achieved by the interaction of processing ease and conventionalization or grammaticalization. Hawkins (2004: 41-42) suggests that processing ease and frequency regulate reductions in form, while frequency and preferred expressiveness regulate grammaticalization preferences.

Which properties get priority for unique assignment to forms in the grammar or lexicon is subject to language-specific choices. In the domain of case marking, it is often the case that the semantic proto-typicality and/or discourse prominence of arguments (e.g., topicality or contrastiveness) that have priority for overt case marking (Legendre, Raymond and Smolensky 1993; Næss 2004; de Hoop and Narasimhan 2008). The use of case morphology to mark argument prominence is said to have identificational motivation. As discussed in section 3, replacing focus is the most strongly contrastive focus type. This explains why replacing focus objects show highest rate of overt case marking.

Furthermore, the account of variable case marking proposed here can explain the

role of animacy and definiteness in the formal realization of arguments. As Lee (2006b, 2007, Lee 2008b) has shown, the animacy and definiteness of subjects and objects are significantly correlated with the choice of case-marked and unmarked forms of subjects and objects in the corpus of colloquial Korean and that the case marking patterns for subjects are the mirror image of the patterns for object case marking: the relative frequency of case-ellipsed forms over case-marked forms was found to increase with subjects high in animacy and definiteness and objects low in those dimensions, and to decrease with subjects low in animacy and definiteness and objects high in the same dimensions.

On the basis of these facts, Lee (2008a) argues that animacy/definiteness effects in Korean are distinguishing (between subjects and objects), rather than identificational, and further argues property enrichment based on frequency and the stereotypicality of the associations between properties of an element as the ultimate basis of the distinguishing function of case, following Hawkins (2004): subjects are more frequently high in animacy and definiteness than low in the same dimensions; objects are more frequently have the opposite properties across languages. As a result, these patterns of frequent association between animacy/definiteness and grammatical functions can lead to an inference. For example, low-prominence in animacy and definiteness permits the inference to 'grammatical objecthood', because of its frequent association, and this inference permits zero case-marking by MiF. There is no such inference, however, when an object is high in animacy and definiteness and hence does not match the default correlation between animacy/definiteness and grammatical function. (Zeevat and Jäger 2002; Hawkins 2004). Thus, on this account, the factors of animacy/definiteness and accessibility can be subsumed under a single and simple principle of form minimization, motivated by processing efficiency.

## **6. Conclusions**

We have argued that gradient patterns of case marking and case ellipsis in Korean should be analyzed as a result of balancing between processing efficiency and the need to express argument strength. We have shown that only an approach to case variation that seriously considers both the economy motivation for case ellipsis and the function of case marking is capable of providing a complete view of the effects of focus types on case variation and that in so doing it may also answer the question why subtypes of focus show different preferences for case marking and case ellipsis.

**Abstract**

This study explores the relation between the lexical semantics of locative verbs and their argument realization. Along with the overview of Pinker's lexical semantics (1989), it proposes the alternatives to his *lexical rules*, assuming the aspectual property as one of syntactically relevant semantic features and children's sensitivity to the distinction of  $\pm$  boundedness (completion / affectedness) as part of innate competence: (1) *Underspecification Hypothesis* for the semantic representation of argument alternation verbs and (2) *Direct linking of aspectual properties to the object position Hypothesis* with emphasis that these aspectual properties directly trigger a linking to the direct object - through the object selection of the two, 'locative' or 'theme' in locative alternations - *without the mediation of lexical rules or thematic hierarchy*.

**key words:** argument alternation, semantic representation of locative verbs, underspecification, aspectual properties, linking rules and thematic hierarchy.

## **1. Problems with locative alternations**

### *1.1. Introduction*

Universal Grammar (UG) can be viewed as part of a theory for explaining Language(L1) acquisition phenomena. An important part of UG in the acquisition of argument structure is to address the interface between semantics and syntax, especially the principled relations between semantic properties of predicators and the surface realization of their arguments. There is a consensus that there are certain aspects of semantics-syntax correspondences which must be driven by underlying principles of UG. One of these principled relations/universal linking rules is a thematic approach

which is based on thematic hierarchy including Universal Theta Assignment Hypothesis (UTAH, Baker 1988).<sup>1</sup>

However, argument structure alternations which seem to violate this universal linking rule of thematic hierarchy have long been identified as a major potential source of acquisition difficulties. Also this raised the problem with the thematic linking principle. The main concern of this study is with two issues related to the acquisition of argument alternation of locative verbs: (1) the problem of linking to the direct object, which violates the universal thematic hierarchy and (2) semantic representation of this alternator / verb. Hence two main goals are on (a) the semantic representation of alternating locative verbs and on (b) how mapping rules work.

### *1.2. Universal Linking theory based on the thematic roles*

In order to capture the observations that in most cases the argument bearing the semantic role of Agent also has the grammatical function of subject, and that the argument bearing semantic role of Theme often has the grammatical function as the direct object of the verb, independent principles are required to establish the links between semantic roles and structurally defined grammatical functions (GFs). And Thematic Hierarchy which determines position of arguments at D structure is proposed to identify principled relations between two.

There are several versions of the Thematic Hierarchy, and that of Larson (1988) is the example used here. Thematic Hierarchy states that theta roles form an ordered list, and that there are rules which link theta roles to positions in syntax. Given the thematic roles a and b, if a > b on the thematic hierarchy, then the element a will be projected at a 'higher' position in phrase structure than the element b, The hierarchy assumed in Larson (1988:382) is as in (1)

#### (1) Thematic Hierarchy.<sup>2</sup>

Agent > Theme > Goal > Obliques (manner, location, time . . .)

---

<sup>1</sup> The assumption is that principles of UG correlate thematic structure with syntactic structure in a uniform fashion. See the next page.

<sup>2</sup> There are various versions of thematic hierarchies (Jackendoff 1987, Fillmore 1968). The relevance of this study is limited to the hierarchy between the two, theme and locative/location.

There is another version of thematic approach similar to thematic hierarchy. In order to strengthen the links between thematic relations and syntax, Baker (1988) proposes the Uniformity of Theta Assignment Hypothesis (UTAH), which states that “identical thematic relationships between items are represented by identical structural relationships between those items at D-structure” (Baker 1988:47). Both of these propose a fundamental connection between meaning or thematic relationships and some level of syntactic representation. The approach that utilizes these thematic hierarchies is often called ‘canonical linking rules’, sometimes universal rules in the sense that it can be a device which helps the task of the acquisition of argument structure.

### *1.3. Problems with locative alternations in English*

However, a major sticking problem for the hypothesis, universal linking based on thematic roles has been the existence of seeming counter-examples to any proposed set of linking rules: for example, including ‘double-object dative’ / ‘ground-object locative’ where the argument traditionally analyzed as the ‘theme’ is not expressed as the verb’s first object.

The major concern of this paper is with the issue related with ‘locative alternations’. That is, how certain aspects of verb meanings are realized in syntax.

There have been much researches on the locative alternations (Pinker 1989, Gropen et al. 1991) since part of the problems with these canonical/universal linking rules comes from argument structure alternations, such as locative verb ones which have both ‘locative/location’<sup>3</sup> and ‘theme’ internal argument.

#### *1.3.1. locative verbs in English*

Before going into the main concern, we look over the problems with locative verbs in general briefly, and then deal with the main concern of this paper, problems of argument alternation verbs like *spray* and *load*.

Locative verbs are verbs involving the transfer of some substance or set of object (Theme, content) into a container or onto a surface (locative/goal ground) as illustrated in (2) and (3)

---

<sup>3</sup> The terms, locative and location can be used interchangeably but the ‘location’ is usually used to refer to a thematic label.

problem of linking to the direct object, which violates the universal thematic hierarchy and (2) semantic representation of these alternator/verbs.

## 2. Pinker's lexical semantic foundation for argument linking and some problems

Pinker (1989) in his book, the Acquisition of Argument Structure, propose the semantic structure theory of linking and lexical rules for the learnability of locative alternation. According to the semantic structure theory of linking, which is sort of lexicalist view, the linking is predictable from lexical semantics, and in that theory, it is lexical rules that change the semantic structure in order to correspond to the linking. That is, it is necessary to change the semantic structure to be compatible with the structural meaning before the operation of linking rules.

Along with such a proposal that the mechanism by which semantic arguments interface with the syntax(argument projection) is situated *in the lexicon*, or more precisely, in the verbal entries, Pinker makes a distinction of semantic structures between broad-range rules of argument structure, which are universal and inviolate; and narrow-range rules<sup>5</sup> of argument structure, which can be language-specific. This study is concerned with the broad-range rules and their relevance to lexical rules.

### 2.1. Pink's two broad semantic classes and the lexical rules

#### 2.1.1 The two broad semantic classes

Pinker's account of locative verbs is that they fall into two different broad semantic classes, which are as follows (Juff 1996:49) (1) those verbs (like *pour* in (2) above ) that specify *movement* and *manner of movement*, plus properties of the entity(the 'content' verbs or Figure object class). The verbs of this class do *not specify any end state* of the Goal - e.g with *pour*, the thematic core of these verbs are: *X cause Y to go to Z*. (2) those verbs (like *fill* in (3) above) which specify that a surface container or medium undergoes 'a change as a result' of the addition of material to it (the 'container' verb or 'Ground' object class). The verb *fill*, for example, specifies a change

---

<sup>5</sup> He proposes these narrow classes of verbs as Constraints on lexical rules that furnish criteria for selecting verbs can solve Baker's paradox in principle. However the details are beyond the scope of this study.

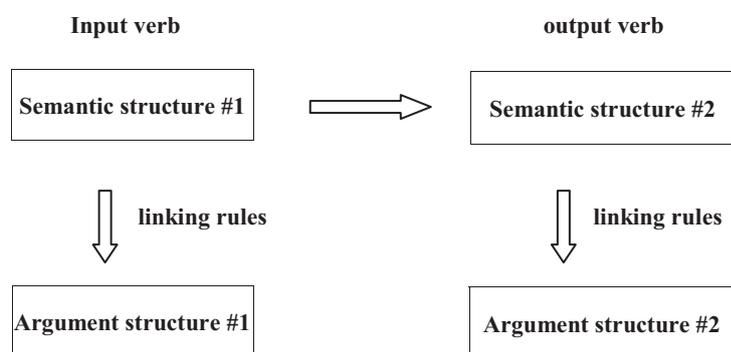

of in the receptacle. The thematic core is described as *X cause Y to go into a state by causing Z to go to Y*.

Pinker suggests that such broad-range rules are indeed part of adult’s competence that is universal linking rule of argument structure. What is worth noting here is the concept of the dichotomy of ‘manner of movement’ verb vs. ‘change of state’ verb in his two broad classes. And it can be seen as parallel with the concept of aspectual properties in event structure ( $\pm$  process vs result state /  $\pm$  telicity, boundedness whatever) and also will be utilized later for an alternative proposal of this study.

### 2.1.2. The Lexical Rules

In Pinker’s model the meaning structures of alternate forms<sup>66)</sup> like *spray/load* will be derived by a ‘lexical rule’ which converts the semantic structure of the content verb to that of a container verb, or container verb to that content verb

**Figure 1** (Pinker 1989:63)

In his view (figure 1), ‘the lexical rule’ acts directly on the verb’s semantic representation, transforming it into a new one. In other words, the new verb has a different meaning from the old one. Semantic structures are mapped onto syntactic argument structures, thanks to linking rules, so when the verb’s meaning changes, its argument structure changes, too, as an automatic consequence according to his universal broad range linking rule. Pinker shows the relations among semantic structures, lexical rules, and linking rules in the following Figure 1.

<sup>66</sup> And, in Pinker’s system a four way classification for locative exists: content [ $\pm$ Alternator] and Container [ $\pm$ Alternator] are presented. Content alternator requires Theme argument, and that verb belongs to the content-oriented verb. Among Pinker’s four way classifications, this study is limited to the issues related to alternators/verbs.

And he provides part of explanations for the predictability of alternation on the basis of the verb meanings like example (6).

- (6) a. spray the plant with water
- b. \*put the plant with water

You can *spray the plant with water* but not *\*put the plant with water*, because “with-locative requires *a specific state change* and *putting* does not specify what it would be (Pinker 1989: 82)”. This explanation could mean that the requirement for the operation of linking rule is the compatibility of verb meanings with structural meanings.

So locative alternation can now be stated simply: It is a rule that takes a verb containing in its semantic structure the core *X causes Y to move into/onto Z* and converts it into a new verb whose semantic structure contains the core *X causes Z to change a state by means of moving Y into/onto it*. Basically such a lexical rule is equivalent to one which change the semantic structures. And then, the operation of two broad range class linking rules like (7) works.

The two broad range class linking rules are summarized in (7)

- (7) a. Manner of movement verbs —> theme-object (structure)
- b. Change of state (result state) verbs —> locative-object (structure)

Pinker (1989) suggests that such broad-range rules are indeed part of adult's competence that is (near) universal linking rule of argument structures and treats alternating verbs as two different words with the same form, that is, polysemy.

In sum, the behavior of locative verbs supports a conception of argument structure alternations as operations that take a verb in one conflation class, serving as the thematic core of one kind of argument structure, and create a new verb, sharing the same root but having an altered semantic representation that places it in a different conflation class serving as the thematic core of a different argument structure (Pinker 1989:81).

However, such an explanation presents a problem for L1 acquisition of semantics-syntax correspondence, the so-called logical problem of language acquisition, which requires a simple model.

## 2.2. *Meaning differences and affected-object-principle*

In locative alternation another frequently discussed concern is with the meaning difference.

### 2.2.1. *Meaning differences*

As mentioned earlier, there are systemic meaning differences in locative alternation along with two Broad Range Rules: For verbs where the items moved in a particular manner, people were more likely to express the moving items (theme) as the object; for verbs where the surface (location) changed state, the location as the object.

Locative verbs are verbs involving the transfer of some substance or set of object (theme/content) into a container or onto a surface (locative/goal). Relevant examples from Pinker (1989: 49) are following.<sup>7</sup>

- (8) a. John *sprayed* paint onto the wall  
b. John *sprayed* the wall with paint.  
(9) a. John *loaded* the truck with hay.  
b. John *loaded* hay onto the truck

Again, there is a meaning difference of *a* and *b*. In the (*a*) sentences the focus is on the 'movement' of the entity denoted by the direct object; in the (*b*) sentences, the focus is on the 'change of state' of the direct object. In addition, the NPs in direct internal argument position (object) in the (*b*) sentences are interpreted as 'wholly affected' (hence sometimes called 'holism') by the action specified by the verb (Gropen et al. 1991a). Here *the wall* and *the truck* in (8*b*) and (9*b*) are understood to be 'completely' sprayed with paint and full of hay, respectively whereas in the (*a*) sentences this is not necessarily so.

---

<sup>7</sup> Among Pinker's four way classification, this study is limited to the phenomena of 'pure alternators /verbs' like *spray* and *load*.

### 2.2.2. *The affected-object-principle/linking rules*

There are some studies that this locative alternation is associated with a subtle but consistent semantic difference in terms of ‘affectedness’. In order to capture such an observation that there is a systematic meaning difference in locative alternations, especially affectedness in object position, Gropen et al (1991a) propose the ‘affected-object-principle linking rules which are assumed as universal’ and suggest that these universal linking rules, shared by parent and child would yield the correct syntactic analysis for the child as long as the child could identify which entities counted as ‘affected’.

In addition, “Rappaport and Levin suggest that the holism effect is actually an epiphenomenon of the fact that the verb specifies a ‘change of state’ (Pinker 1989:78)”. Tenny (1994) emphasizes that only the direct arguments can be holistically or completely involved in the event. There is also a study in which they (*load/spray* alternations) do not appear to be characterizable in terms of thematic role labels alone and recommend the use of ‘± affectedness feature’ for this kind of meaning difference of them. But the way to incorporate it with semantic structure of locative verbs is not mentioned.

### 2.3. *Overview and problems with Pinker’s lexical rules*

Some points we have discussed about are as follows.

1. The operation of the lexical rule is the mechanism through which either of two meaning classes is changed to the other meaning class and then universal linking rules with broad range classes are applied automatically.
2. And his lexical rules of changing the meaning structure assume the distinction between the ‘base’ meaning and the ‘derived’ meaning. That is, we can notice that of the two alternates either one belongs to a ‘base’ meaning and the other to a ‘derived’ one through lexical rules. Consequently, we need a burden of distinguishing which is a base verb and which is a derived one.
3. Furthermore, there are studies that alternate verbs of a kind like *spray* and *load* belong to ‘pure’ alternate verbs, which can mean that lexical rules based on the assumption of the distinction of base vs derived ‘can not’ applied (Kim and Kim 2007).

4. Even Two Broad Range Rules which link the two versions of the alternators refer to specific structural properties of the verbs semantic structures, and are thus reminiscent of 'structure-specific' transformations which recent theories of UG has sought to eliminate in favor of more general principles.<sup>8</sup>

5. Furthermore one thing needs to be considered from the language acquisition perspective: The lexical rules proposed by Pinker does not seem to help the task of the acquisition of argument structure of locative verbs because the burden of explaining learnability / argument acquisition seems to be simply transferred to another one of the constraints on the possibility of lexical rule application, which are much complicate knowledge about Narrow Range Classes.<sup>9</sup> It led me to some doubt on Pinker's lexical rule again, since the simpler the model is the better for learnability.

In sum, generalizations are missed with lexical rules used to account for alternation, and therefore the parts of semantic representation relevant to the syntax need to be simpler for explaining the acquisition problem. If this line of arguments is in a right track, reconsideration of the necessity of lexical rules is required to describe and explain locative alternations and their acquisition.

### **3. Developing alternative ideas: What triggers the linking to the direct object?**

Until now, we have considered the universal linking principle and locative alternation on the basis of Pinker's system. The rest of this paper is to pursue the alternative along with the possibility of the elimination of the lexical rule. Before going into the alternative, let's see some assumptions and terms used here. (1) A fundamental assumption is that formal linguistics (UG) has a crucial role to play in describing and explaining aspects of language acquisition.<sup>10</sup> (2) Linking rules are an inherent part of the interface between lexical semantics and syntactic argument structure, and also assumed as one of innate and universal principles which does play an important role in children's acquisition of syntax and semantics of verb. (3) The structure of event/verb

---

<sup>8</sup> cf. As mentioned earlier: "so when the verb's meaning changes, its argument structure changes, too, as an automatic consequence according to his universal broad range linking rule". However, the universality of thematic hierarchy seems to be viable for me (Kim and Kim 2007). This issue is beyond the scope.

<sup>9</sup> For narrow range classes which are beyond the scope of this study, refer to Pinker (1989).

<sup>10</sup> Also it assumes Interface levels: at which the grammar interfaces (i.e. connects)with speech and thought systems which lie outside the domain of grammar. Phonetic Form is the level at which the grammar interfaces with articulatory-perceptual (speech) systems, and Semantic representation is the level at which it interfaces with conceptual-intentional (thought) systems.

meaning is assumed: a verb is said to have a structured semantic representation with subevents in recent studies of verb meanings (event structure/decompositional approach). (4) The concept of the dichotomy of 'manner' of movement vs 'change of state'(result state) from his Two Broad Range Rules<sup>11</sup> later will be proposed as parallelism with aspectual classes (process vs result/state). That is, the concept of dichotomy, 'manner' of movement vs 'change of state' shows its close association with aspectual properties. (5) For the term 'aspect', there are studies which show some similarities to the dichotomy (Tobin 1993, Tenny 1994, Hale and Keyser 2002). Tobin (1993)'s idea about aspect as opposed concept of 'process vs result' (distinction) is followed; Tobin in his book (1993) presents verb aspect in English in both lexicon and the grammar, and explain like this:

I think there is a coherent system (or several such systems) in English related to 'aspectuality' which may be found in 'verbs' and other 'parts of speech' representing such system - the subject of this book - is based on the subtle semantic distinction between the opposed concept of 'process and result', which will be viewed as distinctive semantic features (Tobin 1993:4).

Also aspectuality, roughly, refers to the property which makes it possible for a sentence to signal whether or not it pertain to something 'boundedness'(Verkuyl 1993). Tenny(1994) defines aspect as *delimitedness*. "Delimitedness refers to the property of an event's having a distinct, definite and inherent endpoint in time." (Tenny 1994:4). (6) In this question, still a universality of linking rules based on thematic hierarchy is assumed (theme > locative). That is, a 'theme to Object' construction is simple and unmarked in general and the other 'locative to Object' construction is more complicate and marked. This assumption is supported by the children's error with *fill*-type and by cross-linguistic studies by Kim (1999) and by L2 data (Kim and Kim 2007).<sup>12</sup>

### 3.1. Semantic representation of locative alternator/verbs

---

<sup>11</sup> His Broad Range Rules could be interpreted that alternation is only possible if the base semantic structure of the verb contains both movement (PATH/MANNER) and change of state(STATE). Any locative verb which alternates must have these two components : PATH/MANNER and STATE. Actually it could be inferred that the logical structure of 'change of state' implies the movement before reaching the result state.

<sup>12</sup> cf. Kim and Kim (2007:456): Markedness Hypothesis of *fill*-type/locative-object construction only.

This study attempts to see the problem of locative alternation as one involving a selection of ‘direct object’ of the two, ‘theme’? or ‘locative’? That is, we can begin with the question : What triggers the linking to direct object? And a related question is what kind of semantic representation is required for argument alternation verbs to be able to describe and explain language acquisition phenomena. The question of the latter is dealt with first.

### *3.1.1. The importance of the lexicon in the linking rules*

In spite of the importance of the lexicon in UG, until recently only a modest amount research has been devoted to the regularities in the lexicon. This has been due partly to the lack of an explicit theory of the lexicon, and partly to the perception that the lexicon is still ‘idiosyncratic’.

Chomsky(1981) also left unanswered the question of how L1 learners know about the subcategorization properties of words, that is, the acquisition of subcategorization properties of words. Also what kind of learning mechanism guides the L1 learners to knowledge of the subcategorial features of a lexical item has been left unclear.

So we must return to the basic question of what the systematic correspondences between syntactic structure and semantic interpretation in the domain of predicate-argument relationships actually are. The solution to that question suggests the need to re-evaluate the status of the *lexicon* within general theories of linking, which are an inherent part of interface between lexical semantics and syntactic argument structure. That is, in order to explain mapping of arguments bearing certain semantic roles to certain grammatical function, linguists have been forced to appeal to the semantics. especially verb semantics including subcategorization of GB, more precisely, the semantic representation of alternators/verbs here. One key subcomponent of UG is the lexicon, since it is there that the meanings that determine syntactic structure are stored.<sup>13</sup> The acquisition of the subcategory requirements of locative verbs in English might provides an interesting case study to illustrate the nature of native speakers’ knowledge of argument structure/the interaction between lexical semantics and syntax.

### *3.1.2. A close association between verb meanings (argument structure) and aspect*

---

<sup>13</sup> It also assumes that the acquisition of lexicon may be modular.

There seems to be a close relation between verb meanings and aspect, as can be seen in English verb classifications: states, activities, accomplishments, and achievements. It is well-known that these four classifications of English verbs are based on aspectual properties of Vendler's theory(1967).

Indeed there are many studies which support the close association of aspectual concept and argument linking of verbs also ( Dowty 1991, Tenny 1994, Ramchand 1998). Dowty (1991:588) argues that both *spray* and *load* entails an 'incremental theme' defined, by him, as "an NP that can 'determine the aspect' of the sentence".<sup>14</sup> Tenny (1994) in his book, *Aspectual Roles and the Syntax-Semantics Interface* also shows some general aspectual constraints on the argument structure/linking of verbs. Ramchand's study (1998) also focuses on the role of aspectual semantics in the syntactic realization of arguments. From these, we can draw that aspectual properties are crucial criteria for verb classifications and helpful for understanding the semantic structure of predicates and their argument structure too. Tenny (1994) argues that linking(the interface between semantics of verbs and syntax) are regulated by aspectual properties, delimitedness in particular.

All of these studies bring my attention to recent recurrent concerns with the relationship between the structure of verb meanings (often called event structures) and syntax.

### 3.1.3. *The notion of affectedness and aspect: the aspectual notion of affectedness*

As mentioned earlier, there are some studies which show the close association of the notion of the affectedness with aspect too (Butt and Geuder 1998, Ranchand 1998). Butt and Geuder (1998) states that in fact, the affectedness effect encountered in argument alternation<sup>15</sup> is reminiscent of 'the aspectual notion of affectedness'. They consider *affectedness* reading in causative alternations as arising out of a particular constellation of argument in an argument structure. Besides there are many approaches which explore the interaction between aspectual properties and syntactic argument realization (Tenny 1994, Vurkyul 1993). Ramchand (1998) shows that the feature of 'affectedness' plays an important role in the description of different transitive/causative types in various languages. So it seems to be indisputable that there is a relationship

---

<sup>14</sup> The emphasis is mine.

<sup>15</sup> In their study, argument alternation refers to specifically causative one.

between the type of complex event and the nature of the argument projection, and the notion of affectedness is now generally acknowledged to be intimately associated with the aspectual semantics of a clause.

Furthermore, recently within minimalism framework Borer (2008) with her two volumes treats the aspect as the key concept of approaching to the syntax-semantics interface.<sup>16)</sup> Pinker (1989:78) also mentions that “Rappaport and Levin suggest that the holism effect is actually an epiphenomenon of the fact that the verb specifies a *change of state*.”<sup>17)</sup> There is also a study in which they (*load/spray* alternations) do not appear to be characterizable in terms of thematic role labels alone and recommend the use of  $\pm$  *affectedness* feature for this kind of meaning difference, but not details (Gropen et al.1991b).

So if the notions such as 'affectedness' can be reconstructed directly in semantic terms and not via the mediation of thematic roles, and if there is indeed a strong interplay between aspect and the arguments of a predicate, the question then arises : whether the affected meanings come from 'lexical verb meanings' or from 'constructional meanings', that is, from the object position ?

### 3.2. *What triggers the linking to the direct object?*<sup>18)</sup>

Along with these backgrounds which we have discussed through the review of literature and some insights which we get from discussions of Pinker's system, the distinction between manner verbs and change of state verbs in Two Broad Range Classes is, in a sense, synonymous to the aspectual dichotomy, movement(process) vs. result (state of change). And from the criticism of his lexical rules, the following two ideas are proposed: (1) *Underspecification hypothesis* of argument alternation verbs and (2) *direct linking* (of aspectual properties) *to the object position hypothesis*. The semantic representation for the alternating locative verbs is underspecified<sup>19)</sup> with respect to aspectual properties such as  $\pm$  boundedness (completion or affectedness) which is going to be called 'Underspecification hypothesis of argument alternation verbs'. And these aspectual properties are realized through direct linking to the *object*

---

<sup>16)</sup> For details, refer to her two volumes(2005) with subtitles : (1) *In name only* (2) *the normal course of events*.

<sup>17)</sup> The emphasis is mine.

<sup>18)</sup> We assume some internal resources contributing to the acquisition as well as primary data (input), such as UG.

<sup>19)</sup> Specification: the set of meaning features used to describe the properties of an item/word.

*position*,<sup>20</sup> which is one of mechanisms for realizing meanings, which can mean *without the mediation of lexical rules or thematic hierarchy*.

And *Aspectual properties* triggers a linking to the direct object, an object selection of the two, *locative* or *theme* in locative alternations. Since we consider the aspectual property as one of syntactically relevant semantic features, and the distinction which children shows the sensitivity to as part of innate competence. This proposal, 'direct linking to object position; hypothesis is plausible.

This proposal is open to various interpretations such as (1) it can mean that aspectual meaning,  $\pm$  boundedness, here the notion of affectedness/ completion, is realized by direct linking to the syntactic object position. (2) The linking is regulated by aspectual properties, especially delimitedness. And (3) without the necessity of Pinker's lexical rule, the operation of linking to the direct object can work.

### 3.3. *Summary and discussions*

This study began with the concern with simply assuming the association of the notion of affectedness to the syntactic position of object, but there were many studies on the close association between argument structures and aspect already. On the basis of some of them this study focused on the followings. Casting doubt on Pinker's requirement of lexical rule application for a new semantic structure before the operation of linking rules, the alternatives to Pinker's system is proposed: (1) elimination of lexical rules and (2) the relationship between affectedness and direct object position, that is, direct linking to Object in the interface. For details and precise formalization, further studies are needed.

The most important points of main ideas which I try to make in this paper are as follows. (1) Argument alternations can be considered as one of mechanisms for expressing *aspectual properties*, here involving  $\pm$  end state/result state which are equivalent to the semantic conflation classes of Pinker's, and hence they can replace Pinker's two broad classes, which showed psychological reality in children (Gropen et al. 1991). (2) Object selection itself without a mediation of lexical rules/ thematic roles can be also one of candidate mechanisms for meaning realization - here again, aspectual

---

<sup>20</sup> Actually the selection of Object argument first; and then linking to the position of Object next might be right procedures. But also it might be simultaneous procedures I think.

meanings/features realization. (3) From this a quite interesting result might come that it could provide an explanation/a reason *why* we alternate argument structures, of which the answer can be for expressing different aspectual meanings/features. (4) For the lexical semantics which must describe the polysemy of verbs taking multiple forms, it can also suggest the idea of underspecification with respect to aspectual properties, leaving exact formalizations for this idea lexical semantists' job with some empirical data..

Along with Pustejovsky's guide (1995), this can be summarized with simple questions and answers. Pustejovsky emphasizes the following important questions for lexicon. (1) The question is whether it is possible to identify the semantic discriminants leading to the distinct behavior of the locative alternating verbs. (2) Perhaps even more interesting is how the polysemy of those verbs taking multiple forms can be represented lexically. The answer to (1) might be that a semantic discriminant leading to the distinct behavior of the locative verbs here is aspectual property, and the answer to (2) might be the way of underspecification with respect to aspectual differences. Furthermore, 'why alternate?' The aspectual differences are realized as direct linking to Object position through object selection, and this can be the very reason for alternating argument structures.

In sum, we could provide answers to the following questions:

1. 'What' allows their alternation? Aspectual properties does.
2. 'Why' do we alternate argument structure? In order to realize different meanings of binary nature of aspect ( $\pm$  endstate).
3. 'How' do we alternate argument structure? By direct linking to the object position from the binary concept of aspectuality, not via lexical rules or thematic roles.

#### **4. Advantages and implications for further studies**

One advantage of this idea might be that direct object selection could offer a much simplified theory of locative alternations and their acquisition.

##### *4.1. Advantages*

1. It could offer a simple linking rule for locative alternate verbs keeping a standard linking rule (based on thematic hierarchy) universal still.
2. It could eliminate arbitrary lexical rules for changing the semantic structures
3. It also provides the reason 'why' argument alternations exist.: to express either one of aspectual meanings, movement vs change of state.
4. There is no need to explain 'holism effect' separately
5. The semantic representation of locative verb is established (fixed), which is simple, and flexible/opened and hence without the stage of lexical rule application. That is, the elimination of lexical rules allow us to get a simpler model.
6. It can provide an explanation for the reason why we alternate the argument structure.

#### *4.2. Implications and discussions*

It is extremely difficult to provide an adequate account of the representation and acquisition of the knowledge and intuitions speakers have about semantics-syntax correspondences. There is still disagreement about what the best approach to the problem of linking is.

There is also continuing disagreement among linguists as to whether the phenomena discussed are to be dealt with in the lexicon or syntax, and whether morphology is subject to the same constraints as syntax. Clearly, these long-standing debates will continue, and even though they are central to the problems, can not be resolved here. However, I have tried steer a path through the different approaches and capture both the richness in meaning and the constraints on lexical representations. It is the view of the lexicon as an autonomous model of grammar that gives rise to the general debate of lexical vs. constructional analysis of various linguistic phenomena. While it seems more and more clear from this recent work that 'lexical semantics' as traditionally conceived must be located constructionally, I think it does more than shift the division of labour from *lexicon* to *syntax*. This work highlights in a particularly vivid way the impossibility of making a principled distinction between lexical-internal relations and lexical-external relations. It is no longer clear that we can find linguistically relevant features which always appear together lexeme internally, and with modes of combination which are different from the syntactic one. It suggests that the division between lexicon and syntax is not universally definable.

From the acquisition perspective, children might have the distinction of aspectual properties, for example, the dichotomy of whether it indicate *endstate* or not. They might notice the affectedness effect from the syntactic position, utilizing the linking rules in general and express the concept in English. That might lead them to the acquisition of the argument alternation.

Finally concerning with the status of thematic roles in linguistic theory, it has a positive role in mapping between syntax and semantics since it points to the linguistic distinctions which do have to be made in any theory of mapping between syntax and semantics.

For further studies to be done, a clear characterization of the movement/ process vs. change of state (result state/affectedness) dichotomy is fundamental for the analysis of locative verbs, and the formalization of it might be the job of the lexical semantists to be done.

## Abstract

In this article, ditransitive verbs are argued to project an applicative projection different from those applicative projections discussed by Pylkkänen (2000, 2008). It is shown that the proposed applicative projection provides a dative position that could give rise to underlying accusative-dative order. The presence of this applicative projection is justified by looking at the case-marking patterns of nominalized clauses involving ditransitive idioms. It is further argued that this dative position does not constitute a  $\theta$ -marking domain, so that only idiomatic dative arguments can occur to the right of accusative arguments.

**Keywords:** applicative projection, ditransitive verb, Japanese, dative-V idiom, accusative-V idiom.

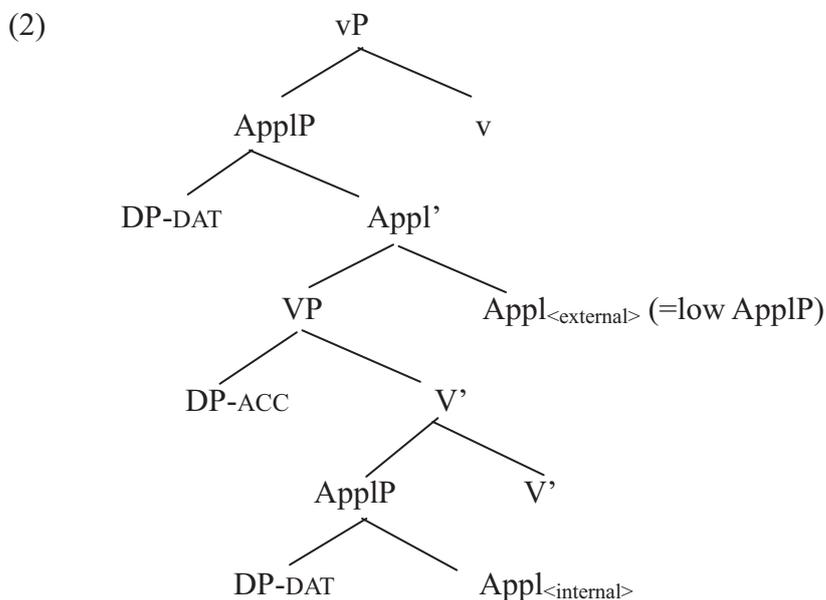

## 1. Introduction

In recent years, a number of researchers (e.g. Marantz 1993, Pylkkänen 2000, 2008, McGinnis 2001) have proposed that a certain type of non-core dative argument should be licensed by an applicative projection. In particular, Pylkkänen (2000, 2008) argues for two types of applicative projections that license dative arguments—the high ApplP, which relates an argument and an event, and the low ApplP, which relates two arguments.

- (1) a. [VoiceP Voice [AppIP DP [AppI' Appl VP ]]] (high Applicative)  
b. [VP V [AppIP DP [AppI' Appl DP ]]] (low Applicative)

Pylkkänen suggests that in Japanese, the dative arguments of ditransitive verbs show the low applicative properties, hence should be licensed in the low ApplP. In this paper, I

suggest the presence of yet another ApplP position that licenses dative arguments—which I refer to as the “internal” ApplP.

According to Pylkkänen (2000, 2008), the low ApplP (which is referred to as the external ApplP in this paper) takes an indirect object as its specifier, and a direct object as its complement.<sup>1</sup> As depicted in (2), we propose that ditransitive verbs have an additional dative position (the internal ApplP) so that they project applicative projections in two different constituent positions.

In Pylkkänen’s system, the base order of ditransitive predicates should, other things being equal, be “dative-accusative”, rather than “accusative-dative”. In this paper, we will show that the internal ApplP allows some dative arguments to be base-generated to the right of direct objects. It is also suggested that ordinary dative arguments cannot occur in the internal ApplP, because this position does not constitute a  $\theta$ -marking domain. The presence of the internal ApplP is empirically justified by looking at the case-marking patterns of nominalized clauses involving dative-V and accusative-V idioms which have the fixed order of two internal arguments.

## 2. Ditransitive Idioms

Let us start by discussing some of the prominent properties of ditransitive idioms discussed by Miyagawa and Tsujioka (2004). The examples in (3) represent dative-V idioms which have the fixed accusative-dative order.

- (3) a. *Taroo-wa omotta koto-o kuti-ni das-u.*  
 Taro-TOP thought thing-ACC mouth-DAT let.out-PRES  
 “Taro says what’s on his mind.”
- b. *Taroo-wa sainoo-o hana-ni kakete-i-ru.*  
 Taro-TOP talent-ACC nose-DAT hanging-be-PRES  
 “Taro always boasts of his talent.”
- c. *Taroo-wa kuruma-o te-ni ire-ta.*  
 Taro-TOP car-ACC hand-DAT put.in-PAST  
 “Taro acquired a car.”
- d. *Taroo-wa itumo zibun-no sippai-o tana-ni age-ru.*  
 Taro-TOP always self-GEN mistake-ACC shelf-DAT raise-PRES  
 “Taro always shuts his eyes to his own mistakes.”

These idioms have the idiomatic sequence of a dative phrase plus verb, and have the fixed order of accusative-dative. Thus, switching the order of arguments results in unacceptability.

- (4) a. ???*Taroo-wa kuti-ni omotta koto-o das-u.*  
 Taro-TOP mouth-DAT thought thing-ACC let.out-PRES
- b. \**Taroo-wa hana-ni sainoo-o kakete-i-ru.*  
 Taro-TOP nose-DAT talent-ACC hanging-be-PRES
- c. \**Taroo-wa te-ni kuruma-o ire-ta.*  
 Taro-TOP hand-DAT car-ACC put.in-PAST
- d. \**Taroo-wa itumo tana-ni zibun-no sippai-o age-ru.*  
 Taro-TOP always shelf-DAT self-GEN mistake-ACC raise-PRES

On the other hand, Miyagawa and Tsujioka observe that Japanese also has ditransitive idioms with the accusative-dative order.

- (5) a. *Taroo-wa hito-no koto-ni kuti-o das-u.*  
 Taro-TOP person-GEN business-DAT mouth-ACC let.out-PRES  
 “Taro cuts in on someone else’s business.”
- b. *Taroo-wa sono-giron-ni hakusya-o kake-ta.*  
 Taro-TOP that-controversy-DAT spur-ACC hang-PAST  
 “Taro added fresh fuel to the controversy.”
- c. *Taroo-wa genkoo-ni te-o ire-ta.*  
 Taro-TOP draft-DAT hand-ACC put.in-PAST  
 ‘Taro revised the draft.’

- d. *Taroo-wa maajan-ni timiti-o age-ta.*  
 Taro-TOP mahjong-DAT blood-ACC raise-PAST  
 “Taro was obsessed with mahjong.”

They are accusative-V idioms, in that the sequence of an accusative phrase and the verb gives rise to an idiomatic meaning. Since the accusative-V idioms have the fixed order of dative-accusative, the two arguments cannot be reversed while retaining the idiomatic meaning, as seen in (6).

- (6) a. \**Taroo-wa kuti-o hito-no koto-ni das-u.*  
 Taro-TOP mouth-ACC person-GEN business-DAT let.out-PRES  
 b. \**Taroo-wa hakusya-o sono-giron-ni kake-ta.*  
 Taro-TOP spur-ACC that-controversy-DAT hang-PAST  
 c. \**Taroo-wa te-o genkoo-ni ire-ta.*  
 Taro-TOP hand-ACC draft-DAT put.in-PAST  
 d. \**Taroo-wa timiti-o maajan-ni age-ta.*  
 Taro-TOP blood-ACC mahjong-DAT raise-PAST

On the provision that rigid idioms are interpretable when reflecting the base ordering of arguments (see Larson 1988, Harley 2002, and others), Miyagawa and Tsujioka (2004) claim that ditransitive verbs can have both the dative-accusative and accusative-dative orders by base-generation. More specifically, they propose that the arguments of ditransitive verbs can be arranged in the following way.

- (7) a. high goal (possessor) .... low goal (locative) .... theme  
 b. high goal (possessor) ....theme ..... low goal (locative)

Notably, they suggest, on the basis of dative-V and accusative-V idioms, that a certain type of dative argument—i.e. low goal (locative)—can be base-generated to the right of an accusative argument.

In effect, the idiom facts show that dative arguments could be generated in the position following accusative ones, but in this paper, we argue that the facts of dative-V idioms point to the different conclusion that an applicative projection that could yield the accusative-dative order via base-generation can only be filled by an idiomatic argument.

To begin with, observe one notable property of the dative-V and accusative-V idioms that is not discussed by Miyagawa and Tsujioka. This has to do with the fact that a particle can be optionally inserted into an idiom sequence, as seen in (8).

- (8) a. *Taroo-wa ittan kuruma-o te-ni(-wa) ire-ta.*  
 Taro-TOP once car-ACC hand-DAT-TOP put.in-PAST  
 ‘Taro once acquired a car.’
- b. *Taroo-wa mada genko-ni te-o/te-mo irete-i-na-i.*  
 Taro-TOP yet draft-DAT hand-ACC/hand-also putting.in-be-NEG-PRES  
 ‘Taro has not (also) had the draft revised yet.’

In contrast, completely frozen idioms—i.e. lexicalized idioms—do not allow the optional occurrence of a particle, as seen in (9) (see Kishimoto 2005, 2006).

- (9) *nuka-ni(\*-mo) kugi* (bran-DAT-also nail) ‘of no use’,  
*noren-ni(\*-wa) udeosi* (shop.curtain-DAT-TOP arm.push) ‘useless’,  
*hi-ni(\*-wa) abura-o sosogu* (fire-DAT-TOP oil-ACC pour) ‘make ... worse’,  
*ude-ni(-\*mo) yori-o kakeru* (arm-DAT-also twist-ACC hang) ‘do skillfully’,  
*tume-ni(\*-wa) hi-o tomosu* (nai-DAT-TOP fire-ACC light) ‘live a poor and  
 miserable life’

The data show that the dative-V and accusative-V idioms are ‘constructional idioms’, which are interpreted with reference to particular syntactic frames.

With this fact in mind, let us discuss the question of whether an applicative projection can give rise to base-generated accusative-dative order. To answer this question, we will look at nominalized clauses formed by the nominalizer *kata*. In the case of accusative-V idioms, all the arguments in the nominalized clause are marked with genitive case.

- (10) *genkoo-e-no/\*-ni te-no ire-kata*  
 draft-to-GEN/-DAT hand-GEN put.in-way  
 ‘the way of revising a draft’

In the nominal clause, dative marking *ni* must be changed to *e-no* ‘to-GEN’, which contains genitive marking. When the dative argument is marked with verbal dative case, unacceptability results. This is naturally expected, since in Japanese, arguments appearing in nominalized clauses are generally marked with genitive case, regardless of their grammatical relations. Interestingly, however, when dative-V idioms are nominalized, the dative arguments retain their verbal marking.

- (11) *kuruma-no te-ni/\*-e-no ire-kata*  
 car-GEN hand-DAT/-to-GEN put.in-way  
 ‘the way of acquiring a car’

As seen in (11), the dative arguments of dative-V idioms must retain their verbal dative marking even under nominalization, and that if nominal marking is assigned instead, unacceptability results. The facts suggest that the dative phrases in dative-V and accusative-V idioms occupy distinct syntactic positions.

Pylkkänen (2000, 2008) posits two types of applicative projection that are claimed to host certain non-core indirect objects. The high ApplP relates an argument and an event. The low ApplP relates two arguments, and specifies a possessive relation. According to Pylkkänen, the dative argument of Japanese gapless adversity passive like (12a) represents a case involving the high ApplP. The low ApplP is associated with a possessor argument in ditransitive constructions like (12b).

- (12) a. *Taroo-ga ame-ni hur-are-ta.*  
 Taro-NOM rain-DAT fall-PASS-PAST  
 ‘Taro got rained on.’ (High Applicative)
- b. *Taroo-ga kodomo-ni hon-o atae-ta.*  
 Taro-NOM child-DAT book-ACC give-PAST  
 ‘Taro gave children sweets.’ (Low Applicative)

When these examples are nominalized, the following patterns emerge.

- (13) a. *Taroo-no ame-no/\*-ni hur-are-kata*  
 Taro-GEN rain-GEN/-DAT fall-PASS-way  
 ‘The way of Taro’s getting rained on’
- b. *Taroo-no kodomo-e-no/\*-ni hon-no atae-kata*  
 Taro-NOM child-to-GEN/-DAT book-GEN give-way  
 ‘The way of Taro’s giving children sweets.’

In both nominalized clauses, the erstwhile dative argument receives nominal marking, which crucially differs from the verbal dative marking assigned to the dative arguments of dative-V idioms. It can be concluded then that the dative argument in the dative-V idiom occupies a dative position that differs from those dative phrases associated with Pylkkänen’s high and low applicatives.

Note that the retention of dative case in the nominalized clause is not due to the fact that the dative argument forms part of an idiom. Japanese has “dative-accusative-V” idioms, where both internal arguments constitute part of idioms.

- (14) a. *Taroo-wa kusai mono-ni huta-o si-na-i.*  
 Taro-TOP sinky thing-DAT lid-ACC do-NEG-PRES  
 ‘Taro does not cover up unfavorable things.’

- b. \**Taroo-wa huta-o kusai mono-ni si-na-i.*  
 Taro-TOP lid-ACC stinky thing-DAT do-NEG-PRES

As shown in (14), the idiom has underlying dative-accusative-V order, since the switching of the two internal arguments results in unacceptability. With this idiom, particles can be optionally inserted into the idiom constituents, as shown in (15).

- (15) a. *Taroo-wa kusai mono-ni-wa huta-o si-na-i (rasii).*  
 Taro-TOP stinky thing-DAT-TOP lid-ACC do-NEG-PRES seem  
 ‘(It seems that) Taro does not cover up unfavorable things.’
- b. *Taroo-wa kusai mono-ni huta-mo si-na-i (rasii).*  
 Taro-TOP stinky thing-DAT lid-also do-NEG-PRES seem  
 ‘(It seems that) Taro also does not cover up unfavorable things.’

This shows that the idiom belongs to the type of constructional idiom, just like dative-V and accusative-V idioms. If (16a) is nominalized, verbal dative marking is not retained.

- (16) *kusai mono-e-no/\*-ni huta-no si-kata*  
 stinky thing-to-GEN/-DAT lid-GEN do-way  
 ‘the way of covering up unfavorable things’

The fact indicates that only the idiomatic dative expression of a dative-V idiom can occupy a position—i.e. the internal AppIP—where verbal marking is assigned even under *kata*-nominalization, and further, that dative arguments positioned higher than direct objects are located in structural positions where nominal marking is allocated.

That some arguments receive verbal marking in nominalized clauses is not surprising if there is a verbal head that licenses verbal marking. In fact, the example in (17) shows that in the *kata*-nominalization, the lower verb is not turned into a nominal.

- (17) *sensei-(ni-totte)-no ronbun-no o-kaki-ni-nari-kata*  
 teacher-for-GEN paper-GEN write-SUBJ.HON-way  
 ‘the teacher’s way of writing a paper’

In (17), *kaku* ‘write’ receives verbal honorific marking *o-...ni-naru*. This fact indicates that *kaku* is construed as belonging to the verb class, retaining its original categorical classification even under nominalization. The claim regarding the categorical status of the verb embedded under *kata* ‘way’ gains further plausibility from the fact that some deverbal nominals take adverbial forms morphologically, as in (18).

- (18) *sensei-no hanasi*

teacher-GEN talk  
 ‘the teacher’s talk’.

Importantly, this type of expression does not count as a verb categorically. Hence, it is not possible to add the verbal honorific marker *o-...ni-naru*, and for the purpose of subject honorification, the nominal honorific marker *o-* must be used, as seen in (19).

(19) *sensei-no o-hanasi/\*o-hanasi-ni-nari*  
 teacher-GEN NOML.HON-talk/talk-VERBL.HON  
 ‘the teacher’s talk’

It is now easy to see that the *kake*-nominal at issue contains a verbal head that licenses verbal marking, despite the fact that it is a nominalized expression. It is plausible to state that in the nominalized clause at issue, verbal marking is licensed by a verbal head with [+V] located in V in the underlying constituent structure, while others—located outside the c-command domain of the verbal head—is licensed by the nominal head *niku-sa* or *yasu-sa* with [+N], as illustrated in (20).

(20) [... DP-GEN ...DP/PP-e-GEN ...DP-GEN .. [VP [AppIP DP-DAT ] V ] -kata ]  
 └──────────────────────────────────┘ └──────────┘ [+V] [+N]  
 nominal marking verbal marking

In any event, the important point is that under *kata*-nominalization, dative arguments are assigned either nominal or verbal marking depending on where they are base-generated. The dative argument in the internal AppIP, which follows the accusative argument, is located in a position for its verbal marking to be licensed by a verbal head V in a nominalized clause. Since the higher arguments do not reside in the domain where licensing by V is possible, they receive nominal marking.

### 3. The structural position of ordinary dative arguments

Let us now turn to the discussion of where ordinary datives are located. In this section, we suggest that non-idiomatic arguments are invariably generated to the left of accusative arguments. Let us consider what happens if the examples in (21), which involves the ditransitive verbs *ataeru* ‘give’ and *okuru* ‘send’, are nominalized.

(21) a. *Taroo-wa kodomo-ni okasi-o atae-ta.*  
 Taro-TOP child-DAT sweets-ACC give-PAST

‘Taro gave the children sweets.’

- b. *Taroo-ga Tokyo-ni nimotu-o okut-ta.*  
Taro-NOM Tokyo-DAT package-ACC send-PAST  
‘Taro sent a package to Tokyo.’

If the clause (21a) is nominalized, the goal argument must receive nominal marking.

- (22) a. *kodomo-e-no/\*-ni okasi-no atae-kata*  
child-to-GEN/-DAT sweets-GEN give-way  
‘the way giving the children sweets’  
b. *okasi-no kodomo-e-no/\*-ni atae-kata*  
sweets-GEN child-to-GEN/-DAT give-way

The same holds true for the dative argument of *okuru* ‘send’ in (21b). In fact, as shown in (23), it receives nominal marking rather than verbal marking when the verb *okuru* ‘send’ is nominalized in combination with *kata*.

- (23) a. *Tokyo-e-no/\*-ni nimotu-no okuri-kata*  
Tokyo-to-GEN/-DAT package-GEN send-way  
‘the way of send a package to Tokyo’  
b. *nimotu-no Tokyo-e-no/\*-ni okuri-kata*  
package-GEN Tokyo-to-GEN/-DAT send-way

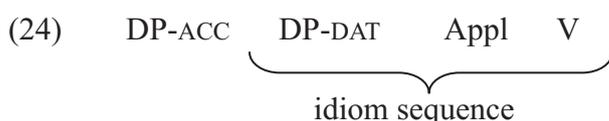

According to Miyagawa and Tsujioka, the dative-marked locative argument of *okuru* could be base-generated to the right of the accusative argument. However, the morphological facts in (23) show, contrary to their claim, that the ordinary goal argument cannot be generated to the right of the accusative. This shows that the locative argument (low goal) cannot be equated with the dative argument of dative-V idioms, since their case marking patterns diverge in the nominalized clauses.

In essence, the dative argument following the accusative argument can bear verbal dative marking even under nominalization. This type of dative argument must occupy the internal ApplP. The dative argument of ordinary ditransitive verbs, on the other hand, must be positioned above accusative arguments, because they are assigned nominal marking in nominalized clauses. This shows that the internal ApplP is not available for ordinary dative arguments, hence can be filled only by idiomatic dative arguments.

#### 4. The Non-thematic Nature of Internal ApplP

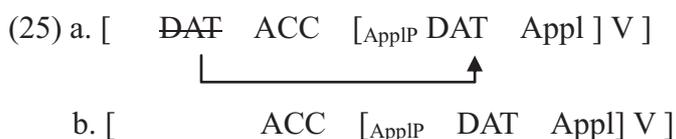

The morphological facts of nominalized clauses formed from ditransitive verbs suggest that the dative argument serving as part of a dative-V idiom should fill the internal ApplP located below VP. By contrast, ordinary datives are base-generated to the left of accusatives. The property that the internal ApplP can host only idiomatic datives follows straightforwardly if it does not constitute a  $\theta$ -marking domain. Given the provision that arguments are not generated below direct objects cross-linguistically, we can now provide an answer to the question of why only idiomatic dative arguments can occupy this position.

According to Chomsky (1981), idioms are interpreted via an idiom rule (without recourse to  $\theta$ -role assignment). Since the idiom string of a dative phrase plus verb in dative-V idioms can be viewed as taking an ordinary accusative argument, it is plausible to state that the dative-V sequence is rendered as some sort of idiomatic complex predicate via idiom formation.

Given this analysis, an ordinary dative argument—which needs a  $\theta$ -role for its appropriate interpretation—cannot be positioned in ApplP. From this, it falls out that the internal ApplP can accommodate only an idiomatic dative argument which is interpretable without being assigned a  $\theta$ -role.

Turning now to question of how the idiomatic dative comes to occupy the internal ApplP, two possible analyses come to mind. One is to generate the dative in the ordinary dative position and is moved into the ApplP via incorporation. The other is to base-generate it in its pre-verbal position (without movement).

At first sight, it looks as though the first movement view is reasonable in view of the fact that the idiomatic dative argument of a dative-V idiom does not allow modifications by adjectives or other expressions, as illustrated in (26).

- (26) \**John-wa kuruma-o {gotugotu-no te-ni/migi-te-ni} ire-ta.*  
 John-TOP car-ACC rough-GEN hand-DAT/right.hand-DAT put.in-PAST  
 ‘John let a car {in the rough hand/in the right hand}.’

One might argue that this property derives from the nature of movement involved in the

derivation of the accusative-dative order. As discussed by Baker (1988), incorporation involves head movement. If the idiomatic datives of dative-V idioms involve incorporation, we would expect that no phrasal expression appears as the dative expression.

Nevertheless, we suggest that the base-generation analysis is favored over the movement analysis. There are two major reasons for this. One is that the property noted in (26) is not exclusively observed in cases where incorporation takes place. Rather, this is just one of the common properties observed idioms, as exemplified in (27) (see Miyaji 1999 and others).

- (27) \**John-ga genkoo-ni {gotugotu-no te-o/migi-te-o} ire-ta.*  
 John-NOM draft-DAT rough-GEN hand-ACC/right.hand-ACC put.in-PAST  
 ‘John put his rough/right hand on a draft.’

Furthermore, if the idiomatic expression were incorporated into the verb, we would not expect particles to intervene between the idiomatic sequences.

- (28) a. *John-wa kuruma-o te-ni-wa ire-ta.*  
 John-TOP car-ACC hand-DAT-TOP put.in-PAST  
 ‘John acquired a car.’  
 b. *John-wa genkoo-ni te-wa ire-ta.*  
 John-TOP draft-DAT hand-TOP put.in-PAST  
 ‘John revised a draft.’

The facts regarding the insertion of particles suggest that the dative expression stands independently of the verb syntactically. If so, it is not plausible to adopt an incorporation analysis for dative-V idioms.

Still, it might be argued that movement is involved in the derivation of dative-V idioms, on the assumption that the dative argument is moved into the internal ApplP. There is good reason to believe that the idiomatic dative does not undergo movement, however. One piece of crucial empirical evidence pointing to the adequacy of the base-generation view can be obtained by looking at the selectional restrictions of ditransitive verbs. Broadly speaking, ditransitive verbs take only one dative-marked argument. Thus, it is generally the case that two dative expressions are not possible in a single clause (cf. Miyagawa and Tsujioka 2004), as illustrated by the verb *ireru* ‘put in’.

- (29) a. \**John-ga tyuushyazyoo-ni syako-ni kuruma-o ire-ta.*  
 John-NOM parking.lot-DAT garage-DAT car-ACC put.in-PAST  
 ‘John parked his car in the garage in the parking lot.’

- b. *John-ga tyuushyazyoo-no syako-ni kuruma-o ire-ta.*  
 John-NOM parking.lot-GEN garage-DAT car-ACC put.in-PAST  
 ‘John parked his car in the garage in the parking lot.’

Interestingly, however, the same verb *ireru* can sometimes have two different dative arguments if one of the dative arguments is used as part of an idiomatic expression.

- (30) *John-ga sensei-ni kore-o goran-ni ire-ta.*  
 John-NOM teacher-DAT this-ACC look-DAT put.in-PAST  
 ‘John showed this to the teacher.’

The sequence *go-ran-ni ireru* ‘show’ is highly idiomatic, but it can be readily confirmed that the idiom belongs to the type of dative-V idioms. As with other dative-V idioms, this idiom allows a particle to attach to the right of the dative expression.

- (31) *John-ga sensei-ni kore-o goran-ni-wa ire-ta.*  
 John-NOM teacher-DAT this-ACC look-DAT-TOP put.in-PAST  
 ‘John showed this to the teacher.’

It is true that many idiomatic expressions do not allow double dative configurations, as they often retain original locatives senses, but the existence of an example like (31), where double datives are allowed in a single clause, would be expected only if the datives are inserted in their positions by way of base-generation.<sup>ii</sup>

Furthermore, we can easily confirm that the idiomatic argument resides in the internal AppIP, while the first one is generated to the left of the accusative argument by looking at the nominalized clause in (32).

- (32) *Sensei-e-no kore-no goran-ni ire-kata*  
 teacher-to-GEN this-GEN look-DAT put.in-way  
 ‘the teacher’s way of showing this to the teacher’

The example in (32) illustrate that the two dative arguments can appear if they occupy in distinct structural positions. This fact would come as a surprise if the idiomatic dative arguments of dative-V idioms are first base-generated in the ordinary dative positions and then moved to the internal AppIP.

## 5. Conclusion

In the light of the morphological facts regarding the nominalized clauses formed

from ditransitive idioms, it has been argued that ditransitive verbs provide at least two distinct syntactic positions for dative arguments, i.e. the internal and external ApplP's. It has also been argued that the base-generation of dative arguments in the internal ApplP is confined to idiomatic dative arguments, due to the fact that this dative position does not constitute a  $\theta$ -marking domain, and that ordinary goals (i.e. high and low goals) can only be base-generated to the left of accusative arguments.

## Notes

\*This is a written version of the paper presented at 18<sup>th</sup> International Congress of Linguists held at Korea University, July 21-26, 2008. I am grateful to the audience for comments and suggestions. I am solely responsible for any errors and inadequacies.

<sup>i</sup> There are a number of different proposals on the argument structures of Japanese ditransitive verbs (see Hoji 1985, Miyagawa 1997, Kishimoto 2001, 2008, Takano 1998, Miyagawa and Tsujioka 2004, and others). In this paper, we follow Pylkkänen's (2000, 2008) proposal on applicative projections, and assume without any further justification that non-core dative arguments are licensed by applicative projections.

<sup>ii</sup> This does not mean that double datives are allowed in all dative-V idioms. See Kishimoto (2008) for a partial list of idioms allowing for double datives.

## **Abstract**

This paper attempts to demonstrate the role of subjectivity in the French tautology “X is X”. This construction, that contains no information value, aims rather to express subjectivity. The notion of subjectivity, according to our definition, is not a component in a lexical sense, but it should be understood as a judgement of the speaker that underlies the language. Regarding subjectivity, this paper discusses three factors : “desirability”, “factuality” and “aspiration”. These three types of subjectivity can be related to three kinds of thought mechanisms conceived by Ch. Bally : fact judgement, value judgement and volition.

**Keyword:** subjectivité, jugement, désirabilité, factualité, souhait

## **1. subjectivité**

Depuis quelques années, nous nous occupons de phénomènes de subjectivité dans le langage, notion qui trouve son origine dans les travaux de Bréal (1976), linguiste français, ou de Tokieda, linguiste japonais, par exemple et qui, au bout d’un intervalle de 100 ans, attire maintenant l’intérêt des linguistes, en particulier celui des cognitivistes. Jusqu’à présent, nous avons traité, dans cette optique, des expressions françaises “encore moins”, “plus ou moins”, “même”, “qui plus est”, “au moins” etc. et celles des locutions japonaises comparables (Abé 2003, 2004, 2006, 2007a, 2007b, 2008 etc.).

Pour ce qui est de la subjectivité, les chercheurs s’intéressent principalement à la notion de factualité par le biais d’études sur la modalité. Par exemple, la

grammaticalisation de la modalité déontique vers la factualité de l'auxiliaire « devoir », etc. Mais nous aimerions signaler, à titre d'hypothèse, l'existence de deux autres formes de subjectivité : la désirabilité et le souhait.

C'est Akatsuka (1997, etc.) qui a la première introduit cette notion de désirabilité dans l'analyse de la construction conditionnelle. Selon elle, si la protase est considérée comme désirable par le locuteur, l'apodose l'est également; si la première est indésirable, la dernière l'est également.

Mais il n'est pas sans intérêt de noter que Bally (1965) avait déjà fait mention, bien que brièvement, de ces trois formes de subjectivité : factualité, désirabilité et souhait, comme on le voit dans (1).

- (1) La phrase est la forme la plus simple possible de la communication d'une pensée. / Penser, c'est réagir à une représentation en la constatant, en l'appréciant ou en la désirant. / C'est donc juger qu'une chose est ou n'est pas, ou estimer qu'elle est désirable ou indésirable, ou enfin désirer qu'elle soit ou ne soit pas. On *croit* qu'il pleut ou *on ne le croit pas*, ou on en *doute*, on se *réjouit* qu'il pleuve ou on le *regrette*, on *souhaite* qu'il pleuve ou qu'il ne pleuve pas. / Dans le premier cas, on énonce un jugement de fait, dans le second un jugement de valeur, dans le troisième une volition. / La première opération relève de l'entendement, la deuxième du sentiment, la troisième de la volonté, qui a son aboutissement dans l'action, aboutissement qui est une des fonctions du langage tout en le dépassant. / La pensée ne se ramène donc pas à la représentation pure et simple, en l'absence de toute participation active d'un sujet pensant. (Bally 1965: 35)

Nous pensons, avec Bally, que le mécanisme linguistique ne se ramène pas seulement à la transmission d'informations, mais qu'il est toujours revêtu du jugement du locuteur. Les informations transmises sont appuyées et enveloppées par la subjectivité. Celle-ci, bien que latente dans la plupart des cas, apparaît parfois à la surface et intervient positivement dans l'interprétation sémantique de l'expression ou de la phrase.

Etant donné qu'il s'agit d'un mécanisme sous-tendant le système grammatical et lexical, la subjectivité opère, pour ainsi dire, d'une manière intercatégorielle. Voyons (2) – (7).

- (2) Il *doit* être malade. [« factualité », auxiliaire]

- (3) *Probablement* il est malade. [« factuelité », adverbe de phrase]
- (4) Il parle l'anglais et, *qui plus est*, l'espagnol. (« A *qui plus est* B » signifie « A a une certaine désirabilité, mais il existe *plus* de désirabilité dans B ») [« désirabilité », marqueur de comparatif]
- (5) Paul n'est pas très intelligent, *seulement* (≠ mais) il est travailleur. (« A. *Seulement* B » signifie « A n'est pas désirable, mais il existe *seulement* une désirabilité B ») [« désirabilité », adverbe de phrase ou conjonction]
- (6) Si tu ne peux pas me prêter de l'argent, pourrais-tu me donner *au moins* quelque conseil? (« *au moins* A » signifie « je désire *au minimum* qu'il se réalise A ») [« souhait », marqueur de superlatif]
- (7) (A quelqu'un qui le sait bien) Un plagiat, c'est un crime. (= Vous ne devez pas le faire) [« souhait », truisme]

## 2. tautologie "X est X"

Il est évident que la construction du type "X est X", par exemple "un chat est un chat", qu'est la tautologie, n'arrive pas à apporter la moindre information, puisqu'elle ne fait que répéter le même nom X. Mais alors pourquoi existe-t-elle? On peut s'étonner également que ses fonctions soient bien comparables entre le français, l'anglais et le japonais.

Nous sommes d'avis que le sémantisme de la tautologie du type "X est X", ainsi que celui de la phrase contradictoire "X n'est pas X", sa contrepartie, n'est réductible ni au contexte, ni au mécanisme intérieur de la construction elle-même, mais à la subjectivité. A la différence de la phrase attributive normale qui transmet, sous forme de "X est Y", une information Y à propos de X, la tautologie est une forme privée d'information. "X est X", formellement une phrase, n'est qu'un cadre vide d'information, pour ainsi dire. Mais celui-ci peut devenir le moyen approprié à l'expression de la subjectivité, d'autant plus qu'il est dépourvu d'information. Et la tautologie nous intéresse dans la mesure où elle met à l'oeuvre les trois subjectivités ci-dessus.

Dans la détermination du sens de la tautologie, le contexte, ainsi que la situation de locution, peut intervenir bien sûr, mais seulement de manière à rendre plus explicite

de quelle subjectivité il s'agit , au cas où il existerait quelque ambiguïté d'interprétation.

### 3. analyses précédentes

Nous pouvons énumérer plusieurs approches précédentes. Dans le cadre de la pragmatique radicale, Grice (1975) et Levinson (1983), par exemple, font appel à la notion d'implication dans la conversation, tandis que Wierzbicka (1987) et Schapira (2000, 2005), formulent des explications du point de vue de la sémantique radicale. On peut dire qu'il s'agit des deux types d'analyse, pour ainsi dire, classiques. Et parmi les études récentes, ce qui me semble avoir le plus de portée explicative est l'approche inspirée par la sémantique du prototype (Sakahara 1992, 2002 et Fujita 1988, 1990, 1993), et celle de la théorie de l'argumentation (Okubo 2002, 2003).

Or, la construction "X est X" elle-même n'étant pas du tout homogène, elle peut se classer en plusieurs types, parmi lesquels nous aimerions nous limiter, dans cette communication, à ces trois types : rehomogénéisation, sous-catégorisation et obligation, qui sont représentées respectivement par (8), (9) et (10).

(8) [sous-catégorisation] Une maison est une maison *seulement si elle a plus de six chambres.*

(9) [rehomogénéisation] *Même s'il n'attrape pas de souris,* un chat est un chat.

(10) [obligation] Cette loi a été passée d'une manière forcée. Mais *une loi est une loi.*

Si la tautologie se trouve accompagnée d'une condition de limitation, comme "seulement si ..." dans (8), on a presque automatiquement l'interprétation "sous-catégorisation". Dans le cas de "la rehomogénéisation", on trouve en principe une expression concessive, comme "même si ..." dans (9). Pour ce qui est du type "obligation", X implique, dans son sens lexical, un devoir, une demande à la réalisation, comme l'indique le mot "loi" dans (10).

Selon Sakahara et Fujita, le type "sous-catégorisation" crée, à l'intérieur de la catégorie X, une sous-catégorie "vrai X", par l'introduction d'un certain trait. Ainsi, dans (8), on constitue, dans la catégorie "maison", une sous-catégorie "vraie maison" qui seule remplit la condition "avoir plus de six chambres".

Pour ce qui est du type “rehomogénéisation”, il a pour fonction de rehomogénéiser la catégorie X qui risquait d’être hétérogénéisée par l’introduction d’un certain trait. Ainsi, d’après Sakahara et Fujita, (9) tiendrait à énoncer que, malgré l’existence d’une différence entre les chats qui “attrapent des souris” et ceux qui “n’en attrapent pas”, la catégorie “chat” est bien homogène. En d’autres termes, il n’existe pas là de variation de degré d’appartenance à la catégorie “chat”, celle-ci étant bien homogène.

Or, s’inspirant de la théorie de l’argumentation de Ducrot et de Carel qui rend compte des phénomènes linguistiques avec des notions de conclusion, explicite ou implicite, et d’argument pour cette conclusion, Okubo suppose que la tautologie du type “rehomogénéisation” fonctionne comme argument pour une certaine conclusion. Par exemple, dans (9), le fait qu’“un chat n’attrape pas de souris” peut constituer un argument en faveur de la conclusion provisoire “on ne doit pas l’élever”, mais la tautologie “un chat est un chat” signifiant “malgré tout il s’agit d’un chat comme les autres” constitue un argument plus fort qui s’oriente vers la conclusion finale “on doit l’élever”.

A la différence des deux types ci-dessus, le type “obligation” semble n’avoir pas attiré assez d’intérêt des chercheurs. Il n’a pas été considéré comme un type bien différent des autres. Et, selon Okubo, il peut s’analyser tout comme (9). L’argument “cette loi a été passée d’une manière forcée” risquerait d’introduire la conclusion provisoire “on n’a pas à la suivre”. Mais, au contraire, l’autre argument, plus fort, “une loi est une loi”, signifiant “malgré tout il s’agit d’une loi comme les autres” amène à la conclusion finale “nous devons nous conformer à cette loi ».

Ces deux approches nous intéressent, principalement par le fait qu’elles font appel à des instruments théoriques assez proches des différentes formes de subjectivité. Mais nous avons l’impression que le concept du degré d’appartenance à la catégorie et celui de l’“argument-conclusion” donnent une image trop concrète de la subjectivité. Nous pensons que celle-ci fonctionne plutôt à l’état pur dans cette construction.

#### **4. sous-catégorisation**

Nous aimerions d’abord signaler que la sous-catégorie, censée être constituée

dans ce type, doit être considérée avant tout comme désirable pour le locuteur, comme le montre la différence de grammaticalité entre (11) et (12).

(11) Une maison est une maison seulement si elle a plus de six chambres.

(12) \* Une maison est une maison seulement si elle a moins de trois chambres.

Mais le trait habituellement négatif peut être pris comme désirable par certains locuteurs. Ainsi (13) indique que l'ajout d'un contexte approprié peut sauver la phrase insolite.

(13) Ma maison est très petite. J'y suis bien habitué. Et j'aime bien les petites maisons. o.k. Pour moi une maison est une maison seulement si elle a moins de trois chambres.

Comparons (14) et (15). Bien que (14) soit naturelle, la deuxième phrase de (15) est déplacée. On voit, dans (15), que la désirabilité accordée à la sous-catégorie constituée dans la première phrase est niée aussitôt après. C'est ce point qui rend insolite la relation entre les deux phrases.

(14) Un jardin est un jardin seulement s'il est plein d'arbres.

(15) Pour moi un jardin est un jardin seulement s'il est plein d'arbres. # Mais j'aime plutôt les jardins sans arbre.

Il est à noter, d'autre part, que le trait qui circonscrit la sous-catégorie peut être très vague. Il peut être par exemple une simple indication temporelle, comme on le voit dans (16). Or, dans (17), le rapport entre les deux phrases est peu naturel. Cela est dû au fait que la désirabilité accordée à la sous-catégorie est niée aussitôt dans la deuxième phrase, tout comme dans (15).

(16) Il y a trente ans un homme était un homme. J'aime les hommes d'autrefois.

(17) Il y a trente ans un homme était un homme. # Je n'aime pas les hommes d'autrefois.

Dans (16), on n'a plus affaire à aucun trait inhérent aux membres de la sous-catégorie. Mais, tout de même, cette sous-catégorie peut bien se constituer et dès qu'elle se constitue, elle s'interprète comme désirable.

Tout nous amène à croire que ce qui est le plus pertinent dans ce type de tautologie c'est la désirabilité, jugement subjectif du locuteur, plutôt que "vrai X" dont parlent les sémanticiens du prototype. J'aimerais donc proposer, à propos de cette tautologie, une paraphrase (18).

(18) Je ne constate une désirabilité qu'à une certaine sous-catégorie de X.

Ce qui est intéressant, c'est qu'une phrase contradictoire comme (19) peut être paraphrasée par (20). Cela indique que ce type de phrase contradictoire concerne la partie expulsée de la sous-catégorie, c'est-à-dire la partie non désirable de X.

(19) La bière sans alcool n'est pas la bière.

(20) A la bière sans alcool, je n'accorde pas la désirabilité normalement attendue de la bière.

Il est à ajouter que, en japonais, ce type de tautologie n'est pas tellement naturel, sinon tout à fait impossible, comme l'indique (21). Cela est dû peut-être au fait qu'il existe une construction équivalente sans sujet, c'est-à-dire plus succincte, comme on le voit dans (22). Or si la phrase est mise au passé, le sujet étant obligatoire, elle redevient naturelle comme dans (23).

(21) ? roku (six) heya (chambre) ijô (plus de) aru (il y a) toki (si) dake (seulement),  
ie (maison) ha (marqueur de nominatif) ie (maison) da (être). (= 11)

(22) roku (six) heya (chambre) ijô (plus de) aru (il y a) toki (si) dake (seulement),  
ie (maison) da (être). (= 11)

(23) san-jyuu (trente) nen (an) mae (il y a), otoko (homme) ha (marqueur de  
nominatif) otoko (homme) datta (être, passé). (= 16)

## 5. rehomogénéisation

On peut remarquer que dans ce cas de la rehomogénéisation également, la désirabilité intervient, mais d'une autre manière. Car, à la différence du cas précédent où une hétérogénéité de désirabilité se constitue à l'intérieur de la catégorie, ici la désirabilité assume plutôt le rôle de rehomogénéiser la catégorie, qui risquait d'être hétérogène. L'opération est donc inverse.

Par exemple, dans (24), "être laid" peut causer une hétérogénéité dans la catégorie "chat" : il existe des chats désirables et indésirables. Mais la tautologie "un chat est un chat" vise ici à dire qu'il ne se trouve pas de différence de désirabilité entre les chats.

(24) Même s'il est laid, un chat est un chat.

On constate donc que cette interprétation de la tautologie est due en principe à un trait qui risquerait d'introduire une différence de désirabilité dans la catégorie donnée. Ainsi comparons (25) et (26). Dans (25), le trait "petit" pouvant causer une différence

de désirabilité entre jardins, le locuteur la nie finalement avec la tautologie. En ce qui concerne (26) où le jardin est déjà bien grand, le locuteur n'a aucune raison d'insister sur l'homogénéité du jardin en général.

(25) Dans notre petit jardin, nous pouvons cultiver des légumes. Un jardin est un jardin.

(26) Dans notre grand jardin, nous pouvons cultiver des légumes. # Un jardin est un jardin.

Nous pouvons donc penser que ce type de tautologie énonce que le degré de désirabilité ne change pas à travers toute la catégorie. Dans (24) et (25), “laid” et “petit” respectivement risquent d'indiquer qu'il existe des membres non désirables. Mais on vise à nier, au moyen de la tautologie, l'existence de l'hétérogénéité de désirabilité.

On peut concevoir bien sûr des cas où la catégorie en principe indésirable risque d'être hétérogène. Dans (27) et (28) par exemple, on a d'abord des facteurs signalant la possibilité de l'existence de membres désirables : “gentil” et “bon pour la santé”, mais la tautologie finalement récupère l'indésirabilité unitaire de la catégorie.

(27) Il a l'air gentil. Mais il faut faire attention. Un criminel est un criminel.

(28) (Nous ne supportons pas l'alcool) On m'a dit que ce vin est très bon pour la santé. Mais il faut faire attention. Du vin, c'est du vin.

Ce qui est intéressant, c'est que la même phrase tautologique peut concerner soit la désirabilité soit l'indésirabilité de la catégorie. Voyons (29) - (31).

(29) Même s'il s'agit d'un seul jour, un jeûne est un jeûne.

(30) Même s'il s'agit d'un seul jour, un jeûne est un jeûne. C'est bon pour la santé.

(31) Même s'il s'agit d'un seul jour, un jeûne est un jeûne. Ce sera dur pour moi.

La même catégorie “jeûne” est considérée comme désirable dans (30), comme indésirable dans (31). On peut avoir une de ces deux interprétations avec l'aide du contexte : “ bon pour la santé ” ou “dur”. C'est pour cela que (29), sans contexte, manque un peu de stabilité.

Il est à remarquer que, dans ce type de tautologie également, le trait qui risque d'introduire une hétérogénéité peut être vague, comme on le voit dans (32) et (33).

(32) A : Les étudiants aujourd'hui ne sont pas ce qu'ils étaient il y a trente ans. Je suis très mécontent d'eux. – B : Les étudiants sont les étudiants, aujourd'hui comme il y a trente ans.

(33) (Le père gronde son fils qui est l'ami d'un voleur) Fils : Un ami est un ami ! –

Père : Un voleur est un voleur !

Dans (32) et (33), il n'est plus question de trait concret. Ce qui est seulement clair, c'est que les jugements sont tout à fait contraires entre les interlocuteurs. L'un défend la désirabilité, l'autre l'indésirabilité.

Tout nous amène à formuler, pour ce type de tautologie, la paraphrase (34).

(34) A propos de la catégorie X, on risque de constater une différence de degré de désirabilité à première vue, mais en fait, bien au contraire, pour moi ce degré reste le même au travers de la catégorie X.

Or on a une phrase contradictoire comme dans (35), qui peut être paraphrasée par (36). On peut donc la considérer comme la négation de la tautologie du type-rehomogénéisation. Mais il se constate une différence : la phrase contradictoire de ce type fait référence à un individu, alors que la tautologie concerne la catégorie prise en bloc.

(35) (A propos d'un robot doté d'une intelligence comparable à celle de l'homme)  
Ce robot n'est plus un robot.

(36) A ce robot, je n'admets pas la même désirabilité qu'aux autres membres de la catégorie, car il a bien plus de désirabilité que les autres.

Il faut ajouter finalement que, dans ce même type de tautologie, l'on peut avoir affaire à la factualité plutôt qu'à la désirabilité. Ainsi dans (37) et (38), il est difficilement imaginable qu'il s'agisse de désirabilité. Ici on insiste sur l'existence même de la catégorie X qui aurait pu se partager en plusieurs sous-catégories.

(37) Quant à la montre, il y en a plusieurs sortes : montre-calendrier, montre digitale, montre de plongée, montre de poche etc. Mais une montre est une montre. Tout sert à mesurer le temps.

(38) Le livre de grammaire enregistre divers emplois d'imparfait. Mais il faut distinguer significations et signifié. Pour moi structuraliste, l'imparfait est l'imparfait. Sa valeur est unique et constante.

Dans ces cas également, on vise à insister sur l'homogénéité de la catégorie X, mais il ne s'agit plus de celle de la désirabilité, mais de celle de la factualité. A cette sous-classe du type-rehomogénéisation, nous proposons donc la paraphrase (39).

(39) Les frontières notionnelles de la catégorie X risquent d'être vagues, mais en fait, bien au contraire, pour moi cette catégorie X existe bien en tant que telle.

## 6. obligation

Le troisième type de tautologie que j'aimerais mentionner, c'est celui qui demande à l'interlocuteur ou au locuteur lui-même de faire quelque chose, par exemple : respecter le règlement, tenir une promesse, remplir un devoir digne de son statut. Voyons (40) – (43). Ce type fonctionne non plus comme un jugement à l'intérieur du locuteur mais au niveau intersubjectif, à la différence des deux types précédents. Nous aimerions donc présenter ici la paraphrase (43).

(40) Même avec un écolier, une promesse est une promesse.

(41) Il faut beaucoup travailler. Un étudiant est un étudiant.

(42) Tu me donneras un peu d'argent. Un ami est un ami.

(43) Je vous demande vivement de réaliser X comme il faut.

Cela nous amène à penser qu'ici c'est le souhait, subjectivité du troisième type, qui intervient ici.

Il est utile d'ajouter que ce type, bien que fréquent en japonais également, montre une curieuse différence : par exemple, la traduction littérale en japonais de (41) et (42) est un peu déplacée, sinon tout à fait inacceptable. Nous avons l'impression que, en japonais, le lexème acceptable est beaucoup plus restreint : loi, promesse, règle etc. qui supposent tous, d'une manière incontestable, leur respect. Point mystérieux pour le moment, mais il nous est permis de penser que ce fait peut être lié à l'absence de l'article en japonais.

## 7. conclusion

Nous sommes d'avis que la tautologie, ainsi que la phrase contradictoire, sont des cadres vides d'information, mais qui ont pour fonction d'exprimer la subjectivité. Cette étude sur la tautologie nous fait entrevoir un tant soit peu que si la factualité a toujours intéressé les linguistes par le biais d'études sur la modalité, la désirabilité et le souhait sont de la même importance.

Or on a d'autres types de tautologie, parmi lesquels le type de « la séparation de deux catégories », où deux tautologies se juxtaposent comme dans (44), et celui de « refus de la réponse » comme dans (45), sont assez courants non seulement en français

mais en japonais. Il nous faudrait rendre compte de tous les phénomènes concernant la tautologie, y compris ces types.

(44) Un étudiant est un étudiant, un professeur est un professeur. Il faut bien garder les distances.

(45) Enfant : « Papa, qu'est-ce que c'est, une personne juridique ? » – Père : « Une personne juridique, c'est une personne juridique ».

Nous avons devant nous divers phénomènes qui attendent d'être expliqués par l'hypothèse de trois formes de subjectivité.

# No Movement Analysis of Scrambling

Hong-Pin Im

Seoul National University  
Gwanak-gu Seoul Korea  
imhp@snu.ac.kr

## Abstract

It is well known that it is crucial that the alleged scrambling in Korean and Japanese, etc. lacks the motivation or driving force for the movement of constituents. The Case theory, EPP and Focus Feature, etc. that are put forth to cope with this problem do not support the movement of the scrambled constituent. The radical LF-reconstruction or the LF-lowering raises serious questions about the movement at S-structure or at LF, due to the infelicitous results that the movement brings about. Thus it is reasonable to claim that the word order of the surface structure should be seen as given, and the semantic interpretation should be done to the given structure.

For this purpose, this paper takes much of the syntactic analysis in terms of the Lexicalist Case Hypothesis (LCH) that says that as far as syntactic case is concerned, the case should be defined on the basis of lexical information given in the lexicon, and the Hypothesis of Variable Medial Projection (=HVMP) that says that the number of medial projections should be matched with the number of arguments of a predicate. On this syntactic analysis, the putative scrambled constituent should be analyzed as syntactic remnant, not given any syntactic function to. According to Ubiquitous Topic Hypothesis (=UTH), the syntactic remnant is to be given a syntactic topic function. The putative scrambled constituent can be called 'word order topic'.

**Keywords:** Word Order Topic, The Hypothesis of Variable Medial Projection, Ubiquitous Topic Hypothesis, Case Lexicalist Hypothesis, LF Reconstruction, LF Lowering.

## 1. Goal

This paper intends to make clear the real nature of scrambling and semantic effects of seemingly scrambling in Korean. In general, the scrambling has been taken to be the operation to rearrange the order of constituents placed at given positions in a sentence. However, from the start, scrambling runs into unexpected difficulties. One is concerned with the basic word order. In Minimalist framework (Chomsky, 1995, etc.), the basic

order of the constituents in a sentence is not fixed or not in a stable state, because the internal merge can be applied even to the structure not full fledged. The order of constituents is largely dependent on factors like Head parameter and/or Linear Correspondence Axiom by Kayne (1994), and the like. The other is concerned with ‘Last Resort.’ Obviously it is not clear what it is the motive or driving force for a constituent to scramble to other position.

The current dichotomy in the approaches to the problem of scrambling seems to be that between the movement approach and the base generation (or non-movement) approach<sup>1</sup>. The former sees that a variety of word orders are the results of movements, whereas the latter sees that they are not the results of movements, but are given as such (Cf. Bayer and Kornfilt 1994, Kiss 1994, Neeleman 1994, Y.-S. Kim 1997, Bošković & Takahashi 1998, Cho and Kim 2000, 2001; Bošković 2004, etc.). Consider the following:<sup>2</sup>

- (1) a. Harry-ga *Mary-eui son-eul* jab-ass-da.<sup>3</sup>  
           NK      GK hand-AK hold-PST-DF  
           ‘Harry held Mary’s hand.’  
   b. *Mary-eui son-eul* Harry-ga jab-ass-da. (Scrambled version of (1a))  
           GK hand-AK      NK hold-PST-DF  
           ‘Mary’s hand, Harry held.’<sup>4</sup>  
   c. *Mary-eui son-eul* Harry-ga [t] jab-ass-da. (Derivation from (1a) to (1b))
- 

The example (1a) exhibits the normal, basic, and/or canonical word order of the typical transitive sentence in Korean. In (1b), it seems that the object of (1a) moves to

---

\*This is a revised and extended English version of the paper presented in Korean at CIL 18 which was held on 22 JUL 2008 in Korea and of the paper presented at the International Conference on Korean Language, Culture and Society held at City University of Hong Kong on 20-21 June 2007, organized jointly by City University of Hong Kong and the International Circle of Korean Linguistics. I am grateful to all the participants of the conferences for their interests shown to the earlier version of this paper, especially to Prof. Harry B. Whitman and Prof K.-S. Kim and Prof J.-H. Han etc. for their interests and critical questions and comments on the earlier paper. My view on the long distance scrambling was presented at the International Conference in Commemoration of the 50<sup>th</sup> Anniversary of Sogang University in Korea. The discussants Prof H.-D. Ahn and J.-B. Kim at the Conference showed great interests and made helpful comments on critical issues.

<sup>1</sup> As to the previous approaches to scrambling, confer to Kiss (1994), where the first branch is divided into the position that sees the scrambling as syntactic phenomenon and the one that sees it as stylistic phenomenon. The latter position is divided into the view that sees the scrambled structure is base-generated and the one that sees it derived by adjunction. The “base-generated” positions are also divided into the position that sees the base as flat and the one that sees it as hierarchical.

<sup>2</sup> In Korean annotations, NK stands for Nominative Case Marker, GK Genitive Case Marker, AK Accusative Case Marker, TK Target Case Marker that comprises Dative Case and Goal or Directive Case, LK Locative Case Marker, SK Source Case Marker, H Modal Particle including the so-called Topic Marker *eun/neun*, PRS Present Tense Marker, PST Past Tense Marker, RPF Respect Prefinal Ending, DF Declarative Final Ending, QF Interrogative Final Ending, CF Connective Final Ending, AF Adnominal Final Ending and CFP Connective Final Ending Phrase.

<sup>3</sup> This paper adopts Korean Official Romanization System for Korean data.

<sup>4</sup> The English annotations in this paper reflect the author’s point of view on scrambling.

the sentence initial position. The movement approach to scrambling (or ‘derivationalist’ hypothesis) sees that the structure of (1b) is derived from the canonical structure like (1a) by way of a movement as shown by arrow in (1c). As to the A or A-bar distinction of the landing site of scrambling, various proposals are put forth, depending on the grammatical theories and versions (Cf. Saito 1985, 1992; Hoji 1985, Webelhuth 1989, Mahajan 1990, Tada 1993, Yoshimura 1992).

In contrast, the base generation (or non-movement) approach to scrambling sees that the structure of (1b) is not derived from the structure like (1a). Instead, as postulated in Y.-S. Kim (1997), Bošković & Takahashi (1998), Cho and Kim (2000, 2001) and Bošković (2004) etc. LF lowering was proposed. The putative scrambled constituent is lowered into its  $\Theta$ -role position, so that its  $\Theta$ -role is checked. Granted that LF lowering can be motivated for the  $\Theta$ -role checking, there still remains a question about how the putative scrambled structure is to be generated.<sup>5</sup>

In this paper it is claimed that there is no such thing as scrambling in Korean, as far as a variety of surface syntactic structures are analyzed in terms of the Hypothesis of Variable Medial Projections (HVMP) and Case Lexicalist Hypothesis (CLH) (Cf. Im 2000, 2007, Im and Lee 2002, etc.). Only there are word order variations as given, which look like seemingly scrambling or rearrangement of constituents. If so, naturally there arises a question about how can be explained the multiple word order variations in surface structures. The answer is not so difficult: The alleged scrambled constituent is given at that position. The semantic and/or pragmatic function of the putative scrambled constituent is that of topic, which is called ‘word order topic’ in this paper.

## 2. Movement Approach and Lack of Motivation

As is well known, the principle that works in the syntactic derivation is the so-called “last resort”. Without any motivation, a constituent should not be moved from one place to another. If (1b) is derived from (1a), the constituent *Mary-eui son-eul* ‘Mary’s hand-AK’ should have motivation to move. If not, the move is not legitimate.?

The Case theory does not work here, because the object is fully equipped with the accusative case marker *eul/reul*. Contra Y.-S. Lee (1994) and Jo (1997) etc., it is obvious that there is no reason for a constituent with a proper Case to move to get the Case, as indicated in Bošković & Takahashi (1998). There is no empty place to be filled by an object NP at sentence initial position, either. Even the bare object NP in situ does not have any reason to move to that position, because that position is not a place where the problem of Case is resolved. Miyagawa (1991) proposed Case solution to scrambling by assigning the abstract case of accusative to the scrambled trace and by seeing that the accusative is realized at the moved position. Y.-S. Lee (1993, 1994) claimed that the complex category ‘I+V’ formed by V raising could assign both the accusative and the nominative Case. However these are nothing but a mere stipulation. Thus, let’s present

---

<sup>5</sup> As to the counter-attack done to LF lowering theory, see Bailyn (2001) and Miyagawa (2006), M.-K. Lee (2006), etc.

the consequence as follows:

(2) Scrambling and Case Theory

Case theory does not work for scrambling.

Purely formal feature like [+EPP] happened to be postulated in the category of T (tense) of TP (Cf. Miyagawa 2001 for Japanese data), or  $\nu$  or T as in Jung (2002) to attract the object to Spec of TP or Spec of  $\nu$ P, or to check off the relevant uninterpretable feature. However, [+EPP] feature is originally related with subject. If that feature is assigned to T or  $\nu$  for object scrambling, the inherent property of [+EPP] must be distorted and perverse. If [+EPP] feature of T or  $\nu$  is checked off by an object or a WH-phrase, then T or  $\nu$  intrinsically has nothing to do with a subject. This is undesirable. And once checked off, the [+EPP] feature cannot work any further. However, it is obvious that there must be scrambling related with the dative, locative and/or instrumental constituent, etc. other than the accusative one. Consider the following:

- (3) a. Harry-ga Mary-ege seonmul-eul ju-eoss-da.  
NK TK gift-AK give-PST-DF  
'Harry gave Mary a gift.'
- b. *Mary-ege* Harry-ga seonmul-eul ju-eoss-da.  
TK NK gift-AK give-PST-DF  
'[literally] \*Harry gave a gift, speaking of Mary.'
- c. *Mary-ege seonmul-eul* Harry-ga ju-eoss-da.  
TK gift-AK NK give-PST-DF  
'Harry gave Mary a gift, speaking of Mary and a gift.'
- d. *Seonmul-eul Mary-ege* Harry-ga ju-eoss-da.  
gift-AK TK NK give-PST-DF  
'Harry gave Mary a gift, speaking of a gift and Mary.'

The example (3a) shows the canonical word order of the verb *ju-* 'give': Dative precedes accusative. In (3b), the dative occupies sentence initial position. If the [+EPP] feature must work for scrambling as in Jung (2002), Boeckx (2004), and H.-Y. Kim (2005) etc., (3b) is derived by [+EPP]. However, once the [+EPP] feature was used up for the scrambling of dative, there remains nothing to be used for other scramblings. But as shown in (3c), the accusative moves in addition to the dative. (3d) which the accusative scrambles across the dative is also problematic for the [+EPP] hypothesis for the same reason. It is evident that Kitagawa (1990), Miyagawa (1991) and Y.-S. Lee (1994) etc. have no ways to deal with these complexities.

The setting up of the feature like [+EPP] also raises the problem of 'look ahead', as in the case of [+Focus] movement approach that will be shortly touched. Thus we can say that:

(4) Scrambling and [+EPP] Hypothesis

EPP hypothesis does not work for scrambling.

The focalist approach to scrambling as in Miyagawa (1997), Choi (1999), M.-K. Lee (2006), Lee and Cho (2003), etc. postulates a feature like [+focus] or a Focus projection i.e. FocP above TP to attract an object. Jung (2002) and Yang and Kim (2005) suggest the INT-move for the topic or focus effect. But crucial questions are raised about the motivation for setting up the arbitrary feature like [+focus] or [+topic] and for setting up the arbitrary projection like FocP. It should be pointed out that the feature like [+focus] or [+topic] also raises 'look ahead' problem, because setting up such features could be thought to be an anticipatory measure for later applications. The same can be said to the focus approach as posited in Lee and Cho (2004) and to the INT-move or the like as stipulated in Jung (2002) and Yang & Kim (2005).

Furthermore, it is obvious that the focus approach is not based on the real data. Consider the following:

- (5) a. Speaker A: Harry-ga Mary-ege *mueos-eul* ju-eoss-ni?  
NK TK what-AK give-PST-QF  
'What did Harry give to Mary?'
- b. Speaker A: *Mueos-eul* Harry-ga Mary-ege ju-eoss-ni?  
what-AK NK TK give-PST-QF  
'What did Harry give to Mary?'
- c. Speaker B: *Chaek-eul* Harry-ga Mary-ege ju-eoss-da.  
book-AK NK TK give-PST-DF  
'A book, Harry gave to Mary.'
- d. Speaker B: Harry-ga Mary-ege *Chaek-eul* ju-eoss-da.  
NK TK book-AK give-PST-DF  
'Harry gave a book to Mary.'
- (6) a. Speaker A: *Chaek-eul* Harry-ga *nugu-ege* ju-eoss-nunja?  
book-AK NK who-TK give-PST-QF  
'The book, to whom did Harry give?'
- b. Speaker A: *Chaeg-eul* Harry-ga *Mary-ege* ju-eoss-da.  
book-AK NK TK give-PST-DF  
'The book, Harry gave to Mary.'

(5a) is a question about the WH-phrase *mueos-eul* 'what-AK'. If WH-word is a focus, then the constituent *mueos-eul* 'what-AK' in (5a) must be a focus. Yet, the constituent *mueos-eul* 'what-AK' still is in situ. This means that the scrambling has nothing to do with WH-focus. Is this unmarked focus in the sense of M.-K. Lee (2006)? It is not certain whether or not WH-phrase is a focus. The real is that WH-phrase is a constituent to be asked for information. If scrambling were focus-driven, then the WH-phrase in (5b) should have moved to get the focus status. But this is not the case, because the WH-phrase is already focus in situ according to the WH-focus hypothesis.

(5d) is a neutral answer to the question of (5a). But (5c) also is a possible answer to (5a) with some emphasis on *chaeg* ‘book’. This means that scrambling cannot be seen as a focus-driven movement, because the answer to the WH-word can be given to the WH-word in situ.

Now consider (6a) and (6b). (6a) is a question about the WH-phrase *nugu-ege* ‘who-TK’. Here again if WH-phrase is a focus, then the constituent *nugu-ege* ‘who-TK’ must be a focus. Nevertheless, the constituent *nugu-ege* ‘who-TK’ does not move to the sentence initial position. If WH-phrase and the alleged scrambled object are foci, then what is the real focus in (6a)? Both are foci? It is conceded that in (6b) *Mary-ege* ‘Mary-TK’ is a focus, because it is newly introduced into the discourse. Then what is the information status of the alleged scrambled object at the sentence initial position? The alleged scrambled object and the element of new information that occurs in the answer, are they both foci? At least not both are foci. It is evident that the alleged scrambled object is not a focus as new information. Let’s present this as follows:

(7) Scrambling and Focus Hypothesis

Focus hypothesis does not work for scrambling.

What about the [+topic] hypothesis for providing the driving force for scrambling? This paper considers the putative scrambled phrase a kind of topic, but not involved in movement, contra Bailyn (2001) and Park (2007), etc.<sup>6</sup>

#### 4. Against Movement Approach to Scrambling

It is already proposed that scrambling is not movement, in Bayer & Kornfilt (1994), Kiss (1994), Neeleman (1994), Y.-S. Kim (1997), Bošković & Takahashi (1998), Cho and Kim (2000, 2001), and Bošković (2004), etc. largely based on the scope phenomenon, anaphor binding fact, superiority condition, idiom interpretation, and parasitic gap resolution, etc. Though some evidences are convincing, the grammatical judgments on the relevant examples are too subtle to be established. Some phenomena are not found in Korean, since Korean has nothing to do with the syntactic WH-movement and superiority condition, etc. As to Korean, let’s consider following evidences for non-movement approach to scrambling.

First, it should be pointed out that the position from which the alleged scrambled constituent is considered to be extracted could be filled with some resumptive lexical elements.

---

<sup>6</sup> Song (2004) sees that the constituent *chaeg-eul* in the example *Mary-ga chaeg-eul na-ege ju-eoss-da* ‘Mary, a book, gave to me.’ functions as a topic and that the constituent *na-ege* ‘to me’ as a focus. This paper in part agrees with Song’s (2004) interpretation, but it is different from Song (2004) in seeing that the constituent *Chaeg-eul* is a topic *relative to* the rest of the sentence. The rest of the sentence is qualified as a comment *relative to* the topic. Information status of a constituent is determined with regard to discourse syntactic contexts.

- (8) a. *Chaeg-eul* Suzie-ga  $e_i$  silheoha-n-da.<sup>7</sup>  
 book AK NK dislike-PRS-DF  
 ‘The book, Suzie dislikes.’
- b. *Chaeg-eul* Suzie-ga *gugeos jachae-reul* silheoha-n-da.  
 book AK NK it self-AK dislike-PRS-DF  
 ‘The book, Suzie dislikes it itself.’
- c. *Chaeg-eul* Suzie-ga *geu eotteon geos-do* silheoha-n-da.  
 book AK NK that which one even dislike-PRS-DF  
 ‘The book, Suzie dislikes anything like that.’

As indicated related with (1c), the derivationalist sees that in (8a) there is a gap between the subject and the predicate. If once a trace always a trace,<sup>8</sup> the gap cannot be filled with other lexical materials. But as shown in (8b) and (8c), the gap can be filled with other materials, like *it itself*, *anything like that*, etc. It cannot be said that scrambling involves movement, since there is no trace in (8b, c) from which the putative scrambled phrase is extracted. It is not the case that after scrambling the referring lexical elements are inserted. Thus we can say that:

(9) Scrambling and Resumptive Lexical Elements

The putative scrambled gap can be filled with other heavy lexical materials. This means that scrambling is not movement.

Second, some reciprocal facts support non-movement approach to scrambling. It is not without apparent counterexamples.<sup>9</sup> Consider the following:

- (10) a. *Seoro-reul* [Mary-wa Suzie]-ga  $e_i$  bipanha-yeoss-da.  
 each other AK and NK criticize-PST-DF  
 ‘Mary and Suzie criticized each other, speaking of each other.’
- b. [Mary-wa Suzie]-ga *seoro-reul* bipanha-yeoss-da  
 and NK each other-AK criticize-PST-DF  
 ‘Mary and Suzie criticized each other.’

To avoid complications, let’s assume that the Korean reciprocal *seoro* ‘each other’ is an anaphor, which has its antecedent within governing category in terms of Binding Theory (A) of Chomsky (1981). In movement approach, (10a) and (10b) are assumed to have the same meaning. At movement approach, the reciprocal in (10a) is reconstructed into the position indicated by  $e_i$  in (10a). Though LF structure of (10a) is not distinct from that of (10b), it has been unnoticed that (10a) is not so good as (10b).

<sup>7</sup> In (8a), the symbol  $e$  stands for an empty category, not a trace. Derivationalists see this as a trace left by movement.

<sup>8</sup> It happens that some defending traces are erased in Chomsky (1982) etc. But the examples of (8a-c) have nothing to do with the defending trace.

<sup>9</sup> This indicates such examples as (10a). Confer the discussion related with (10a).

Notwithstanding, (10a) and (10b) are taken to support the movement approach by derivationalists. However, counterexamples are found against the movement approach, as given in Y.-S. Kim (1997).

- (11) a. Harry-ga [Mary-wa Suzie]-reul seoro-ege  $e_i$  sogaeaha-yeoss-da  
 NK and AK each other-TK introduce-PST-DF  
 ‘Harry introduced Mary and Suzie to each other.’  
 b. ?\*Harry-ga seoro-ege [Mary-wa Suzie]-reul sogaeaha-yeoss-da  
 NK each other-TK and AK introduce-PST-DF  
 ‘\*Harry introduced to each other Mary and Suzie.’

Distinct from (11a), (11b) is infelicitous. In (11b), the reciprocal *seoro* ‘each other’ does not have the antecedent in its governing category. By contrast, (11a) is felicitous, in which the accusative antecedent precedes the dative reciprocal. This means that in (11a) the reciprocal is bound in its governing category. If in (11a) the accusative antecedent *Mary-wa Suzie-reul* ‘Mary and Suzie-AK’ were extracted from canonical object position, and if the anaphor interpretation should be done at LF reconstructed structure, then the proper interpretation on the reciprocal could not be obtained. In (11a), the antecedent of the reciprocal is not the reconstructed object in the position  $e_i$ , but the putative scrambled object in front of the reciprocal. Now we can say that:

(12) Scrambling and Construal of Reciprocals

Some reciprocal facts support the non-movement approach to scrambling.

Third, some reflexive facts support the non-movement approach to scrambling. To begin with, consider the following examples that seem to support movement.

- (13) a. *Jagi<sub>i</sub>-reul* Mary<sub>i</sub> -ga  $e_i$  bipanha-yeoss-da  
 self AK NK criticize-PST-DF  
 ‘Mary criticized herself, speaking of Mary.’  
 b. Mary<sub>i</sub> -ga *jagi<sub>i</sub> -reul* bipanha-yeoss-da  
 NK self AK criticize-PST-DF  
 ‘Mary criticized herself.’

(13a) and (13b) are both felicitous, seemingly satisfying movement approach. According to that approach, in (13a) the reflexive *jagi* ‘self’ should be interpreted at LF reconstructed structure. Derivationalists claim that the meanings of (13a) and (13b) are not different. However, it has been unnoticed that (13a) is not so good as (13b). When other lexical materials intervene between the preceding reflexive and the following coreferential NP, the reversed order like (13a) becomes still worse,

- (13’) a. ??*Jagi<sub>i</sub> -reul* manheun saramdeul ap-eseo Mary<sub>i</sub>-ga  $e_i$  bipanha-yeoss- da.  
 self AK many people front-LK NK criticize-PST--DF

- ‘[literally] \*Herself, Mary criticized in front of many people.’  
 b. ??*Jagi<sub>i</sub> -reul* Suzie-ga jamdeun sai-e Mary<sub>i</sub> -ga *e<sub>i</sub>* bipanha-yeoss-da.  
 self AK NK asleep while-LK NK criticize-PST-DF  
 ‘[literally] \*Herself, Mary criticized while Younghi is sleeping.’

(13’a, b) are not good at the coreferential interpretations of the reflexives *jagi* ‘self’ with the subjects *Mary*. If the putative scrambled reflexives should be construed at LF reconstructed structures, it is unthinkable why such infelicities happen to arise. More serious are the examples (14a, b), which seem felicitous, but whose reflexives seem to be not bound within governing categories at LF reconstructed structures.

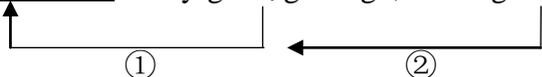

- (14) a. ?*Mary-eui geurim-reul* byeok-eseo *jagi-ga e<sub>i</sub>* tte-eoss-da.  
 GK picture-AK wall-SK self-NK take off--PST-DF  
 ‘[literally] ?Mary’s picture, she herself took it off from the wall.’  
 b. ?*Mary-eui geurim-reul jagi-ga e<sub>i</sub>* silheoha-n-da  
 GK picture-AK self-NK dislike-PRS-DF  
 ‘[literally] ?Mary’s picture, she herself dislikes it.’

(14a) and (14b) exhibit the alleged scrambled structures of the objects *Mary-eui geurim-reul* ‘Mary’s picture-AK’. It should be noted that (14a) and (14b) are not totally infelicitous, though not perfectly grammatical. If the reflexives in (14a) and (14b) must be construed at LF reconstructed structure, the proper interpretations could not be obtained. It is recognized that the reflexives in (14a, b) should be construed at the given surface structures. Thus we can say that:

(15) Scrambling and Reflexive Interpretation.

Some reflexive facts support the non-movement approach to scrambling

Fourth, it is undeniable that the fact that conjoined sentences may share one and the same putative scrambled constituent as shown in (16a) undermines viability of the movement approach to scrambling.

- (16) a. *Mary-eui geurim-reul* Harry-ga *e<sub>i</sub>* geuri-go, Suzie-ga *e<sub>i</sub>* pal-ass-da.  
 GK picture-AK NK draw-CF NK sell-PST-DF  
 ‘Mary’s picture, Harry painted and Younghi sold.’  
 b. *Mary-eui geurim-reul* Harry-ga *e<sub>i</sub>* geuri-go, Suzie-ga *e<sub>i</sub>* pal-ass-da.  

In (16a), the first and the second conjunct share the putative scrambled constituent *Mary-eui geurim-eul* ‘Mary’s picture-AK’. If the shared constituent *Mary-eui geurim-eul* ‘Mary’s picture-AK’ in (16a) is moved both from the first conjunct and from the second one to the sentence initial position, it is natural to say that ① and ② moves in

the fashion of arrow marked in (16b) are not possible. Some tricky movement like Across the Board (ATB) might be proposed to resolve this difficulty. But it is nothing but a makeshift. Now we can sum this as follows:

(17) Scrambling and Shared Constituents

The fact related with shared constituents in conjoined structure support the non-movement approach to scrambling

Fifth, the constituent that has no rigid canonical position like topic or adverbials as in (18) must undermine the validity of the movement approach.

- (18) a. *Mary-reul* Harry-ga son-eul jab-ass-da.  
           H          NK hand-AK hold-PST-DF  
           ‘As for Mary, Harry held her hands.’  
 b. Harry-ga *Mary-reul* son-eul jab-ass-da.  
           NK          H hand-AK hold-PST-DF  
           ‘As for Mary, Harry held her hands.’  
 c. Harry-ga  $e_i$  son-eul jab-ass-da, *Mary-reul*.  
           NK hand-AK hold-PST-DF H  
           ‘Harry held Mary’s hands, speaking of Mary.’

In (18a), the sentence initial *reul*-constituent *Mary-reul* is considered *reul*-topic in Im (1987, 2006, 2007), etc. We don’t know where the *reul*-topic comes from. The most plausible position for the original *reul*-topic might be that before *son-eul* ‘hand-AK’ as in (18b). However, it lacks necessity for the *reul*-topic to be placed there. Usually it is believed that topic occurs in sentence initial position. However, this is nothing but a fixed idea, because there are many kinds of topic in Korean, which seem to have no rigid canonical positions. In (18c), should the tail or afterthought *Mary-reul* be assumed to come from the  $e_i$  marked position? It is not.

Sentence adverbials are on a par with the marked topic constituents in that they also have no rigid canonical positions.

- (19) a. Mary-ga na-ege *eoje* seonmul-eul ju-eoss-da  
           NK me-TK yesterday gift-AK give-PST-DF  
           ‘Mary gave me a gift yesterday.’  
 b. Mary-ga *eoje* na-ege seonmul-eul ju-eoss-da  
           NK yesterday me-TK gift-AK give-PST-DF  
           ‘Mary gave me a gift yesterday.’  
 c. *Eoje* Mary-ga na-ege seonmul-eul ju-eoss-da  
           yesterday NK me-TK gift-AK give-PST-DF  
           ‘Yesterday, Mary gave me a gift.’

(19a-c) exhibit a variety of positions for time adverbial *eoje* ‘yesterday’ to occur.

It occurs sentence medially as in (19a, b) as well as sentence initially as in (19c). Time adverbials can be said free constituents. It can occur anywhere between major constituents. Derivationalists might set up a canonical position for time adverbials to occur. But where is it? Maybe it might be sentence initial position, because the time is related with the proposition as a whole. Even though it is agreed that the typical position for time adverbials is sentence initial, other occurrences of time adverbials cannot be derived from that position.

The situation becomes more complicated when other sentence adverbials are introduced into.

- (20) a. *Dahaenghi* Mary-ga na-ege *eoje* seonmul-eul ju-eoss-da  
 fortunately NK me-TK yesterday gift-AK give-PST-DF  
 ‘Fortunately, Mary gave me a gift yesterday.’  
 b. Mary-ga *dahaenghi* *eoje* na-ege seonmul-eul ju-eoss-da  
 NK fortunately yesterday me-TK gift-AK give-PST-DF  
 ‘[literally] Mary gave me a gift fortunately yesterday.’  
 c. *Eoje* Mary-ga na-ege *dahaenghi* seonmul-eul ju-eoss-da  
 yesterday NK me-TK fortunately gift-AK give-PST-DF  
 ‘[literally] Yesterday Mary gave me fortunately a gift.’

(20a-c) have the modal adverbial *dahaenghi* ‘fortunately’ in addition to the time adverbial. Ordinarily, modal adverbs are considered sentential adverbials, so that it is posited sentence initially. Then the modal adverbial and time adverbial compete on the sentence initial position. There is no resolution for this conflict, because sentence initial position is restricted to only one. In this case, how can we say that other occurrences of adverbials are derived from sentence initial position? Perhaps some stipulation might be put forth. But it is evident that it is not so significant. Thus we can say that:

(21) Scrambling and Free Constituents

Free constituents like topics and adverbials, etc. for which no rigid canonical positions are posited, weaken the movement approach to scrambling.

Sixth, LF reconstruction that the movement approach often postulates for semantic interpretation makes void the semantic effects brought about by putative scrambling. When reconstructed into its extracted position, the scrambled element loses its semantic effects completely. It is undeniable that the putative scrambled constituent has its own function. One example to show the wrong result of LF reconstruction is the idiom chunk.

- (22) a. Geu gage-ga pari-reul nalli-n-da  
 that store NK fly-AK make fly-PRS-DF  
 ‘[literally] That store makes flies fly.  
 ‘[paraphrase] That store’s business is slack.’  
 b. \*Pari-reul<sub>i</sub> geu gage-ga e<sub>i</sub> nalli-n-da

fly-AK that store-NK make fly-PRS-DF

Clearly, (22b) is odd, due to the damage from the putative scrambling. However, if the undoing reconstruction at LF assumed in the movement approach comes to restore idiom effect, then (22b) should be perfect. But this is not true. Thus we can say that:

(23) Scrambling and Idiom Chunk

The damage done to idiom chunk by scrambling and restored by LF reconstruction gives damage to the movement and reconstruction approach.

Seventh, if the putative scrambled constituents do have semantic effects not prepared in the underlying structure, then the putative scrambling violates the principle of ‘meaning preserving’ of transformation. On the other hand, if scrambling applies in PF as a stylistic rule, then it should be permitted that PF rule is sensitive to meaning changing. However, it is wrong to take the position that PF rule could change the meaning arbitrarily.

Eighth, scope facts with regard to quantification undermine the merit of the movement approach.

- (24) a. Modeun namhaksaeng-i eotteon yeohahsaeng-eul joaha-n-da.  
 every boy student-NK some girl student-AK like-PRS-DF  
 ‘Every boy student likes one girl student.’ [ $\forall > \exists$ ,  $\exists > \forall$ ] (for Korean)
- b. Eotteon yeohahsaeng-eul modeun namhaksaeng-i  $e_i$  joaha-n-da.  
 some girl student-AK every boy student-NK like-PRS-DF  
 ‘One girl student, every boy student likes.’ [ $\exists > \forall$ ,  $\forall > \exists$ ] (for Korean)

In (24a), both wide and narrow scope readings on existential quantifier are available on a par. On the other hand, in (24b) the wide scope reading on existential quantifier is more available than the narrow one, though not excluding the latter.<sup>10</sup> LF reconstruction will make void these subtle differences. Let’s present this as follows:

(25) Scrambling and Scope Interaction between Quantifiers

The fact that LF reconstruction nullifies the subtle superior effects of the preceding quantifier over the following one undermines the movement and

---

<sup>10</sup> It is noted that scope phenomenon interacts with various semantic and pragmatic factors. The predicate *joaha*- ‘to like’ in (24b) makes it easy to read the scope of existential quantifier narrowly over the universal quantifier. As for the predicate *geuriweoha*- ‘to miss’, the narrow scope reading is more available than the wide one as in the example below (b). It is because the act of *geuriweoha*- ‘miss’ is more personal or private than that of *joaha*- ‘like’

- (a) Modeun namhaksaeng-i han yeohahsaeng-eul geuriweoha-n-da.  
 every boy student-NK one girl student-AK miss-PRS-DF  
 ‘Every boy student misses one girl student.’ [ $\forall > \exists$ ,  $\exists > \forall$ ] (for Korean)
- (b) Han yeohahsaeng-eul modeun namhaksaeng-i  $e_i$  geuriweoha-n-da.  
 one girl student-AK every boy student-NK miss-PRS-DF  
 ‘One girl student, every boy student misses.’ [ $\exists > \forall$ ,  $\forall > \exists$ ] (for Korean)

reconstruction approach.

Ninth and the last, scope facts relative to modal particle (or delimiter) *man* ‘only’ threaten the existence of scrambling as movement.

- (26) a. Mary-ga na-(ege)-*man* seonmul-eul ju-eoss-da  
NK me-(to)-only gift-AK give-PST-DF  
‘[literally] Mary, only to me, gave a gift.’  
b. Mary-ga seonmul-eul na-(ege)-*man* ju-eoss-da  
NK gift-AK me-(to)-only give-PST-DF  
‘Mary gave a gift only to me.’  
c. Na-(ege)-*man* Mary-ga seonmul-eul ju-eoss-da  
me-(to)-only NK gift-AK give-PST-DF  
‘Only to me, Mary gave a gift.’

The influence of the modal particle *man* ‘only’ in (26a) ranges over the scope from the constituent *na-(ege)-man* ‘only to me’ to *ju-eoss-da* ‘gave’. So (26a) means that Mary ‘didn’t give a gift’ to others except me. By contrast, in (26b) the scope ranges over only two constituents, i.e. *na-(ege)-man* ‘only to me’ and *ju-eoss-da* ‘gave’. Thus (26b) means that a gift, Mary ‘didn’t give’ to others except me. On the other hand, in (26c) the scope of the particle *man* ‘only’ ranges over the entire sentence. Thus (26c) means that it is not the case that ‘Mary gave a gift to others’ except me. It is obvious that there are subtle and important meaning differences among (26a-c). If LF reconstruction returns the modal particle phrase to its original position, these semantic differences among (26a-c) disappear. Thus we can say (27):

(27) Scrambling and Scope Interpretation of Modal Particle *man* ‘only’

The fact that LF reconstruction nullifies the scope distinctions with respect to the modal particle *man* ‘only’ crucially weakens the movement and reconstruction approach.

In sum, though superficially some facts regarding reflexives and reciprocals might seem to support movement approach to scrambling, it is obvious that movement approach must run into counterexamples that are not to be so easily coped with.. It is evident that the movement approach has fatal weakness and that it cannot be supported empirically as well as theoretically.

## 5. Syntactic Analysis and Remnant Constituent

Basically, this paper claims that syntactic analysis should be based on the lexical information given in the lexicon, which could be called the ‘Lexicalist Case Hypothesis’ (LCH, Cf. Im 2006). Let’s present this as follows:

(28) Case Lexicalist Hypothesis (CLH)

As far as syntactic Cases are concerned, they should be defined on the bases of the lexical information given in the lexicon.

Let's assume the simple lexical information of the verb *jab-* 'hold' as follows:

(29) Some Lexical Information of *jab-*

- a. POS (Part Of Speech): V
- b. Argument Information: <NKP, AKP, \_ >
- c. Semantic Information: 'hold'

(29a) shows the part-of-speech (POS) information of *jab-* 'hold'. The word *jab-* is a verb in Korean. (29b) shows the argument information of the verb *jab-*. According to (29b), the verb *jab-* is two-place predicate. It is typical transitive verb. (29c) shows the semantic information of the verb *jab-* 'hold'.

The information contained in the angled bracket in (29b) indicates that the verb *jab-* 'hold' takes AKP (=Accusative Case Phrase) and NKP (=Nominative Case Phrase) as its regular arguments to make a VP (in terms of VP-internal Subject Hypothesis) category. Consider how the syntactic structure of (1a, b) repeated as (30a, b) can be analyzed.

- (30) a. Harry-ga *Mary-eui son-eul* jab-ass-da.  
NK GK hand-AK hold-PAST-DF  
'Harry held Mary's hand.'
- b. *Mary-eui son-eul<sub>i</sub>* Harry-ga *e<sub>i</sub>* jab-ass-da.  
GK hand-AK NK hold-PST-DF  
'Mary's hands, Harry held.'

Before carrying out a full syntactic analysis of a sentence, it is necessary to carry out morphological analyses and partial syntactic analyses of the target phrases and elements given in the sentence. In (30a), the constituent *Mary-eui* 'Mary-GK' is analyzed into GKP (Genitive Case Phrase), *Mary-eui son* 'Mary's hand' into NP, *Mary-eui son-eul* 'Mary's hands-AK' into AKP, *Harry* into NP, *Harry-ga* into NKP, the element *-ass-* into PF (Prefinal Ending [denoting tense]), and *-da* into DF (Declarative Final ending) by reference to the lexical information given in the lexicon and to some partial rules of combinations. This is a very simple picture of morphological and partial syntactic analyses. The full details of analyses are more complex (Cf. Im & Lee 2002).

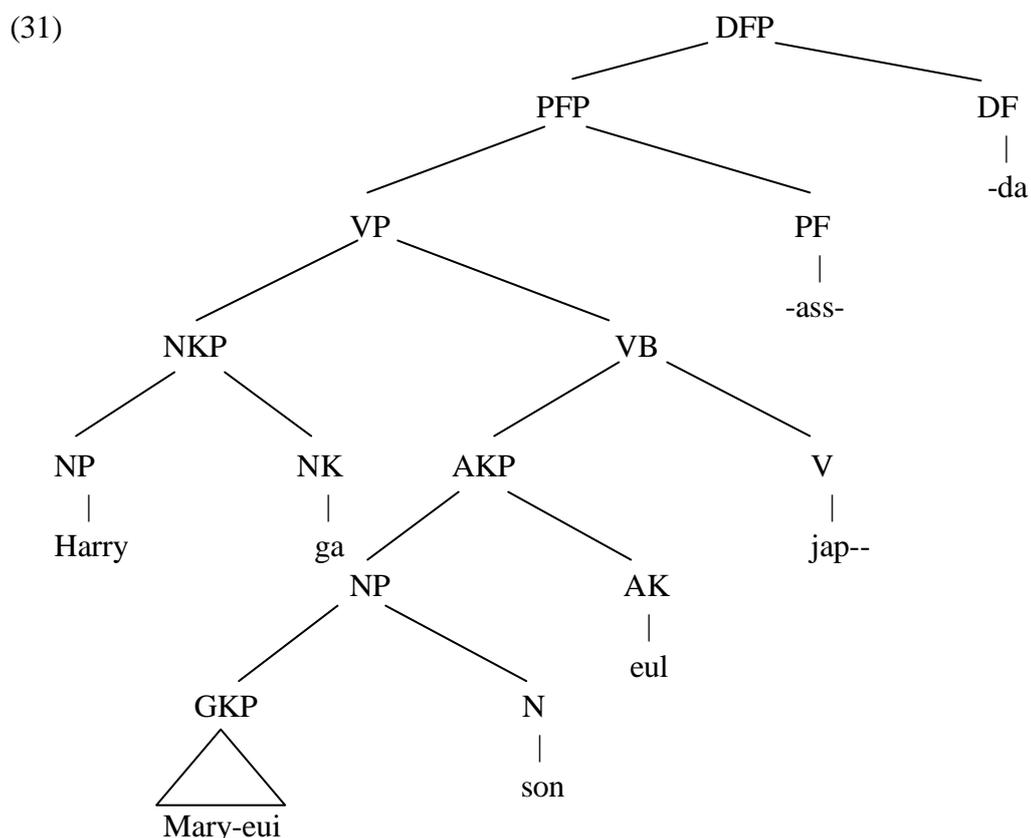

Now (30a) is amenable to syntactic analysis under the HVMP (Hypothesis of Variable Medial Projection)<sup>11</sup> which correlates the number of argument(s) of a head with

---

<sup>11</sup> According to the HVMP, syntactic analysis for structure building proceeds by setting up bar projections as many as the number of argument(s) of a verb, based on the lexical information given as in (29b). On this principle, two-place predicate has two bar levels: one is V-bar (=VB) and the other V double bar (=VBB, in this case, this is maximal, hence VP). The "double object construction," or three-place predicate has three bar levels; one is V-bar (=VB), a second V double

the number of medial projection(s). By the HVMP, we can apply the lexical information to the syntactic analysis. One of the important principles that works here is the ‘Principle of Strict Correspondence’ which indicates that the target constituent can be analyzed as such, only when the order and contents coincide with the information given in the argument information in the lexicon.

Keeping these principles in mind, we can analyze (30a) in a proper and principled way. In the first place, the verb *jab-* ‘to hold’ takes an AKP *Mary-eui son-eul* to make VB (V’), since AKP in (29b) is the first argument from the right to be combined with the head. And then the VB in turn takes an NKP *Harry-ga* to make VP (VBB, this is maximal, hence VP), since NKP is next to AKP from the right. The element *-ass-* ‘past tense marker’ analyzed as PF takes VP to make PFP (Prefinal Ending Phrase, this is usually called TP). And then DF *-da* takes PFP to make DFP (Declarative Final Ending Phrase, or this is usually called CP). The tree diagram (31) above reflects the results of the syntactic analyses just described.

In contrast, (30b) is distinct from (30a) in that the putative scrambled constituent is positioned sentence initially and the canonical object position is vacant. In this case, the syntactic analysis based on the HVMP cannot proceed in the same fashion as in (30a). The object cannot be properly analyzed, because it is not in its canonical position. The verb

---

bar (=VBB), and a third V triple bar (=VBBB, in this case, this is maximal, hence VP). The principle is very simple and easy. Cf. Im (2006, 2007).

*jap-* ‘hold’ takes nothing to project VB (V'). In this case, the verb *jap-* cannot take the sentence initial AKP to make VB projection, due to the Principle of Strict Correspondence. The sentence initial AKP in (30b) is not the proper argument of the predicate *jap-* ‘hold’, so the verb V projects to VB without taking AKP. It occurs at the sentence initial position for the purpose of discourse strategy.

The VB (30b) in turn takes NKP *Harry-ga* to make VP in terms of the HVMP. The next step is to cope with the putative scrambled constituent. The point is that the sentence initial AKP in (30b) is not analyzed with the information given in the lexicon in (29b), due to the Principle of the Strict Correspondence. The argument information given in (29b) with respect to AKP is exhausted to analyze the empty argument given next to the verbal head in (30b). That is to say, (29b) no longer has the information with which to analyze the sentence initial constituent with *eul/reul*. We cannot help but say that the first constituent *Mary-eui son-eul* ‘Mary’s hand-AK’ in (30b) is a remnant which is left unanalyzed in the syntactic analysis in terms of the HVMP. This can be called ‘syntactic remnant’. Let’s present this as follows:

(32) Syntactic Remnant

The constituent that does not occur at canonical position and cannot be analyzed properly in terms of ‘Strict Correspondence Principle’ is called syntactic remnant.

In this paper, it is claimed that the syntactic remnant should be analyzed as a ‘syntactic topic’, because the remnant should be settled syntactically at any rate. It is unthinkable for a constituent in a sentence to remain not endowed any syntactic function. The most appropriate function to be given to the syntactic remnant is that of syntactic topic. This may be called ‘word order topic,’ due to the relatedness of topic with word order. Let’s present this as follows:

(33) Syntactic Remnant and Word Order Topic

The Syntactic Remnant of syntactic analysis to which no proper syntactic function can be given, which has no other salient feature except word order is to be characterized as ‘word order topic’.

(33) is a statement which presupposes that there are many kinds of topic in Korean at least. Usually, it is assumed that only the *eun/neun* phrase at sentence initial position is to be qualified as a topic in Korean. However this is nothing but a fixed idea, because the discourse-pragmatic *aboutness* relation does massively hold between a preceding constituent and the following one in a sentence or in a discourse, even between a thing and the calling of it, or even between a thing and the response to it, etc. This extends to the effect that any major constituent in a sentence can be a discourse-pragmatic topic. The relevant principle may be called ‘Ubiquitous Topic Hypothesis’,<sup>12</sup> which is summarized

---

<sup>12</sup> For the justification of Ubiquitous Topic Hypothesis, see Im (2006, 2007) and Im & Lee (2002), etc.

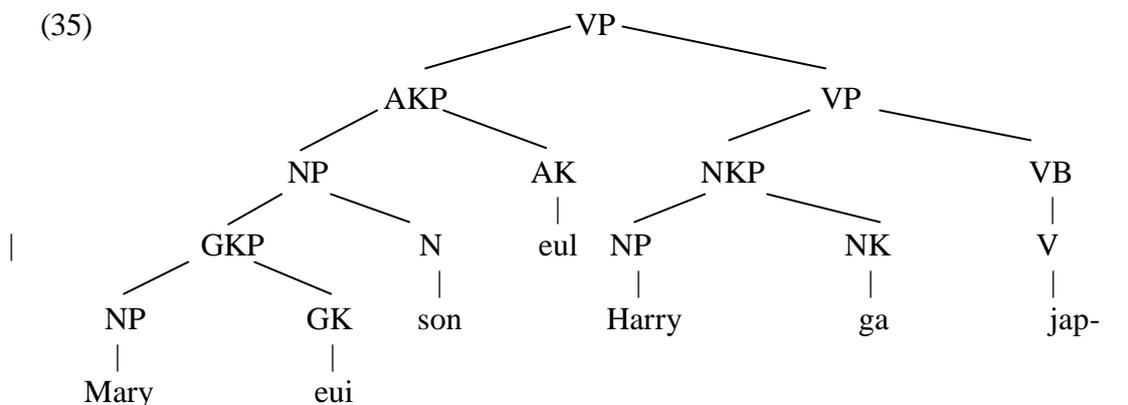

as follows:

(34) Ubiquitous Topic Hypothesis (UTH)

Strictly speaking, any major constituent can be a topic in a sentence. Here “major constituent” refers to semantically and/or pragmatically important constituents in a sentence or a discourse.

In terms of (34), the syntactic remnant can be characterized as a syntactic topic, because the sentence initial AKP is talked about in the rest of the sentence. By the UTH of (34), all of the constituents of a sentence may be called discourse-pragmatic topic. It is often said that a subject is an unmarked topic (Cf. Lambrecht (1994) among others). But this is not so significant from the point of view of syntactic analysis. Major constituents in a sentence already have the splendid syntactic function just like a subject, an object, etc. However, when (34) applies to syntactic remnants, the situation becomes totally different. Functionally naked constituent makes a stately syntactic constituent. It is inevitable to apply UTH to the syntax of Korean, Japanese and the like, because in these languages syntactic remnants are too often encountered.

From these considerations, we can get the following tree diagram (35) for (30b). (35) shows only VP structure.

In (35), the putative scrambled constituent AKP occurs at VP adjunction structure. The structure is on a par with those of other marked topics in Korean, like *eun/neun* topic, *i/ga* topic, *eul/reul* topic, etc. The shared constituency of the putative scrambled element like (16a) supports the postulation of adjunction structure. The sentence initial AKP is not a simple AKP, but a topicalized AKP.

## 6. Evidences for Word Order Topic

Some empirical evidences like the following can be found to support topichood of the putative scrambled constituents.

First, it should be noted that the ‘paraphrase’ relation by topic introducing

expressions presumably supports the topic-comment articulation in the putative scrambled structure. Consider the following:

- (36) a. *Mary-ege<sub>i</sub>(ro malha-myeon)* Harry-ga *e<sub>i</sub>* seonmul-eul ju-ass-da.  
           TK (speaking of)                  NK          gift-AK give-PAST-DF  
           ‘Speaking of Mary, Harry gave a gift.’
- b. *Seonmul-eul<sub>i</sub>(ro malha-myeon)* Harry-ga *Mary-ege e<sub>i</sub>* ju-ass-da.  
           gift-AK (speaking of)                  NK          TK          give-PAST-DF  
           ‘Speaking of a gift, Harry gave to Mary.’
- c. *Harry-ga seonmul-eul<sub>i</sub>(ro malha-myeon)* *Mary-ege e<sub>i</sub>* ju-ass-da.  
           NK          gift-AK (speaking of)                  TK          give-PAST-DF  
           ‘Harry gave to Mary, speaking of a gift.’

(36a) is an example that the dative constituent (Target Case in this paper) is allegedly scrambled to the sentence initial position. The expression in the bracket of (36a) shows that the sentence initially scrambled *Mary-ege* ‘Mary-TK’ can be paraphrased with *Mary-ro malhamyeon* ‘speaking of Mary’ i.e. the topic-introducing expression in the sense of Lambrecht (1984). The same can be said to (36b). The sentence initially scrambled constituent *seonmul-eul* ‘a gift-AK’ can be paraphrased with *seonmul-ro malhamyeon* ‘speaking of a gift’. Nearly the same can be said to (36c). In (36c), the object is allegedly scrambled before the dative. It is also paraphrased with *seonmul-ro malhamyeon* ‘speaking of a gift’. Someone might well say that the paraphrase relation cannot prove anything. However, it is undeniable that it provides some clue to the real nature of the scrambling. It is significant to the discourse-syntactic status of the allegedly scrambled constituent that every scrambled constituent could be paraphrased with topic-introducing expression. Now we can state the paraphrase relation as follows:

˘ (37) Paraphrase Relation with Topic-Introducing Expression

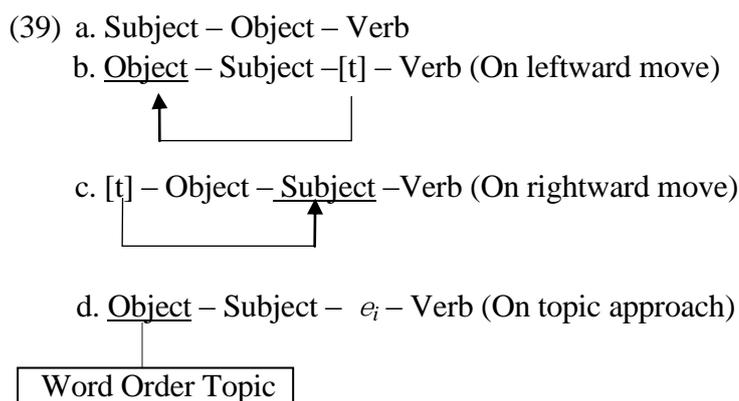

That the allegedly scrambled constituent in a sentence can be paraphrased with topic-introducing expressions says that the scrambled constituent has the status of syntactic topic.

According to (37), in (36a) the putative scrambled TKP given first is a word order topic, and the rest of (36a) can be qualified as a comment. In (36b) the putative scrambled AKP in the sentence initial position also is a word order topic, and in (36c) the AKP put in front of TKP also is a word order topic with respect to the rest of the sentence. This can be summarized as follows:

(38) Evidence 1 for Word Order Topic

As usual, the putative scrambled constituent shows the paraphrase relation with topic-introducing expressions. This means that the alleged scrambled constituent in a sentence gets the status of syntactic topic.

Second, this paper's approach just sketched as in (35), which sees the putative scrambled constituent as a word order topic (henceforth, 'topic approach') can perfectly catch the non-directionality of topic structure. At movement approach, scrambling is always leftward move as in (39b). The movement is always leftward in the generative approach. However there is no theory-external reason to see the scrambling as the leftward move. Even the rightward move could describe the whole picture of scrambling, positing some arbitrary feature on the right side. The movement can be shown symbolically as in (39b, c) below.

(39a) shows canonical basic word order for transitive structure in Korean. (39b) schematically shows the leftward move as assumed in the movement approach. However the same structure as (39b) can be resulted from the rightward movement, which is shown in (39c). The surface effect is not distinct from each other in both movements except the trace position. However, in the topic approach as shown in (39d), this kind of directionality conflict of movement does not arise. In (39d), the object in sentence initial position is nothing but a word order topic in our term. Is it moved from the canonical object position? Such question does not arise in (39d). Only the given surface structure is the object of syntactic analysis. Thus it can be said that the word order topic approach is superior to the movement approaches in coping with the arbitrary directionality problems. Let's present this as follows:

(40) Evidence 2 for Word Order Topic

Since the topic approach to scrambling has no directionality problem, it is superior to the movement approaches.

Third, the word order topic is on a par with the particle topic like *eun/neun* topic, *i/ga* topic and *eul/reul* topic, in Korean, in not occurring in the discourse initial sentence as in (41a).

- (41) a. \*Yesnal yesnal goryeojjeog-e *gonju-reul<sub>i</sub>* han imgeumnim-i  $e_i$  sarangha-  
 once upon a time-LK princess-AK one king-NK love-  
 yeoss-seupni-da.

PST-RPF-DF

‘\*Once upon a time, a princess, a king loved.’

- b. Yesnal yesnal goryeojjeog-e han imgeumnim-i gonju-reul sarangha-  
once upon a time-LK one king-NK princess-AK love-  
yeoss-seupni-da.

PST-RPF-DF

‘Once upon a time, a king loved a princess.’

- c. \*Yesnal yesnal goryeojjeog-e han imgeumnim-i gonju-*neun* sarangha-  
once upon a time-LK one king-NK princess-H love-  
yeoss-seupni-da.

PST-RPF-DF

‘\*Once upon a time, a king loved her, speaking of a princess.’

(41b) is a typical example of the discourse initial sentence, the function of which could be said in large to introduce brand-new entities into a discourse. It is agreed that the brand new entity does not occur as a marked topic, and it is obvious that (41a) is not felicitous. This means that the putative scrambled constituent performs a function of word order topic. (41c) is also infelicitous, with the *eun/neun* topic relative to the object. In this respect, the word order topic is on a par with *eun/neun* topic in the basic aspect of the topic.<sup>13</sup> Thus we can say that:

(42) Evidence 3 for Word Order Topic

The fact that the putative scrambled constituent does not occur in discourse initial sentences, on a par with particle topic, supports the word order topic.

Fourth, the putative scrambled constituent can hardly be used in on-the-spot description of an event as in (43).

- (43) a. ??As! *Kkoch-eul<sub>i</sub>* Mary-ga *e<sub>i</sub>* tta-ass-da

ala flower-AK NK pick-PST-DF

‘Look! Flower, Mary picked.’

- b. \*Eomeona! *Eolgul-eul<sub>i</sub>* Mary-ga *e<sub>i</sub>* ssis-eoss-da.

oh face-AK NK wash-PST-DF

‘[literally] \*Oh dear! Speaking of the face, Mary washed.’

(43a) and (43b) are not felicitous. That is due to the conflict between the exclamation and the putative scrambling. Exclamation is suitable to represent the on-the-spot description of an event,<sup>14</sup> whereas the putative scrambled constituent represents the marked topic that presupposes some previous situation. Thus we can say that:

<sup>13</sup> Here the basic aspect of the topic refers to the presentational aspect of topic. Cf. Im (2007).

<sup>14</sup> The ‘on-the-spot description of an event’ might be similar to the *thematic judgement* introduced in Kuroda (1972). But the former is more immediate response to the event than the latter.

(44) Evidence 4 for Word Order Topic

The fact that the putative scrambled constituent does not occur in the on-the-spot description of an event supports the word order topic.

Fifth, by the same token, the putative scrambled constituent can hardly be used in a new announcement of an event or a fact, and in a first declaration of laws or regulations and the like.

- (45) a. ??*ilban sangdaeseong wollli-reul*<sub>i</sub> Ainshutain-i 1916 nyeon-e *e*<sub>i</sub> balpyoha-  
the general relativity principle-AK Einstein-NK year-LK present-  
-yeoss-da (as a first announcement of the fact)  
-PST-DF

‘The Principle of the General Relativity, Einstein presented in 1916.

- b. ??*gingeupjochi 9ho-reul*<sub>i</sub>, neo-neun *e*<sub>i</sub> eogyeoss-eumeuro, chepoha-  
Emergency Measure 9-AK you H violate because arrest-  
n-da  
PRS-DF

‘[literally]\*Emergency Measure 9, because you violate, you are under arrest.’

Both (45a) and (45b) are not felicitous as a first announcement of an event. This is due to the indefiniteness of the putatively scrambled object in (45a, b). The firstly announced entity should be in its own syntactic position. Only in that case, the intended meaning involved in the newly introduced entities can be communicated. Otherwise, the purport of the intention of the speaker might be distorted. Thus we can say that:

(46) Evidence 5 for Word Order Topic

The fact that the putative scrambled constituent does not occur in a first announcement of an event supports the word order topic.

Sixth, the putative scrambled constituent can hardly be used in a sentence involved in describing an entity that has a consciousness problem, especially in introducing contexts. Consider the following:

- (47) a. *Jamja-neu-n ai-ga mom-eul duicheogi-n-da*  
sleep-PRS-AF child-NK body-AK twist and turn-PRS-DF

‘The sleeping child twists and turns its body.’

- b. \**Mom-eul Jamja-neu-n ai-ga e<sub>i</sub> duicheogi-n-da*. (in introducing contexts)  
body-AK sleep-PRS-AF child-NK twist and turn-PRS-DF

‘The sleeping child twists and turns its body.’

- (48) a. *Bihaenggi-ga bakui-reul naery-eoss-da*.  
airplane-NK wheel-AK lower-PST-DF

- ‘The airplane lowered the wheel.’  
 b. \**Bakui-reul<sub>i</sub> bihaenggi-ga e<sub>i</sub> naery-eoss-da.* (in introducing contexts)  
 wheel-AK airplane-NK lower-PST-DF  
 ‘The wheel, the airplane lowered.’

The example (47a) without the putative scrambling has nothing infelicitous. However, (47b) shows infelicity. This is due to the consciousness constraint working in the discourse initial sentence, which prohibits scrambling of the constituent like the entity *jamjaneun ai* ‘the sleeping child’ that cannot be seen to have consciousness. The same can be said to (48b), since it is agreed that an airplane has no consciousness. What is the reason of this fact? As to the unconscious entity, its action or motion is not related with the consciousness, so the body parts or the related things involved in action is not salient independently. That body parts or the related things involved in action is given the special attention of the speaker means that the entity does have a consciousness, especially in introducing contexts. But if they are definite, the consciousness constraint disappears, because the body parts or the related things involved action is afore-mentioned, i.e. having the experience to be the target of a consciousness once. This means that the alleged scrambled constituent shares the topichood with other particle topics. Now we can say that:

(49) Evidence 6 for Word Order Topic

The fact that the putative scrambled constituent has Consciousness Constraint supports the word order topic.

Seventh, as explicated in (35) and hinted with respect to (16), the shared constituent not only supports the postulation of adjunction structure, but lends the support for the word order topic syntactically. The shared constituent should be posited at VP or PFP (Prefinal Ending Phrase, usually IP) adjunction position, so that the resulting structure is equivalent to topic-comment structure. Let’s present this as follows:

(50) Evidence 7 for Word Order Topic

The shared constituent lends the support for the word order topic syntactically.

Though the proof of the topichood of the putative scrambled constituent is sufficient, the word order topic is a very weak topic, in contradistinction with the particle topics, etc., because it does not have a strong marking for topic except the mere trait appearing in the order of constituents.

## 6. Conclusion

As is well known, various hypotheses has been put forth concerning the motivation of the so-called scrambling. However, it is evident that Case theory, EPP feature, and

Focus Feature, etc. does not support the movement of the putative scrambled constituent. The radical LF-reconstruction or the LF-lowering raises serious questions about the movement at S-structure or at LF, due to the infelicitous results that the operations bring about.

Thus it is reasonable to claim that the word order of the surface structure should be seen as given, and the semantic interpretation should be done to the given structure. To do this, it is necessary to analyze the syntactic structure as given. Or it will lose the subtle differences between the original structure and the alleged scrambled structure.

For this purpose, this paper takes much of the syntactic analysis in terms of the Lexicalist Case Hypothesis (LCH) that says that as far as syntactic case is concerned, the case should be defined on the basis of lexical information given in the lexicon, and the Hypothesis of Variable Medial Projection (HVMP) that says that the number of medial projections should be matched with the number of arguments of a predicate. On this syntactic analysis, the putative scrambled constituent should be analyzed as syntactic remnant, not given any syntactic function to. The Ubiquitous Topic Hypothesis (=UTH) applied, the syntactic remnant could be given a syntactic topic function. The putative scrambled constituent can be called 'word order topic'.

The facts that the word order topic cannot be used in a discourse-introducing sentence, nor in on-the-spot descriptions of events, nor in a sentence announcing a brand-new news, etc. suggest that the scrambled constituents have the definiteness effects, one of the important and remarkable features of the marked topics in Korean.

# The effects of vowel quality on stress placement of English nonsense words

Hyo-young Kim

Kookmin University  
861-1 Jeongneong, Seongbuk, Seoul, Korea

[Hyk8392@yahoo.co.kr](mailto:Hyk8392@yahoo.co.kr)

## Abstract

This paper examines the effect of vowel quality, especially [a], on stress placement for English nonsense words. To that end, an experiment with 7 nonsense English words with the vowel [a] was conducted with 102 Korean college students. The result shows that stress is given on the second syllable when the words have [a] on the second syllable while stress is assigned on the first syllable if [a] is on the first syllable. Consequently, we can conclude that [a] affects the decision of stress placement by Korean learners of English when they encounter unknown words.

**Keywords:** English stress, vowel quality, Korean learners, nonsense words

## 1. Introduction: two previous experiments

This paper examines the effect of vowel quality, especially [a], on stress placement for English nonsense words. For that purpose, a small scaled experiment was conducted. Before introducing the experiment, it is necessary to introduce two other experiments, which were carried out previously (Kim 2002; Kim2006).

Traditionally stress is thought not to be stored in the lexicon but derived by stress rules which are internalized in native speakers' mind. According to the rules *Canada* has regular stress while *banana* has irregular stress since stress is assigned to the penultimate syllable when it is heavy as in *agenda* and *tomato*. Otherwise, antepenultimate syllables get stress as in *Canada* and *America*.

But it has been thrown into doubt that native speakers would really feel *banana* irregular. In other words, would native speakers assign stress on the first syllable when they are given new, strange words with the same syllable configuration as *Canada* and *banana*?

To find out the answer to the question, an experiment was conducted with native speakers, who were 16 college students, U of Michigan, Ann Arbor (Kim 2002). They were given nonsense words like *conamo*, *timona* and *spumad* and asked to mark the syllable they would prefer to stress. The result was surprising. Almost 60% of the college students put stress on the second syllable. That is, they prefer *banana* to *Canada*, which is not accordance with the stress rules believed to be internalized in native speakers' minds.

(1) Stress of nonsense nouns by native speakers

Test Words	Americans(Kim 2002)	
	Sss	sSs
Conamo	6	7
Timona	7	9
Spumado	4	11
Borica	4	9
Pecido	3	11
Stugany	9	5
Gelico	5	8
Limana	3	11
Tenarow	5	9
Cadoma	2	12
Pimedo	5	10
Padory	5	9
Whiloda	4	7
합계(%)	31.5	59.9

There was only one word which does not follow the stress pattern of *banana*. That is *Stugany*. It was *STUgany* not *stuGAny*. Stressed syllables are marked with capital letters. To find out why *stugany* behaves differently from other words, Collins Cobuild dictionary is consulted. It was found that there are 30 words beginning with *stu*. Interestingly, all of them have stress on the first syllable, *STU-*. Thus, we can ascribe the first syllable stress on *Stugany* to analogy to existing words.

After the experiment with native speakers of English, a question arises: how Koreans learning English as a foreign language would stress the same nonsense words. The reason to come to the question is that Koreans are not native speakers and thus they do not have the internalized stress rule in their minds and also their native language,

Korean, does not have stress at all. If they have Korean stress rules, it is possible they could apply the Korean rules when they encounter new words which they do not know the stress of.

So, another experiment was designed with 23 Korean college students (Kim2006). The result is given here.

(2) Stress of nonsense English nouns by Koreans

Test Words	Koreans(Kim2006)	
	S s s	s S s
Conamo	3	17
Timona	10	10
Spumado	7	10
Borica	5	10
Pecido	9	10
Stugany	12	4
Gelico	13	7
Limana	4	13
Tenarow	1	16
Cadoma	12	8
Pimedo	5	14
Padory	12	5
Whiloda	4	15
합계(%)	27.3	86.9

Koreans' response was very similar to that of native speakers as can be seen above. 86% percent of the students chose stress pattern of *banana*. And again *Stugany* has stress on the first syllable as was with native speakers. There are three more words with stress on the first syllable: *gelico*, *cadoma* and *padory*. Putting aside *gelico*, *cadoma* and *padory* seem to have something in common. Both of the words have the vowel [a] in the first syllable. Thus, it was temporarily concluded that Koreans have tendency to stress the syllable with [a] when there is [a] in the words. There are 6 words with [a] in them: *Cadoma*, *Padory*, *Conamo*, *Spumado*, *Limana*, *Tenarow*. All of them have stress on the [a] syllable.

## 2. Current Experiment

Eventually we arrive at the purpose of the current research: it is to test the hypothesis that it is the vowel [a] which attracts stress. More concisely, the current study is to see if the vowel [a] has influence on the Korean learner's decision of stress location of unknown English words.

For the experiment 6 nonsense words were used. All of them were words used in the previous experiments. Only the vowels were switched around. For example, previous *Conamo* and *Padory* were changed into *Canomo* and *Podary*. The test words are *Podary*, *Codama*, *Canomo*, *Tanerow*, *Spamudo*, *Staguny*, and *Lamina*. Subjects were 102 college students taking Introduction to Phonetics or Introduction to Linguistics. They were asked to choose stress pattern they would use for given nonsense words. Responses from students who have been taught about English stress rules are not included. The result is given (3) and (4).

### (3) Words with [a] in the second syllable

	Sss	sSs	total
Codama	14	88 (86%)	102
Podary	50	52 (51%)	102
Total	64	140 (69%)	204

### (4) Words with [a] in the second syllable

	Sss	sSs	Total
Tanerow	61 (60%)	41	102
Canomo	70 (69%)	32	102
Spamudo	82 (80%)	20	102
Staguny	80 (78%)	22	102
Lamina	35 (34%)	67	102
Total	328 (64.5%)	182	510

The result clearly shows that when the words have [a] on the second syllable, stress is given on the second syllable. If [a] is on the first syllable, stress is assigned on the first syllable. Consequently, we can conclude that [a] affects the decision of stress placement by Korean learners of English when they encounter unknown words.

### 3. Discussion

To find out why it should be [a], let's consider the phonetic features of [a]. [a] is the lowest vowel in English with the great jaw opening. The low vowel is the most sonorous (Ladefoged 2001). And according to researchers sonorous sounds are perceived as prominent and prominent sounds attract stress (Hayes 1995). In addition, according to Rice (1996), low vowels are longest monophthongs phonetically and are not only longer than the other short vowel but also even longer than long vowels. These long vowels have been reported to be fully stressed than high vowels and in some languages, which do not have long vowels, syllables with a low vowel take priority of attracting stress counting as heavy (Greenberg and Hichcock 2001; Ahn 2003).

Let us consider English words with penultimate stress. When the penultimate syllables contain the vowel [a] there is only one consonant between the vowels as in (5) but when the penultimate vowel is not [a] there is geminate as in (6).

(5) Alabama, banana, cadaver, Gestapo, errata

(6) Achilles, antenna, dilemma, committee, gorilla, spaghetti

The next question to ask is why non native speakers are influenced by phonetic features of vowels. It may be that they do not have internalized stress rules for native language and that they do not master the stress rules of the target language, either, yet. However, they know there must be one stress per word in English.

### 4. Conclusion

Further, following questions could be pursued. First, a similar experiment with words with [a] in both the first and the second syllables would be carried out. Secondly, it would be investigated whether there is a hierarchy in degree to attract stress among vowels other than [a]. If so, further research could examine whether the vowel hierarchy accords with the sonority hierarchy. Finally, it may be checked whether more proficient learners are freer from the effect of phonetic features of vowels.

Finally, it would be good to point out the limitations of this research. This paper has not provided an explanation for words without [a] but stressed on the first syllable like *GElico* and words with [a] on the first syllable but stressed on the second syllable like *LaMIa*. To make stronger the claim that [a] attracts stress, statistical analysis

seems to be needed.

# On the Nature of the Dative Case in Korean Dative Experiencer Constructions

Ilkyu Kim

Hankuk University of Foreign Studies  
Imun-dong, Seoul, Hankuk University of Foreign Studies  
onefinedayjazz@hufs.ac.kr

## Abstract

Most previous studies on Korean psych-predicates have treated the dative case in Dative Experiencer Constructions (DECs) as inherent case, which means that it is not assigned systematically by the syntactic or semantic structures of the predicate but determined by a certain thematic role, which is experiencer in this case. Contrary to these studies, the goal of this paper is to show that the dative in DECs is not inherent or quirky case but semantic structural case. That is, I argue, under the framework of Conceptual Semantics, that the dative case is predictable from the lexical conceptual structure of the psych-adjectives that constitute DECs.

**Keywords:** dative, dative experiencer construction, psych-predicates, Conceptual Semantics, Case-mapping in Tiers

## 1. Introduction

Most previous studies on Korean psych-predicates have treated the dative case in Dative Experiencer Constructions (DECs) as inherent case, which means that it is not assigned systematically by the syntactic or semantic structures of the predicate but determined by a certain thematic role, which is experiencer in this case.<sup>1</sup> Contrary to these studies, the goal of this paper is to show that the dative in DECs is not inherent or quirky<sup>2</sup> case but

---

<sup>1</sup> The notion of inherent case is usually contrasted by the notion of (syntactic) structural case as in Chomskyan tradition:

Inherent Case (Chomsky 1981: 171)

Structural Case in general is dissociated from theta-role; it is a structural property of a formal configuration. Inherent Case is presumably closely linked to theta-role.

<sup>2</sup> By the term ‘quirky’, I mean “there is no regularity to be captured: the case assignment is truly exceptional to the system and no syntactic or semantic regularities can be detected” (Butt

semantic structural case. That is, I argue that the dative case is predictable from the lexical conceptual structure of the psych-adjectives that constitute DECs.

In doing so, first, I will briefly introduce Korean DECs and the problems of the previous studies which see dative as inherently given by experiencer in section 2. In sections 3 and 4, I will look into Korean DECs in more detail regarding their case marking patterns and some other related characteristics, which would be the basis for understanding the nature of the dative case more thoroughly. Especially in section 4, I will show that a corpus study done using the World Wide Web empirically supports the most important characteristic that I suggested in section 3, which is polysemous nature of psych-adjectives in DECs. After that, in section 5, I propose the semantic structures of the psych-adjectives of DECs, which are the key to the understanding of the nature of the dative case and the characteristics of the construction discussed in section 3 and 4. The framework used for the formalizing the semantic structures of the psych-predicates is Jackendoff's (1983, 1990, 2002, 2007) Conceptual Semantics. Then, in section 6, based on the semantic structures (conceptual structures) of the psych-predicates, I will show how the dative case is predicted by the semantic structures of the psych-adjectives, using the semantic case-mapping in tiers, a linking theory, first proposed by J S Jun (2003), which is based on Conceptual Semantics. Lastly, section 7 concludes the paper.

## 2. Previous Studies on the Nature of Dative in DECs

Like many South Asian and Indo-European languages, Korean is known to have dative experiencer constructions. Two example sentences are shown in (1). Here, notice that the word order is not strict. The experiencer argument can either precede the stimulus argument or follow the stimulus as shown in (1a) and (1b).

- (1) a. na-eykey Yumi-ka mwusepta/cilwuhata.  
I-DAT Yumi-NOM scary/boring  
'Yumi is scary/boring to me.'
- b. i yenghwa-ka na-eykey mwusepta/cilwuhata.  
this movie-NOM I-DAT scary/boring  
'This movie is boring to me.'

As many researchers have argued with other languages, majority of Korean

linguists from various theoretical backgrounds (e.g. Y-J Kim 1990, Gerdtts & Youn 2001, S-G Lee 2007, S Nam 2007), except for some Role and Reference Grammarians (e.g. B-s Yang 1994, K-s Park 1995, J-H Han 1999), have argued without any empirical evidence that the dative case in DEC's is inherently or lexically assigned to experiencer which is the thematic role required by the psych-predicate.<sup>3</sup>

However, two kinds of empirical facts show that the dative in DEC's is not inherent for two reasons. First, dative does not guarantee the thematic role of the argument to which it is assigned. For example, as J S Jun (2003a, b) has argued, Korean dative can be assigned to arguments with various kinds of thematic roles such as recipient, destination, point in time, age, proportion, reference, source, cause, and agent in passive.<sup>4</sup>

The second reason is that the thematic role, i.e., experiencer, does not necessarily take dative case. Some two place psych-predicates like *cohta* 'like' and *silhta* 'hate' do not go along with dative experiencer (2a). And more importantly, all the one-place psych-adjectives cannot take dative for their experiencer arguments (2b,c).

- (2) a. ??na-eykey ttalki-ka cohta/silhta<sup>5</sup>.  
 I-DAT strawberry-NOM like/dislike  
 'I like/dislike strawberries.'
- b. \*na-eykey oylopta/collita/holkapwunhata ...  
 I-DAT lonely/sleepy/light-hearted  
 'I am lonely/sleepy/light-hearted.'
- c. ne cikum kipwun-i etteni?  
 you now feeling-NOM how  
 'How do you feel now?'
- na-(\*eykey/nun/??ka<sup>6</sup>) sulphe/mwusewe/kippe  
 I-DAT/TOP/NOM sad/scared/pleased

<sup>3</sup> This is mainly because only nominative and accusative cases are thought of as (syntactic) structural cases in many theoretical frameworks.

<sup>4</sup> See J S Jun (2003b) for the example sentences in which dative-marked NPs are used for various kinds of thematic roles.

<sup>5</sup> In fact, DEC's with the psych-adjective *silhta* 'hate' is treated as grammatical in Nam (2007) and S-J Ko (2004). However, I follow H-K Yoo (1998) and Y-J Kim (1990) who treats them as ungrammatical. Moreover, most native Korean speakers that I consulted with said the sentences were ungrammatical.

<sup>6</sup> The reason why the nominative case *-ka* on the experiencer argument makes the sentence sound strange seems the matter of pragmatics not of syntax or semantics. That is, the pragmatic information that the nominative carries causes conflicts with the question. Explaining the exact mechanism regarding this phenomenon is beyond the scope of this paper.

‘I am sad/scared/pleased.’

Since all these facts strongly show that the dative case is not inherent case assigned to experiencer arguments, now we should determine its status between quirky and (either syntactically or semantically) structural. And we should first look into the possibility of its being structural case because if it turns out that the dative case is not structurally determined, we can automatically conclude that it is truly quirky, which means that in this case the dative in DEC's shows “random lawlessness” (Butt 2006: 125).

### 3. Characteristics of Korean DEC's

Now, I will introduce some important characteristics of Korean DEC's, many of which have been left unexplained by most previous studies. These characteristics must be captured and explained by a proper case theory, because, first, many of the characteristics are about case patterns of DEC's and secondly, as I will show below, all of the characteristics are closely related to the nature of the dative case.

The first characteristic is that if it is a DEC it must have a stimulus argument. That is, one-place psych-adjectives, which take only experiencer arguments but not stimulus arguments (cf. (2b)), can never be used as DEC's.

(3) nay-ka    oylopta/collita/simsimhata...  
I-NOM    lonely/sleepy/bored  
‘I am lonely/sleepy/bored.’

On the other hand, if the experiencer argument is assigned nominative, the sentences become grammatical as shown in (3).

Second, the stimulus arguments in DEC's must be marked nominative.<sup>7</sup> This means that some psych-predicates that take non-nominative cases for their stimulus arguments cannot constitute DEC's. For example, as shown in (4), the predicate

---

<sup>7</sup> In fact, the stimulus argument also can take the topic marker -(n)un. Korean psych predicate constructions are most natural when either the experiencer or the stimulus argument takes the topic marker. This is related to the semantic nature of the psych predicates. That is, predicates that we are concerned with in here “all involve stative predicates which ‘sound’ most natural when they contain a topic nominal rather than a nominal with basic nominative ... or dative” (Shibatani 2001: 309). However, I exclude the topic marker from the discussion, because its existence or not has little to do with distinguishing DEC's from any other psych-predicate constructions.

*sepsephata* ‘disappointed’ takes dative for its stimulus arguments and it can never take dative experiencer.

- (4) na-\*eykey ne-eykey sepsephata.  
I-DAT you-DAT disappointed  
‘I am disappointed at you.’

Third, unlike non-DECs, DECs allow their experiencer arguments to take nominative case instead of dative. That is, dative-nominative alternation of experiencer is always possible in DECs (5).

- (5) na-eykey/ka Yumi-ka mwusepta/cilwuhata.  
I-DAT/NOM Yumi-NOM scary/boring  
‘Yumi is scary/boring to me.’

In fact, this nominative-dative alternation of experiencer has been one of the core issues dealt with by many previous studies on Korean psych-predicates, but most of them, particularly Chosmkyan syntacticians who have tried to account for the phenomenon purely syntactically, could not explain when and why the case alternation should occur if it occurs.<sup>8</sup> However, within the Conceptual Semantics approach taken here, the ‘when’ and ‘why’ questions are answered naturally, as will be shown below.

The last characteristic of Korean DECs, which is the key to the understanding of the characteristics introduced so far as well as the nature of dative case, is that the psych-adjectives that constitute DECs are polysemous between the meaning of an objective property of an entity and one’s psychological state.

Although the polysemous nature of some (but not all) psych-adjectives in Korean have been mentioned and analyzed by some researchers (in particular by semanticists rather than syntacticians), there are few who have noticed this characteristic has something to do with the case phenomena. That is, the fact that only DECs, among many kinds of psych-predicate constructions, can have polysemous psych-predicates have been captured by few studies.<sup>9</sup>

Let us look at some evidence for the polysemous nature of some psych-predicates.

---

<sup>8</sup> For more on the problems of the previous studies on the dative-nominative alternation of Korean psych-adjective constructions, see I Kim (2008).

<sup>9</sup> One exceptional case is S Nam (2007) who tries to explain the dative-nominative alternation of experiencer with respect to the polysemy of the psych-adjectives, which is done under the framework of the Generative Lexicon Theory.

The first evidence comes from the fact that some psych-adjectives can take either animate or inanimate nominative-marked arguments as their subject. This is strange if the adjective has only one meaning of referring to one's psychological state, because inanimate entities cannot have any psychological state. For example, we can see by (6) that what is known as a psych-adjective *kipputa* 'pleased' is acceptable only when it takes an animate nominative-marked argument.

- (6) a. *nay-ka/nun* (*kipputa/mwusepta*).  
 I-NOM/TOP pleased/scared  
 'I am pleased.'
- b. *ku inhyeng-i/un* (#*kipputa/mwusepta*).  
 the doll-NOM/TOP pleased/scary  
 'The doll is pleased.'

On the other hand, another psych-adjective *mwusepta* 'scared, scary' can be used with both an animate and an inanimate nominative/topic-marked NP. This indicates that *mwusepta* 'scared, scary' is somewhat different from *kipputa* 'pleased' and the difference is that *mwusepta* 'scared, scary', unlike *kipputa* 'pleased', can refer not only to one's psychological state but also to an objective property of an entity. We can see this by the fact that the natural interpretation of (6b) with the predicate *mwusepta* is only 'The doll is scary' but not 'The doll is scared'.

The second evidence comes from the possibility of psych-adjectives' being able to modify the following NP. To be more specific, what is important is the fact that some psych-adjectives can be used to modify an inanimate NP and represent the property but not the psychological state of the modified NP. For example, (7a) is clearly different from (7b) in that the adjective *cilwuhata* 'boring/bored' can both represent the properties of the inanimate NPs and the psychological states of the animate NPs that they modify, while *kipputa* 'pleased/happy' can only modify the psychological states of the animate NPs.

- (7) a. *cilwuhan* *pulloku/kkwum/yenghwa/Jane/Tom/tongsayng* ...  
 boring *blog/dream/movie/Jane/Tom/brother* ...  
 'boring *blog/dream/movie*'
- b. *kippun* #*pulloku/#kkwum/#yenghwa/Jane/Tom/ tongsayng*...  
 happy *blog/dream/movie/Jane/Tom/brother* ...  
 'happy #*blog/#dream/#movie/Jane/Tom/brother* '

Some might argue that *kipputa* ‘pleased’ can be thought of also as a polysemous adjective in the sense that it can modify the inanimate NPs like *nal* ‘day’ and *sosik* ‘news’ as in *kippun nal* ‘happy day’ and *kippun sosik* ‘happy news’. However, it is different from other typical polysemous adjectives since it does not pass the first criterion. That is, although *kipputa* can modify the NPs *nal* ‘day’ and *sosik* ‘news’ it cannot be used as a predicate with the same NPs as in (8).

- (8) *ku nal/sosik-i kipputa.*  
 the day/news-NOM happy  
 #‘The day/news is happy.’  
 ‘(I am) happy with the day/news.’

As shown in (8), the sentence is unacceptable with the adjective’s referring to the property of *ku nal* ‘the day’ or *ku sosik* ‘the news’. But it is much more natural if the experiencer argument *na* ‘I’ is thought to be ellipsed and the predicate refers to the psychological state of the experiencer. This shows that *kipputa* ‘pleased’ refers to the psychological state of the abbreviated experiencer rather than the objective property of the modified NPs like *nal* ‘day’ and *sosik* ‘news’.

One thing to note is that still to some people *kippun* in *kippun sosik* ‘happy news’ or *kippun nal* ‘happy day’ nevertheless can be thought of as referring to the property of *sosik* ‘news’ or *nal* ‘day’ intuitively. And I attribute this characteristic, as H-K Yoo (1998) also noticed, to the semantic change the adjective is going through. That is, *kipputa* ‘pleased’ originally meant only one’s psychological state but its meaning is becoming ambiguous between ‘pleased’ and ‘pleasing’ at least when it modifies the NP *sosik* ‘news’ or *nal* ‘day’ as time goes by. In fact, this kind of semantic change, whether from psychological state to property or from property to psychological state, is often found cross-linguistically. For example, the English word *sad* is not only used as referring to one’s psychological state but also as referring to the property of an entity in sentences like *This book is sad*.

Lastly, we can see that some psych-predicates are polysemous by looking at how some English words that refer to an objective property or psychological state are translated into Korean. For example, Korean does not have two different words for *bored* and *boring*, but one adjective *cilwuhata* represents both meanings. Many other English word pairs such as *interesting/interested*, *scary/scared* show the same pattern. This strongly shows that some Korean psych-adjectives are polysemous between the

two meanings.

Since it is clear that some psych-adjectives are polysemous between the meaning of an objective property of an entity and one's psychological state, in what follows, I will show that only the meaning of the predicate that allows a DEC is polysemous between the two meanings, while the psych-predicate that does not allow dative experiencer is monosemous with the meaning of one's psychological state.

#### 4. A Corpus Study

Regarding the last characteristic of the DEC, there must be some evidence that shows that only polysemous psych-adjectives are used for making DECs. And according to a small corpus study conducted using the World Wide Web, it is really the case.<sup>10</sup>

I randomly picked out 21 psych-adjectives and they were divided into two groups, i.e., polysemous vs. monosemous predicates, according to the criteria introduced in section 3. And I got 13 monosemous and 8 polysemous psych-adjectives as shown in (9).

(9) a. 13 Monosemous (pure) Psych-Adjectives:

*silhta* 'dislike', *kipputa* 'pleased/happy', *tamtamhata* 'light-hearted',  
*soksanghata* 'distressed/annoyed', *sepsephata* 'sorry/feel regretful',  
*twulyepta* 'afraid', *anthakkapta* 'sorry/pitiful', *holkapwunhata*  
'unencumbered', *pwukkulepta* 'shy/coy'. *changphihata* 'humiliated',  
*koylopta* 'painful/feel painful', *hayngpokhata* 'happy', *kwunkumhata*  
'wonder'

b. 8 Polysemous Psych-Adjectives:

*cilwuhata* 'bored/boring', *mwusepta* 'horrible/horrified', *caymissta*  
'fun/feel fun', *selphuta* 'sad/feel sad', *cikyepa* 'tiresome/tedious',  
*akkapta* 'precious/regrettable', *elyepta* 'difficult/feel difficult', *himtult*  
'painful/feel painful'

---

<sup>10</sup> The reason why I used the World Wide Web as the corpus is that DECs and nominative experiencer constructions (NECs) without topic marker –(n)un on stimulus arguments is marginally acceptable and very uncommon. These two facts can be, as Barddal (2006) has already argued, a strong motivation for using the World Wide Web as a corpus.

"Recent research on corpora has shown that the World Wide Web can be regarded as a representative language corpus, despite the fact that it is both unbalanced and uncontrolled for. ... the Web is in fact the best corpus to use when searching for low-frequency marginally-acceptable data, and that the gigantic size of the Web compensates for the fact that it is both unbalanced and uncontrolled for." (Barddal 2006: 67)

I looked at the first 200 sentences for each predicates that I found through the web. Interestingly, I found at least one DEC in the second group but did not found any DEC in the first group except for *tamtamhata* ‘light-hearted’, *twulyepta* ‘afraid’, *changphihata* ‘humiliated’, *koylopta* ‘painful/feel painful’. And according to an additional corpus study done with the four exceptional predicates, it turned out that they also have some property-like characteristics.<sup>11</sup> For example, all the four predicates were found to be used in modifying inanimate NPs, which means they are, in at least some people’s mental lexicon, stored as polysemous rather than as monosemous. Therefore, the result strongly supports that only polysemous psych-adjectives allow DECs and dative case is assigned when the predicate is used with the meaning of property but not with the meaning of one’s psychological state.

In the following sections, I will show that it is the objective property meaning of the polysemous psych-adjectives that causes the experiencer argument to take the dative case. Moreover, I will show the two meanings of the polysemous psych-adjectives can not only explain the dative-marking of experiencer but also naturally explain the rest of the characteristics of DECs introduced in section 3.

## 5. Semantic Structures of Polysemous Psych-Adjectives

In formalizing the two different meanings of the polysemous psych-adjectives, I adopt the conceptual structures of psych-predicates proposed by Jackendoff (2007). According to him, adjectives that refers to an property of an entity such as *interesting*, *boring*, etc. are called evaluative predicates, and evaluative predicates can represent either subjective or objective evaluation depending on the existence of a specific evaluator in the sentence. Thus, his subjective evaluation roughly equals to the notion of one’s psychological state and his objective evaluation equals to the notion of an objective property of an entity.<sup>12</sup> Jackendoff provides conceptual structures of both objective and subjective evaluations as shown in (10).

---

<sup>11</sup> See the appendix for some of the example sentences in the corpus.

<sup>12</sup> Although the subjective evaluation and one’s psychological state is the same in terms of propositional meaning, their conceptual structures are different, which will be shown below.

(10) Objectification and Subjectification (Jackendoff 2007: 240)

Y BE [Property  $\lambda z$  [X BE [F<sup>13</sup> (z)]]]  $\Leftrightarrow$  default

(e.g. Y is interesting to X)

Y BE [Property  $\lambda z$  [YA BE [F (z)]]]

(e.g. Y is interesting)

(where Y is the entity being evaluated, X is the experiencer, and YA is the generic perceiver)

Here, Jackendoff (2007) proposes the mechanism that accounts for how evaluative predicates are sometimes used as subjective evaluation and sometimes as objective evaluation. If a specific evaluator is introduced by *to X* form then the construction becomes subjective evaluation whereas the construction is used as objective evaluation with no specific evaluator, which, according to Jackendoff, is a default construction.<sup>14</sup>

Although I basically agree with his understanding of objectification and subjectification, I disagree with Jackendoff's (2007) idea that the objective evaluation has the generic perceiver in its conceptual structure. (cf. Lasersohn 2005). Instead, I argue that the conceptual structure of objective evaluation should be the same as that of ordinary properties like *big*, *small*, *blue*, and *yellow*. And I propose a different conceptual structure for the objective evaluation like the following:

(11) Conceptual Structure of objective evaluation/property

Y BE [Property INTEREST]

(e.g. Y is interesting)

(But I should say that whichever is used, it doesn't affect my analysis regarding the nature of the dative case in DEC's.)

Another point on which I differ from him is the conceptual structures of subjective evaluation and one's pure psychological state. Jackendoff originally distinguishes evaluative adjectives (e.g. *interesting/boring/...*) from psych-adjectives (*interested/bored/...*) on the level of the thematic tier as in (12), but later he argues that the distinction on the level of the macrorole tier is enough as in (13).

---

<sup>13</sup> F refers to FEELING and INTEREST should take the place of F in this case.

<sup>14</sup> Jackendoff's positing objective evaluation as the default meaning of adjectives such as interesting and boring goes well along with my positing those predicates basically represent objective properties of an entity.

- (12) a. Frank is amazing to Sam.  
 FRANK BE [ $\lambda z$  [SAM BE [AMAZED (z)]]]  
 SAM EXP FRANK
- b. Sam is amazed at Frank.  
 SAM BE [AMAZED (FRANK)]  
 SAM EXP FRANK
- (13) a. Frank is amazing to Sam.  
 SAM BE [AMAZED (FRANK)]  
 SAM EXP FRANK
- b. Sam is amazed at Frank.  
 SAM BE [AMAZED (FRANK)]  
 SAM EXP FRANK

(Jackendoff 2007: 237)

First, in (12a), Jackendoff paraphrases the sentence as ‘Frank is such that Sam is amazed at’ and proposes FRANK BE [ $\lambda z$  [SAM BE [AMAZED (z)]]] as the thematic tier, in which the notation  $\lambda z$  can be read informally as ‘such that’ and the bound variable  $z$  that serves as argument of AMAZED can be read as the resumptive pronoun ‘him’.

Although this lambda abstraction very well captures the meaning of evaluation and the semantic difference between psychological state and evaluation, he does not give any detailed semantic analysis of one’s psychological states such as *interested*, *bored*, *scared*, etc. Instead, he just uses the state function BE and the words themselves (cf. (12b) and (13b)) for representing the conceptual structures of the words, which causes the circulation problem and thus cannot be the satisfying semantic (or conceptual) representation of the words.

Moreover, as shown in (13), he argues that (12a) and (13a) are “logically equivalent” and the prominence of stimulus in (12a) can be captured on the level of the macrorole tier by underlining a more prominent argument. This means that “EXP, unlike AFF, does not inherently determine which macrorole is linked to subject position. Rather, each EXP verb must individually mark its subject” (Jackendoff 2007: 235). In other words, when it comes to evaluative or psychological adjectives, children have to learn predicate by predicate which argument is more prominent and thus realized as a syntactic subject.

The psychological predicates expressing EXP, on this view, are genuine

counterexamples to the linking universals, and children do have to learn them one by one. Fortunately, they are learnable, given that children actually hear the relevant sentences that show them the right order of arguments. So in terms of learning, the position proposed here isn't too problematic. (Jackendoff 2007: 213)

I do not agree with his idea that attributes the syntactic difference to idiosyncratic nature of predicates, and propose a systematic account for the syntactic difference caused by different LCSs in section 6.

Now, I propose three conceptual structures: first, the conceptual structure of objective evaluation. Second, the conceptual structure of subjective evaluation, and last, the conceptual structure of one's pure psychological state.

(14) Conceptual Structure of Objective Evaluation

(e.g. X is boring.)

thematic tier: X BE [<sub>Property</sub> BOREDOM]

macrorole tier: EXP X

(15) Conceptual Structure of Subjective Evaluation

(e.g. X is boring to Y.)

thematic tier: X BE [<sub>Property</sub> λz [Y FEEL [BOREDOM (z)]]]

macrorole tier: Y EXP X

(16) Conceptual Structure of Psychological State

(e.g. X is bored (with Y).)

thematic tier: X FEEL [<sub>Property</sub> BOREDOM <(Y)>]

macrorole tier: X EXP (Y)

Here, I will not go into any detail about the macrorole tier. It will suffice to say that the postulation of macrorole tier is very useful in capturing semantic difference between some predicates and the function EXP here takes experiencer argument at its left and stimulus argument at its right. For example, the arguments marked with red color show that Y is the experiencer in the sentence *X is boring to Y*, but X is the experiencer in the sentence *X is bored with Y*. And as mentioned above, objective evaluation is given by default and the sentence is interpreted as subjective evaluation only when an adjunct, which is a PP in English, is added to the sentence.

## 6. Semantic Case-Mapping in Tiers

Given these conceptual structures, now I can account for the dative and nominative cases each of which is assigned to the experiencer and the stimulus. In doing so, I use the linking theory called semantic case-mapping in tiers, first proposed by J S Jun (2003a).

The linking theory consists of a thematic hierarchy and some linking principles. First, the thematic hierarchy is the same as what Jackendoff (1990) proposed, but it needs to be modified a little because the action tier has been changed into macrorole tier by adding a new function EXP after the thematic hierarchy was first introduced. Since the function EXP, unlike the function AFF, does not show which of its argument is more prominent, that is, since we cannot determine which argument is more prominent between experiencer and stimulus, it is reasonable to ignore the EXP function when we consider a thematic hierarchy. That is why I added a condition that says “only when the function is AFF”.

### (17) Thematic hierarchy (a revised version)

Order the A-marked arguments in the macrorole tier from left to right (only when the function is AFF), followed by the A-marked arguments in the main conceptual structure clause of the thematic tier, from least embedded to most deeply embedded.

The linking principles are shown in (18). First, lexical or inherent cases are linked to the argument. Then, nominative is assigned to the leftmost A-marked constituent in the thematic hierarchy. After that, accusative is assigned to the second A-marked constituent. And finally, dative is assigned by default to any remaining constituents. When we apply these principles to the conceptual structures proposed above, we get the following result.

### (18) Semantic case-mapping in tiers (J S Jun 2003)

- A. Lexical case, whether thematic or truly quirky, is linked to appropriate semantic entities prior to structural case-mapping in tiers.
- B. Structural case-mapping:
  - a. Order the A-marked constituents in the verb's LCS according to the thematic hierarchy, followed by any optional arguments/obliques.
  - b. NOM is assigned to the leftmost (or highest) A-marked constituent.
  - c. ACC is assigned to the second highest A-marked constituent.

- d. DAT is assigned by default to any remaining constituents that do not get either NOM/ACC or lexical case.

All the characteristics of DECAs mentioned above are clearly captured by conceptual structures ((14)-(16)) and the linking principles in (18). First, the fact that Korean DECAs always have nominative-marked stimulus is captured by the interaction of the conceptual structure (15) and the linking principles (18), particularly (18B-b). And the fact that DECAs can always show the case alternation phenomenon is captured by the second (15) and the third conceptual structures (16). That is, polysemous psych-adjectives have both (15) and (16) as their conceptual structures and whether the experiencer argument is assigned nominative or dative is determined by which conceptual structure the predicate takes; if the predicate takes (15) as its semantic structure, the experiencer argument gets dative case by the linking principle (18B-d), but if the predicate takes (16) as its semantic structure, experiencer gets nominative by the linking principle (18B-b). Finally, the last characteristic that the psych-predicates in DECAs are polysemous is captured by the fact that experiencer can take dative case only when the meaning of the psych-adjective is a property but not the psychological state. If the predicate is monosemous and refers only to one's psychological state, then the possible conceptual structure is only the third one (16), and there is no possibility for the monosemous psych-predicate to have dative experiencer, which can only be realized in the conceptual structure of subjective evaluation.

My analysis is better than the previous analyses that consider dative as inherent case without any special reason, because in addition to the dative case itself, I can explain all the unique characteristics of Korean DECAs systematically. That is, why dative experiencer constructions must have stimulus arguments, why those stimulus arguments must be marked nominative, why the dative case marked on experiencer arguments can always alternate with nominative case, and why the psych-adjectives in dative experiencer constructions are always polysemous between the meaning of an objective property and pure psychological state.

## **7. Conclusion**

I have shown in this paper that looking into the lexical semantics of Korean psych-adjectives is the key to answering the ultimate question of what the nature of the dative case in DECAs is. By analyzing the polysemous nature of some psych-adjectives, I have

shown that experiencer can get DAT only when the predicate is polysemous and refers to the property of stimulus not the psychological state of experiencer.

Although I do not deny the existence of truly inherent or quirky cases, I believe many cases that have been thought of as quirky or lexically inherent are in fact not like that at all and can be explained systematically, especially when we look into the conceptual structures of the predicates.

# Dialectal variations on the syllable-final nasal merger in Taiwan Mandarin

Janice Fon & Jui-mei Hung

Graduate Institute of Linguistics, National Taiwan University  
1 Roosevelt Rd. Sec. 4, 317 Lexue Bldg., Taipei, Taiwan ROC 10617

## Abstract

This study looked at the dialectal variations of syllable-final nasal merger in Taiwan Mandarin. Twenty-two native speakers, half from the northern dialect, and half from the southern dialect, participated in a reading experiment, which included *zhuyin*-, syllable-, and sentence-reading. Results showed that the northern speakers had two merging rules, /in/ → [iŋ] and /əŋ/ → [ən], while the southerners had an additional third merger, /iŋ/ → [in]. Northerners preferred /in/ → [iŋ] over /əŋ/ → [ən], while southerners had about equal preference for both rules. The /iŋ/ → [in] merger, however, was the most dispreferred. In general, northerners had higher merger rates than southerners, and sentence-reading encouraged the more merger application than the other two conditions.

**Keywords:** nasal merger, dialectal variation, Taiwan Mandarin, sound change.

## 1. Introduction

Mandarin allows two syllable-final nasals, /n/ and /ŋ/. Both can occur with the five vowels in the system, /i/, /ə/, /a/, /u/, and /y/, but only VN sequences containing the former three result in monophthongal realizations of the vowel for both nasals (Duanmu 2002). Previous studies showed that there is a tendency for the two nasals to be neutralized after these vowels in Taiwan Mandarin, but researchers disagree upon its direction, robustness, and cause.

Kubler (1985), Tse (1992), Yueh (1992), and Yang (2007) claimed that /iŋ/ and /əŋ/ tend to be realized as [in] and [ən], respectively, as shown in (1), but /aŋ/ remains relatively stable. Yang found the merging process to be almost complete [96% for /iŋ/; 95% for /əŋ/], while Tse argued that the mergers were just at their burgeoning stage [22% for /iŋ/; 23% for /əŋ/]. Yueh's speakers were somewhere between those in Yang and Tse [40% for /iŋ/; 64% for /əŋ/], and variation in location, gender, and age did not

show much difference. Possible causes for such a discrepancy might be twofold. One is the time difference among the three studies. The mergers might indeed have been at a relatively early stage in 1992, but have gradually matured within a time span of 15 years. The other possibility might be methodology. Yang asked subjects to participate in a riddle-guessing game in which targets were embedded in the answers to the riddles, while Tse and Yueh requested speakers to read target syllables in a number of contexts. Different styles might have thus been elicited, resulting in inconsistencies between the two studies.

(1) /ŋ/ → [n] / {i, ə} \_\_\_\_

Kubler (1985) attributed the cause of the mergers to the influence of Min, a powerful substrate language in Taiwan, in which 73–88% of the population are ethnically Min, and thus almost all people have at least some passive knowledge of the language (Chen 1979; Chen 1989; Huang 1993). This view is further supported by Yang's (2007) finding that the mergers were not consistently found in Mandarin in China, in which Min speakers only accounted for less than 4% of the total population (Zhang 1989; Zhu 2002). On the other hand, Tse (1992) and Yueh (1992) claimed that this neutralization is an innovation favored by the younger generation. Therefore, it could not have been due to a negative transfer from Min since most of the younger generation acquired Mandarin as (one of) their first language(s) and both Mandarin monolingual and Mandarin-Min bilingual speakers showed a similar trend. Instead, the rules are motivated by frontness assimilation, as both /i/ and /ə/, as well as /n/, are produced in the front half of the vocal tract.

Ing (1985) had a different observation. Instead of merging [ŋ] with [n], speakers seem to merge the two nasals reciprocally. /in/, /ən/, and /an/ tend to be realized as [iŋ], [əŋ], and [aŋ], respectively, while /iŋ/, /əŋ/, and /aŋ/ tend to be realized as [in], [ən], and [an], respectively, as shown in (2) and (3). Similar to Kubler (1985), Ing also claimed that the mergers are due to influences of Min and various other non-standard Mandarin varieties.

(2) /n/ → [ŋ] / {i, ə, a} \_\_\_\_

(3) /ŋ/ → [n] / {i, ə, a} \_\_\_\_

Chen (1991a; 1991b), Lin (2002), and Hsu (Hsu 2006; Hsu & Tse 2007) provided the third view. They found the nasal mergers to occur only with /i/ and /ə/, and

only in /in/ and /əŋ/ sequences. /in/ tends to be realized as [iŋ], and /əŋ/ tends to be realized as [əŋ], as shown in (4) and (5), respectively. No mergers occur for sequences involving /a/. Chen (1991a) found the rates to be vowel-dependent, with /in/ → [iŋ] being the leading merger across age groups, while Hsu claimed that /əŋ/ → [əŋ] is the leading merger instead, especially in the old group (Figure 1). In general, Chen's subjects were more likely to apply the mergers than those of Hsu. It is difficult to attribute the discrepancy to simple methodological differences. Both Chen and Hsu employed a reading task for elicitation, with the former using word lists and the latter using sentences. If there should be any differences, one would expect to find sentence-reading to be a more encouraging task for application of mergers instead. Time difference is also a far-fetched possibility. Results from comparable groups, matched by birth year (Hsu's 1951-60 vs. Chen's 1951-62) or by age (Hsu's 1951-60 vs. Chen's 1938-49; Hsu's 1981-90 vs. Chen's 1965-68), are incongruent with each other. The other possibility might be speakers' backgrounds. Although both studies recruited subjects from the Taipei area, Hsu included only people who were native to Taipei, while Chen's speakers were university faculty and staff members, college students, and high school English teachers, forming a rather heterogeneous group.

(4) /n/ → [ŋ] / i \_\_\_\_

(5) /ŋ/ → [n] / ə \_\_\_\_

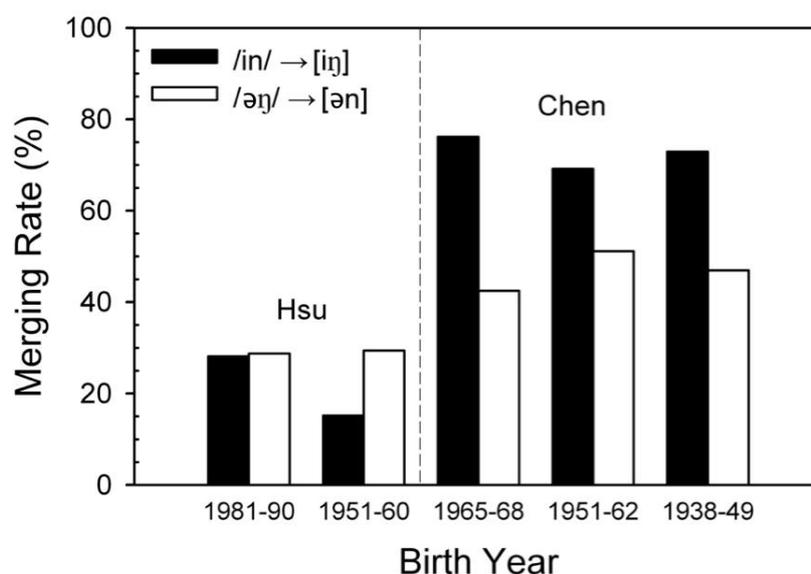

Figure 1: Merging rates in Chen (1991a) and Hsu (2006). Hsu's 1951-60 subjects are comparable to Chen's 1951-62 subjects in birth year, and to Chen's 1938-49 subjects in age. Hsu's 1981-90 subjects are comparable to Chen's 1965-68 in age.

The mergers are fairly consistent across genders and language backgrounds (Hsu 2006; Hsu & Tse 2007). Both Min and non-Min speakers show the same pattern, regardless of age groups to which they belong. Females show higher rates than males, although the trend is statistically insignificant [27% vs. 16% for /in/; 31% vs. 27% for /əŋ/].

Chen (1991b) surmised that the fluidity between [n] and [ŋ] might have a historical root. Several /iŋ/ sequences in modern Mandarin are originally pronounced as /in/ (e.g., *qingjia* ‘in-laws’), and /ən/ sequences are originally pronounced as /əŋ/ in Middle Chinese (e.g., *zhenjie* ‘chaste’). That the two mergers are also found in Singapore Mandarin, whose substrate languages have a much wider spectrum than those of the Taiwan variety, also support this view (Chen 1986; Chen 1991b). In other words, Taiwan Mandarin speakers are essentially reliving the diachronic merger rule synchronically. On the other hand, Lin (2002) proposed that a synchronic phonological process of [αhigh] assimilation is at work, characterizing [ŋ] and [i] as both [+high], and [n] and [ə] as both [–high]. Table 1 is a summary of the nasal mergers observed in the previous studies.

Table 1: A summary of the nasal mergers.

Studies	Preceding vowels		
	/i/	/ə/	/a/
Kubler (1985)			
Tse (1992)			
Yueh (1992)	/ŋ/ → [n]	/ŋ/ → [n]	no merger
Yang (2007)			
Chen (1991a; 1991b)			
Lin (2002)			
Hsu (2006)	/n/ → [ŋ]	/ŋ/ → [n]	no merger
Hsu & Tse (2007)			
Ing (1985)	/n/ → [ŋ]	/n/ → [ŋ]	/n/ → [ŋ]
	/ŋ/ → [n]	/ŋ/ → [n]	/ŋ/ → [n]

## 2. Specific aims

The above contradictory observations do not seem to be easily reconcilable. Ing (1985) is the most different, proposing reciprocal merging after the three vowels. The two remaining camps agree on the merging direction after /ə/, but disagree on the direction after /i/. One possibility might lie in dialectal variations, as these studies recruited subjects from different populations. Lin (2002) and Hsu (Hsu 2006; Hsu & Tse 2007) studied only native Taipei residents, Yueh (1992) studied native Taipei and Tainan (a southwestern city) residents, while Chen (1991a; 1991b), Tse (1992) and Yang (2007) studied speakers who were affiliated with universities, *i.e.*, students, staff members, or faculty members, whose language backgrounds can be heterogeneous. Kubler (1985) and Ing (1985) focused mainly on L2 Mandarin speakers whose L1 is Min. Therefore, the first aim of the study is to investigate whether dialectal variations can resolve the incongruence in merging directions.

Even though no dialectal differences were found in Yueh (1992), there are at least two reasons why Taipei and non-Taipei speakers might potentially be different. First of all, although most speakers in Taiwan are Mandarin-Min bilinguals (Huang 1993), the official language Mandarin is used more often in Taipei than any other areas in Taiwan (Ang 1997), as it is the political, economic, and cultural center of the country. Taipei also has the largest Mainlander population, who mainly uses Mandarin, compared to any other places in the country (Yang 2004). Of the nearly 3 million Mainlanders in Taiwan, about 20% of them are Taipei residents, constituting 22% of the city population. As a result, Mandarin-Min bilinguals in Taipei tend to use Min less frequently than Mandarin, and are oftentimes less fluent as well (Huang & Fon 2008). Secondly, the two main dialects of Min in Taiwan, Zhang and Quan, are unevenly distributed. Quan speakers mainly reside in Taipei and the west central coastal strip, while Zhang speakers are dominant in the west central non-coastal areas (Ang 2004). Speakers in the southwestern part of Taiwan predominantly speak a variety of Min that is a more balanced mixture of Zhang and Quan, although the former is still more influential than the latter (Ang 2005; Li 2007). Table 2 shows the allowable VN sequences relevant to this study in the three Min dialects. All three dialects allow /in/, /an/ and /aŋ/, and disallow /ən/. Quan permits /iŋ/ but not /əŋ/, while Zhang and Mix permit /əŋ/ but not /iŋ/. If the application of the merger is to a large extent determined by the influence from Min (Ing 1985; Kubler 1985), then differences in language composition between Taipei and non-Taipei areas would predict a split in nasal merger applications among speakers.

Table 2: A summary of allowable VN sequences in Quan, Zhang, and Mix dialects of Min.

	Quan			Zhang/Mix		
	/i/	/ə/	/a/	/i/	/ə/	/a/
/n/	/in/	—	/an/	/in/	—	/an/
/ŋ/	/iŋ/	—	/aŋ/	—	/əŋ/	/aŋ/

Besides merging directions, previous studies also disagree on merging rates. Take the most widely agreed upon Rule (5) for example, merging rates are about 17–31% (Tse 1992; Yueh 1992) for minimal pairs, 42% for isolated syllables (Yueh 1992), 28–46% for words (Chen 1991a; Tse 1992; Yueh 1992), 29% for sentences (Hsu 2006), 38% for passages (Yueh 1992), 30% for tongue twisters (Yueh 1992), and 95% for riddle guessing (Yang 2007). It is possible that the mergers are still in a volatile state, and the disparate results might actually reflect their different facets, depending on how self-conscious the speakers were towards their own pronunciations. Therefore, the second aim of the study is to determine how robust the rules are, and whether the merging process is fully phonologized. If the mergers are robust and the merging process is close to complete, as suggested by Yang (2007) for Rule (1), and Chen (1991a) for Rule (4), then one should be able to find merging patterns to be relatively stable across different contexts, and little or no context effects should be found. On the other hand, if the mergers are unstable and are still in progress, as indicated by Tse (1992) and Yueh (1992) for Rule (1), Hsu (2006) for Rule (4), and Chen (1991a) and Hsu (2006) for Rule (4), then one should be able to find a large context effect. Application rates should be much higher in contexts in which speakers are less aware of their pronunciation.

Previous studies also disagree upon the cause for the mergers. Some argued that it is due to a negative transfer from the substrate language Min (Ing 1985; Kubler 1985), others claimed that the merger is an innovation due to assimilation (Lin 2002; Tse 1992; Yueh 1992), and still others believed that it is a recurring trend from the past (Chen 1986; Chen 1991b). Therefore, the third aim of the study is to look into possible causes for the merger. Although it is difficult to verify the third proposal based on empirical data, it is possible to tease apart the first two causes based on differential sensitivities to the pronunciation norm between males and females (MacLagan et al. 1999; Trudgill 2000). If the nasal merger is indeed caused by a negative transfer from Min and is thus somewhat stigmatized, then one should be able to find educated females less willing to

apply the merger than educated males. On the other hand, if the merger is an assimilation-based innovation by young speakers, then gender differences should be mitigated or even reversed, with educated females being more likely to apply the merger than educated males.

### 3. Method

#### 3.1. Subjects

Twenty-two native speakers of Taiwan Mandarin, 13 female and 9 male, participated in this study. Half of them were from Taipei, constituting the northern group, and half of them were from southeastern Taiwan, constituting the southern group. All speakers were university students and college graduates. Their ages ranged from 19 to 27, with an average of 21.36 years of age ( $SD = 2.66$ ). Both groups stayed in the respective areas for approximately 20.64 years ( $SD = 2.87$ ), and the southern group had only stayed in Taipei for less than six months. All speakers were Mandarin-Min bilinguals and had acquired both languages as their L1. The northern group speaks a variety of Min that is closer to the Quan dialect, while the southern group uses a variety that is closer to the Mix dialect. They were asked to self-rate their Min proficiency on a Likert scale of 1 to 5. The northerners had an average of 3.09, while the southerners had an average of 4.27. Table 3 shows the relevant summary statistics of the two groups.

Table 3: Summary statistics regarding the two groups of subjects. Numbers in parentheses indicate standard deviation.

	Northern	Southern	Statistics
Age	21.82 (2.18)	20.91 (3.11)	$t(20) = .79$ , ns.
Years in the area	20.91 (2.59)	20.36 (3.23)	$t(20) = .44$ , ns.
Years in Taipei	20.91 (2.59)	0.45 (0.15)	$t(10.07) = 26.18$ , $p < .0001^*$
Min proficiency	3.09 (1.22)	4.27 (1.01)	$t(20) = -2.47$ , $p < .05$

\*Levene's test for equality of variances showed that the assumption for equal variances was violated. Therefore, the  $df$  was adjusted accordingly.

#### 3.2. Stimuli

Twelve minimal pairs of /n/- and /ŋ/-ending syllables were used as stimuli, including four /in/-/iŋ/ pairs (e.g., *xin* ‘heart’ vs. *xing* ‘star’), four /ən/-/əŋ/ pairs (e.g., *shen* ‘body’ vs. *sheng* ‘to give birth’), and four /an/-/aŋ/ pairs (e.g., *fan* ‘to flip’ vs. *fang* ‘square’). Syllables were presented in two forms, Chinese characters and *zhuyin* symbols, a local phonetic system taught in elementary schools to facilitate character pronunciation. In addition, syllables were embedded in carrier sentences written in Chinese characters, and were placed in sentence-final positions to avoid anticipatory coarticulation on the nasals. The last words of the carrier sentences were also carefully chosen so that they contained no other nasal-ending syllables except for the target stimuli. An example is given in (6). Additional 48 non-nasal-ending syllables and 72 sentences in which the last words contained no nasal-ending syllables were also included as fillers. In total, 4 (syllables) × 2 (nasals) × 3 (vowels) × 3 (conditions: *zhuyin*, character, sentence) = 72 stimuli and 48 (filler syllables) + 72 (filler sentences) = 120 fillers were included in the study.

- (6) *xin* ‘heart’  
*Wang laoshi feichang you aixin.*  
 Wang teacher very have loving-heart  
 Mr. Wang is very kind-hearted.

### 3.3. Equipment

Recordings were done using a SONY PCM-M1 Digital Audio Recorder with Maxell R-64 DA 60 min DAT tapes and a SHURE SM10A head-mounted microphone.

### 3.4. Procedure

Subjects were recorded in a quiet room. They were presented with stimuli printed on index cards and were asked to read them in a natural fashion. The stimuli were blocked by condition and each session contained an additional fourth block of a pronunciation check (see below). Subjects were allowed to rest between blocks if necessary. For the reading tasks, the order of presentation within each block and the order of the blocks were randomized for each subject. The pronunciation check was always the last block. The check was a paper-and-pencil test consisting of 36 multiple-choice questions, including 24 target syllables and 12 non-nasal-ending fillers printed in Chinese characters in a semi-randomized order. For each syllable, subjects were required to

circle the dictionary pronunciation of the character, represented by the *zhuyin* symbols, from four available choices. The check was to ensure that subjects knew the underlying pronunciation of the stimuli, as most Chinese characters are not very transparent in this regard. After the recording, subjects were asked to fill out a questionnaire regarding their language backgrounds. An average session lasted about 20 min. Subjects were paid for their effort.

#### 4. Results

Table 4 shows the number of nasal mergers with regards to the preceding three vowels. It is clear from the table that merging rates were not evenly distributed. There was only one instance of /an/ → [aŋ], two of /ən/ → [əŋ], and none of /aŋ/ → [an], implying that nasals were fairly stable in these positions. Most of the mergers occurred with /in/ and /əŋ/ and a few occurred with /iŋ/. However, the distribution of the three was fairly different, as shown in

Table 5. For /in/ sequences, all northerners showed instances of merging, while only seven southerners did [ $\chi^2(1) = 2.75, p = .097$ ]. Two males and two females did not show any sign of this merger. On the other hand, for /əŋ/ sequences, all except for two northerners, one male and one female, and one southern female showed instances of merging, indicating this rule is prevalent among both groups of speakers [ $\chi^2(1) = 0, ns.$ ]. As for /iŋ/ sequences, except for one, all instances occurred in southerners, and only seven southern speakers showed instances of merging [ $\chi^2(1) = 4.91, p < .05$ ]. The four southerners who did not show any sign of this merger were all female. All southern males showed signs of this merger. The following analyses on merging rates focused on only these sequences and only on speakers that showed evidence of the mergers.

Table 4: Nasal mergers regarding the three preceding vowels.

Merging direction	Preceding vowels			Total
	/i/	/ə/	/a/	
/n/ → [ŋ]	159	2	1	162
/ŋ/ → [n]	25	144	0	169
Total	44	146	1	331

Table 5: Number of subjects applying the merging rules.

Group	Merging rules			<i>N</i>
	/in/ → [iŋ]	/iŋ/ → [in]	/əŋ/ → [ən]	
Northerners	11	1	9	11
Southerners	7	7	10	11
Total	18	8	19	22

The first merging rule examined is /in/ → [iŋ]. As shown in Figure 2, there was a marked contrast between northerners and southerners, and between males and females. For northerners, their merging rates were fairly high (80–90%) regardless of gender and condition (Figure 2a). For southerners, the overall merging rates were lower, and there was a gender split (Figure 2b). Females were more like their northern counterparts showing high merging rates (60–70%) across conditions, while male merging rates were only comparable in the sentence condition (62%). In *zhuyin* and character conditions, the merging rates were relatively low (25%). Different presentation conditions did influence merging rates, but except for southern males, the influence was relatively minor. For northerners and southern females, the differences were usually within 5–10%. However, for southern males, there was a big increase of close to 40% from *zhuyin* and character conditions to the sentence condition.

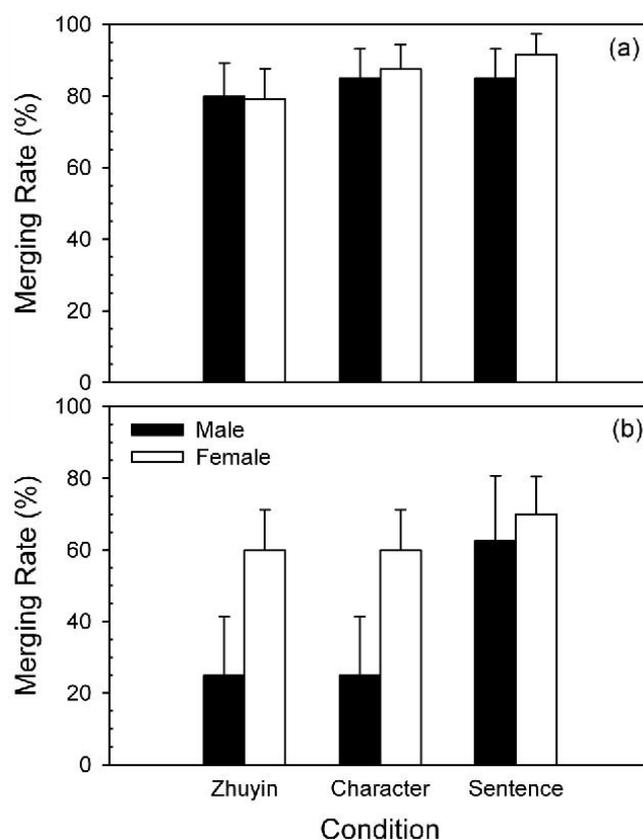

Figure 2: Average merging rates of /in/ → [iŋ] in (a) northerners and (b) southerners. Error bars represent standard error.

The second merger examined is /əŋ/ → [ən]. As shown in Figure 3, there was again a large difference between northerners and southerners, and between males and females. For northerners and southern males, merging rates for *zhuyin* and character conditions were comparable, around 55–75%, but southern females showed very low merging rates of only about 20–25%. For the sentence condition, there was a strong group difference. Northerners showed almost complete merging (95–100%), while southerners only merged around 65–75% of the time, regardless of gender. The influence of presentation conditions was dependent on Group and Gender. For southern males, the difference was fairly minor, around 7%. For others, the increase from *zhuyin* and character conditions to the sentence condition was as large as 20–40%.

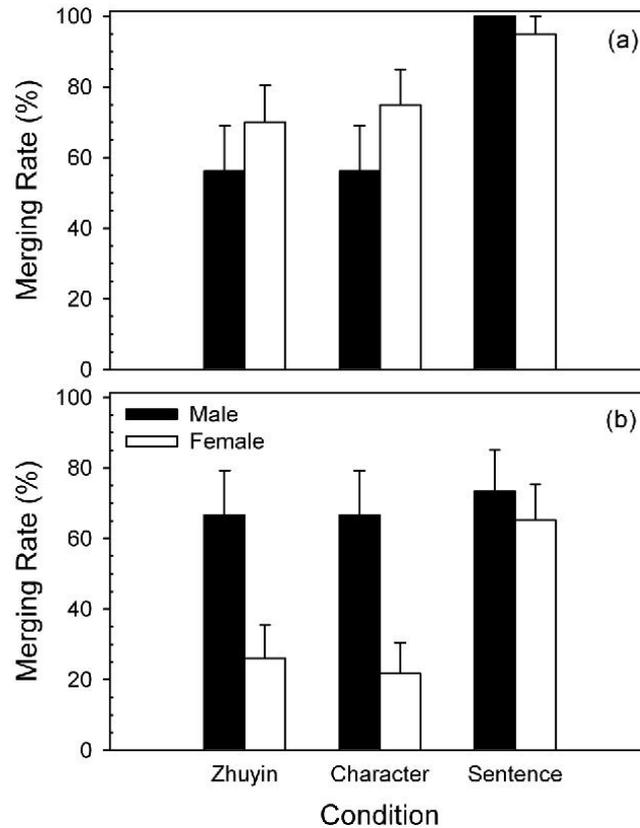

Figure 3: Merging rates of /əŋ/ → [ən] in (a) northerners and (b) southerners. Error bars represent standard error.

The third merger examined is /iŋ/ → [in]. Since there was only one instance in the northern group showing this merger, the following analyses included only southerners. As shown in Figure 4, the overall merging rates were fairly low, compared to the other mergers. There was a gender difference regarding the presentation conditions. For male speakers, the merging rates hovered around 35–45%, regardless of conditions. On the other hand, female speakers tended to have lower merging rates in non-sentence conditions (0–20%), and higher rates in the sentence condition (45%). Merging rates in the sentence condition were more comparable between the two genders. However, a logistic regression with Gender and Condition as predictors showed that both main effects and interaction effects were not significant.

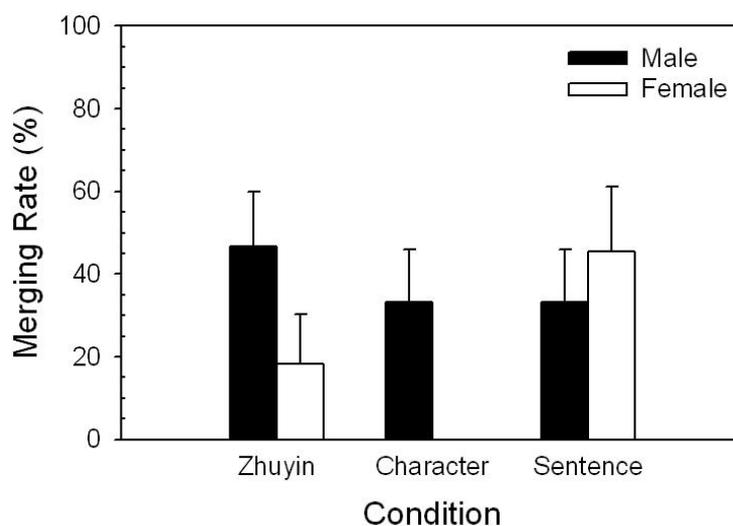

Figure 4: Merging rates of /iŋ/ → [in] in southern speakers. Error bars represent standard error.

## 5. Discussion

Three mergers were found in this study, /in/ → [iŋ], /əŋ/ → [ən], and /iŋ/ → [in]. No consistent merger involving /ən/, /an/, or /aŋ/ was found. This was congruent with the mergers proposed by most of the findings in previous studies (Chen 1991a; 1991b; Hsu 2006; Hsu & Tse 2007; Ing 1985; Kubler 1985; Lin 2002; Tse 1992; Yang 2007; Yueh 1992).

There was indeed a split between Taipei and non-Taipei speakers, contrary to Yueh's (1992) findings. Northerners only had /in/ → [iŋ] and /əŋ/ → [ən], while southerners had all three mergers. Based on merging rates and number of subjects who had the rule, the /in/ → [iŋ] merger seemed to be very robust in northerners. All speakers showed evidence of applying this rule and not much variation was found, as the merging rates were fairly high regardless of presentation contexts (*zhuyin*: 80%; *character*: 86%; *sentence*: 89%). In fact, of the 11 northerners, only three produced non-merging tokens. None only merged in the sentence condition. This was consistent with most of the previous studies that also looked at Taipei speakers (Hsu 2006; Hsu & Tse 2007; Lin 2002). However, the merging rates in this study were not comparable with Hsu's (2006) 28%.

In other words, the merger is likely to be sensitive to style differences. In formal genres, the merger is optional and the application rate is fairly low, as in Hsu (Hsu 2006;

Hsu & Tse 2007). However, in more colloquial genres, it has probably already been phonologized as a stable and standard rule, and its status has become essentially obligatory, as shown in this study.

That gender only exerted minor effects, with females showing slightly higher merging rates than males (85% vs. 92%) corresponds well with Hsu (2006). This implies that the rule is probably considered to be fairly neutral, and thus females were taking the lead, making negative transfer from Min an unlikely cause (MacLagan et al. 1999; Trudgill 2000). Besides, since the Quan dialect of Min allows both /in/ and /iŋ/ sequences (Table 2), merging the former with the latter is not well motivated from a transfer perspective. Instead, the origin of the rule is probably a [+high] assimilation with the preceding vowel, as was suggested by Lin (2002).

On the other hand, southerners did not show as much support for this rule, and much variation was observed. Of the 11 speakers, there were four that did not show any evidence of applying the merger, and for those who did, only two consistently merged regardless of conditions. Two speakers applied it only in the sentence condition. Although it could still be regarded as a common rule, the application rates were much lower than those of northerners (*zhuyin*: 50%; character: 50%; sentence: 68%).

The discrepancy between male and female merging rates was also much larger in the south, with females being again higher than males (63% vs. 38%), implying that this is probably regarded as a prestigious rule by the southerners, and females were trying to mainstream themselves to the pronunciation norm by taking the lead (MacLagan et al. 1999; Trudgill 2000). In other words, similar to the northern group, the cause of the merger is not likely to be negative transfer. Besides, the fact that the Mix dialect of Min allow /in/ but not /iŋ/ sequences would also make this an ill-motivated transfer. Instead, a [+high] assimilation with the preceding vowel should be the cause (Lin 2002), as in the northern group. However, since only Quan but not Mix allows /iŋ/ sequences, Min might have indeed somewhat contributed to the differential merging rates between the north and the south by providing an extra source of support for this merger to occur in the northern group, resulting in more stable application of the rule, while at the same time creating a counteracting force in the southern group, resulting in lower merging rates, and fewer people adopting the merger.

The differential effects of presentation conditions on male and female speakers were also intriguing. The overall pattern for female speakers was more like their northern counterparts. Only slight differences across conditions were found. On the other hand, male speakers showed high merging rates only in the sentence condition. This suggests that the rule is more stable and is probably also more phonologized in

female than in male speakers. Most male speakers tend to treat this merger as optional and would apply it frequently only in connected speech, which is also an indicator of its assimilatory origin.

Based on merging rates and the degree of prevalence of the merger, one suspects that the /in/ → [iŋ] rule probably originated from the north as a result of [+high] assimilation and was gradually spread to the south. As Taipei Mandarin is considered to be the standard variety, the rule is not regarded as stigmatized. Therefore, female speakers in both groups boldly took the lead and became more fervent in supporting the merger than their male counterparts. It is surmised that the rule should be able to gain its popularity among the southern speakers, especially males, given enough time.

The second merger, /əŋ/ → [ən], also seemed to be very robust in the north, although compared to /in/ → [iŋ], it was slightly less popular. Two speakers did not show any sign of this merger, and of the nine that did, only five consistently merged regardless of presentation conditions. One showed merging only in the sentence condition. Merging rates were lower than those of the /in/ → [iŋ] merger in the non-sentence conditions, but somewhat higher in the sentence condition (*zhuyin*: 64%; character: 67%; sentence: 97%). This is congruent with the relative merging rate differences in Hsu's (2006) sentence-reading results (/in/ → [iŋ]: 28%; /əŋ/ → [ən]: 29%). However, the absolute rates in this study were much higher than those in Yueh (1992) (syllable: 45%) and Hsu (2006), and were more comparable to those in Yang's (2007) study (riddle: 95%).

Therefore, the /əŋ/ → [ən] merger is probably an optional rule that is sensitive to style differences. Merging rates in formal contexts are fairly low, but are higher in more colloquial genres. Unlike /in/ → [iŋ], it is not a very stable merger across different presentation conditions. Merging rates for the sentence condition were about twice as high as those for *zhuyin* and character conditions, implying that the rule, though prevalent, is not yet completely phonologized.

Similar to /in/ → [iŋ], gender also exerted only minor influences on the /əŋ/ → [ən] merger. Females had higher merging rates in *zhuyin* and character conditions, but males were higher in the sentence condition [*zhuyin*: 56% vs. 70%; character: 56% vs. 75%; sentence: 100% vs. 95%]. This was in general comparable to the results in Yueh (1992) and Hsu (2006), implying that the rule is likely to be fairly neutral, and female speakers were taking the lead. The fact that merging rates were slightly higher for male instead in the sentence condition might be due to a ceiling effect, since the merging process was close to absolute. The pattern thus indicates that negative transfer from Min is an unlikely cause. That the Quan dialect of Min disallows both /ən/ and /əŋ/

sequences also supports this view. Instead, the rule is probably motivated by a [+front] assimilation, as proposed by Yueh (1992) and Tse (1992), or a [-high] assimilation, as proposed by Lin (2002).

For southerners, this rule was also fairly popular. Ten out of eleven showed evidence of having this merger. However, only two consistently merged regardless of conditions. Three speakers applied this rule only in the sentence condition. Merging rates were slightly lower than those for /in/ → [iŋ] in the non-sentence conditions, but were about the same in the sentence condition (*zhuyin*: 42%; character: 39%, sentence: 68%). Overall, merging rates were also much lower than those in the north and were comparable to those in Yueh (1992) (syllable: 38%).

Similar to the pattern in /in/ → [iŋ], there was a large gender difference in southerners' merging rates, but the direction was the exact opposite, with males being higher than females (69% vs. 38%), implying that the rule is probably deemed as a stigmatized one by southerners, and females were avoiding it (MacLagan et al. 1999; Trudgill 2000). However, negative transfer from Min is an unlikely cause, since the Mix dialect allows /əŋ/ but not /ən/, making the rule ill-motivated. Instead, the rule might have the same assimilatory root as in the north, be it [+front] (Tse 1992; Yueh 1992) or [-high] (Lin 2002), but somehow it does not share the same neutral social attitude. Nevertheless, since the Mix dialect allows /əŋ/ but Quan does not, Min might have contributed somewhat to the differential merging rates between the north and the south by creating a counteracting force in the south, resulting in lower merging rates.

As with /in/ → [iŋ], there was also a differential effect of presentation conditions on the two genders, but the pattern was reversed. Males showed a more stable merger regardless, while females showed a larger condition effect, with merging rates being much higher in the sentence condition. This suggests that the rule is probably more stable and more phonologized in male than in female speakers. Most female speakers tend to only apply this optional rule frequently in connected speech.

Compared with /in/ → [iŋ], more people are applying /əŋ/ → [ən], suggesting that the latter probably has a longer history than the former, congruent with Hsu and Tse's (2007) claim. The rule is likely to have a northern origin, as merging rates were much higher in the north than the south. This hypothesis is consistent with the small gender differences in the north, but inconsistent with the large gender differences in the south. Southern females are shying from applying the rule in non-sentence conditions, which should have not been the case if the rule was originally from a standard dialect area. One would have predicted a pattern similar to /in/ → [iŋ] instead. The geographical split in speakers' attitude towards the rule seems to imply that other factors specific to the

south might be influencing southerners' percept.

The third merger, /iŋ/ → [in], only seemed to exist in the south, contrary to Yueh's (1992) findings. Of the 11 southern speakers, there were four that did not show any evidence of applying the rule, and for those who did, none of them consistently merged regardless of conditions. Two speakers applied it only in the sentence condition. Although the rule could be regarded as a common one based on number of speakers that had the merger, the application rates were fairly low compared to the first two rules (*zhuyin*: 35%; character: 19%; sentence: 38%). The rates were quite comparable to those in Yueh (1992) and Tse (1992) (syllable: 19–26%; word: 28–33%; paragraph: 36%), but were in strong contrast with Yang's (2007) data (95%), reflecting its sensitivity to style variations.

The gender differences in /iŋ/ → [in] were like those for /əŋ/ → [ən]. Female speakers were much less likely to merge than males in non-sentence conditions (40% *vs.* 9%), but were more comparable with males in the sentence condition (33% *vs.* 45%). Although the pattern was statistically insignificant, it implies that the rule is probably stigmatized, and females were avoiding it when they were more aware of their pronunciation (MacLagan et al. 1999; Trudgill 2000). Since the Mix dialect of Min allows /in/ and disallows /iŋ/, it is likely that the rule is due to negative transfer from Min, and is thus less preferred, as was suggested by Kubler (1985) and Ing (1985). That the Quan dialect allows both /iŋ/ and /in/ sequences also explains why this rule is not well motivated and thus not popular in the north. [+front] assimilation (Tse 1992; Yueh 1992) is not an attractive explanation since it could not explain why northern speakers are precluded from the rule.

Compared with /əŋ/ → [ən], the merging rates of /iŋ/ → [in] were much lower. One possibility might be that the latter is a newer rule, and is therefore still in its burgeoning stage, as was suggested by Tse (1992). However, this is inconsistent with its negative transfer origin since the influence of Min on Mandarin could be dated as far back as 1945, when the large influx of Chinese immigrants started (Huang 1993). Instead, one suspects that the lower merging rates of the rule is due to its highly marked status, and thus it is less preferred in read speech.

## 5. Conclusion

In this study, one looked at northern and southern speakers regarding their merging patterns, and found dialectal variations not only in the type of rules adopted,

but also in the application rates for the same mergers. One suspects this might be related to speakers' differential attitudes towards the rules, in addition to the different points of origin, which will merit further studies.

# **A Discourse Analysis of Language Scaffolding: In a Cross-age Tutoring Program**

**Ji Young Kim**

University of Florida  
298 Diamond Village #13  
Gainesville, FL, 32603  
ibppy014@ufl.edu

## **Abstract**

This study analyzes a discourse of cross-age tutoring for oral language development as well as literacy for reading in English with English as a second language (ESL) and native English-speaking (NES) in school-age learners. The theoretical framework is based on a sociocultural view of learning, particularly the hypothesized the zone of proximal development (ZPD) (Vygotsky, 1978), on the concept of scaffolding (Bruner, 1983; Wood, Bruner, & Ross, 1976). Halliday's (1994) systematic functional approach is hired in the linguistic analysis of the tutoring discourse. The finding shows that typical features of topical, interpersonal, and textual themes in similar or different patterns between two groups to learn beyond their original ability and knowledge by language scaffoldings of questioning, confirming, clarifying, modeling, and negotiating.

**Keywords:** language scaffolding, cross-age tutoring, the Zone of Proximal Development, Functional Linguistic Approach

## **1. Introduction**

The growing numbers of students who speak English as a second language are faced with the challenge of academic achievements on standardized assessments in school systems due to limited language proficiency and lack of content knowledge. Especially vocabulary in reading comprehension of content subjects is identified as general concerns for English language learners (Stoller & Grabe, 1995; Schmitt & Meara, 1997; Ordonez, Carlo, Snow & McLaughlin, 2002; Birch, 2007). Many ESL and EFL students, including native English speaking students withlow literacy are frustrated to read stories, articles, or books that are too difficult for them and this problems might cause tardiness of independent reading and they are left behind for a quite long period.

The research questions posed in this study are (1) How do we motivate these

students to read with more interests and attention? (2) Which strategy and instruction can facilitate students to read effectively?" From this inquiry, I analyze two discourses in the cross-age reading programs between high school tutors and elementary tutees in ESOL and mainstream classroom to explore how they interact with each other in reading comprehension and vocabulary acquisition in terms of the language scaffolding in English. The concept of language scaffolding and the Zone of Proximal Development (ZPD) are considered to explore benefits from the instruction of cross-age tutoring, using the tool of Systemic Functional Linguistics (SFL).

## **2. Theoretical background**

### *2.1. Language Scaffolding and ZPD*

The metaphor of scaffolding is a popular and useful idea in psychology and education to emphasize the importance of tutoring which means learners are considered as a building and they actively construct themselves to move forward (Berk & Winsler, 1995). This metaphor tells us meaningful idea that children are actively engaged in learning by social interactions with other people who are more knowledgeable and competent in collaborative activities. Scaffolding allows learners to expand their knowledge beyond their levels. Vygotsky's (1978) concept of the Zone of Proximal Development (ZPD) is associated with the meaning of scaffolding in terms of two different levels of learning by collaborative learning instruction: the actual development of learning by learner themselves and the potential development under guidance or collaboration with more capable peers. From the perspective of second language acquisition, the concept of ZPD can be defined as the difference between the L2 learner's developmental level as determined by independent language use, and the higher level of potential development as determined by how language is used in collaboration with a more capable interlocutor (Ohta, 1995). Therefore, cross-age tutoring is able to activate these two different levels of development in language learning effectively from active interactions between tutors and tutees.

This study mainly focuses on the language scaffolding in the discourses of cross-age tutoring in terms of how the tutors support and scaffold the tutees to acquire new vocabulary and to comprehend reading passages by producing appropriate interlocution. Additionally this study explores how and why the tutees of English language learner respond to the scaffoldings, using their native language and English dynamically.

## 2.2. *Cross-age Tutoring*

Cross-age reading programs are used as a promising way of helping students improve their reading ability in instructional contexts. Although the focus of cross-age tutoring program is the development of students' literacy, according to the literature review by Cohen, Kulik & Kilik (1982), both tutors and tutees gain positive attitudes toward reading and development of social skills as well as improvement of reading comprehension from cross-age tutoring projects. More recent studies also show the effectiveness of such programs in the same domains such as reading ability, motivation for reading, and interpersonal skills (Marios, 2000; Thrope & Wood, 2000; Kalkowski, 2001; McCabe & Millar, 2003).

Although many studies have shown the gains for both tutees and tutors, there has been little research on language scaffolding and L1 uses in such programs. Therefore, this research of language scaffolding between the tutors and the tutees is able to give meaningful insight into cross-age tutoring in English language acquisition by comparing two different language groups of cross-age pairs – one is Korean-Korean pair and the other is native-native speakers of English.

## 2.3. *Understanding of Thematic Analysis in Functional Linguistic Approach*

In general, theme is the starting point of a clause which provides familiar information from previous text or presumed understood in functional grammar. The remained part of a clause is a rheme which modifies and develops themes, providing unfamiliar or new information (Halliday & Matthiessens, 2004). Writer and speakers must consider what their readers and listeners are likely to expect at any given point, and then use the thematic content of their messages to influence these expectancies. A few ESL/EFL students probably tend to fail to provide this expectation chain and to communicate clearly with their audience in their speaking and writing (Thompson, 1985). There are three main types of themes in functional grammar– Topical (experiential), and textual theme to organize a text and communicate effectively (Halliday & Matthiessens, 2004). Topical themes generally refer to constituents of human experiences such as participants itself (generally considered as a subject or a thing in a subject position), the participants with a process (generally considered as a verb), or any circumstantial factors (generally considered as a prepositional phrase) such as time, manner or cause (Halliday & Matthiessens, 2004). Other elements in the clause preceding topical themes are either interpersonal or textual in function, playing no part

in the experiential meaning of the clause (Halliday & Matthiessens, 2004). The categories of interpersonal themes generally include modal or comment adjunct, vocative, or finite verbal operator. In textual themes, there are various types of continuatives, conjunctions, and relatives.

In the analysis, I consider each clause independently in a sentence and all themes in the position of proceeding process in a clause separately investigated in terms of the functions in the discourse. I mainly examine how the tutors (Native English Speaker: NES) construe themes in a clause by means of topical, interpersonal, and textual themes. The purpose of L1 use by the tutee of English language learner (ELL) is also analyzed when and why L1 is used in the context and interpreted with a view of vocabulary acquisition across languages.

### **3. Methodology**

#### *3.1. Sample of data*

The discourses of data analysis come from cross-age tutoring projects conducted over a four-year period in K-12 classrooms across the state of Florida. The pairs of tutoring consist of high school student tutors and elementary and kindergartener tutees. In the samples of this study, the first pair of a tutor and a tutee has the same language background of Korean and show different level of English language proficiency. In the second group of tutoring, both the tutor and the tutee are native English speakers, but the tutee is in emergent reading stage. It means the tutoring sessions were videotaped for 20 minutes and transcribed in English, including their first language. Each pair reads a book and then talks about the story, characters and new vocabulary in the middle and at the end of reading. Although the nature of cross-age tutoring is described as collaboration and interaction, the tutor mainly leads the session and the tutee responds to the questions about the story or new vocabulary with very simple words due to limited oral proficiency or lack of vocabulary knowledge in English for English language learners. Because of this reason, the tutors' utterances are mainly analyzed.

#### *3.2. Attention to institutional context*

The given sample data were analyzed by the Systemic Functional Linguistics approach. In the analysis, the thematic analysis is employed as an analytic tool to show the variations of linguistic choices and patterns in a clause level. After analyzing each

clause, each type of themes is categorized into conceptual terms of language scaffolding from coding such as modeling, engaging, encouraging, checking, affirming, paraphrasing, repeating, etc. Separately, the purpose of L1 use by the tutee of English language learners is also analyzed in terms of when and why L1 is used in the context and interpreted with a view of meta-cognition across languages in vocabulary acquisition.

#### 4. Findings

The findings from this study would represent the similarities and differences in the thematic structures between the two discourses. The similar features of spoken instruction genre might emerge from the overall interpretation of the analysis, and then more detailed interpretation would present the differences in terms of the frequency and linguistic variation of each type of themes between two pairs. 113 clauses are taken from the first group of English language learners and 161 clauses are taken from the second group of native English speakers. Each clause has at least one topical theme in that, but, sometimes, multiple topical themes are presented as follows: *in this picture* (experiential: E), *where (E) is the crowd?*; *what (E) does (textual: T) this (E) say?*; *when (E) the bird (E) picked up?*; regardless of grammatically correct or not.

##### 4.1. Frequency of topical, interpersonal, and textual themes

As regards similarities in both discourses, more interpersonal themes and fewer textual themes are used than written texts due to the features of spoken genres <Table 1>. Both writers construed their spoken text with instructional expressions by asking questions, explaining some process, encouraging the tutee to describe their thoughts which are teacher-like ways with various types of themes. However, the characteristics of formal spoken discourses are shown more evidently from the ELL tutor's speech. He used more formalized expression rather than natural spoken and daily like description.

	ELL	NES
Total of clauses used	(113)	(161)
Topical Experiential: E	55%	67%
Interpersonal: IN	19%	20%
Textual: T	25%	13%

Total of Themes	(100%)	(100%)
-----------------	--------	--------

Table 1. Frequency of topical, interpersonal, and textual themes used by ELL and NES

(1) ELL

- a. Can (T) you (E) remember that some people who make some very good pieces very expensive something?
- b. We (E) finished the Curious George here and then (T), uhm, (T) I (E)'ll (IN) give you some more questions about it.

(2) NES

- a. So, (T) what (E) are you guys thinking what's gonna happen in the story?
- b. So, (T) tell me what happen.
- c. You guys (E) are playing games are being involved teamwork?

As we see above, both speakers also used spoken-like conjunctions to make a connection logically in their mind among each clause and sentences such as 'so,' 'and,' and 'then.' These seem to be used habitually to think internally rather than build textual cohesion which is defined as a typical function of conjunctions.

Topical (Experiential)(55%)	Interrogative	What
	Demonstrative	This or that
	Pronoun	You, he, we, I, they, it
	Circumstance	in this picture, with this picture
	Descriptive	The picture, this picture,
	New vocabulary	opposite, masterpiece, crowd,
Interpersonal (19%)	Modal	can, may, will
	Comment adjunct	just
	Finite verbal operator	do, does, didn't, did, don't, have
	Imperative	let's
	Vocative	0
Textual (25%)	Continuative	next time, then
	Conjunction	so, and, yeah, here, that, oh, if, but, right here, um.
	Relative	Who

Table 2. The frequency of three types of themes used by ELL

Topical(Experiential) (67%)	Interrogative	What, When, Which, Where, How
	Demonstrative	This or that, there
	Pronoun	You, you guys, he, We, I, they, it, all
	Circumstance	in the story
	Descriptive	That idea, introduction, the bird, everyone, someone, everything, the stone, Anasi
	New vocabulary	
Interpersonal (20%)	Modal	Can/can't/couldn't, might be, will/will not/would, should, had better, are gonna/ are not gonna
	Comment adjunct	just, just like, like, really
	Finite verbal operator	do,does,didn't,did,don't,have/haven't/has
	Imperative	let's
	Vocative	Cole
Textual (13%)	Continuative	Then,After,after that, one day, tomorrow, now
	Conjunction	so,and,yeah,well,oh, but, all right, huh.
	Relative	0

Table 3. The frequency of three types of themes used by NES

The variations in each type of themes show how the speakers differently thematized their spoken structures.

#### 4.2 *The variations of topical themes*

Topical themes generally refer constituents of human experiences of participants, circumstances, and processes (Halliday & Matthiessens, 2004). Topical themes are divided into two types of themes: (1) marked and (2) unmarked. Unmarked topical themes are prominent elements in a clause which are generally considered subjects in traditional grammar, and marked topical themes are standing-out or marked alternatives such as prepositional phrases which might not serve a subject in the clause (Halliday &

Matthiessens, 2004).

Interrogative clause of 'what is ----?' marked 22% among 114 topical themes in ELL's speech. This is probably used to check unknown vocabulary for tutees, including do, does, and did of finite verbal operators (although they are classified into interpersonal themes in functional grammar) in order to make questions or checking the tutee's understandings.

### (3) ELL

- a. What (E) is it?
- b. What crowd (E) is?
- c. What (E) is the word?
- d. What (E) does (T) this (E) say?

The tutor focuses more on vocabulary instruction of unknown words, making the tutee pay attention to them by asking the tutee to describe the meaning of words. In fact, among topical themes, new vocabulary words such as opposite, masterpiece, and crowd are repeated several times in a topical theme positions and explained by the tutor with pictures and writings repeatedly. It corresponds with the result of unknown words in thematic positions. In the discourse of NES, there is no unmarked topical theme in theme position. On the contrary, the tutor of native English speaker presented more various types of interrogatives of wh-question.

### (4) NES

- a. Where (E)'s the father now?
- b. What (E) are you thinking about this book so far?
- c. Which one (E) do (IN) you (E) want,
- d. What (E) happened?
- e. Yeah,(T) how (E) did (IN) he (E) fall?

The utterances by the native English tutor seem to be more various and more focus on the understanding of the story itself rather than just ask the meaning of a word. It can be generalized that ELLs put more emphasis on vocabulary acquisition rather than reading comprehension itself and NESs focus more on reading comprehension because they do not have as many difficulties in understanding the meaning of vocabulary in reading. This tendency might be proved in future study to compare their differences between English language learners and native English speakers.

In addition, demonstratives of this and that are frequently presented to refer some previous words in the book or to talk about the meaning of words by looking and pointing pictures or words. By using descriptive circumstance of prepositional phrase such as 'in the picture,' 'with the picture,' and 'in the story', the tutor scaffolds the tutee's understanding new vocabulary and the story.

The high frequency of you probably is related to asking questions about the tutee's thinking and understanding such as, 'Do you think,' 'Do you know,' and 'Do you remember?' in ELL's speech. However, in the discourse of NES, the tutor used 'you guys' frequently.

(5) NES

- a. You guys, (E) do (IN) you (E) like this book?
- b. You guys, (E) do (IN) remember the end of the story?

#### 4.3 Knowledge checking and engaging in interpersonal themes

Interpersonal themes generally express a speaker's commitment or reaction to a situation by using adverbs and a speaker's angle or validity by using modals (Whittaker, 1995). In these two discourses, *just* is mainly used as a reactionary adverb.

(6) NES

- a. Just like (IN) in the story (E) do teamwork.
- b. Just (IN) draw a picture in this box.

(7) ELL

- a. Just (T) one word (E) we (E) can (IN) use in one sentence.

Compared to different genre of written discourse, the interactional dialogic genre generally shows high frequency of interpersonal themes. Along with frequency of interrogative of *wh-* and pronoun *you* or 'you guys', in the analysis of interpersonal theme, absolutely modal of *can* marked 42% among whole interpersonal themes in the ELL's speech. In both mood of interrogatives and declaratives *can* is used to check or engage the tutee's knowledge of previously learned vocabulary, replacing *do* to make a question. Furthermore, using the modal of *can* definitely shows engagement of the tutees in the tutoring session as an active thinker.

(8) T : Can (In) you (E) remember that some people who make some very good pieces

very expensive something?

T : What (E) is this? [points at the word]

B : close

T : No. Can (IN) you (E) remember? Crowd?

What (E) are these [points at people in the book]

B : people

T : Yeah, people. Many people (E) and (T) so (T)

what (E) is crowd?

While the tutor of ELLs mainly used *can* as a modal, the tutor of NES presented more various type of modals such as *might be*, *will/will not/would*, (12%), *should*, *had better*, and *are gonna/are not gonna* (13%).

(9) NES

- a. We (E) are gonna (IN) do now....
- b. We (E) are not gonna (IN) do just let you see it.
- c. We (E)'re gonna (IN) do a little bit a drawing.
- d. Well, (T) we (E) are gonna (IN) have to go.

(10) ELL

- a. Next time (T) we (E) are writing about a story.

The native speaker used 'are gonna' with pronoun *we* and the imperatives 'lets' function as a linguistic tool for making the tutees and the tutors are engaged with the context and introduce next processes, including the tutors themselves.

(11) ELL

- a. And so lets (IN) write story. Story, then, title. Writing like a story with title something Ok and so [xxx] February 4 [interrupted by teacher].
- b. So lets (IN) write one word Ok let's (IN) start [xxx] just one word we can use in one sentence.

(12) NES

- a. Let's (IN) start of the beginning, all right?
- b. We (E)'re gonna (IN) do a little bit a drawing.

#### 4.4 Han Logical connection of discourse by using textual themes

As might be expected, in informal spoken discourses, textual themes are less frequent than in written discourses. Textual themes generally function to help listeners or speakers to follow the flow of speech. In these discourses, the speakers commonly used great number of conjunctions such as 'so' and 'and' or both together (62% versus 46%). Their function in the discourses for the speakers to think and arrange their thought, giving signals of continuation of logical flow to the tutees.

(13) NES

- a. Now, (T) we' (E) re gonna (IN) do three steps. So (T), if (T) you (E) were poor at throwing ropes, it (E) could not (IN) be safe to save people. But (T) someone (E) can (IN) help you.

(14) ELL

- a. So (T) just (IN) think about it. Master (E) is something very highest or people they make a piece.
- b. I (E) bring candy for you before. And so (T) what (E) does(T) it(E) taste like?

One more interesting finding in the analysis of textual themes is probably the use of 'yeah' as a starting point to give some affirmation. Both tutors affirmed the tutees by using 'yeah' when the tutees said correct answers or understood clearly.

(15) NES

- a. Yeah, (T) what (E) are you thinking?
- b. Yeah, (T) what (E) happen?
- c. Yeah, (T) how (E) did (IN) he (E) fall?

(16) ELL : Yeah, (T) you (E) can (I) put rush and so peppermint

- a. Yeah, (T) they (E) like him.
- b. Yeah, (T) that (E)'s right.

#### *4.5 Negotiation and modification of the meaning*

As I mention, ELLs in cross-age tutoring program seem to focus more vocabulary learning rather than comprehending the story itself. In the process of negotiation and modification of the meaning of a word, the tutors tried to build the concepts of a word by giving examples from their prior experience and knowledge, and modifying the meaning to make the tutees engaged in the context.

(17) ELL

- a. [xxx] here is you with a kind of plum here and you are the customer. The customer is used money. The customer orders [pointing at drawing] he comes [xxx] and that's you the customer and [xxx] give some more money. So...
- b. So what is a masterpiece? Can you remember? Masterpiece. Oh masterpiece is [draws] can remember [xxx] picture? Do you know the Mona Lisa? So the Mona Lisa is a drawing and [draws] this picture is a masterpiece. Can you remember that some people who make some very good pieces very expensive something?
- c. If you make or break something in your house glasses or something like that, your mom gets very angry and makes a punishment. That is a scold, can you remember? Give me a comparison rushing. Do you know what is rushing?

(18) NES

- a. When you work together everyone is different. You can make safe. You can help people and save people by putting what you can do well all together. Understand? So if you were poor at throwing ropes, it could not be safe to save people. But someone can help you. That's a kind of teamwork.
- b. It's wonderful. You guys are doing teamwork? You guys are playing games are being involved teamwork? You guys play soccer, or.

According to the study about negotiation in interactional tasks of second language acquisition by Foster & Ohta (2005), learners tend to co-construct meanings in interactional tasks to clarify, comprehend, and confirm by active assistance and initial self-repair of own utterances. In the discourses, the tutors and tutees build common context to understand the meaning of new concept by giving and taking descriptive utterances to make sure their understanding.

In particular, the use of L1 by the tutee in the moments of new vocabulary acquisition in the discourse of ELLs shows how L1 literacy could facilitate learning new vocabulary in L2 as a resource for vocabulary acquisition from the deliberate process of interactions by sharing and negotiating.

- (19) T: Yeah, you can put rush and so peppermint  
 B: Peppermint?  
 T: you don't know?  
 B: No  
 T: Can you remember what is mint is?  
 B: No, no.  
 T: [looks through book] Is it at page 74? Where is those peppermint here  
 [shows picture] have you tasted before?  
 B: No  
 T: I bring candy for you before? And so what does it taste like.  
 B: 박하 (peppermint)  
 T: You are right it taste cool.
- (20) T: The crowd. Can you know what crowd is? In this picture where is the crowd? Crowd in this picture.  
 B: Oh, 양보하다 (yield).  
 T: No,  
 B: 처음보는데.... (I've never seen that.)  
 T: You may see it in the picture.  
 T: What is this? [points at the word]  
 B: cl..ose, close.  
 T: No. Can you remember? Crowd? What are these [points at people in the book]  
 B: people  
 T: Yeah, people. Many people and so what is crowd?

The tutee of English language learner tended to use L1 to clarify the meaning of new vocabulary and to confirm his response by repeating, including self-correction of his own utterances by thinking alone.

## 5. Limitation

In this study, thematic structures are used to analyze the utterances of the tutors mainly. As a unit of analysis, clause structures are considered but there are many utterances which are not analyzed because of the incomplete structures. In the following example, the tutor and the tutee are interacting with each other by using short expressions which are not complete clause. In the process of the interaction, the tutee

shows his knowledge by modeling and demonstrating the motion to show his understanding and finally they get to the point of common knowledge. As this analysis mainly relies on the clause structure, many meaningful nonverbal and simple verbal responses are ignored unconsciously.

(21) B: Mmmmm (murmuring) George was getting hungry! Suddenly there was a...

T: [xxx]

B: Tapping

T: Yeah tapping. Not [a] sound, [ae] sound.

B: Tapping

T: Do you know what is tapping?

B: [demonstrates] Knock.

T: [taps on desk]

In addition, although the cognitive approach to cross-age tutoring has been aimed by using the concept of the Zone of Proximal Development, there were not objective results from the qualitative data of thematic analysis. In future studies, the quantitative approach to the effect of language scaffolding with plans of concrete and systematic instruction in cross-age tutoring might give more validity.

## 5. Conclusion

This study tried to explore how language scaffolding functions in reading comprehension and vocabulary acquisition in a cross-age tutoring program. From the thematic analysis of Systemic Functional Linguistics, we are acknowledged some similarities and differences between two different language groups –English language learners and native English speakers, focusing on the tutors' utterances in the tutoring sessions. The finding shows that typical features of spoken discourses in school which means topical themes are used to draw instructional dialogic interaction between tutors and tutees by means of various types of topical themes – interrogatives, demonstratives, pronouns, and descriptive themes in clauses. However, two different language groups show different linguistic choices in terms of variation of clause structures and grammatical properties of topical themes.

Interpersonal themes represent speakers' angle and encouragement for listeners to check and engage prior knowledge with current learning by employing modals and different types of mood with finite verb operators such as 'do,

does, did' and 'let's.' Textual themes function in the discourses as a logical connector for both tutors and tutees, mainly using 'so' and 'and' as a signal of flow of thinking. In the process of clarifying, comprehending, and confirming meanings in the discourses, the negotiation and modification are developed by giving and taking in English and their native language to build common knowledge context.

Several previous studies have focused more on sociocultural aspects of cross-age tutoring considerably. In this study, main focus was on the cognitive approach to the instruction program and comparison between two different language groups. As Foster & Ohta (2005) mentioned, two approaches have different strengths and weaknesses between sociocultural and cognitive approaches by using qualitative and quantitative methods. This study showed the richness of interaction by providing language scaffolding in cross-age tutoring programs as well as variations of linguistic choices between two different language groups.

In conclusion, I would like to go back to the research questions: (1) How do the language scaffoldings function to acquire new vocabulary and to comprehend reading in cross-age tutoring? The children develop their learning beyond their original ability through the interactions of cross-age tutoring by language scaffoldings. (2) How does the tutee respond to the scaffoldings, using his native language and English dynamically? L1 use functions to give clear understanding and build common knowledge context by endeavor of questioning, confirming, clarifying, modeling, and negotiating effectively. Finally, this implicates that literacy instruction should be intensively focused on L2 development, while also providing students access to the acquisition of literacy skills in their native language which may play an important role in the development of biliteracy.

## **Abstract**

This research is designed to compare the distribution of linguistic features in the spoken and written English of Korean and British university students, and to assess the native-like English proficiency of Korean learners. Forty-two Korean and British students undertook the same spoken and written tasks involving descriptive narratives. Approximately 32,000 words of English data were subsequently examined in terms of the frequency of 45 key linguistic features (as identified by Biber, 1988) using the *Oxford WordSmith Tools* 4.0 software and also by manual investigation. The findings showed that the Korean students' written English proficiency was more native-like than their spoken English proficiency. It was also found that, to a certain extent, the Korean learners tended to write as the native English speakers spoke.

**Keywords:** spoken English, written English, Korean EFL learners, linguistic features

## **1. Background**

For about a century, a series of studies have been undertaken into the relationship between speaking and writing based on the notion that they are basically different modes of expression of linguistic meaning (Akinaso, 1982; Sperling, 1996). Early studies between the 1960s and the 1980s had a range of sometimes inconsistent findings in terms of the occurrences of certain linguistic features in speech and writing. One of major findings was that written text is characterised by complex sentence structures and compact information, while spoken discourse is exemplified by simpler constructions and less dense information (e.g. Blass & Siegman, 1975; Horowitz & Newman, 1964; O'Donnell, 1974; Preston & Gardner, 1967). However, these views were challenged by Halliday's hypothesis (1979, 1985, 2002) concerning the different types of complexity

in spoken and written language. He asserted that speaking is syntactically complex, while writing is lexically complex. This view was partly supported by the studies of Poole and Field (1976) and Beaman (1984). More recent studies have shown that the linguistic characteristics of speech and writing often overlap in ways that reflect their text types, styles, production processes, purposes or communicative contexts. Still, it is also generally agreed that each mode of language is characterised and differentiated to a certain degree (Biber, 1988; Hughes, 1996; McCarthy, 2001).

The relationship between spoken and written English has contributed to developmental models of speech and writing. Studies on the interactive development of the speech and writing of both adult (e.g. Cayer & Sacks, 1979) and young (e.g. Hidi & Hildyard, 1983; Hildyard & Hidi, 1985; Kantor & Rubin, 1981; Kroll, 1981) native English speakers; and Vann's model (1981) for learners of English as a foreign language (EFL) all claim that 'initial' language learners are less able to differentiate their speech from their writing. It is mainly because their writing skills are not yet as developed as their spoken ones so their speech drives their writing. According to the language developmental models, language learners assimilate, differentiate and appropriately integrate spoken and written language as they improve their language skills (Kantor & Rubin, 1981; Kroll, 1981; Vann, 1981). In terms of pedagogic viewpoint, Tribble (1996) asserts that it is necessary to understand the differences between speech and writing in order to become a good writer (p. 16). From a broader sense, McCarthy (2001) states that "understanding these differences is a useful step on the road to better organisation of skill-based language teaching, offering a window into the immense variety of discourse-types that exist in our complex societies" (p. 94).

The differences between spoken and written English can be also considered from the perspective of *native-like selection*. According to Pawley and Syder (1983, p. 191), *native-like selection* is the ability of native speakers to convey their meaning by selecting an expression that is not only grammatical but also natural and idiomatic to native speakers' ears. This is not a matter of syntactic rules alone, nor of the complexity of the text, since even grammatically correct sentences can be non-native-like or highly marked (or typologically less frequent). The notion of native-like selection is usually applied to the choice of individual linguistic items or expressions. Still, it can be used as a metaphor to explain using linguistic features in the appropriate mode of language. There may be no clear boundary between native-like and non-native-like mode choice between speech and writing. However, just as not all possible utterances of English are actually suitable for use, not all of them are as appropriate for frequent use in speech as in writing (or vice versa) in an English-speaking community (Lewis, 1997).

Given these notions, productive language proficiency essentially involves the ability not only to speak and write but also to use and differentiate the two modes appropriately. It means that second or foreign language learners need to develop a certain degree of mode awareness between speech and writing for achieving ‘native-like’ spoken and written proficiency in their target language. From this perspective, there is a need to undertake a study comparing the two modes to assess the productive English proficiency of Korean EFL learners and their pedagogic implications for language teaching should be modified accordingly.

## **2. Aims of the Research**

On the basis of the above notions, this research aimed to compare the distribution of linguistic features in the spoken and written English of Korean and British university students and to measure native-like mode selection of the Korean EFL learners. The specific purposes of this research were:

1. To compare the spoken and written English abilities of the Korean and the British university students with respect to the occurrences of 45 linguistic features;
2. To examine the extent to which Korean EFL learners are able to differentiate appropriately between spoken and written English, as native English speakers do.

## **3. Data Collection**

### *3.1. Data Collection*

In order to develop the corpus for this study, four tasks were chosen from the spoken tasks of Sookmyung Women’s University-Multimedia Assisted Test of English (SMU-MATE, hereafter MATE). MATE is a selection of spoken and written English tests developed and administered by Koreans. MATE aims to have test-takers produce English samples in a variety of subject areas, which can be used to represent their overall English (van Vlack, 2002a). MATE tasks cover different levels of difficulty in using English. The MATE speaking test comprises eight tasks taking 25 minutes. The test-takers begin with relatively simple tasks such as requesting some basic autobiographical information (e.g. phone number, job, or free time activities). The test then moves on to more difficult tasks such as asking for a description of a picture, the

interpretation of information or an opinion. On the other hand, the MATE writing test consists of three tasks and participants [are allowed](#) 37 minutes to complete [it](#). As with spoken tasks, they are linearly arranged from the easiest to the most difficult.

Part of MATE was used in this research because firstly MATE has been acknowledged and authorised by the Korean MOE as one of the successful standardized spoken and written tests of English developed by Koreans for Korean EFL learners (SMU-MATE, 2008). Secondly, MATE is appropriate for Korean EFL learners, since it provides familiar contexts to them with the use of English in Korean society. This may help to avoid the possible tension that would be caused by the students having to perform the tasks in English. Thirdly, MATE tasks make it possible to collect language samples containing different levels of difficulty of English because they are arranged according to levels of difficulty across a wide scope of subject matter (van Vlack, 2002a).

Among the MATE spoken tasks, the easiest task along with the three most difficult tasks were excluded. Accordingly, only four speaking tasks of relatively modest difficulty were chosen for data collection. The tasks used for the data collection were arranged to increase in level of difficulty and each task contained at least one picture to prompt a descriptive narrative. The key directions for each task were as follows (see Appendix I for one task including a picture):

Task 1. Describe the girl in the picture;

Task 2. Describe the daily routine of a drama writer according to the six given pictures;

Task 3. Describe the event based on the six given pictures;

Task 4. Explain the graph.

The text type of the data to be collected was purely descriptive narrative. Narrative is a non-reciprocal and commonly used text type when someone recounts an anecdote to someone else (Beaman, 1984; Brown & Yule, 1983). Since this text type occurs in both speech and writing, it provides linguistically comparable spoken and written data. Thus, it has been often used in previous studies comparing the two modes of language (e.g. Beaman, 1984; Redeker, 1984; Tannen, 1982). Narrative, thus, is ideal to investigate the spoken and written English in an in-depth analysis in this research.

### *3.2. Participants*

In this research, 42 Korean and British university students were participated. For

the Korean participants, 21 students at Sookmyung Women's University in Seoul, Korea were chosen through undertaking the speaking test of MATE and the survey about their English language learning history. As a result, they were considered to be representative of Korean female university students with the average English ability and educational background.<sup>1</sup> They were aged between 20 and 22, and were studying different arts or science subjects at undergraduate level. At the time of data collection, they were in their third- or fourth-year in university.<sup>2</sup>

The British participants were chosen to be equivalent to the Koreans in terms of age and educational background. Twenty-one British female university students participated in this research and, at the time of data collection, they were in their second year of undergraduate study at the University of Manchester, UK.<sup>3</sup> They were aged between 20 and 22 years old and were also studying a range of arts and science subjects. For the British participants, no pre-assessment of their speech or writing was carried out.

### *3.3. Procedures for Collecting Data*

The selected tasks were carried out twice by the participants for gathering spoken and written data. They conducted the tasks first for speaking and later for writing, with a three-week interval between the two sessions. The same tasks were used twice to ensure the spoken and written English data would be linguistically comparable. In addition, the interval was applied to minimise the possible influence about writing caused by the familiarity on the tasks.

The time allocations to complete the tasks followed those given in the MATE test. Thus, the same thinking time (ranging 15 – 20 seconds) and response time (ranging 60 – 80 seconds) of the MATE speaking tasks was applied to the speaking in this research (see van Vlack, 2002a). On the other hand, when the tasks were used again for writing, the participants were given 40 minutes altogether to carry out the four tasks. This time limit was allocated because the moderate level MATE writing tasks are designed to be completed in 10 minutes each (see van Vlack, 2002b). As in the MATE writing test, the participants had to use their own judgment to allocate the given 40 minutes among the four tasks.

---

<sup>1</sup> The 21 Korean participants were chosen for they attained the level of 'Moderate High'. The statistics show that a total of 42.7% Korean MATE takers were at this level as of May 2004 (SMU-MATE, 2004). The participants had experienced about 10-year-old English language education from primary to tertiary education in Korea and had never studied abroad.

<sup>2</sup> University in Korea usually consists of eight semesters in four years (or four semesters in two years of vocational college).

<sup>3</sup> Most British university education consists of six semesters in three years.

## 4. Data Analysis

### 4.1. Linguistic Features Analysed in the Research

The selection of linguistic features for this research drew on Biber's study of 67 linguistic features (1988). From among these, the most appropriate 45 linguistic features for investigating the data in this research were selected. The features consist of grammatical classes (e.g. nouns, pronouns and adverbs), syntactic features (e.g. relative clauses, adverbial clauses and complement clauses) and lexical-grammatical features (e.g. modals, hedges and negations). They included all items where occurrences: (a) could be accurately identified within the data of both native and non-native English speakers; and (b) were not heavily constrained by the tasks used in this research (see Table 1).

TABLE 1  
Linguistic Features Analysed in this Research

45 Linguistic Features	
A. Lexical Features	1. <u>Standardised</u> Type/Token Ratio 2. Mean Word Length
B. Demonstratives	
C. Pronouns and Pro-verb <i>do</i>	1. Impersonal Pronoun <i>it</i> 2. Demonstrative Pronouns 3. Indefinite Pronouns 4. Pro-verb <i>do</i>
D. Nominal Forms	1. Nominalisations 2. Gerunds
E. Adjectives	1. Attributive Adjectives 2. Predicative Adjectives
F. Adverbs	
G. Specialised Adverb Classes	1. Downtoners 2. Hedges 3. Amplifiers 4. Emphatics
H. Stative Forms	1. <i>Be</i> as a Main Verb 2. Existential <i>there</i>

I. Perfect Aspect	
J. Passives	1. Agentless Passives 2. <i>By</i> -passives
K. Modal Auxiliary Verbs	1. Possibility Modals 2. Necessity Modals 3. Predictive Modals
L. <i>To</i> -infinitives	
M. Subordinations: Complementation	1. <i>That</i> Complements 2. WH-clause Complements

P. Subordinations: Adverbial Clauses	1. Causative Adverbial Subordinator 2. Concessive Adverbial Subordinators 3. Conditional Adverbial Subordinator 4. Time Adverbial Subordinators 5. Other Adverbial Subordinators
Q. Prepositional Phrases	
R. Conjuncts	
S. Coordination: <i>and</i>	1. Phrasal Coordination 2. Independent Clause Coordination
T. Negation	1. Synthetic Negation 2. Analytic Negation
U. Discourse Particles	

#### 4.2. Frequency Counting and Analysis Methods

The participants' speech was transcribed and their written texts were typed up, producing analysable spoken discourses and written texts. In these procedures, no alteration was made to correct errors, misspelled words, repetitions or inappropriate expressions made by the participants. The transcripts of the speech of the 21 Korean and the 21 British participants were merged into a single text file respectively. The 21

written scripts of each group of participants were also merged. As a result, four analysable spoken and written corpora were created and composed of 32,291 words in total, as Table 2 shows.

TABLE 2  
Number of Words in the Spoken and Written Data

Data of Korean Students		Data of British Students	
Speech	6,430	Speech	8,047
Writing	7,116	Writing	10,698
Total	13,546	Total	18,745
Total: 32,291 words			

The number of words in the spoken and written English of Korean and British participants varied. For this reason, in this study, the analysis of the frequencies of linguistic features was undertaken through a proportional approach. Indeed, a frequency index per 1,000 words was used for this study (cf. Beaman, 1984; Biber, 1988). The frequency index was calculated by dividing the actual number of occurrences of a linguistic feature by the total number of words in each text and multiplying by 1,000.

For counting the occurrences of the linguistic features analysed in the data, this research employed a combination of computational analysis and manual investigation, using the *Oxford WordSmith Tools 4.0* software. For each linguistic feature, comparative analyses were carried out in terms of the modes of language and of the English of the two groups of participants, in association with the linguistic functions of the features within the text.

## 5. Distribution of Linguistic Features

The distribution of 45 linguistic features revealed diverse and complicated results concerning the mode distribution of the linguistic features in the speech and writing of the Korean and the British participants. The overall distribution of the features is summarised here.

Firstly, overall, most of the linguistic features analysed occurred more frequently in the English of the British students than in that of the Korean students. Indeed, the native English speakers used 35 linguistic features more often than the Korean learners

did. There were, however, nine linguistic features which were used more frequently by the Korean students than the British students as follows (See Appendix II for the occurrences of the features):

Demonstratives, Predicative Adjectives, Amplifiers, <i>be</i> as a Main Verb, Conditional Adverbial Subordinators, Conjuncts, Phrasal Coordination, Independent Clause Coordination, Discourse Particles
--

For example, demonstratives occurred approximately twice as often in the speech and writing of the Korean learners as in that of the British students

Secondly, 24 of the linguistic features analysed showed the same mode distribution between speech and writing in the English of the Korean and the British students. Nineteen linguistic features, on the other hand, showed contrasting mode distribution between the speech and writing of the Korean and the British students as follows (See Appendix III for the occurrences of the features):

Features Favoured More in KS than in KW and Favoured More in BW than in BS
Demonstrative Pronouns, Downtoners, Amplifiers, Necessity Modals, Conditional Adverbial Subordinators
Features Favoured More in KW than in KS and Favoured More in BS than in BW
Impersonal Pronoun <i>it</i> , Indefinite Pronouns, Pro-verb <i>do</i> , Gerunds, Predicative Adjectives, Hedges, Emphatics, <i>Be</i> as a Main Verb, Existential <i>there</i> , Possibility Modals, WH-clause Complements, Causative Adverbial Subordinators, Phrasal Coordination, Analytic Negation

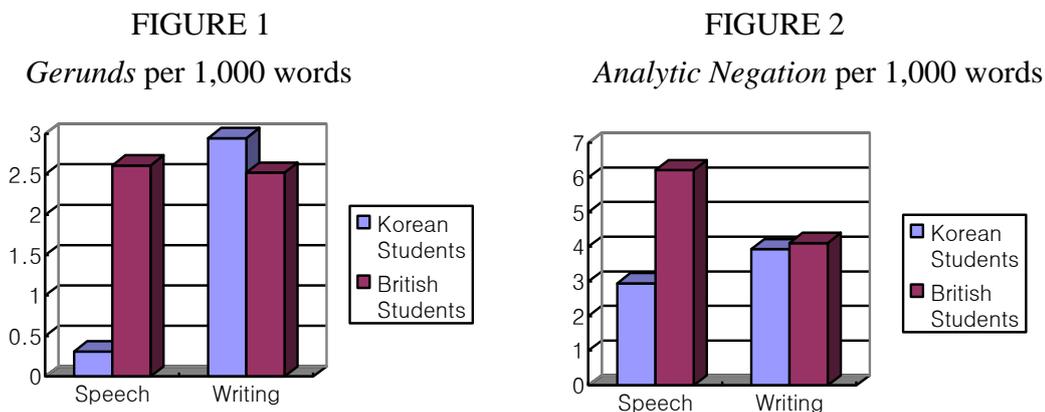

*Note.* KS stands for the speech of the Korean participants; KW for the writing of the Korean participants; BS for the speech of the British participants; and BW for the writing of the British participants.

For example, impersonal pronoun *it* occurred more often in the writing than in the speech of the Korean participants, whereas this feature appeared more often in the speech than in the writing of the British participants.

## 6. Conclusions

The distribution of linguistic features was explored from a broader and more

explanatory perspective. This allowed for two over-arching conclusions to be drawn. Firstly, the Korean students' written English was more native-like than their spoken English. The distributions of gerunds and analytic negation, shown in Figures 1 and 2, provide evidence of this.

This finding indicates that the Korean students had more difficulty in speaking than in writing English. Interestingly, the Korean university students' better English proficiency in writing than in speech does not mirror the existing language developmental models for native English speakers in childhood (e.g. Kantor & Rubin, 1981; Kroll, 1981) and even Vann's model (1981) which is designed specifically for EFL learners. Vann states that as the learners' English abilities improve, they write with great care to avoid errors, but speak comparatively fluently. In this regard, the English ability of the Korean students in this study reveals a contrasting developmental relation between speech and writing, since they were better in written English than in speech.

Secondly, to a certain degree, the Korean students wrote as the British students spoke. This is exemplified by the distributions of hedges and possibility modals in the data, as shown in Figures 3 and 4. Approximately 75% of the difference in the mode distribution of such features between the two groups of participants is explained by the fact that the Korean students overused the features in their writing. In other words, the Korean participants used these items as features of writing, while the British participants used them as features of speech.

FIGURE 3

*Hedges per 1,000 words*

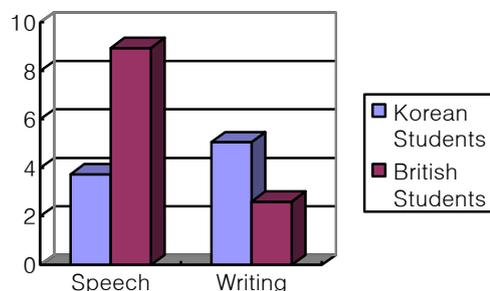

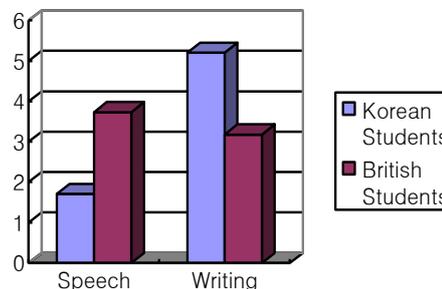

FIGURE 4

*Possibility Modals per 1,000 words*

This is probably because the differentiation of the language modes of the Korean learners was more prone to be driven by their writing than by their speech and, as shown earlier, the Korean learners had better English proficiency in writing than in speech. Therefore, when they confused their language mode selection, they wrote as the British students would speak, rather than speaking as their British counterparts would write.

## 7. Closing Remarks

It has been shown that the characteristics of the English of the Korean learners indicate that their abilities are more advanced in writing than in speech. In addition, the Korean learners struggle to develop native-like mode selection between speech and writing in English. Based on these findings, brief suggestions are made to improve the English proficiency of Korean learners within a classroom ELT context in Korea. Firstly, it is recommended that English grammar and vocabulary should be taught by integration into communicative spoken and written activities, so the learners will have more opportunities to productively (rather than receptively) use the linguistic features in English. Secondly, it could be suggested that teachers should use authentic and up-to-date spoken and written English materials in class in order to increase the students' exposure to the current English.

## Abstract

This paper investigates cancellation of intervention effects (IE) in Korean without recourse to scrambling. Scrambling has been long considered as the only way to cancel IE, since Beck (1996)'s work. It is observed, however, that a D(iscourse)-linked *wh-in-situ* also has the same effect as scrambling. Along this line of reasoning, this paper explores a possibility that scrambling can be understood as an instance of D-linking, given the assumption that a scrambled *wh-in-situ* is associated with an existence of presupposition which is the characterization of D-linking.

**Keywords:** intervention effects, scrambling, D-linking, presupposition, negative *wh*-questions

## 1. Introduction

This paper investigates cancellation of intervention effects (IE) in Korean by a D-linked *wh-in-situ*. By common consent, scrambling of a *wh-in-situ* phrase over an intervener has been considered as the only way to circumvent the ungrammaticality of sentences induced by intervention effects (Beck 1996, Beck and Kim 1997, *inter alia*). It is observed, however, that there is another way to circumvent intervention effects without recourse to scrambling, and D-linking property of *wh-in-situ*, in particular the association with an existence of presupposition carried by D-linking, appears to be responsible for the cancellation of IE without scrambling. It follows then that there is a possibility that scrambling can be alternatively understood as an instance of D-linking, and the main goal of this paper is to explore the possibility that the cancellation of intervention effects can be uniformly understood in terms of parallelism between scrambling and D-linking following Erteschik-Shir (1997) offering an account of negative *wh*-questions, which corresponds to the configuration of intervention effects.

## 1.1 Issues

There are certain configurations in Korean and Japanese as well as other languages where a *wh*-in-situ cannot be preceded by a certain type of expression, such as NPIs, and focus-bearing elements as illustrated in (1-2):

### (1) Korean

- a. \***Amwuto** *mwues-ul ilk-ci anh-ass-ni?*  
anyone what-Acc read-Comp Neg-Past-Q  
'What did no one read?'
- b. ??**John-man**<sub>i</sub> *nwu-ka t<sub>i</sub> manna-ss-ni?*  
John-only who-Nom meet-Past-Q  
'Who met only John?'

### (2) a. Japanese

- \***Taroo-sika** *nani-o kawa-nakat-ta no?*  
Taro-only what-Acc buy-Neg-Past Q  
'What did only Taro buy?' (Takahashi 1990)

### b. Hindi

- ??**Koi nahiiN** *kyaa paRhaa*  
anyone not what read-Perf.M  
'What did no one read?' (Beck 1996a, ba)

### c. Turkish

- \***Kimse kimi görmedi?**  
anyone who-Acc see-Neg-Past?  
'Whom did nobody see?' (Beck 1996a, ba)

The examples in (1-2) have been described as exhibiting *intervention effects*, given the assumption that there is a group of expressions preventing an interpretation of a *wh*-in-situ (Beck 1996, Beck and Kim 1997, Y. Choi 2007, Hagstrom 1998, Hoji 1985, A. Kim 2006, S. Kim 2002, Ko 2005, Miyagawa 2002, Szabolcsi 2006, Tomioka 2007, inter alia). Interestingly, it has been observed that the sentences in (1-2) become grammatical when a *wh*-in-situ is scrambled over the NSI as in examples (3-4):

(3) Korean

- a. *Mwues-ul<sub>i</sub> amwuto t<sub>i</sub> ilk-ci anh-ass-ni?*
- b. *Nwu-ka John-man manna-ss-ni?*

(4) a. Japanese

*Nani-o<sub>i</sub> Taroo-sika t<sub>i</sub> kawa-nakat-ta no?*

b. Hindi

*Kyaa<sub>i</sub> koi nahiiN t<sub>i</sub> paRhaa?*

c. Turkish

*Kimi<sub>i</sub> kimse t<sub>i</sub> görmedi?*

The fact that scrambling of a *wh*-in-situ is obligatory to avoid the ungrammaticality of a sentence induced by intervention effects has drawn lots of attention, since scrambling in Korean and Japanese is optional. For this reason, the leading idea of intervention effects, mainly proposed by Beck (1996), has claimed that intervention effects are constraints on LF movement of a *wh*-in-situ (also Hagstrom 1998, Hoji 1985, A. Kim 2006, Ko 2005, Miyagawa 2002, Szabolcsi 2006, Takahashi 1990). In the line of Beck (1996) (also Beck and Kim 1997), intervention effects have been considered as a violation of LF movement constraints where scope-bearing elements prevent a *wh*-in-situ from moving to SpCP at LF. Beck proposes two LF licensing conditions as in (5), and (6-7) illustrate intervention effects and the cancellation of intervention effects by scrambling respectively:

(5) a. Quantifier Induced Barrier (QUIB)

The first node that dominates a quantifier, its restriction, and its nuclear scope is a Quantifier Induced Barrier (QUIB)

b. Minimal Quantifier Structure Constraint (MQSC)

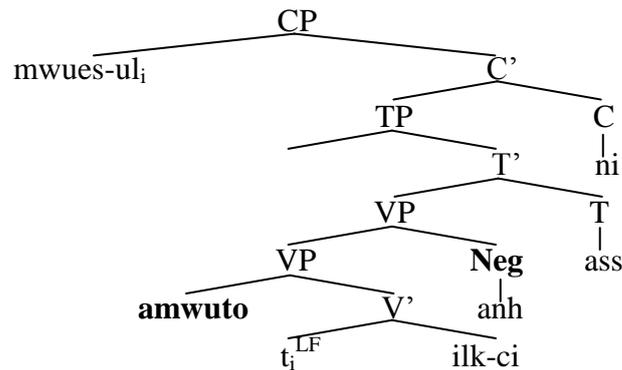

If an LF trace  $\beta$  is dominated by a QUIB  $\alpha$ , then the binder of  $\beta$  must also be dominated by  $\alpha$ . (Beck 1996:39)

(6) a. \**Amwuto mwues-ul ilk-ci anh-ass-ni?*

anyone what-Acc read-Comp Neg-Past-Q

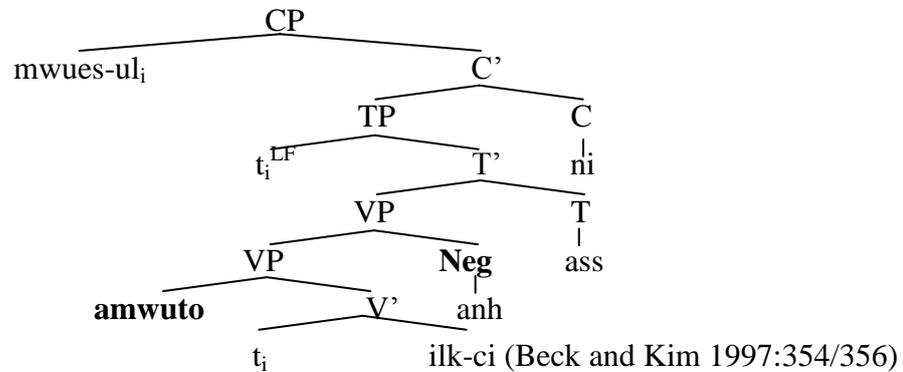

‘What did no one read?’

b.

- (7) a. Mwues-ul amwuto ilk-ci anh-ass-ni?  
 what-Acc anyone read-Comp Neg-Past-Q

b.

However, the quantificational approach faces the major problem that not all scope-bearing elements induce intervention effects. To resolve this problem, several approaches have been lined up to answer to the question of how to define the natural class of problematic interveners, and the question of how scrambling of a *wh*-in-situ salvages the grammaticality in terms of non-movement based approach. On one hand, Beck (2006) and S. Kim (2002) propose that interveners should be construed as focus-bearing elements. On another hand, Tomioka (2007) claims that intervention effects are the result of ill-formed information structure.

## 2. D-linking

Although each theoretical approach to intervention effects has its own issues, one thing remains certain in every approach that scrambling of a *wh*-in-situ over a problematic intervener has been considered as the only way to save the grammaticality of the sentence. For example, under the LF movement approach, scrambling is not supposed to be subject to the LF constraints given in (5-6), since scrambling is overt movement, not

LF movement. However, it appears that scrambling is not the only way to cancel intervention effects. Consider the following example:

- (8) a. \***Amwuto** *mwues-ul* ilk-ci        **anh-ass-ni?**  
 anyone    what-Acc   read-Comp   Neg-Past-Q  
 ‘What did no one read?’
- b. *Ulysses, Dubliners, Finnegans Wake-cwung,*  
*Ulysses, Dubliners, Finnegans Wake-among,*  
**amwuto** *mwues-ul* ilk-ci        **anh-ass-ni?**  
 anyone    what-Acc   read-Comp   Neg-Past-Q  
 ‘Among *Ulysses, Dubliners* and *Finnegans Wake*, what did no one read?’

The wh-phrase in (8b) occurs in an intervening position for licensing of the subject NSI, but the sentence still comes out grammatical without recourse to scrambling of the wh-in-situ, which is in contrast to (8a). The contrast between (8a) and (8b) lies in whether a relevant discourse is provided to limit the range of possible answers to the wh-in-situ phrase *mwues-ul*. As a result, the wh-in-situ in (8b) is associated with an existence of presupposition provided by the previous discourse *Ulysses, Dubliners, Finnegans Wake-cwung*. In contrast to (8b), the wh-in-situ in (8a) is not necessarily associated with an existence of presupposition, and the result comes out ungrammatical.

The existence of presupposition associated with a wh-phrase can be characterized as the “characterization of D-linking” (Pesetsky 1987, 2000). Pesetsky (1987) argues that the role of D-linking is to limit the range of possible answers, so discourse participants can draw a felicitous answer to the question from the set established in the discourse. This is what we exactly observe in (8b).

The presuppositionality of a D-linked wh-phrase is also evaluated in example (9):

- (9) (*John is looking at empty dishes all eaten by his younger brother and saying....*)
- a. **Nay-ka** **mwues-ul** mek-eya-hal-ci        molu-keyss-e.  
 I-Nom    what-Acc    eat-should-do-Comp   not.know-Decl  
 ‘I don’t know what I should eat.’
- b. \***Nay-ka** **enu umsik-ul** mek-eya-hal-ci        molu-kess-e.  
 I-Nom    which food-Acc    eat-should-do-Comp   not.know-Decl  
 ‘I don’t know which food I should eat.’ (inspired by von Stechow 1998)

*Which*-phrase is considered as D-linked inherently unlike other *wh*-phrases. The ungrammaticality of (9b) is caused by the fact that the *wh*-in-situ *enu umsik-ul* ‘which food’ cannot be properly D-linked, because the previous discourse in (9b) allegedly denies the presupposition associated with ‘which food’. There is no problem in (9a), however, because *mwues-ul* ‘what’ in (9a) is not necessarily D-linked.

It is not difficult to find D-linked contexts where intervention effects disappear without scrambling of a *wh*-in-situ. First of all, when a sentence ends with the Q-morpheme *-nuntey* instead of *-ni*, intervention effects do not show up:

- (10) a. \***Amwuto** *nwukwu-lul* manna-ci anh-ass-**ni**?  
 anyone who-Acc meet-Comp Neg-Past-Q  
 ‘Who didn’t meet anyone?’  
 b. **Amwuto** *nwukwu-lul* manna-ci anh-ass-**nuntey**?  
 anyone who-Acc meet-Comp Neg-Past-Q  
 ‘Who didn’t meet anyone?’

The Q-morpheme *-nuntey* only selects a *wh*-interrogative reading of a *wh*-word in Korean (Jang 2001), unlike another Q-morpheme *-ni* which can select either an indefinite or a *wh*-interrogative reading of a *wh*-word in Korean:

- (11) a. John-i chayk-ul ilk-ess-**ni**?  
 John-Nom book-Acc read-Past-Q  
 ‘Did John read a book?’  
 b. \*John-i chayk-ul ilk-ess-**nuntey**?

Interestingly, the Q-morpheme *-nuntey* forces a *wh*-in-situ to have a D-linked interpretation, whereas *-ni* does not necessarily have. The D-linking property of *-nuntey* is evidenced by the fact that a *wh*-word cannot appear in discourse-initial position when marked by *-nuntey*:

- (12) Q: a. John-i mwues-ul ilk-ess-**ni**?  
 John-Nom what-Acc read-Past-Q  
 ‘What did John read?’  
 b. \*John-i mwues-ul ilk-ess-**nuntey**? (discourse-initial)

Since the *-nuntey* marked wh-phrase cannot appear in a discourse-initial position, it is supposed that *-nuntey* gives rise to some sort of existence presupposition associated with the wh-in-situ, which accords with the main characterization of D-linking.

Second, a topic-marked wh-in-situ does not trigger intervention effects, although it appears at the intervening position. Given the assumption that topics are discourse-familiar, a topic-marked wh-phrase is definitely D-linked:

- (13) a. \***Amwuto** *nwukwu-lul* manna-ci **anh**-ass-ni?  
           anyone    who-Acc    meet-Comp   Neg-Past-Q  
       b. **Amwuto** *nwukwu-nun* manna-ci **anh**-ass-ni?  
           anyone    who-Top    meet-Comp   Neg-Past-Q  
           ‘Who did no one meet?’

Third, *which*-phrase, which is generally considered to be D-linked, also cancels intervention effects without recourse to scrambling:

- (14) **Amwuto** *enu mwuncey-lul* pwul-ci **anh**-ass-ni?  
           anyone    which question-Acc   solve-Comp   Neg-Past-Q  
           ‘Which question did nobody solve?’

From this, it seems obvious that there are two ways to circumvent intervention effects, one by scrambling and the other by D-linking. According to Pesetsky (1987), D-linked wh-phrases are not supposed to undergo LF movement, so cancellation of intervention effects by D-linking might not pose a problem for the movement-based approach, in particular based on LF wh-movement. This is because the LF movement-based approach could postulate that intervention effects are supposed to target only non-D-linked wh-in-situ phrases. However, when we juxtapose a property of a scrambled wh-in-situ with that of a D-linked wh-phrase, it appears that there is a parallelism between them. This strongly suggests that scrambling can be alternately construed as an instance of D-linking, and therefore cancellation of intervention effects by scrambling of a wh-in-situ is uniformly analyzed as the effort to circumvent intervention effects by D-linking.

Boeckx and Grohmann (2004) discuss parallel behaviors between scrambling and D-linking. They point to the parallel behaviors of D-linked wh-phrases and scrambled elements (in particular, long-scrambled elements in Japanese) with respect to the Superiority Condition, discourse effects, semantic vacuity, insensitive to island effects,

and clitic doubling. Some of properties, which both D-linked wh-phrases and scrambled elements seem to share, are also found in Korean. First, neither D-linked wh-phrases or scrambled elements obey the Superiority Condition:

- (15) a. **Nwukwu-eykey<sub>i</sub> mwues-ul<sub>j</sub>** John-i t<sub>i</sub> [Mary-ka t<sub>j</sub>  
 who-Dat what-Acc John-Nom Mary-Nom  
 ilk-ess-ta-ko] malhay-ss-ni?  
 read-Past-Decl-Comp say-Past-Q  
 ‘Who did John tell that Mary read what?’
- b. \***Mwues-ul<sub>j</sub> nwukwu-eykey<sub>i</sub>** John-i t<sub>i</sub> [Mary-ka t<sub>j</sub> ilk-ess-ta-ko]  
 mal-hayss-ni?
- (16) a. **Enu-haksayng-eykey<sub>i</sub> enu-chayk-ul<sub>j</sub>** John-i t<sub>i</sub> [Mary-ka t<sub>j</sub>  
 which-student-Dat which-book-Acc John-Nom Mary-Nom  
 ilk-ess-ta-ko] malhay-ss-ni?  
 read-Past-Decl-Comp say-Past-Q  
 ‘Which student did John tell that Mary read which book?’
- b. ?**Enu-chayk-ul<sub>j</sub> enu-haksayng-eykey<sub>i</sub>** John-i t<sub>i</sub> [Mary-ka t<sub>j</sub>  
 ilk-ess-ta-ko] mal-hayss-ni?

As in (15-16), the non-D-linked wh-phrases *mwues-ul* ‘who’ and *nwukwu-lul* ‘what’ are sensitive to the Superiority Condition, whereas the D-linked *enu haksayng* ‘which student’ and *enu chayk* ‘which book’ are not. The same pattern is observed in scrambled elements as follows:

- (17) a. **John-eykey<sub>i</sub> ku chayk-ul<sub>j</sub>** Bill-i t<sub>i</sub> [Mary-ka t<sub>j</sub>  
 John-Acc that book-Acc Bill-Nom Mary-Nom  
 ilk-ess-ta-ko] malhay-ss-ta.  
 read-Past-Decl-Comp say-Past-Decl  
 ‘Bill told John that Mary read that book.’
- b. **Ku-chayk-ul<sub>j</sub> John-eykey<sub>i</sub>** Bill-i t<sub>i</sub> [Mary-ka t<sub>j</sub> ilk-ess-ta-ko]  
 malha-ss-ta.

Second, interpretations of both D-linked wh-phrases and scrambled elements depend on previously established discourse. It is generally accepted that *which*-phrases generally construed as D-linked cannot easily appear in an “out-of-blue” context:

(18) John bought something expensive yesterday.

a. **What** did he buy?

b. #**Which** car did he buy? (Boeckx and Grohmann 2004)

(19) John-i ecey nwukwu-lul manna-ss-e.

John-Nom yesterday who-Acc meet-Past-Decl\

‘John met somebody yesterday.’

a. **Nwukwu**-lul manna-ss-ni?

who-Acc meet-Past-Q

‘Who did he meet?’

b. ??**Enu haksayng**-ul manna-ss-ni?

which student-Acc meet-Past-Q

‘Which student did he meet?’

This is because *which*-phrases require discourse-dependent interpretations compared with other *wh*-phrases such as ‘what’ in (18).

Third, Boeckx and Grohmann (2004) point out that movement of D-linked *wh*-phrases and scramble elements are semantically vacuous, and thus both *wh*-phrases and scrambled elements must be interpreted in their original position. Concerning D-linked *wh*-phrases, Rullman and Beck (1998) argue that *which*-phrases must be interpreted in base position, so that *which*-phrases in SpCP in surface syntax must undergo reconstruction into its original position. This is because the presupposition associated with *which*-phrases is projected from the *which*-phrase’s base position. One of the main pieces of evidence for the reconstruction of *which*-phrases is that Karttunen’s theory of question (1977) cannot explain the *de dicto* reading of *which*-phrases as Groenendijk and Stokhof (1982) point out:

(20) a. Which students called?

b. Karttunen (1977)

$\lambda w \lambda p \exists x [\text{student}(w)(x) \ \& \ p(w) \ \& \ p = \lambda w' [\text{called}(w')(x)]]$

c. {John called, Mary called}

As in (20c), the information that John and Mary are students is not a part of the propositions. However, there is a case that a speaker must be aware of that John and Mary are students, which is the *de dicto* reading of the *which*-phrase. To resolve this, Rullmann and Beck put *which*-phrases within the translation of the question as given in (21):

(21) Rullman and Beck (1998)

- a.  $\lambda w \exists x [p(w) \ \& \ p = \lambda w' [\text{student}(w')(x) \ \& \ \text{called}(w')(x)]]$
- b. {John is a student who called, Mary is a student who called}

Like D-linked wh-phrases, scrambled elements undergo reconstruction too. As shown below, the scrambled universal quantifier NP *enu chaykina* does not have a wide scope with respect to the existential quantifier *nwukwunka*:

(22) *Enu chaykina*<sub>i</sub>    **nwukwunka**    Mary-ga    t<sub>i</sub>    ilk-ess-ta-ko  
every book    somebody    Mary-Nom    read-Past-Decl-Comp  
malhay-ss-ta  
say-Past-Decl

- a. For some x, x is a person, x thinks that for every y, y is a book, Mary read y.
- b. ??For every y, y is a book, there is some x, x is a person, such that x think that Mary read y.

The lack of the wide scope reading of the universal quantifier in (22b) shows that the scope of the scrambled element is confined within its original position, and the scrambled element is supposed to undergo reconstruction.

To this point, this section has discussed the parallel behaviors between scrambled elements and D-linked wh-phrases, providing convincing evidence as to the idea that scrambling can instantiate a D-linking process. The next section will explore the possibility of what kind of a principled account can capture a parallelism between scrambling and D-linking in a consistent manner in terms of the nature of negative wh-questions discussed in Erteschik-Shir (1997).

### 3. Possibilities

Given that the configuration of intervention effects corresponds to the one in which a wh-phrase is questioned over a NPI associated with negation, I propose here that the cancellation of intervention effects by D-linking can be manifested within the correlation between discourse properties of negation and that of a wh-phrase based on a focus-structure analysis given by Erteschik-Shir (1997). Erteschik-Shir (1997) discusses how a focus structure analysis captures several discourse phenomena. Her main theoretical mechanism is based on the concepts of topic and focus to explain how information structure of a sentence can be understood within the correlation between these two pri-

mitive notions. Although there is a substantial amount of literatures on discourse analyses on the basis of focus-structure, the discussion here focuses on Erteschik-Shir (1997)'s analysis of negation and wh-questions to show how her analysis can uniformly capture the cancellation of intervention effects by scrambling and D-linking.

Let us first discuss the discourse properties of negation. Erteschik-Shir (1997) discusses that the function of negation is to eliminate one of the members of a restrictive set. Consider example (23):

$$(23) \text{ John didn't [eat } \left( \left\{ \begin{array}{l} [\text{the PIZZA}]_{\text{FOC}} \\ \text{delicacy}_1 \\ \text{delicacy} \end{array} \right\} \right)_{\text{TOP}} ]_{\text{FOC}} \text{ (Erteschik-Shir 1997:102)}$$

In example (23), the restrictive set is constructed along the contextually determined discourse. The focused NP *pizza* in (23) is construed as one of the members in the restrictive set composed of implicit subordinate topics including *delicacy* as in (23). Since the focused NP *pizza* is associated with negation, it is removed from the restrictive set by the function of negation, which is to eliminate one of the members of a restrictive set.

From this, let us return to intervention effects, in particular involving NPIs:

(24) a. \***Amwuto** *mwues-ul* *ilk-ci* **anh-ass-ni?** (non-D-linking)  
 anyone what-Acc read-Comp Neg-Past-Q  
 ‘What did no one read?’

b. *Ulysses, Dubliners, Finnegans Wake-cwung,*  
*Ulysses, Dubliners, Finnegans Wake-among,*  
**amwuto** *mwues-ul* *ilk-ci* **anh-ass-ni?**  
 anyone what-Acc read-Comp Neg-Past-Q  
 ‘Among *Ulysses, Dubliners* and *Finnegans Wake*, what did no one read?’

Concerning the configuration of intervention effects, where a wh-in-situ is questioned over a NPI, a NPI is also supposed to introduce a set of restrictive contexts along the contextually determined dimension, since the interpretation of NPI depends on the appearance of negation. It follows then that when a wh-phrase is questioned over a NPI just like (24a), which corresponds to the configuration of intervention effect, it is expected that only D-linked wh-phrase, which is associated with the existence of presupposition, can provide such kind of a restrictive set. Erteschik-Shir proposes that D-

linked wh-phrases have a subordinate structure in which a NP associated with *which* is introduced as the topic which is contextually constructed as given in (25):

- (25) a. *who* (non-D-linked): [who]<sub>FOC</sub>  
 b. *which student* (D-linked): [[which]<sub>FOC</sub> [student]<sub>TOP</sub>]<sub>TOP</sub>

In her analysis, a *which*-phrase known to be D-linked consists of a subordinate f-structure, where the *which* part is construed as a focus and the NP ‘student’ associated with *which* provides a contextually determined set of ‘students’. This is in contrast with non-D-linked wh-phrases such as *who* as in (25a), which does not necessarily have a subordinate f-structure. Based on this, it becomes clear why D-linked wh-phrases circumvent intervention effects without scrambling of a wh-in-situ. Since D-linked wh-phrases are able to provide a restrictive set which is contextually determined, it is possible for a NPI associated with negation to eliminate one of the members from the restrictive set. However, non-D-linked wh-phrases do not necessarily introduce the restrictive set for partitioning by negation, and intervention effects emerge.

Along the same line of reasoning, why a scrambled wh-phrase saves the grammaticality of sentences nicely falls out. Consider example (26) where intervention effects are obviated by scrambling of a wh-in-situ over a NPI:

- (26) *Mwues-ul<sub>i</sub> amwuto t<sub>i</sub> ilk-ci anh-ass-ni?*  
 what-Acc anyone read-Comp Neg-Past-Decl  
 ‘What did no one read?’

When a wh-in-situ is fronted by scrambling, the fronted position is guaranteed for being interpreted as the topic of a sentence. Given the assumption that the nature of topic is associated with presupposition, a scrambled wh-phrase is also supposed to provide the restrictive set for partitioning, just like D-linked wh-phrases. This is why the grammaticality of a sentence is salvaged by scrambling of a wh-in-situ.

#### 4. Conclusion

This paper has examined the possibility that the cancellation of intervention effects by scrambling can be construed as an instance of D-linking process. This line of reasoning has been evidenced by the fact that a D-linked wh-phrase also cancels intervention effects without scrambling, which has been construed as the only way to cancel

intervention effects. If the current assumption is on the right track, a slew of studies claiming that scrambling is a purely optional movement operation, so scrambling is semantically vacuous (Saito 1989) seem to be in question. However, the discussion about scrambling is beyond the scope of discussion here, so I will leave it for the future research.

# **Analysis of Linguistic Expressions for motion events in English, German and Korean**

**Kangho Lee**

(Hanyang University, Seoul, Korea)  
Dep. of German Language & Literature,  
Hanyang University, 17Heangdang-dong,  
Seungdong-ku, 133-791, Seoul Korea  
Email: liekangh@hanyang.ac.kr

This work is a linguistic analysis of motion events in English, German and Korean with a focus on the analysis of two different languages, German and Korean. Two main points will be covered. First, the typological status of the Korean language from the view point of Cognitive Linguistics will be determined. Second, the issue of what type of German expressions could be candidates for the expressions of motion will be examined. Until now, the German expressions that include both prefix (=prefix verb) and particle (=particle verb) are known to be semantically equivalent. In this work, I will argue that the semantics of the two words are different, although their function in a certain context is the same. The Particle verb in German can have a prepositional argument, which denotes the “Path” according to Talmy (1996). However, this is not obligatory or explicitly presented. This paper examines the interesting theoretical question of how the semantics of German particle verbs are interpreted in context. Another issue is whether Korean can fit into Talmy’s typological categories as the motion expressions in Korean show great variation and are therefore too difficult to assign to one of the categories. As far as the typological classification of German is concerned, it cannot be treated as a *satellite* language as before, because of the productive use of the particle verb as a new stem whose function is not restricted to express “Manner” but extends to “Path” in the sense of Talmy. The results can be taken as the establishment of objects in the expression of motion events in languages, so that the analysis may help further contrastive inquiry in this field in English, German and Korean.

**Keywords:** typology, particle verb, expressions of motion, *satellite*, verb-framed languages

## **1. Previous works in Talmy’s frame: contrastive Korean and English**

There have been many attempts in linguistics to provide a typology of languages, Schlegel, Humboldt, Greenberg. Talmy’s typology and Slobin’s research on *manner* salience have been a recent source of interest to researchers investigating interactions between language and thought. However, questions have been raised about the accuracy of these attempts.

I would like to talk about three points related to the accuracy of current linguistic typologies of language: First, I introduce previous works using Talmy’s frame, especially the contrastive analysis of Korean and English. Second, Lexicalization of Motion Events in Korean is discussed, and finally Prefix verbs vs. Particle verbs in

German are analysed.

I would like to talk about three points: First, I introduce previous works using Talmy's frame, especially the contrastive analysis of Korean and English. Second, Lexicalization of Motion Events in Korean is discussed, and finally Prefix verbs vs. Particle verbs in German are analysed.

While studying Talmy's framework, it came to my attention that Korean may not work according to Talmy's typological categories because the motion expressions in Korean are too diverse and therefore too difficult to assign to one of the categories. Talmy's framework also does not work with German.

Talmy (1991, 2000) has argued that probably all languages of the world can be categorized in terms of verb-framing or satellite-framing. The group of verb-framed languages includes all-Romance languages, Semitic languages (e.g. Arabic and Hebrew), Japanese and many others. Satellite-framed languages besides English and German are all Indo-European languages (apart from the Romance languages), Finno-Ugric languages and Chinese.

According to Talmy, a (dynamic) motion event has four basic components:

*Motion*: Presence of motion.

*Figure*: The moving object.

*Ground*: The reference-point object with respect to which the Figure moves.

*Path*: The course followed by the Figure with respect to the Ground.

As Loucks and Pederson said, these components seem intuitively essential in describing any act of motion.

Let me explain with examples supplied by Ungerer and Schmid concerning the analysis of motion event with their examples.

(1) *E. The boy went **out** of the yard.*

(2) *G. Der Junge ging aus dem Hof **hinaus**.*

“The boy went from the yard **out**.”

(3) *Fr. Le garçon **sortit** de la cour.*

“The boy **exited** from the yard.”

(4) *Sp. El chico **salió** del patio.*

“The boy **exited** from the yard.”

These examples show two things. First, English express the *Path* by means of a particle, and French incorporates the *Path* in the verb meaning. Second, it is evident that German runs parallel to English and Spanish parallel to French. In German the *Path* is expressed in a verbal particle (here separated from the complex verb *hinausgehen* and moved to clause-final position), and this is similar to the English particle. In Spanish, on the other hand, the *Path* is incorporated in the verb just like in French.

To give you an idea of how straightforward the difference between French and Spanish on the one hand and English and German on the other hand is, a comparison is presented in Table I to show you the major verbs expressing motion.

Table I. *Motion* and *Path* in major verbs of motion in French, Spanish, English and German

French	Spanish	English	German
entrer sortir ascendre descendre traverser	entrar salir Subir (ascender) Bajar (descender) traspasar	go in (enter) go out (exit) go up (ascend) go down (descend) go over (cross, traverse)	hineingehen hinausgehen hinaufgehen hinuntergehen hinübergehen

For English this is notably true of the combinations with the verb *go*, which is of Germanic origin and belongs to the core vocabulary. As the verbs in parentheses show, the English verbs of Latin origin are also available, but they belong to more formal stylistic level and are therefore less frequent.

Turning to the expression of *Manner* in the description of motion events, the four languages pair off exactly in the same way. To show this, I will again first give an example of a whole sentence as rendered in the four languages, where this time the linguistic elements denoting the *Manner* component are highlighted:

(5) E. *The boy **rode** out of the yard.*

(6) G. *Der Junge **ritt** aus dem Hof hinaus.*

“The boy rode from the yard out.”

(7) Fr. *Le garçon sortit **à cheval** de la cour.*

“The boy exited **on horse** from the yard.”

(8) *Sp. El chico salió a caballo del patio.*

“The boy exited **on horse** from the yard.”

In English and German the *Manner* of the movement is incorporated in the verb, while in French and Spanish the *Manner* is added as a separate adverbial.

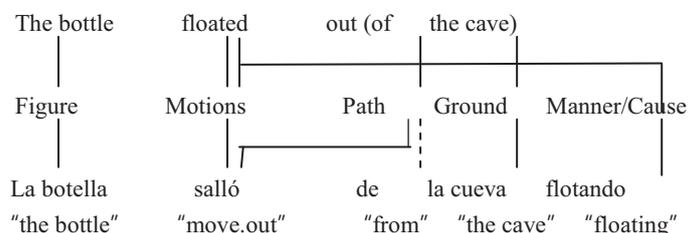

Table II. Expression of *Motion*, *Manner* and *Path* in verbs of motion in English, German, French and Spanish

English	German	French	Spanish
(a) <i>Motion + Manner</i>			
walk ride drive	(zu Fuß) gehen reiten fahren	aller à pied aller à cheval aller en vitute	ir a pie montar caballo (ir a caballo) Ir en coche (conducir)
(b) <i>Motion+ Manner+Path</i>			
walk into drive into ride into fly into crawl into cimb into	hineingehen hineingahren hineinreiten hineinfliegen hineinkriechen hineinklettern	entrer en marchant entrer en voiture entrer à cheval entrer en volant entrer en rampant entrer en grimpant	entrar (caminando) entrar conduciendo el coche entrar a caballo entrar volando entrar arrastrándose entrar escalando

While *Manner* is an optional element, a component of the co-event in Talmy’s terminology that can remain unexpressed, *Path* is one of the central elements of the framing motion event. One way of expressing the framing function of *Path* is through the verb, as in French *entrer* and Spanish *entrar*. In view of this, French and Spanish can be called verb-framed languages (Talmy 1991: 481, cf. 2000: 117, 221). Conversely, *Path* can be rendered by a particle, as in English *go into*, or by a verbal particle, as in German *hineingehen*. To capture the common function of these last two elements, they have been subsumed in one grammatical category by Talmy, labelled *satellites*. Hence, English and German can be called satellite-framed languages. Table III is a slightly simplified version of a diagram Talmy uses to summarize his results.

Table III. Typology of Motion Events: Expression of *Path* and *Manner* in motion events in English and Spanish (based on Talmy 1991, cf. 2000: 49ff.)

**English: satellite-framed**

**Spanish: verb-framed**

So far, I have roughly tried to explain Talmy’s framework, so that I could apply it to Korean examples for further discussion. Now, I would like to introduce the work of Choi and Bowermann (1991) , who analyzed Korean with Talmys framework. By providing many examples, Choi and Bowermann argued that Korean presents a mixed picture. In transitive clauses for caused motion, Korean conflates *Motion* with *Path*, like Spanish. But in intransitive clauses for spontaneous motion, Korean encodes *Motion*, *Path* and (optionally) *Manner* or *Cause* with separate constituents, a pattern not described by Talmy.

To explain motion events in Korean, let me begin with Choi and Bowerman (1991: 88) in more in detail.

- (9) *John-I pang-ey (ttwui-e) tul- e o- ass- ta*  
 J.- Subj room-LOC (run-CONN) enter-CONN come-PST-DECL  
 [Figure] [Ground] ([Manner]) [Path] [Motion+Deixis]  
 “John came in(to) the room (running).”

- SUBJ-Subject marker
- OBJ-Object marker
- LOC- Locative marker
- CONN- Connection suffix
- PST – Past tense marker
- DECL – Declarative ending
- CAUS – Causative suffix

In this example, *John* is the *Figure*, and *Pang* (room) is the *Ground*. The locative suffix – *ey* (to, at) on *Pang* indicates only that *Pang* represents the goal or location of the event specified by the verb. The fact that John changed his location is specified by

the rightmost verb, *o-* (come). John's *Path* with respect to the Ground is specified by the verb *:tul-* (enter). John's *Manner* of motion is specified by *ttwui-* (run).

Choi and Bowerman thought that *Manner* in Korean, *ttwui*, is expressed as a type of event as you can see in example 9. However, I think that it is neither a verb nor a auxiliary verb, but an adverb, which can be easily verified by adding the suffix *-se*: *ttwui-e-se*. The suffix *-se* has the function "to transfer original verb to an adverb." This would be a further criteria that would be used to decide whether it is a compound verb or not. In contrast to Korean, *Motion* in English is characteristically conflated with *Manner* or *Cause*, and *Path* is expressed separately by prepositions or particles (Talmy 1985).

The combination [Motion+Manner] in English, for example, is found in

- (10) *The rock **slid/rolled/bounced** down (the hill).*
- (11) *John **walked/skipped/ran** into the room.*
- (12) *John **slid/rolled/bounced** the keg into the storeroom.*

The combination [Motion+Cause] is seen in

- (13) *The wind **blew** the napkin off the table.*
- (14) *John **pushed/threw/kicked** the keg into the storeroom.*

The combination [Motion+Deixis] is also found in English, as in

- (15) *John **came/went** into the room and John **took/brought** the keg into the storeroom.*

As these clauses illustrate, English uses the same verb connotations in both intransitive clauses expressing spontaneous motions and transitive clauses expressing motions caused by an agent. In addition, it marks *Path* in the same way in clauses of both types, using prepositions and particles like *in (to)*, *out (of)*, *on (to)*, *off*, *up*, *down*, and *away*.

In English, it is often obligatory to spell out *Path* rather completely, even when it can be readily inferred from context. If we heard,

- (16) *John threw his key **to** his desk/ **to** his drawer.*

we could reasonably suppose that the keys ended up *on* the desk or *in* the drawer. Still, according to Choi und Bowerman, these clauses sound odd: *on* and *in* are needed. Even when it is grammatical to specify *Path* less completely, fuller information is often given, especially in everyday speech; compare 17 with 18.

(17) *John took his keys **from** his desk/ **from** the drawer (a bit formal or bookish)*

(18) *John took his keys **off** his desk/**out** of the drawer (completely colloquial).*

In Korean, in contrast, a *Path* verb can often be omitted if a transitive verb expressing the Cause of the motion is supplied. According to Choi and Bowerman (1991: 94), this can be redundant to Korean speakers.

(19) *John-I yelswey-lul chayksang-ey tency-ess-ta.*  
 John-SUBJ key-OBJ desk-LOC throw-PST-DECL

“John threw keys **to** desk.”

(20) *John-I yelswey-lul chayksang-ey tency-e noh- ass- ta.*  
 John-SUBJ key-OBJ desk-LOC throw-CONN put-on-PST-DECL

Furthermore, Choi and Bowerman find example (20) very unnatural, but I think it is quite normal. And I think, it should be interpreted as redundant in true sense, that is, it could be omitted, but it could also stay. This brings a very theoretically interesting point, that is, it should be named “pleonastic,” which express a similar construction with the same reason, i.e. a pleonastic prepositional phrase, which I would like to explain more in detail by analyzing German. The principle is the same, even if the two languages are radically different.

To summarize, English uses the same verb conflation patterns in both intransitive clauses expressing spontaneous motion and transitive clauses expressing caused motion, and it encodes *Path* separately with the same *Path* markers (particles and prepositions) whether the clause is transitive or intransitive. Korean, in contrast, uses different

lexicalization pattern for spontaneous motion and caused motion, and most of its *Path* markers (verbs) in the two cases are distinct.

I have tried to explain the difference between Korean and English in the critical point of view by dealing with the previous work of Choi and Bowerman, which is also based on Talmy's Framework. Let me summarize it with Table IV.

Table IV. Comparison of English and Korean conflation patterns for motion events

English		Korean		
Spontaneous motion				
Verb [Motion + Manner] [Motion + Cause] [Motion + Deixis]	Particle [Path]	Verb [Manner]	Verb [Path]	Verb [Motion + Deixis]
Caused Motion				
Verb [Motion + Manner]	Particle [Path]	Verb [Cause]	Verb [Motion + Path + Deixis]	

To classify these differences, Talmy (1991, 2000) has developed a typology, that is, a verb-framed language: *Path* expressed by the main verb in a clause vs. Satellite-framed languages where *Path* is expressed by an element associated with the verb. We can easily find the usefulness of this classification by the translation between German and French clauses, in which the aspectual meanings are expressed by different word classes. We can see it in (21).

- (21) (a) *Der Vogel flog herein*  
*l'oiseau entra en volant*
- (b) *Er hinkte davon*  
*il s'éloigna en boitant (d'un pas boitant, de son pas boitant etc.)*

Working within Talmy's framework, Slobin (1996) also addressed this exact issue in a comparative study of translations of English-language novels into Spanish and vice versa. As Ungerer and Schmid,

by looking at the cross-linguistic differences from the cognitive perspective of the event-frame in which they are embedded, the difficulties faced by translators become more transparent. Thus, what seems to be at stake is not just a random collection of *untranslatable* verbs, but completely different mapping systems of cognitive frame components onto linguistic elements. (Ungerer & Schmid 2006: 235)

In Table IV, we can see that English matches well with Talmy's frame, that is, English can be classified as a satellite-framed languages in the typology. However, Korean cannot be consistently classified into any class of Talmy's typology. According to Choi and Bowerman, Korean presents a somewhat less obvious picture. In transitive clauses for caused motion, it conflates *Motion* with *Path*, like Spanish. However, in intransitive clauses for spontaneous motion, it encodes *Motion*, *Path* and *Cause* with separate constituents, which is a pattern not described by Talmy. In other words, Choi and Bowerman suggested a few Korean examples that may not work under Talmy's frame. In addition to that suggestion, I would like to add more reasons to argue that Talmy's Framework is not appropriate for classification of Korean in typology.

## 2. Lexicalization of Motion Events in Korean

With Talmy's framework, I start with Korean examples of a single verb, which express motion in various basic components:

(22) [Motion+ Deixis]: *kata* (go), *ota* (come)

[Motion+PATH]: *oleta* (ascend), *naylita* (descend), *kenneta* (go over), *tolta* (turn around)

[Motion+MANNER]: *kita* (creep), *ketta* (go on foot), *ttuita* (run or jump), *tallita* (dash), *nalta* (fly), *heyumchita* (swim)

In Korean, motion events rarely occur with single verbs, but are more likely to occur with a compound verb. Concerning the classification of verbal phrases, I have in a recent paper (Lee 2007b: 282) classified three groups of phrases.

perspective of “caused motion,” the combination shows too much variation. Because of this variation of Korean, I conclude that Korean does not belong to any classification Talmy has created.

### 3. Prefix verb vs. Particle verb in German

We have seen that the *Manner* of the movement is incorporated in the verb in German in contrast to Spanish or French, in which *Path* is incorporated.

- (25) a. Gr. *gehen, laufen, rennen, hinken, schleichen, hüpfen, bummeln, staksen*  
(*go (on foot), run, dash, limp, creep, jump, stroll, stalk*)  
b. Sp. *Entrar (enter), salir (exit), subir (ascend)*  
c. Fr. *Entrer (enter), sortir (exit), moter, descendre, avancer, reculer*

Let me illustrate with examples in which a simple verb and a verb with prefix (=prefix verb) and verb with particle (=Particle verb) are expressed in a clause. For German examples, I borrow some examples from Olsen (1996: 314).

- (26) a. *Er fährt seinen Jeep durch das überschwemmte Gelände.*  
“He passed in his Jeep through the overflowed region.”  
b. *Er durchfährt das überschwemmte Gelände mit seinem Jeep.*  
“He passed through the overflowed region in his Jeep.”  
c. *Er fährt seinen Jeep durch.*  
“He passed through in his Jeep.”

Motion events include conceptually the initial and the end place (=P-relation), functions most prepositions have when they are used as adverbials in the form of a prepositional phrase. Initial is usually the position of the object represented.

In (26)b and (26)c, incorporation of the P-relation to semantic of motion verb combines *Manner* and *Path*. However, the result of this operation is different according to type of verb. In (26)b, the object of preposition is found in the direct object with the effect of focusing on the aspect of *Path* and consequently weakening the aspect of

*Manner*. When “das überschwemmte Gelände” is used as a direct object, it gains an additional function that was not available when used as an object of the preposition. When the internal argument of the P-relation lies in the scope of P-predication, it is escalated to be the object of prefix verb and consequently lies in scope of verbs of *Manner*. This demands a change of view, that is, the stretch is treated as a homogeneous and closed section. When we illustrate it, it looks something like this:

Table VI. Object of prefix verb: scope of *Manner* verbs

In the illustration in Table VI, a circle indicates a region, which seems to be a unit. For the building of prefix verb this representation of P-relation is typical. That is, the inner argument of P-relation is raised the direct object of prefix verb.

- (27) a. *Er spritzt Wasser auf Passanten.*  
 “He sprays water on a passenger.  
 ➤ *Er bespritzt Passanten mit Wasser.*  
 “He sprinkles a passenger with water.”
- b. *Er streut Zucker über den Kuchen.*  
 “He powders sugar on the cakes.”  
 ➤ *Er überstretu den Kuchen mit Zucker.*  
 “He powders cakes with sugar.”
- c. *Sie zieht eine goldenen Faden durch die Handarbeit.*  
 “She interweaves a golden string with her hands.”  
 ➤ *Sie durchziehen die Handarbeit mit einem goldenen Faden.*  
 “She interweaves handwork with a golden string.”
- d. *Er fliegt seine Maschine unter das feindliche Radarsystem.*  
 “He flies the plane under the radar system.”  
 ➤ *Er unterfliegt mit seiner Maschine das feindliche Radarsystem.*  
 “He underflies the radar system with the plane.”

The Particle verb in German also has virtually or implicitly the prepositional argument. However, this is not obligatory or explicitly presented like (26c). Olsen (1996: 309) has already described this in formal semantic terms based on the notation of Wunderlich (1993) with another example *auflegen* (put on). She distinguished between the function of *auf* as prefix and the function of particle.

- (28) a. auf: [-v, -n,  $\alpha$ dir]  $\lambda v \lambda u [\{\alpha \text{ BECOME}\}(\text{LOC}(u, \text{AUF}^*[v]))]$   
 b. auf: [-v, -n, +Part]  $\lambda u \exists v [\{\alpha \text{ BECOME}\}(\text{LOC}(u, \text{AUF}^*[v]))]$

Contrary to (26b), the particle verb retains the grammatical relation, but changes the relation between direct object and P-relation. Particle verb presupposes that the region of *durchfahren* is known, so that *Manner* is more focused than *Path*. That is, with application of existential binding of inner argument, the *Manner* is automatically more focused.

Concerning the difference between prefix and particle, Stiebels and Wunderlich (1994: 953) said:

There is only one specific function of particles that is not available for prefixes. Since particles are taken from the set of prepositions or adverbs, they can saturate one of the verb's arguments in certain instances, in particular a PP argument.

It seems that they give emphasis to the parallel semantic equivalence, when they are used in text. However, P-relation is not saturated in particle verb, but *unterdrückt* (oppressed) (Olsen 1996: 311).

Consequently P-relation in particle verb is often not expressed, as we can see in the following (29), in which P-relation is symbolized with bracket.

- (29) a. *Sie bauen einen Seitenflügel an (das Hauptgebäude).*  
 "She is going to build a side panel right next to (the center building)."  
 b. *Sie schrieb die Formeln auf (einen Zettel).*

- “ She wrote down (a formula).”
- c. *Sie leiten den Verkehr um (die Stadt).*  
 “They detour traffic (the city).”
- d. *Er fuhr seinen Jeep durch (das überschwemmte Gelände).*  
 “ He passed by his Jeep through (the overflowed region).”
- e. *Wir fahren mit der Fähre über (den Fluß).*  
 “We take a ferry across (the river).”

I have tried to explain until now, that Particle verbs express P-relation that is not obligatory. That is, it is optional. P-relation can be expressed, or left to context as in example (30).

- (30) *Sie legt eine Folie auf.* (for example: *auf den Projektor/den Kopierer/...*)  
 “She puts a transparency on.” (for example: on the project/ the copier)

This delivers to us a very interesting theoretical question: How can the Lexeme and the Context interact in Text or in producing Text by speaking? I have addressed this problem recently (Lee 2007a). I have observed the different functions of preposition, on one hand when it denotes static location like 31 and on the other hand when it denotes dynamic change of location as in 32.

- (31) *Die Verkehrspolizistin steht **auf** der Strasse.*  
 “The (female) traffic police stands on the street.”
- (32) *Peter schob den LKW **in** die Garage.*  
 “Peter parks the truck in the garage.”

According these different functions, I describe two semantic representations of (31) and (32) in (33)a and (33)b.

- (33) a. Präp.[dir]  $\lambda w \lambda v$  [LOC(v, PRäP\*(w))]  
 b. Präp.[+dir]  $\lambda w \lambda v$  [BECOME(LOC(v, PRäP\*(w)))]

BECOME means the change of location like 28. There are two types of location: when intransitive motion verb is used like (34a), and transitive motion verb is used, like (35b).

- (34) a. *Manfred eilte in die Tagesbar.*  
 “Manfred rushes into the bar.”  
 b. *Peter schob den LKW in die Garage.*  
 “ Peter parks the truck in the garage.”
- (35) a. SF:  $\lambda P\lambda x[\text{EIL}(x) \ \& \ \text{MOVE}(x) \ \& \ P(x)]$   
 b. SF:  $\lambda P\lambda y\lambda x\lambda s[s\text{INST}[\text{SCHIEB}(x,y) \ \& \ \text{MOVE}(y)\ \& \ P(y)]]$

In (35b), INST is two arguments predicate. That connect proposition and variable of situation. Variable is determined according to modus in clause and tempus. See Bierwisch (1989) for details.

The semantic representations of preposition in (34a,b) are same and can be represented as (33b). However, particle verb, which does not denote one concrete argument, cannot express one argument of P-Relation, so semantic representation of the particle is shown in (36).

- (36) Part.[+dir]  $\lambda v [\text{BECOME}(\text{LOC}(v, \text{PR}\ddot{a}\text{P}^*(u))]$

In this sense, I agree with Stiebel when he argued that semantic representation of particle verb include as a substitute of one inner argument *ungebundene Parameter* (not linked) (1996: 88). This could be determined in context according to the Levelt model on SF based conceptual structure (=CS). To summarize, the semantic representation of a Particle is different from that of preposition, in other words, the prefix in prefix verb is compositional and a particle of the particle verb is a sort of application.

The function of a particle is different not only from a preposition, but also from the function of an adverb in a clause. Let’s see the following example. I translate German to English literally.

- (37) *Er läuft durch den Wald durch.*

“He runs through through the forest.”

(38) a. *Er ist durch den Wald [durchgelaufen].*

“He has run through through the forest.”

b. *Er ist [durch den Wald durch] gelaufen.*

“He has run through the forest through.”

When we transform clause (37) into perfect tense, we get two clauses like (38a) and (38b). In (38a), the verb *durchlaufen* is as particle verb and contrary, in (38b), a simple verb with a complex argument. Therefore, (37) is understood as ambiguous.

PP in (39), in which a particle is used, functions as a modifier of particle verb *durchlaufen* (run through). Contrary to This, PP in (40), in which *durch* functions as adverb, functions as a complement to the simple verb *laufen*.

(39) *Er ist [pp durch den Wald] durchgelaufen.* PP= Modifier to *durchlaufen*

(40) *Er ist [pp durch den Wald durch] gelaufen.* PP= complement to *laufen*

With this criterion, we can choose the particle verb as a candidate, which could express *Path* in the motion of event. The same criterion is adapted already in the describing of the Motion event in Korean, that is, when the component of motion is the form of adverb expressed, we exclude this expression.

Preposition, adverb and particle are based on very similar relations to each other. The question, whether *durchlaufen* exists as a unit or a complex construction of two units, i.e. *durch* and *laufen* after grammatical operation of joining together, is a sort of fundamental question concerning the organization of grammar. Even if the meanings of clause (38a) and (38b) as a whole are semantically equivalent, when they are used in text, I think, the particle verb *durchlaufen* is a new independent Lexeme, which is not related to the base verb *laufen*. Its semantic form I have above shown.

I have tried until now to explain that the function of prefix, adverb and particle are different. However, are they also different, when Particle verb is used with PP, even if PP is not necessary? This is *plenatische direktionale* (pleonastic directional) in the sense of Olsen (1996).

- (41) a. *Sie legte eine Folie **auf den Projektor auf**.*  
 “She puts a transparent foil on the projector.”
- b. *Sie schüttet das Wasser **aus dem Eimer aus**.*  
 “She empties the water from the bucket.”
- c. *In Brot wird noch ein /b/ **vor die Lautfolge** /rot/ vorgeschaltet.*  
 “In (german word) Brot a /b/ is proceeding before the sound sequence of /rot/.”
- d. *Sie setzen nachts unbemerkt **über den Sund von Schweden über**.*  
 “She crosses over nights unnoticed across the Sund of Sweden.”  
 (= “She crosses the board of the Sund of Sweden overnight in secret.”)

Verbs like *legen*, *schütten*, *schalgen*, *setzen*, *drängen* etc. are verbs of motion or verbs of caused motion that denote *Manner*.

We have seen in (29) already, that Particle verb *unterdrückt* (oppressed) the P-relation. In other words, the development of Particle verb has its origin in oppressing the inner argument. Despite this function, we can ask questions like “why is the pleonastic directional introduced and expressed again.” The function of pleonastic directional is a sort of compensation. To be specific, use of pleonastic-directional compensates the weakening of the *Path* which is derived from using the particle verb, especially when the meaning of *Manner* is not suitable to the context.

In this regard, I agree with Olsen (1996: 327): “Das Deutsche ist [...] keine echte Modus-Sprache” (When I translate literally, “German is not a real candidate for a *Manner-language*”)

#### 4. Conclusion and Discussion

The motion event in Korean is so diverse, that it is not appropriate to classify Korean using the Typology of Talmy (1996). German is also not captured in Typology of Talmy, for a different reason than in Korean: particle verb is recently very often used and according to its function, it has the status of new stem. Its function is not restricted to express *Manner* but extends to *Path*, so it cannot be classified as a satellite language

in the sense of Talmy's typology.

When I consider these facts, I think, I can foretell three directions for typological research. First, we can extend the ways of doing typological research by modifying Talmy's framework, for the reason that *satellite* in Talmy's work is too restricted, as Matsumoto (2007) has recently asserted. He thinks that *Path* can be encoded by a nonsister of a verb. In this way, we may be able to solve the problem superficially. For example, we can embrace as a candidate of *Path* denoting expressions, the prepositional phrase in Korean and German, which is named by Olsen *pleonastische Direktionale* (=pleonastic directional)(cf. Olsen 1996). However, when if we pursue it this way, there is one problem, that is, it is difficult to differentiate between a preposition and a Particle in each case, especially concerning German because they can have the same function in a certain context.

Second, we can approve the possibility of particular languages (in plural form), "Technique of individual language" in the sense of Coseriu that can be represented as an abstract Form, that embrace the expression in context, as we demonstrate in semantic representation in describing German. However, we would not be able to solve the problem completely using this approach. For example, divergence comes out in German, that is, German cannot be easily classified. It is difficult to decide whether it belongs to verb-framed languages or satellite-framed languages.

Two ways above presuppose anyway, that Talmy's framework could nevertheless exist, despite its theoretical weakness. However, with Talmy's framework Korean cannot be classified to any Group, neither verb-framed languages nor satellite-framed languages. We can consequently regard Korean as an exceptional case. However, I think, it is not a satisfactory solution.

Third, we could search for another way to investigate so that we do not regard Talmy's framework as the starting point of research anymore, because in Korean, due to the diversity of Motion expressions, cannot be classified in the two ways above. We can only determine the tendency of any language from the point of view of typology. In other words, we cannot determine a language as a unit of any particular classification because language and its configuration change with time. Thus, the change of meaning of Lexeme demands not only a synchronic but also a diachronic point of view. Therefore, we need an alternative approach; that is, we need more abstract type of

typology that can include the dynamics of languages. In other words, in typological research, we need to work on establishing a new “type of type” to which Coseriu (1988) gives the name “Typus.”

## Abstract

The interpretation of tenses in Japanese complex sentences involves the tense markings of both matrix and subordinate predicates, Aktionsarten of the predicate, and the hierarchical level to which the subordinate clause belongs. While this is a complicated enough task, a problem still remains of why the tense interpretation is affected by Minami's (1974) four-level sentential hierarchy, as many other linguistic phenomena are. This paper addresses these questions. We show that the behaviour of tenses result from general mechanisms invoked during a semantic evaluation, specifically from local vs. broad opening of bindings and from restrictions on what bindings are licensed to be open.

## 1 Introduction

This paper presents a unified account of a significant set of linguistic data involving tense in Japanese complex sentences which seemingly must undergo complicated interpretations. We start with the observation that the behaviour of this kind of tense reflects the hierarchical structure of Japanese sentences posited by Minami (1974) which is associated with heterogeneous linguistic facts including scopes of modalities, focus, topic/subject coreference, etc. This makes the complex tenses a part of regularities which are found throughout the Japanese syntax. Using Scope Control Theory (Butler 2007), a semantic system that facilitates fine-grained management of scopes, we give an explanation of the linguistic data, arguing that the tense interactions are brought about by placement restrictions and a semantics with operator-variable dependencies.

## 2 The Minami Hierarchy

Subordinate clauses in Japanese sentences have been observed by Minami (1974) to behave differently in relation to whether various constituents can occur within them. A subject is not included in the type of subordinate clause with the most strict limitations labeled 'Level A':

- (1) Tarō **ga** [uwagi wo nui]<sub>A</sub> de hangā ni kake-ta.  
 NAME NOM jacket ACC undress SCC hanger LOC hang PAST  
 ‘Taro took off his jacket and hung it on a hanger.’

A certain group of auxiliary verbs and adverbials are not allowed in this kind of subordinate clause, either. For example, the negative (*nai*), past (*ta*), polite (*masu*), and tentative/voluntative (*ō/darō*) auxiliaries and tense and place adverbs are illicit, whereas the causative and passive auxiliaries (*(sa)seru/(ra)reru*) can occur in this group of subordinate clauses.

In another type of subordinate clause, those labeled ‘Level B’, a subject may appear:

- (2) [**Tarō ga** uwagi wo nugu]<sub>B</sub> to Haruko ga hangā ni kake-ta.  
 NAME NOM jacket ACC undress SCC NAME NOM hanger LOC hang PAST  
 ‘Taro took off his jacket and Haruko hung it on a hanger.’

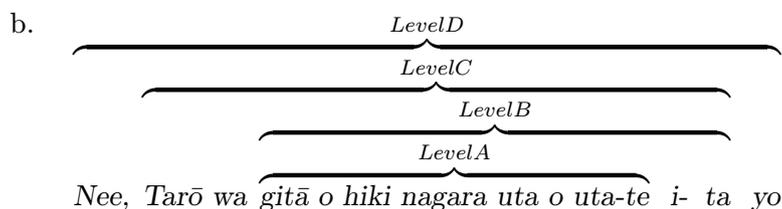

Those constituents that were not allowed in Level A subordinate clauses, the negative, past, polite, and tentative/voluntative auxiliaries and tense and place adverbs are appropriate if embedded in this kind of subordinate clause.

Lastly, Level C subordinate clauses can contain constituents that are ungrammatical within a Level B subordinate clause, a topic for instance.

- (3) [**Haruko wa** Itaria e it-ta]<sub>C</sub> ga, Akiko wa Supein e it-ta.  
 NAME TOP Italy GOAL go PAST ADVS NAME TOP Spain GOAL go PAST  
 ‘Although Haruko went to Italy, Akiko went to Spain.’

Minami extends his idea from syntax of subordinate clauses to the general structure of the Japanese sentence. According to him, levels A, B, C, and D, with D being the outermost level equivalent to a complete sentence, constitute a layered structure, with the outer levels enclosing the inner levels. Sentence (4a) is analysed into four hierarchical levels as shown in (4b).

- (4) a. Nee, Tarō ga gitā wo hiki nagara uta wo utat-te i- ta  
 ADDR NAME NOM guitar ACC play SIML song ACC sing PROG PST  
 yo.  
 MDLP  
 ‘I will tell you, Taro was singing a song, playing the guitar.’

It is known that heterogeneous linguistic facts such as topic/subject coreference and focus in complex sentences are involved with this hierarchy.

### 3 Tense in Complex Sentences

The interpretation of tense in Japanese subordinate clauses is determined by (i) tense marking of the subordinate predicate, (ii) Minami’s hierarchical level the

subordinate clause belongs to, (iii) tense marking of the matrix predicate, and (iv) Aktionsarten (dynamic vs. stative) of the predicates.

In the Level A subordinate clause, the predicate is always without tense marking. Its tense is interpreted to be identical with that of the matrix predicate.

- (5) Tarō ga [shimbun o yomi]<sub>A</sub> **nagara** gohan o taberu.  
 NAME NOM newspaper ACC read SUCC meal ACC eat-NPST  
 ‘Taro will eat reading the newspaper.’  
 ( $E_s = E_m$ ,  $n < E_m$ )

In the following,  $n$ ,  $E_m$ ,  $E_s$  stand for the utterance time and the eventuality times of the matrix and subordinate clause.  $=$ ,  $<$ , and  $\subseteq$  indicate temporal equality, linear order, and inclusion.

In Level B subordinate clauses, the predicate is tense-marked either by the presence of a past auxiliary verb *ta* or its absence. Its temporal information is interpreted, depending on

- (i) the subordinate predicate tense marking,
- (ii) the matrix predicate tense marking, and
- (iii) the subordinate predicate Aktionsarten (dynamic vs. stative).

When the matrix predicate is with the past tense marker *ta*, the eventuality time of the subordinate clause is interpreted in relation to that of the matrix clause. In (6a), the eventuality time of the embedded dynamic predicate *sotsugō-suru* (graduate-NONPAST) is later than that of the matrix predicate *ryokō-shi-ta* (travel-PAST). Note that the sentence provides no explicit information about whether the former is earlier than the utterance time (i.e., past) or later (i.e., future). In (6b), the eventuality time of the subordinate predicate *sotsugyō-shi-ta* (graduate-PAST) precedes that of the matrix predicate.

- (6) a. [Haruko ga sotsugyō-suru]<sub>B</sub> **node** issho-ni ryokō-shi-ta.  
 NAME NOM graduate-NPST CAUS together travel PST  
 ‘Because Haruko is/was going to graduate, I made a trip with her.’ ( $E_m < n$ ,  $E_m < E_s$ )
- b. [Haruko ga sotsugyō-shi-ta]<sub>B</sub> **node** issho-ni ryokō-shi-ta.  
 NAME NOM graduate PST CAUS together travel PST  
 ‘Because Haruko had graduated, I made a trip with her.’  
 ( $E_s < E_m < n$ )

If the subordinate predicate is stative and is without past tense marking as in (7a), its eventuality time is construed as being simultaneous with that of the matrix predicate. To put it more formally, the former includes the latter. If the subordinate predicate is *ta* marked as in (7b), its eventuality time is earlier than that of the matrix predicate as in (6b) with the dynamic subordinate predicate.

- (7) a. [Haruko ga yasun-de iru]<sub>B</sub> **node** denwa-shi-ta.  
 NAME NOM take time off PROG-NPST CAUS call PST  
 ‘Because Haruko was absent, I called her.’  
 ( $E_m \subseteq E_s$ ,  $E_m < n$ )

Table 1: Tense in subordinate clause with past matrix sentence

	Dynamic	Stative
non- <i>ta</i> (non-past)	$E_m < E_s$	$E_m \subseteq E_s$
<i>ta</i> (past)	$E_s < E_m$	

- b. [Haruko ga *yasun-de* *i-* *ta*]<sub>B</sub> **node** *denwa-shi- ta*.  
 NAME NOM take time off PROG PST CAUS call PST  
 ‘Because Haruko had been absent, I called her.’  
 ( $E_s < E_m < n$ )

Table 1 summarises the temporal relationships between the eventuality times of the matrix and subordinate clauses and the utterance time, in case the latter is marked by *ta*.

By contrast, when the matrix predicate is not marked by *ta*, the tense of the subordinate clause is interpreted in relation to the utterance time. The eventuality time of the subordinate non-past dynamic predicate *sotsugyō-suru* (graduate-NONPAST) as in (8a) is later than the utterance time. In other words, it is to happen in the future. If the subordinate predicate is *ta*-marked, its eventuality time is earlier than the utterance time: it stands in the past.

- (8) a. [Haruko ga *sotsugyō-suru*]<sub>B</sub> **node** *issho-ni ryokō-suru*.  
 NAME NOM graduate-NPST CAUS together travel-NPST  
 ‘Because Haruko is going to graduate, I will make a trip with her.’ ( $n < E_m, n < E_s$ )
- b. [Haruko ga *sotsugyō-shi- ta*]<sub>B</sub> **node** *issho-ni ryokō-suru*.  
 NAME NOM graduate PST CAUS together travel-NPST  
 ‘Because Haruko graduated, I will make a trip with her.’  
 ( $E_s < n < E_m$ )

The utterance time also plays an essential role in the case of embedded stative verbs. In (9a), where the subordinate predicate is with the non-*ta* form, it indicates a state which holds at present. If the embedded verb is suffixed with *ta*, it stands in the past.

- (9) a. [Haruko ga *yasun-de iru*]<sub>B</sub> **node** *kanashii*.  
 NAME NOM take time off PROG-NPST CAUS be sad-NPST  
 ‘Because Haruko is absent, I am sad.’  
 ( $n \subseteq E_s, n \subseteq E_m$ )
- b. [Haruko ga *yasun-de* *i-* *ta*]<sub>B</sub> **node** *kanashii*.  
 NAME NOM take time off PROG PST CAUS be sad-NPST  
 ‘Because Haruko was absent, I am sad.’  
 ( $E_s < n \subseteq E_m$ )

Table 2 outlines the tense interpretation of subordinate clauses in case the matrix clause is in the non-past form.

Finally, tense interpretation of the Level C subordinate clause is made totally independent of that of the matrix clause. A non-*ta*-marked subordinate dynamic

Table 2: Tense in subordinate clause with non-past matrix sentence

	Dynamic	Stative
non- <i>ta</i> (non-past)	$n < E_s$	$n \subseteq E_s$
<i>ta</i> (past)	$E_s < n$	

predicate as in (10a) is construed as meaning an event happening in the future, regardless of the tense of the matrix predicate. Similarly, a *ta*-marked predicate in the subordinate clause, as in (10b), stands for an event that takes place in the past.

- (10) a. [Haruko wa Supein e *iku*]<sub>C</sub> **ga** Akiko wa Itaria e *it- ta*.  
 NAME TOP Spain GOAL go-NPST ADVS NAME TOP Italy GOAL go PST  
 ‘Although Haruko will go to Spain, Akiko went to Italy.’  
 ( $E_m < n, n < E_s$ )
- b. [Haruko wa Supein e *it- ta*]<sub>C</sub> **ga** Akiko wa Itaria e *it- ta*.  
 NAME TOP Spain GOAL go PST ADVS NAME TOP Italy GOAL go PST  
 ‘Although Haruko went to Spain, Akiko went to Italy.’  
 ( $E_m < n, E_s < n$ )

#### 4 Scope Control Theory

The analysis of tense in Japanese complex sentences that this paper offers will be formulated in terms of Scope Control Theory or SCT (Butler 2007). SCT is a small logical language which attempts to approximate the dependency structures in natural languages by fine-grained and restricted scope management. It does this by combining ideas from the static setup of dynamic semantics by Dekker (2002) and Cresswell (2002) with the sequence semantics of Vermeulen (1993).

In the appendix, SCT evaluation is defined with a translation  $(g, e)^\circ$ , taking assignment  $g$  and SCT expression  $e$  and returning a translation into a formula of predicate logic notation. An assignment is a mapping that assigns a (possibly empty) sequence of predicate logic variable names to each SCT name. Such translation provides a ‘snapshot’ of the dependencies semantic evaluation establishes. If desired, translation could be replaced by a full semantic evaluation, returning truth conditions with respect to models.

The building blocks of SCT expressions are six operators:

- **Use**  $(x, e)$  Supports scope creation or binding
- **Hide**  $(x, e)$  Terminates usage count
- **T**  $(x, i)$  Builds a term for name  $x$
- **Close**  $(x, e)$  Creates fresh scopes for  $x$  based on usage count
- **Lam**  $(x, y, e)$  Shifts a scope’s binding name from  $x$  to  $y$
- **Rel**  $(\vec{x}, \vec{y}, r, \vec{e})$  Builds a relation  $r$  with sequence of arguments  $\vec{e}$ , changing the assignment for each argument based on SCT name sequences  $\vec{x}$  and  $\vec{y}$

```
(16) let rel s l = Rel (nil, nil, s, l) in rel "smiles" [T ("x", 0)] ≡
      (λrel.rel "smiles" [T ("x", 0)])(λs.λl. Rel (nil, nil, s, l)) →
      (λs.λl.Rel (nil, nil, s, l) "smiles" [T ("x", 0)] →
      (λl.Rel (nil, nil, "smiles", l) [T ("x", 0)] →
      Rel (nil, nil, "smiles", [T ("x", 0)]))
```

We will also utilise `case` expressions with the form of (17), allowing for the construction of an expression that performs a case analysis based on the result of pattern matching.

```
(17) case exp
      of pattern_1 => exp_1
       | pattern_2 => exp_2
       ...
       | pattern_n => exp_n
```

The idea is that `exp` is evaluated by attempting to match it to one of the patterns, in the given order. When a successful match occurs, the variables contained in the pattern are bound to their matching values, and the corresponding expression is evaluated to give the result of the overall `case` expression. For example, the expression of enriched notation (18) reduces to (19).

```
(18) letrec clean n name f =
      (case n
       of 0 => f
        | n => Lam (name, "r", clean (n-1) name f)
       )
      in clean "x" 2 T ("r", 0)
```

```
(19) Lam ("x", "r", Lam ("x", "r", T ("r", 0)))
```

The reduction of (18) involves a recursive call to `clean`, which has patterns to match either 0 or a number greater than 0 supplied as the second parameter. The recursive call decreases by one the number of the second parameter and terminates when this is 0.

## 5 Tense in Simple Sentences

For the interpretation of tense, we introduce two binding names, `"ev"` (event time) and `"it"` (intermediate time), on which time values (scopes) can be stacked.

We can use SCT to instrument and observe the behaviour of dependencies by making points of an evaluation sensitive to what should and should not be present as a binding. We will see that, in doing this, we place constraints on what are possible language forms.

Let's suppose that evaluation is sensitive to the presence of `"it"` bindings. This is achieved with a call to `check`, (20).

```
(20) let check f = Hide ("it", Rel (["it"], ["r"], " ", [f]))
```

We assume the predicate forms `rit`, (21), and `rev`, (22), for clauses that take event arguments.

```
(21) let rit s = check (Use ("it", rel s [T ("it", 0)]))
```

```
(22) let rev s = check (rel s [T ("ev", 0)])
```

With `rit` and `rev` invoking `check`, it follows that they will show a complementary distribution:

- `rit` requires one and only one "it" binding;
- `rev` requires at least one "ev" binding and no open "it" binding.

We now require tense operators that will provide bindings for the tense names "it" and "ev". Let's start with the postfix operator `ta`, (25), which encodes (dynamic and static) past-tense. This takes two arguments: an SCT expression `f`, and a number `n`. This opens a new "ev" binding over `f` with a call to `exists`, (23), which provides a way to mimic in SCT the role of existential quantification introducing a fresh binding. It is required that the value of the new binding is before (`<`) the value of the binding that was the zero level "ev" binding when the new "ev" binding was introduced.

```
(23) let exists x f = Hide (x, Close (x, Use (x, f)))
```

```
(24) letrec cleanup n x f =  
    (case n  
      of 0 => Hide (x, Rel ([x], ["r"], " ", [f]))  
       | n => Lam (x, "r", cleanup (n-1) x f)  
    )
```

```
(25) let f n ta =  
    cleanup n "it" (  
      Hide ("it",  
        exists "ev" (  
          rel "^" [rel "<" [T ("ev", 0), T ("ev", 1)], f])))
```

The `n` argument of (25) provides the number of times `cleanup`, (24), shifts a zero level "it" binding to an "r" binding. Since `Hide ("it", #)` is in the immediate scope of `cleanup # "it" #`, all values on the "it" stack must be cleared. The extra work of clearing "it" bindings is essential: if there is an open "it" binding, any `rev` occurrence will bring about evaluation failure, leaving the `ta` operator with (almost) no binding prospect.

Next, we introduce the postfix operator `non_ta_dyn`, (26), which encodes non-past dynamic tense. Note that the extra work of clearing away any open "it" binding is again required, but for a different reason. Since `non_ta_dyn` introduces a new "it" binding, and if there was already a new "it" binding open then there will be more than one "it" binding open, which no predicate with a tense argument can support.

```
(26) let f n non_ta_dyn =  
    cleanup n "it" (  
      exists "it" (  
        rel "^" [rel "<" [T ("ev", 0), T ("it", 0)], f]))
```

Finally, we introduce the postfix operator `non_ta_stat`, (27), which encodes non-past static tense. This differs from (26) only in the form of the tense relation.

```
(27) let f n non_ta_stat =
      cleanup n "it" (
        exists "it" (
          rel "&" [rel "⊆" [T ("ev", 0), T ("it", 0)], f]))
```

With this machinery for tense, let's consider a treatment of (28). We can provide (28) with the parsed form of (29).

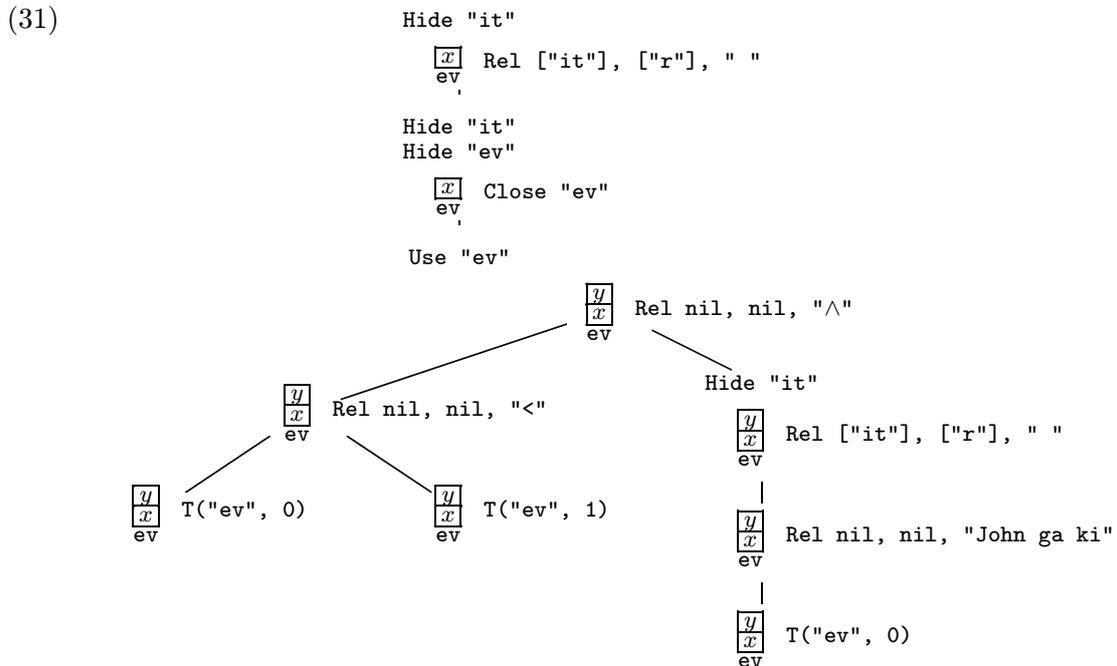

```
(28) John ga ki-ta.
      NAME NOM come-PST
      'John came.'
```

```
(29) (rev "John ga ki") 0 ta
```

In (30), we see the result of evaluating (29) against an assignment  $g$  that assigns a scope value  $x$  to "ev" (utterance time).

```
(30) (g,(29))° = ∃y(y < x ∧ John ga ki(y))
```

We can illustrate the translation of (30) with (31), which shows the creation of a new event time,  $y$ , which provides the event time for the main predicate and which is predicated as being before the utterance time  $x$ .

What is interesting to note about (29) is that the particular form of the clausal predicate, `rev`, gets enforced. Changing the form of the clausal predicate to `rit` gives (32), which as (33) indicates can have no evaluation. This holds because `rit` requires an "it" binding and such a binding is not opened by `ta`, and moreover removed if present.

(32) (rit "John ga ki") 0 ta

(33)  $\forall g : (g, (32))^\circ = *$

## 6 Tense in Complex Sentences

To give an SCT analysis of the data of section 3 for complex sentences, we need a way to capture instances of coordination. Let's introduce coordination with the infix operator `coord` of (34). This creates a subordinate clause by combining a clause `f` with a relation name `s`. The subordinate clause combines with a matrix clause `f'`. The result is an `s`-relation that combines `f` and `f'`.

(34) `let (f coord s) f' = rel s [f, f']`

### 6.1 Level A account

A Level A subordinate clause excludes operations that are able to introduce new "ev" or "it" bindings, leading to a tense interpretation that is inherited from the matrix clause. To see how this accounts for the Level A data, let's consider (5), which is repeated as (35).

(35) Tarō ga [shimbun o yomi]<sub>A</sub> nagara gohan o taberu.  
 NAME NOM newspaper ACC read SIML meal ACC eat-NPST  
 'Taro will eat reading the newspaper.'

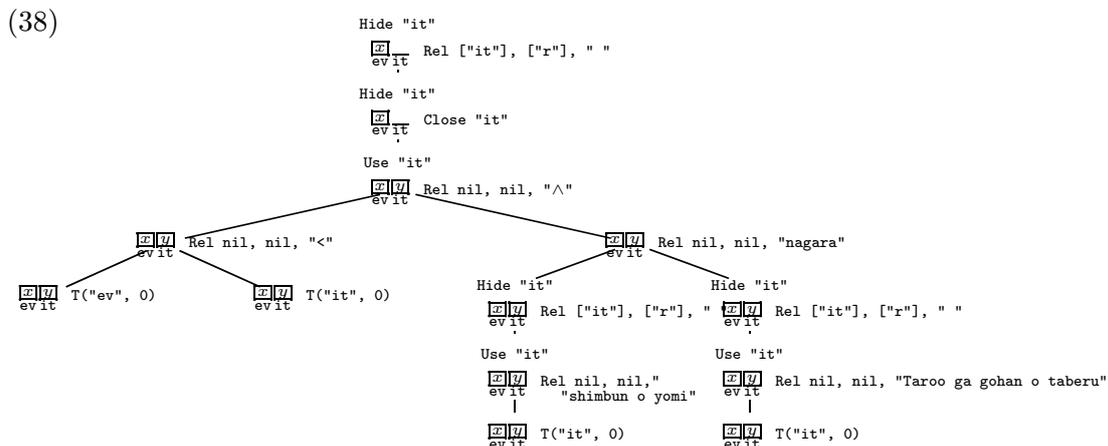

We can take (35) to have the parsed form of (36).

(36) ((rit "shimbun o yomi" coord "nagara") (rit "Taroo ga gohan o taberu")) 0 non\_ta\_dyn

In (37), we see the result of evaluating (36) against some assignment `g` that assigns a scope value `x` to "ev" (utterance time).

(37)  $(g, (36))^\circ$   
 $= \exists y (x < y \wedge \text{nagara}(\text{shimbun o yomi}(y), \text{Taroo ga gohan o taberu}(y)))$

We can illustrate the translation of (37) with (38).

With (36), the matrix clause has `non_ta_dyn` as its tense operator, and so an "it" binding is opened. As can be seen from (38), once open, the "it" binding is present ever after. This forces the matrix predicate to have an `rit` form and so be linked to the "it" binding. And since the subordinate clause is only a predicate and happens to occur in the same environment as the matrix predicate, it too must have the `rit` form and so be linked to the same "it" binding. It follows from this shared binding that the event time of the subordinate clause is (contained in) the same event time as the matrix.

## 6.2 Level B account

With a Level B subordinate clause, the Level A constraint of allowing only predicate material is relaxed. This creates an opportunity for the operators (25)–(27) to occur inside the subordinate clause. And with the occurrence of the tense operators, it follows that there will be the opportunity for the introduction of new "ev" or "it" bindings, together with relations established with the "ev" binding inherited from the matrix. Since the "ev" binding of the matrix may or may not have changed from the utterance time value inherited from the context of utterance (the initial "ev" binding), the form of tense in the matrix clause may or may not affect the subordinate clause. We will proceed by looking first at a case where the matrix clause does affect the subordinate clause, and then at a case where there is no affect.

The data of (6) and (7) show that, if the matrix is marked by *ta*, the tense of the subordinate clause is interpreted in relation to the changes made by the matrix tense. To see why, let's consider (6a), which is repeated as (39).

- (39) [Haruko ga **sotsugyō-suru**]<sub>B</sub> *node* *issho-ni* **ryokō-shi- ta**.  
 NAME NOM graduate-NPST CASL together travel PST  
 ‘Because Haruko is/was going to graduate, I made a trip with her.’  
 ( $E_m < n$ ,  $E_m < E_s$ )

We can take (39) to have the parsed form of (40).

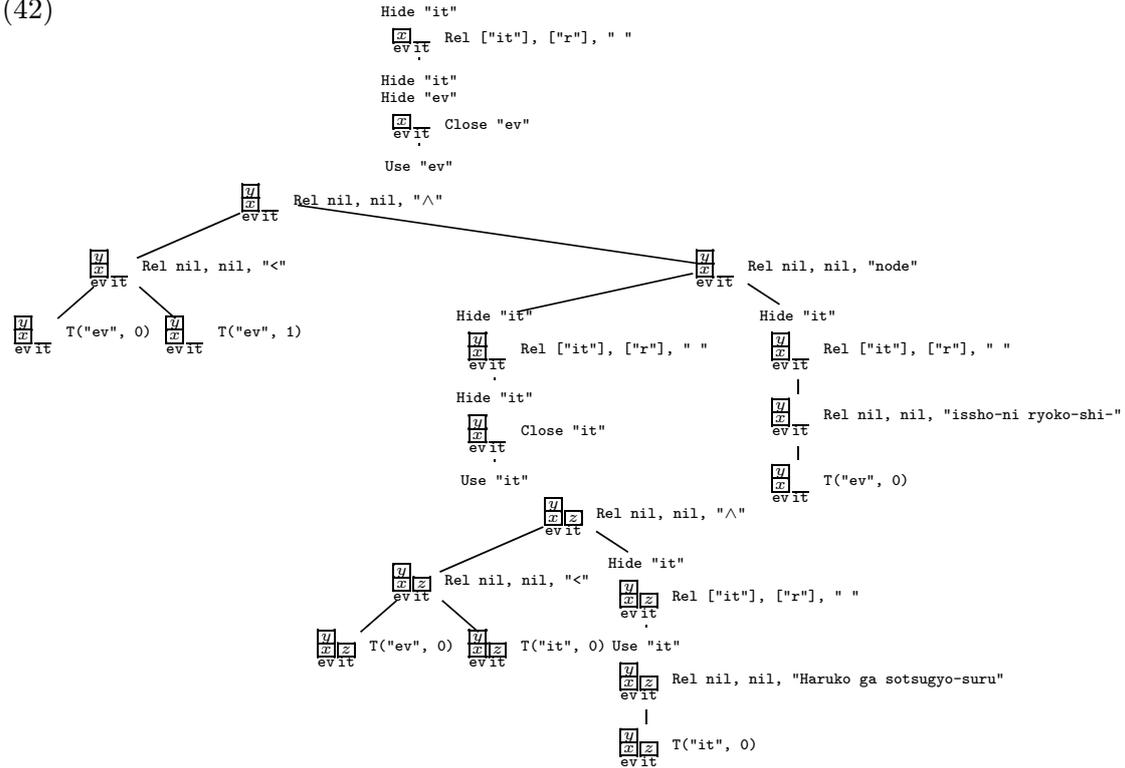

- (40) (((rit "Haruko ga sotsugyo-suru") 0 non\_ta\_dyn coord "node") (rev "issho-ni ryoko-shi-")) 0 ta

In (41), we see the result of evaluating (40) against an assignment *g* that assigns a scope value *x* to "ev" (utterance time).

- (41) ( $g, (40)$ )<sup>o</sup> =  $\exists y(y < x \wedge \text{node}(\exists z(y < z \wedge \text{Haruko ga sotsugyo-suru}(z)), \text{issho-ni ryoko-shi-}(y)))$

We can illustrate the translation of (41) with (42). This shows how the contribution of the past tense in the matrix—namely, the introduction of a new "ev" binding—is carried down into the subordinate clause. It moreover holds that the newly introduced "ev" binding occludes the original "ev" binding and so any comparison in the subordinate clause to the "ev" binding can only be with respect to the newly introduced "ev" of the matrix. It is for this reason that the tense interpretation of the subordinate clause is made dependent on the tense of the matrix. Also note that `ta` and `non_ta_dyn` of (40) both have 0 as their number argument. This is required, since, as can be seen from (42), it is only in the subordinate clause that an "it" binding is introduced, and so the need for "it" garbage collection never arises.

(42)

The facts of the other sentences of (6) and (7) can be explained in exactly the same way as for (39). This is because `non_ta_stat` and `ta` share with `non_ta_dyn` the property of giving an event comparison with respect to what is the zero level "ev" binding before they apply, and, as we can see with (42), this will be the tense introduced in the matrix when the matrix is *ta* marked.

The data of (8) and (9) show that, if the matrix predicate is in a non-past form, the subordinate clause undergoes a tense interpretation in relation to the utterance time, and is thus interpreted independently of the tense of the matrix clause. To see why, let's consider (9a), which is repeated as (43).

- (43) [Haruko ga yasun-de iru]<sub>B</sub> node kanashii.  
 NAME NOM take time off PROG-NPST CASL be sad-NPST  
 'Because Haruko is absent, I am sad.'  
 ( $n \subseteq E_m, n \subseteq E_s$ )

We can take (43) to have the parsed form of (44).

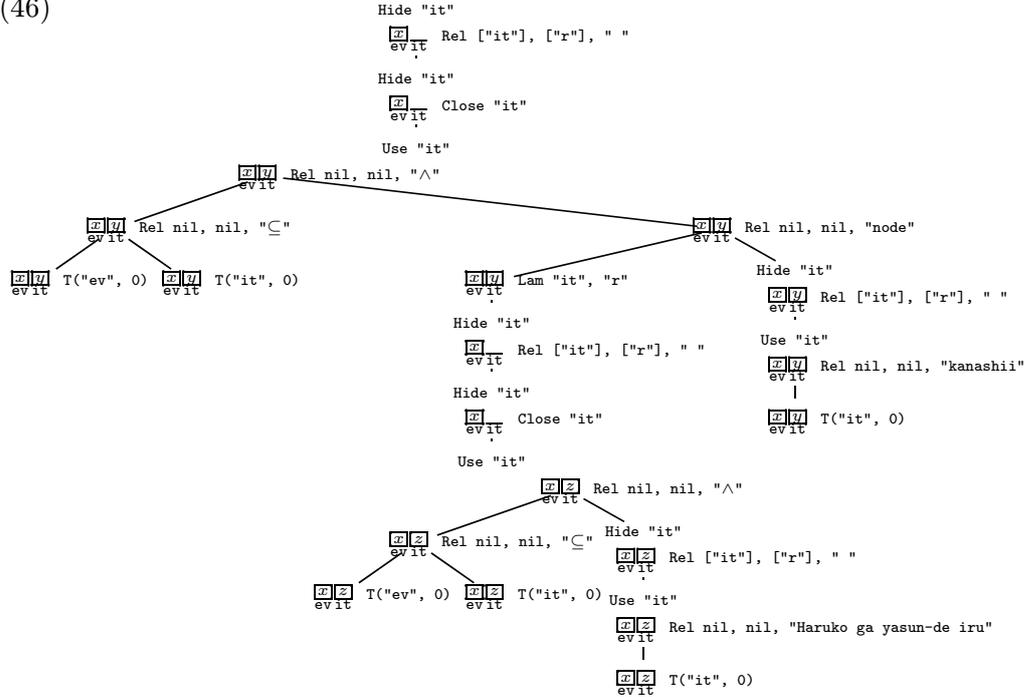

- (44) (((rit "Haruko ga yasun-de iru") 1 non\_ta\_stat coord "node") (rit "kanashii")) 0 non\_ta\_stat

In (45), we see the result of evaluating (44) against an assignment  $g$  that assigns a scope value  $x$  to "ev" (utterance time).

- (45)  $(g, (44))^\circ$   
 $= \exists y(x \subseteq y \wedge \text{node}(\exists z(x \subseteq z \wedge \text{Haruko ga yasun-de iru}(z)), \text{kanashii}(y)))$

We can illustrate the translation of (45) with (46). The change made to the assignment by the matrix is a new "it" binding. This doesn't occlude the initial "ev" binding, and so any link to the "ev" binding in the subordinate clause is to the one and only "ev" binding, which was provided by the initial state of the assignment as the utterance time. It follows that the eventuality times of the predicates in the matrix and subordinate clause are independent.

(46)

The facts of the other sentences of (8) and (9) can be explained in exactly the same way as for (43). This is because `non_ta_dyn` and `ta` share with `non_ta_stat` the property of giving an event comparison with respect to what is the zero level "ev" binding before they apply, and, as we can see with (46), this will be the utterance time.

### 6.3 Level C account

The final ingredient that we need to consider for our analysis is the role played by Level C. We will suppose that introduction of a Level C clause serves to garbage collect any "ev" bindings that have been opened in a superordinate clause. This is achieved with `eventlevelc` of (47).

(47) `let eventlevelc n f =  
 cleanup n "ev" (Use ("ev", Hide ("ev", f)))`

An application of `eventlevelc` is sensitive to the environment in which it occurs. Specifically, a value must be given for `n` that will ensure that all bindings from the "ev" sequence, with the exception of the most deeply embedded, are cleared (shifted to "r" bindings). This ensures that one and only one value, corresponding to the utterance time, is left as the "ev" binding.

To see `eventlevelc` applied, let's consider (10a), which is repeated as (48).

- (48) [Haruko wa Supein e **iku**]<sub>C</sub> *ga* Akiko wa Itaria e **it-ta**.  
 NAME TOP Spain GOAL go-NPST ADVS NAME TOP Italy GOAL go PST  
 ‘Although Haruko will go to Spain, Akiko went to Italy.’  
 ( $n < E_s, E_m < n$ )

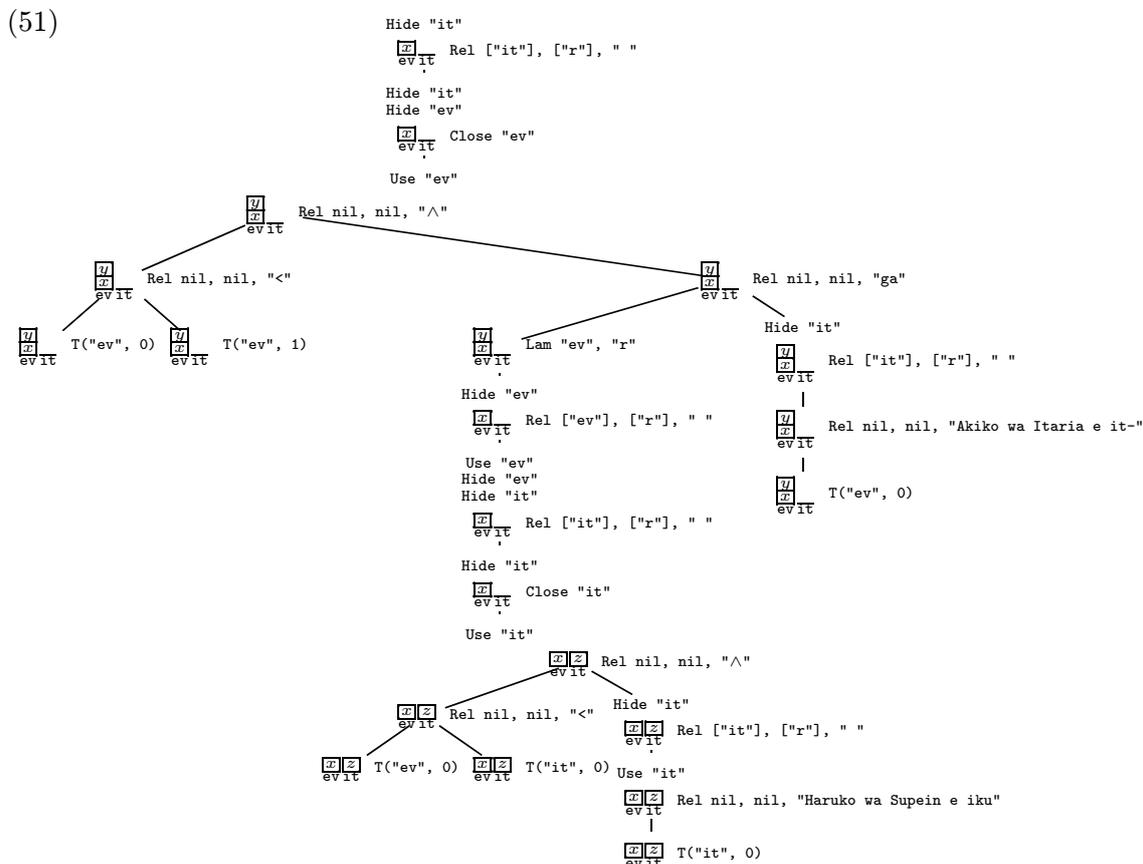

We can take (48) to have the parsed form of (49).

- (49) ((eventlevelc 1 ((rit "Haruko wa Supein e iku") 0 non\_ta\_dyn) coord  
 "ga") (rev "Akiko wa Itaria e it-")) 0 ta

In (50), we see the result of evaluating (49) against an assignment  $g$  that assigns a scope value  $x$  to "ev" (utterance time).

- (50)  $(g, (49))^\circ = \exists y(y < x \wedge \text{ga}(\exists z(x < z \wedge \text{Haruko wa Supein e iku}(z)), \text{Akiko wa Itaria e it-}(y)))$

We can illustrate the translation of (50) with (51). What is important to note is that any new "ev" bindings introduced with the matrix clause get removed as bindings with shifts to "r" bindings. This essentially removes the involved scopes from further consideration. This leaves the initial "ev" (utterance time) as the only scope that is maintained. With these garbage collection changes to the assignment, it follows that the eventuality times of the predicates of the matrix and subordinate clause will be mutually unconnected, but they will both be connected to the eventuality time of the utterance.

## 7 Conclusion

We have seen how tense relations get interpreted differently in the three types of subordinate clause in Japanese. The different consequences were derived from the same operator variable mechanisms being applied in accordance to what can occur and what has already occurred with the hierarchical structuring of the matrix and subordinate clauses. We can characterise the specific results of this paper as follows:

- With Level A, there can be no tense operations in a subordinate clause. With no tense operations allowed internally to the subordinate clause, it follows that the matrix and subordinate clause will be forced to share dependence on the same tense binding.
- With Level B, tense operations are possible. Dependencies of one event time with another can only be with respect to the current "ev" binding, since before a tense operator can be used any existing "it" binding must be garbage collected, else the new tense operation would not be possible. With past tense a fresh "ev" binding is opened, making this the current "ev" binding for a subsequent tense operation, thereby enforcing dependence. In contrast, non-past tense (either dynamic or static) makes no change to the "ev" binding, but instead introduces a fresh "it" binding, the type of tense binding that is garbage collected before a tense operation can occur, so that there can be no dependence of a subsequent tense operation on a non-past tense operation.
- With Level C, tense operations are possible, but only after a cleanup of any "ev" bindings that may have been added in a superordinate clause.

## Appendix

In this appendix, SCT evaluation is defined, taking the form of a translation from expressions of SCT into expressions of predicate logic notation.

SCT makes extensive use of sequences and operations on sequences. Below are the important notations:

- $[x_0, \dots, x_{n-1}]$ : a sequence with  $n$  elements,  $x_0$  being frontmost.
- $\vec{x}$ : abbreviation for a sequence.
- `nil`: the empty sequence.
- $\vec{x}_i$ : the  $i$ -th element of a sequence, e.g.  $[x_0, \dots, x_{n-1}]_i = x_i$ , where  $0 \leq i < n$ .
- $|\vec{x}|$ : the sequence length, e.g.  $|[x_0, \dots, x_{n-1}]| = n$ .
- `cons`( $y, [x_0, \dots, x_{n-1}]$ ) =  $[y, x_0, \dots, x_{n-1}]$ .
- `snoc`( $y, [x_0, \dots, x_{n-1}]$ ) =  $[x_0, \dots, x_{n-1}, y]$ .

Translation is always with respect to a *scope sequence assignment*. This is a mapping,  $g$ , that assigns a (possibly empty) sequence of predicate logic variable names to each SCT name:  $g : \text{Name} \rightarrow \text{Var}^*$ . Let  $SSA$  be the set of scope sequence assignments. The empty assignment,  $\lambda$ , assigns `nil` to every SCT name.

For translating to predicate logic notation, the members of  $SSA$  can only be scope sequence assignments that contain no repetition of a predicate logic variable name, either in the same assigned sequence or across assigned sequences. This condition applies because, with predicate logic notation, variable names (scopes) must be kept distinct.

We employ relations on scope sequence assignments ( $r \subseteq SSA \times SSA$ ) with pairs of scope sequence assignments  $(g, h)$ , so that a relation will take us from  $g$  to  $h$  or vice versa. As a convention, relations are named reading from  $g$  to  $h$ .

$$(g, h) \in \text{pop}_x \quad \text{iff} \quad h \text{ is just like } g, \text{ except that,} \\ g(x) = \text{cons}((g(x))_0, h(x)).$$

$$(g, h) \in \text{shift}(op)_{x,y} \quad \text{iff} \quad \exists k : (h, k) \in \text{pop}_y \text{ and } k \text{ is just like } g, \\ \text{except that, } g(x) = op((h(y))_0, k(x)).$$

Basic relations on scope sequence assignments are illustrated in (52), moving from  $g$  to  $h$ . Boxed letters represent scopes while unboxed letters represent SCT names.

$$(52) \quad \begin{array}{ccc} & & \boxed{y} \boxed{x} \\ & \nearrow \text{pop}^{\text{"x"}} & \underline{x} \quad \underline{y} \\ \boxed{z} \boxed{y} \boxed{x} & \xrightarrow{\text{shift}(\text{cons})^{\text{"x"}, \text{"y"}}} & \boxed{y} \boxed{x} \boxed{z} \\ \underline{x} \quad \underline{y} & & \underline{x} \quad \underline{y} \\ & \searrow \text{shift}(\text{snoc})^{\text{"x"}, \text{"y"}} & \boxed{z} \boxed{y} \\ & & \underline{x} \quad \underline{y} \end{array}$$

Relations can be iterated  $n$  times when augmented with a positive superscript  $n$ , e.g. (53).

$$(53) \quad \left( \frac{\boxed{y}}{\boxed{x}} \underline{\quad} \underline{\quad}, \underline{\quad} \frac{\boxed{y}}{\boxed{x}} \right) \in \text{shift}(\text{snoc})_{\text{"x"}, \text{"y"}}^2$$

We first need to define a ‘usage count’ operation on SCT expressions, denoted by  $x(e)$ . This count operation formally defines the contribution of the Use and Hide operators.

$$\begin{aligned} x(\mathbf{T} (y, i)) &= 0 \\ x(\mathbf{Use} (y, e)) &= \begin{cases} x(e) + 1 & \text{if } x = y \\ x(e) & \text{otherwise} \end{cases} \\ x(\mathbf{Hide} (y, e)) &= \begin{cases} 0 & \text{if } x = y \\ x(e) & \text{otherwise} \end{cases} \\ x(\mathbf{Close} (y, e)) &= x(e) \\ x(\mathbf{Lam} (y, z, e)) &= x(e) \\ x(\mathbf{Rel} (\vec{y}, \vec{z}, r, \vec{e})) &= \sum_{i=0}^{|\vec{e}|-1} x(\vec{e}_i) \end{aligned}$$

A formal definition for the other SCT operators is given below in terms of translation with respect to a scope sequence assignment,  $g$ .

- $(g, \mathbf{T} (x, i))^\circ$ 
  - return  $(g(x))_i$ , provided  $0 \leq i < |g(x)|$
  - otherwise return \*
- $(g, \mathbf{Use} (x, e))^\circ$ 
  - return  $(g, e)^\circ$
- $(g, \mathbf{Hide} (x, e))^\circ$ 
  - return  $(g, e)^\circ$
- $(g, \mathbf{Close} (x, e))^\circ$ 
  - if  $x(e) = 0$  return  $(g, e)^\circ$
  - else  $\exists h : (h, g) \in \mathbf{pop}_x^{x(e)}$  return  $\exists (h(x))_0 \dots (h(x))_{x(e)-1} (h, e)^\circ$ , provided  $(h, e)^\circ \neq *$
  - otherwise return \*
- $(g, \mathbf{Lam} (x, y, e))^\circ$ 
  - $\exists h : (g, h) \in \mathbf{shift}(\mathbf{cons})_{x,y}$  return  $(h, e)^\circ$
  - otherwise return \*
- $(g, \mathbf{Rel} (\vec{x}, \vec{y}, r, \vec{e}))^\circ$ 
  - return  $r((0, g, \vec{x}, \vec{y}, \vec{e})^\circ, \dots, (|\vec{e}| - 1, g, \vec{x}, \vec{y}, \vec{e})^\circ)$ , provided for  $0 \leq i < |\vec{e}|$ ,  $(i, \vec{x}, \vec{y}, \vec{e})^\circ \neq *$
  - otherwise return \*
- $(n, g, \vec{x}, \vec{y}, \vec{e})^\circ$ 
  - if  $|\vec{x}| = 0$  return  $(g, \vec{e}_n)^\circ$
  - else  $\exists h_0 \dots h_{|\vec{x}|} : h_0 = g$  and for  $0 \leq i < |\vec{x}|$ ,  
 $(h_i, h_{i+1}) \in (\mathbf{pop}_{\vec{x}_i}^{|\vec{x}_i| - \sum_{k=0}^n \vec{x}_i(\vec{e}_k)}; \mathbf{shift}(\mathbf{snoc})_{\vec{x}_i, \vec{y}_i}^{|\vec{x}_i| - \sum_{k=n}^{|\vec{e}|-1} \vec{x}_i(\vec{e}_k)})$  return  $(h_{|\vec{x}|}, \vec{e}_n)^\circ$
  - otherwise return \*

The following points explain the actions and roles of each operator.

- The **T** operator creates terms, with a name and number as arguments. Terms are found at the lowest hierarchical level of expressions, and so are the last steps in translation. The translation is only grammatical if every term finds a binding scope at the name and sequence position denoted by the term's name and number arguments. The number is usually zero. Successful translation of a term returns a predicate logic variable which, for example, fills an argument slot in a predicate.

- **Use** operators form countable entities with usage counts that signal the scope requirements of an expression. Although **Use** operators do nothing when they are translated themselves, **Use** operators figure prominently in the overall translation process because usage counts occur during the translations of **Close** and **Rel**, where they support two important processes: scope creation and binding. **Use** operators can tell **Close** operators how many scopes to create (creation support), and can tell **Rel** operators the scopes that are to be made available for given names of a given argument (binding support). The usage count operation, together with the length operator, allows numbers to be incorporated into SCT for checksum calculations.
- **Hide** operators prevent **Use** operators occurring under them from being counted in usage counts. **Hide** operators contribute nothing when translated themselves. It is customary for **Hide** operators to come directly above **Close** operators for a particular binding name, because this prevents an embedded **Use** from also adding to the usage counts of higher **Close** or **Rel** operators for the same name, which would bring about evaluation failure. **Hide** operators are important because they can be taken to mark localities that enable the re-use of names, which is necessary for embeddings.
- The **Lam** operator contributes to the binding process by modifying assignments with a `shift(cons)` operation. One scope is moved from the front of a named sequence to the front of a (possibly) differently named sequence, that is, from one binding to another. For example, this makes garbage collection possible, allowing for a binding that would conflict with the binding requirements of an embedding to be shifted to a binding where it can be essentially forgotten and so no hindrance for the evaluation of the embedding.
- The **Close** operator provides an environment in an SCT expression where new scopes can be opened. **Close** does two things on translation: it changes the assignment and participates in building the predicate logic translation. **Close** creates new scopes in the assignment corresponding to a usage count for the number of **Use** that are not occurring under **Hide**, for a particular name  $x$ . When the usage count is greater than zero, **Close** operators translate into existential quantifiers, which thereby introduce fresh bindings into the predicate logic translation. **Close** operators are usually found at the hierarchical top of the SCT expression for a sentence.
- The **Rel** operator plays the most important part in translation. **Rel** does two things on translation. Firstly, it builds relations, which not only includes predicates like *smile*, *see*, but all other relations natural languages can have, e.g., coordinating relations like conjunction. The number of arguments of the relation that will be built is equal to the number of elements of  $\vec{e}$ , the expression sequence of the **Rel** operator. Secondly, if given a non-empty argument  $\vec{x}$ , the **Rel** operator changes the initial assignment  $g$ , by removing and sorting scopes, to form new assignments  $j_0, \dots, j_{|\vec{e}|-1}$ . Each  $j$  assignment will be used to translate each element of  $\vec{e}$  to construct each argument of the resulting relation. The changes that are made to  $g$  depend on the name sequences given

as arguments  $\vec{x}$  and  $\vec{y}$ , with the number of specific changes made (with `pop` and `shift(snoc)`) depending on the usage counts of elements of  $\vec{x}$  in parts of  $\vec{e}$ .

# Korean postpositions : clitics and weak syntactic heads

KO, Kil Soo

LLF/University of Paris 7  
gogiri72@linguist.jussieu.fr

## Abstract

This paper is to examine Korean postpositions and define their grammatical status in view of their description in HPSG. We show that they differ syntactically from suffixes and propose to treat them as clitics. They are phonologically dependent and attach to the preceding word in the phonology. We propose subsequently to treat them as weak syntactic heads, showing that they have head properties but contribute little to the syntax of the phrase. They take the host phrase as complement but share (most of) its syntactic properties. We propose also to divide them into 3 subtypes, based on their distribution: arking, oblique and semantic postpositions and to describe their syntactic information in terms of case and marking features.

**Keywords:** postposition, clitic, weak syntactic head, case feature, marking feature.

## 1. Introduction

Postpositions in Korean (henceforth P) show controversial behaviors. First, they attach to a lexical item like suffixes but affect the phrase including it like words. Second, we may omit some of them without effect on the syntax but not others.<sup>1</sup>

- (1) Paul-\*(do) Mary-ui sajin-(eul) John-\*(ege) boi-eoss-da.  
Paul-also Mary-gen photo-acc John-dat show-past-decl.  
Paul also showed Mary's photo to John.

*-eul* in (1) is attached to a noun *sajin*, but indicates that *Mary-ui sajin* is the object of the verb. It can be omitted but *-ege* after the dative complement is not optional, though both are considered as case elements. *-do* has no effect on the syntax of the subject NP but its omission is forbidden because it conveys a pragmatic meaning.

---

\* We wish to thank Anne Abeillé, Jean-Marie Marandin and Jesse Tseng for comments and suggestions. All remaining errors are of course our own.

<sup>1</sup> The transcription of the data follows “the Romanization of Korean” issued by the Korean Ministry of Culture and Tourism, without taking into account the phonetic variations.

Therefore, we must decide whether to treat P as suffixes or words and answer to subsequent questions, before describing their grammar. And we will treat them as clitics and weak syntactic heads. First, we show that P differ syntactically from suffixes and propose to consider them as clitics, taking into account their morpho-phonological dependency. They are words attaching to the preceding word in the phonology. We present briefly possible accounts for other suffix-like behaviors. Second, we propose to treat P as weak syntactic heads, showing that they have head properties but that some P may be omitted or appear without syntactic effect, unlike ordinary heads. Third, we propose to divide P into 3 subtypes: marking, oblique and semantic P, based on their distribution and contribution to the syntax and to use case and marking features to differentiate them.

Our analysis and its description in HPSG will be presented after a brief review of previous analyses in the next section.

## 2. Previous analyses

P are analyzed as words or suffixes in previous works. In the first analyses, they are words having a phrasal scope. They combine with a phrase affected by them (Yoon 1995, Chae & No 1998, *etc.*):

- (2) [Mary-ui sajin] + eul ‘Mary-gen photo-acc’

Some works introduced a derivation from (2) to (3): move the last word of the preceding phrase and attach it to P, taking into account the morpho-phonological dependency (Im 1989, Shi 1994, *etc.*):

- (3) [Mary-ui \_\_\_] sajin-eul ‘Mary-gen photo-acc’

P are inflectional suffixes in the second analyses (Sells 1995, Kim & Choi 2005, Yoo 2002, *etc.*). They attach to a lexical base or root. Their syntactic and semantic information is incorporated into the latter’s and percolated up to the mother phrase (Kim & Choi 2005). Then P may neither appear alone nor be separated from the lexical host:

- (4) - Paul-man o-ass-ni?  
       Paul-only came?  
       Did only Paul come?  
       - eung, \*(Paul)-man o-ass-da.  
       Yes, \*(Paul)-only came.
- (5) a. Paul-i chaeg-do gabang-e neoh-eoss-da.  
       Paul-nom book-also bag-loc put.  
       Paul put (the) book(s) in the bag too.

- b. Paul-*{amado,#}*-i chaeg-*{amado,#}*-do gabang-*{amado,#}*-e  
 Paul-*{perhaps,#}*-nom book-*{perhaps,#}*-also bag-*{perhaps,#}*-loc  
 neoh-eoss-da.  
 put.

Like other suffixes, some P show morpho-phonological variation (6); some hosts change their form (7); P are stacked in a strictly restricted order (8).

- (6) a. Mary-*{ga,leul,neun,wa,na,...}* ‘Mary-*{nom,acc,top,and,or,...}*’  
 b. Paul-*{i,eul,eun,gwa,ina,...}* ‘Paul-*{nom,acc,top,and,or,...}*’
- (7) a. *{nae,je,ne,nu}*-ga ‘*{I,I,you,who}*-nom’  
 b. *{na,jeo,neo,nugu}*-*{leul,neun,ege,...}* ‘*{I,I,you,who}*-*{acc,top,dat,...}*’
- (8) a. Paul-*{man,kkaji,jocha}*-*{i,eul,eun,do}*  
 Paul-*{only,up to,even}*-*{nom,acc,top,also}*  
 a’. \*Paul-*{i,eul,eun,do}*-*{man,kkaji,jocha}*  
 b. jib-*{e,eulo,eseo}*-*{man,kkaji,jocha}*  
 house-*{loc,to,at}*-*{only,up to, even}*  
 b’. \*jib-*{man,kkaji,jocha}*-*{e,eulo,eseo}*

P are divided into several subtypes in previous works. 2 groups are distinguished from the syntactic point of view: case P and non case P (Lim 2004, *etc.*). Case P includes 2 subtypes: grammatical case P that can be omitted and semantic case P that are not optional. Non case P are divided into several groups according to their semantic types:

(9)

Subtypes		P items
Case P	Grammatical P	-i/ga ‘nom’, -(l)eul ‘acc’, -ui ‘gen’
	Semantic P	-e ‘loc’, -ege ‘dat’, -(eu)lo ‘to’, <i>etc.</i>
Non case P	Specific P	-jocha ‘even’, -kkaji ‘up to’, <i>etc.</i>
	Topic marker	-(n)eun ‘top’
	Additive/restrictive P	-do ‘also’, -man ‘only’
	Conjunctive P	-(g)wa ‘and’, -(i)na ‘or’, <i>etc.</i>
	Vocative P	-(y)a ‘voc’

### 3. Our analysis

This section presents our analysis based on 3 proposals: to treat P as clitics and as weak syntactic heads and to divide P into 3 subtypes according to their syntactic information.

### 3.1. P's morphological status

P differ from suffixes in several respects, though they show suffix-like behaviors. 1) In contrast to suffixes, most P combine with various categories: noun, verb and adverb.

- (10) a. Paul-{i,eul,eun,do,man, ... }  
           Paul-{nom,acc,top,also,only, ... }  
       b. meog-go-{ga,leul,neun,do,man, ... }  
           eat-Comp-{nom,acc,top,also,only, ... }  
       c. ppalli-{ga,leul,neun,do,man, ... }  
           quickly-{nom,acc,top,also,only, ... }

Unlike inflectional suffixes, they are compatible with the adverb which is non flectional category, as given in (10c). Unlike derivational suffixes, they don't change the category.<sup>2</sup> So, the verb and the adverb in (10) can't appear in positions that accept only an NP.

2) Syntactic rules affect "X+suffix" but not "X+P" (Nam 1996, Zwicky & Pullum 1983), as illustrated in the following examples:

- (11) a. Paul-i           o-ass-da.  
           Paul-nom    come-past-decl.  
       b. geu-\*(ga)    o-ass-da.  
       c. [\_\_ o-n]        Paul-(\*i)-eul    manna-ss-da.  
           [\_\_ come-rel] Paul-(\*nom)-acc met.
- (12) a. namu-kkun-i    o-ass-da.  
           tree-person-nom came.  
       b. geu-\*(kkun)-ga o-ass-da.  
       c. [\_\_ o-n]        namu-\*(kkun)-eul manna-ss-da.  
           [\_\_ come-rel] tree-\*(person)-acc met.
- (13) a. chingu-deul-i    o-ass-da.  
           friend-plural-nom came.  
       b. geu-\*(deul)-i    o-ass-da.  
       c. [\_\_ o-n]        chingu-\*(deul)-eul manna-da.  
           [\_\_ come-rel] friend-\*(plural)-acc met.

-i/ga in (11) is not affected when the host is replaced by a pronoun and disappears when the host is relativized. On the contrary, the derivational suffix *-kkun* disappears in (12b) but moves together with the host in (12c). The plural suffix *-deul* in (13) shows different

---

<sup>2</sup> Cf. categories like PP and KP, *etc.* are often used in previous works.

behaviors: it is not affected by the pronominalization like P while it is relativized with the host like derivational suffixes.

3) P but not suffixes show restricted distributions in the coordination. Some P can't be attached to the first conjunct (14a) while others can't be omitted at the last conjunct (15b).

- (14) a. Paul- $\{i,eul,ui,eun,do\}$ -gwa      Mary- $\{i,eul,ui,neun,do\}$   
          Paul- $\{nom,acc,gen,top,also\}$ -and Mary- $\{nom,acc,gen,top,also\}$
- b. Paul-gwa      Mary-(i,eul,ui)  
          Paul-and      Mary-(nom,acc,gen)
- (15) a. jib- $\{e,eseo,eulo\}$ -na      haggyo- $\{e,eseo,lo\}$   
          house- $\{loc,at,to\}$ -or      school- $\{loc,at,to\}$
- b. jib-na      haggyo- $\{e,eseo,lo\}$   
          house-or      school- $\{loc,at,to\}$

On the contrary, suffixes appear freely at each conjunct and don't show such restrictions.

- (16) a. namu-(kkun)-gwa      sanyang-(kkun)-eul      balabo-da.  
          tree-(person)-and      hunting-(person)-acc      watch.  
          watch a woodcutter/tree and a hunter/hunting.
- b. sanae ai-(deul)-gwa      yeoja ai-(deul)-eul      manna-da.  
          boy child-(*plur*)-and      girl child-(*plur*)-acc      meet.  
          meet a boy/boys and a girl/girls.

4) P have a phrasal scope. They take the whole coordination in their scope when they appear at the last conjunct, as in (14b) and (15b). But suffixes have a narrow scope and affect only the conjunct to which they are attached. So, if we delete its suffix, the first conjunct denotes a tree or trees in (16a) and may be interpreted as singular NP in (16b):

- (17) a. namu-wa      sanyang-kkun-eul      balabo-da.  
          tree-and      hunting-person-acc      watch.  
          watch a tree/trees and a hunter.
- b. han      sanae ai-wa      yeoja ai-deul-eul      manna-da.  
          one      boy child-and      girl child-plur-acc      meet.  
          meet a boy and girls.

Therefore P are words combining with a phrase. But we propose to treat them as clitics, taking into account their dependency illustrated in (4) and (5). In other words, P are dependent words and attach in the phonology to the last word of the phrase they combine with. Then the lexical host can't be an empty element: it may neither be a null pronoun nor be omitted, as illustrated in (4). (5b) will be ruled out in the syntax or in the

phonology: an adverb modifying the verb can't be embedded and the attachment in the phonology bans inserting a pause.

It is possible to account for P's suffix-like behaviors. As for P's variation in (6), we can register in the lexicon all variants with a restriction on the host's final phoneme or introduce a rule (or function) changing P's form in the phonology. For example, the variation between *-i* and *-ga* can be described by 2 lexical entries in (17) or by a rule in (18)<sup>3</sup>:

(17) a. *-i*: after a host terminating with a consonant

b. *-ga*: after a host terminating with a vowel

(18) '*nom*' → *-i* after a consonant, but *-ga* after a vowel

Idiosyncratic host forms in (7) can be accounted for in the same way. For example, we may use a phonological rule in (20) or record 2 entries in (21) for the alternation between *na* and *nae* in (19)<sup>4</sup>:

(19) a. *nae*/\**na-ga* 'I-*nom*'

b. \**nae*/*na*-{*leul,ui,neun,do,ege, ...*} 'I-{*acc,gen,top,also,dat, ...*}'

(20) 'I' → *nae* before *-i/ga*, but *na* before other P

(21) a. *nae*: it combines with *-i/ga*.

b. *na*: it combines with P other than *-i/ga*.

Ordering restrictions on P's stacking in (8) can be summarized: oblique case P < semantic P < marking P, if we revise P's subtypes (see 3.3).

### 3.2. P's syntactical status

We propose to treat P as weak syntactic heads taking the host phrase as their

---

<sup>3</sup> The first solution seems preferable, since there are non phonological variations too: the dative complement is marked by *-ege* or *-e* according to its semantic type [+/-animate] and the subject is followed by *-kkeseo*, instead of *-i/ga*, if the referent is socially superior to the speaker.

i. *chaeg-eul chingu*-{*ege,\*e*}/*haggyo*-{*\*ege,e*} *bonae-ss-da*.

book-acc friend-dat/school-dat sent.

(I) sent a/the book to a/the friend.

ii *ai*-{*ga,\*kkeseo*}/*abeonim*-{*\*i,kkeseo*} *o*-(*si*)-*ass-da*.

child-nom/father-nom come-(hon)-past-decl.

(My) father came.

<sup>4</sup> It seems also possible to treat idiosyncratic forms and *-i/ga*, for example *nae-ga*, as complex words, because these host forms are not numerous and they appear only before *-i/ga*.

complement and sharing (most of) its syntactic properties (Tseng 2002, Abeillé *et al.* 2005).

P show head properties. 1) They follow always the host phrase and Korean is a head-final language:

- (22) a. [Paul-gwa Mary]-{ga,ege,eun, ...}  
           [Paul-and Mary]-{nom,dat,top, ...}  
       b. \*[Paul-gwa-{ga,ege,eun, ...} Mary]  
       c. \*{ga,ege,eun, ...}-[Paul-gwa Mary]

2) Semantic case P, such as *-ege*, *-e*, *-eseo*, *etc.*, determine the syntactic and semantic function of the phrase. And they are not optional in most contexts.

- (23) a. Paul-i Mary-\*(ege) insa-leul ha-yeoss-da.  
           Paul-nom Mary-dat greeting-acc did.  
           Paul said hello to Mary.  
       b. Paul-i jib-\*(eseo) jam-eul ja-n-da.  
           Paul-nom home-loc sleep-acc sleep-prof-decl.  
           Paul sleeps at home.

3) Grammatical case P, such as *-i/ga*, *-(l)eul*, and *-ui*, restrict the function and the distribution of the phrase (24a). They can't be omitted in (24b-c), which means that they enable the phrase to appear in these positions.

- (24) a. Paul-{i,\*eul,\*ui} Mary-{\*ga,\*leul,ui} pal-{\*i,eul,\*ui} jab-ass-da.  
           Paul-{nom,acc,gen} Mary-{nom,acc,gen} arm-{nom,acc,gen} caught.  
           Paul caught Mary's arm.  
       b. gongbuha-gi-neun doseogwan-eseo-\*(ga) joh-da.  
           study-nominalizer-top library-loc-\*(nom) is good.  
           the library is a good place to study in.  
       c. [haggyo-eseo-\*(ui) saenghwal]-edaehae mud-da.  
           [school-loc-\*(gen) life]-about ask.

4) Other P take the host phrase as semantic argument, though they don't change its syntactic function:

- (25) seonmul-eul Paul-ege-{neun,do,man,kkaji,jocha} bonae-ss-da.  
           gift-acc Paul-dat-{top,also,only,till,even} sent  
           (I) sent a gift only/also/up/even to Paul.

5) *-(n)eun* and *-do* can be used instead of *-i/ga* in (24b):

- (26) gongbuha-gi-neun doseogwan-eseo-{neun,do} joh-da.  
           study-nominalizer-top library-loc-{top,also} is good.

6) Some P restrict the host's (semantic) property:

- (27) a. *NP-dat*: [+animate]-{\*e,ege} vs. [-animate]-{e,\*ege}  
 b. *NP-nom*: [-hon]-{i/ga,\*kkeseo} vs. [+hon]-{\*i/ga,kkeseo}

We then consider P as syntactic heads and the host phrase as their complement.

But the following data shows that some P differ from ordinary heads:

- (28) a. Paul-(i) Mary-(ui) ileum-(eul) bull-esss-da.  
 Paul-nom Mary-gen name-acc called.  
 Paul called Mary's name.
- b. Paul-{eun,do,man,jocha} chaeg-{eun,do,man,jocha}  
 Paul-{top,also,only,even} book-{top,also,only,even}  
 ppalli-{neun,do,man,jocha} ilg-neun-da.  
 fast-{top,also,only,even} read-prog-decl.  
 Paul read books fast.

We propose to treat P as weak syntactic heads having underspecified syntactic properties and sharing those of the complement. P in (28a) can be omitted, because they have underspecified syntactic properties. P in (28b) share the complement's syntactic properties and consequently have no effect on the syntax of the phrase.

P in (28) share the category of the complement. For example, *-man* in (28b) forms an NP after an NP but an AdvP after an AdvP. It shares also the case value of an NP and the form value of a VP. These values are percolated up to the mother phrase and checked by the verb:

- (29) a. Paul-i nol-{ji,\*go}-man anh-ass-da.  
 Paul-nom play-Comp-only didn't.  
 Paul didn't only play.
- b. Paul-i nol-{\*ji,go}-man sipeoha-yeoss-da.  
 Paul-nom play-Comp-only wanted.  
 Paul wanted only to play.

P in (28a) share the complement's syntactic properties too. But they restrict the phrase's distribution, as illustrated in (24a). In order to account for the fact, we introduce the marking feature and attribute different values to them (Abeillé *et al.* 2004). Then they percolate different values to the mother phrase and the latter appear in different positions. For example, *Paul-i* and *Paul-eul* appear in subject and object positions respectively whereas *Paul* is compatible with both positions<sup>5</sup>.

We treat semantic case P as weak heads, too. But, they can't be omitted (30a) and

---

<sup>5</sup> So, marking P in our analysis differ from case markers or case marking elements in derivational approaches that manifest a case value without assigning it.

forbid a phrase to appear in direct positions (30b-c):

- (30) a. Paul-i jib-\*(eseo) jam-eul ja-n-da.  
 Paul-*nom* house-(*loc*) sleep-*acc* sleep.  
 Paul sleeps at home.
- b. jib-#{e,eseo,lo}-i muneoji-eoss-da.  
 house-{*loc,loc,by*}-*nom* broke  
 the house broke down.
- c. Paul-eun jib-#{e,eseo,lo}-eul ji-eoss-da.  
 Paul-*top* house-{*loc,loc,by*}-*acc* built.  
 Paul built a house.

We will treat them as having a specified case value, oblique in our analysis. They share the complement's syntactic properties but not the case value. And they combine only with an NP complement, since it is the only category compatible with a case value.

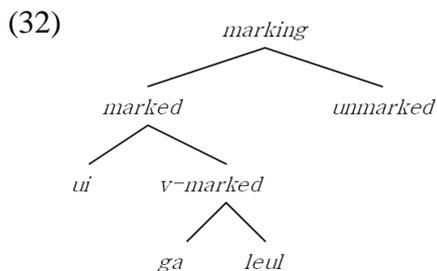

### 3.3. P's syntactic information and subtypes

We propose to divide P into 3 subtypes: marking P, oblique P and semantic P, and to use marking and case features in order to account for their difference in the syntax.

1) Grammatical case P (-i/ga, -(l)eul, -ui) and 2 non case P (-(n)eun, -do) must be grouped together, because they have similar behaviours. They can't be followed by other P (8); they can't appear together (31); they allow a phrase to appear in inaccessible positions, as illustrated in (24b) and (26).

- (31) \*Paul-{i,eul,ui,eun,do}-{i,eul,ui,eun,do}  
 Paul-{nom,acc,gen,top,also}-{nom,acc,gen,top,also}

We treat them as marking P having a specified value for the marking feature. Their marking value forbids other P to appear after them and restricts the phrase's distribution in the sentence. But it doesn't affect the syntactic function of the phrase, since marking P can be omitted. We use the following values set:

The *v-marked* value forbids the mother phrase to appear inside an NP, for example as a genitive complement. It is attributed to -(n)eun and -do that don't restrict the

distribution of the mother phrase while *-i/ga* and *-(l)eul* have more specified values. On the contrary, *-ui* conveys *ui* value and its mother phrase can't appear as a verbal constituent. The value *unmarked* is given to non marking P.

2) *-i/ga*, *-(l)eul* and *-ui* are not case P, since they have properties of non case P. They can be omitted as shown in (28a); they can attach to an oblique complement or an NP adjunct without changing its function (33); they combine with non case categories (33-34):

- (33) a. Paul-i bang-e-leul deuleoga-ss-da.  
 Paul-nom room-loc-acc entered.  
 Paul entered the room.
- b. Paul-i bang-eseo-leul nao-ass-da.  
 Paul-nom room-from-acc came out.  
 Paul came out of the room.
- (34) a. bi-ga manhi-{ga,leul} naeli-eoss-da.  
 rain-nom much-{nom,acc} fell.  
 It rained much.
- b. Paul-i wain-eul manhi-leul masi-eoss-da.  
 Paul-nom wine-acc much-acc drank.  
 Paul drank wine much.
- (35) a. na-neun wain-eul masi-go-{ga,leul} sip-eoss-da.  
 I-top wine-acc drink-Comp-{nom,acc} wanted.  
 I wanted to drink wine.
- b. na-neun wain-eul masi-ji-leul anh-ass-da.  
 I-top wine-acc drink-Comp-acc didn't.  
 I didn't drink wine.

Moreover, we can account for the fact that they restrict the phrase's distribution by introducing the marking feature. And our analysis has an advantage to describe in a coherent way the fact that marking P restrict the distribution of the AdvP modifier and the VP complement:

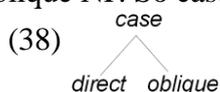

- (36) a. Paul-i wain-eul manhi-{\*ga,leul} masi-eoss-da.  
 Paul-nom wine-acc much-{\*nom,acc} drank.
- b. na-neun wain-eul masi-go-{\*ga,leul} iss-da.  
 I-top wine-acc drink-Comp-{nom,acc} am.  
 I am drinking wine.

3) We treat semantic case P as case P but attribute to them the same value: *oblique*, because it isn't easy to differentiate the syntactic function of oblique NP. For example,

*bang-e* ‘room-loc’ and *bang-eseo* ‘room-from’ in (33) are both oblique complements though they have different semantic functions. Moreover, it is difficult to distinguish oblique complement and NP adjunct without reference to the verb’s meaning, since most case P are compatible with both functions. For example, *-eseo* forms an oblique complement in (33b) but an NP adjunct in the following example:

- (37) Paul-i bang-eseo ja-n-da.  
 Paul-nom room-loc sleep-prog-decl.  
 Paul sleeps in the room.

We then consider all case P as having the *oblique* value. They combine with an NP and form an oblique NP. The latter appear in oblique positions, as oblique complement or adjunct. We introduce *direct* value to distinguish the NP in direct positions from the oblique NP. So case feature have 2 specified values:

Values like *nom*, *acc*, *etc.* are removed, because P considered as marking them are no more case P in our analysis. The *direct* value is introduced directly by nominal items, since an NP without a P may appear as subject or object.

4) All other P are treated as semantic P. They convey a contextual meaning and can’t be omitted. But they have no specified syntactic information, since they have no effect on the syntax of the phrase.

P then are divided into 3 subtypes, as illustrated in (40), based on the following properties:

- (39) a. marking P are optional and combine with various categories.  
 b. oblique P are not optional and combine only with NP.  
 c. semantic P are not optional and combine with various categories.

(40)

examples	marking P	oblique P	semantic P	in previous works
<i>-i/ga</i> ‘nom’, <i>-(l)eul</i> ‘acc’, <i>-ui</i> ‘gen’	X			grammatical case P
<i>-e</i> ‘loc’, <i>-ege</i> ‘dat’, <i>-(eu)lo</i> ‘to, by’, <i>etc.</i>		X		semantic case P
<i>-jocha</i> ‘even’, <i>-kkaji</i> ‘up to’, <i>etc.</i>			X	specific P

-(y)a ‘voc’	X			vocative P

#### 4. Descriptions in HPSG

This section shows how to describe our analysis in HPSG model (Pollard & Sag 1994, Sag *et al.* 2003, *etc.*). We introduce CL (Monachesi 1998) and MARKING (Abeillé *et al.* 2004) features to P’s feature structure and adopt the notion of weak head (Tseng 2002, Abeillé *et al.* 2005).

##### 4.1 P’s feature structure

In our analysis, P are clitics and weak syntactic heads. They select a non empty phrase as complement and attach to its last word in the phonology. They share the complement’s syntactic properties. And they are divided into 3 types: marking P, oblique P and semantic P. Marking P have a specified marking value while others have an *unmarked* value. Oblique P conveys an *oblique* case value.

If we introduce CL and MARKING features, P have a feature structure as follows:

$$(41) P \rightarrow \left[ \begin{array}{l} \text{HEAD}/[1] \\ \text{CL}+ \\ \text{MARKING} \textit{marking} \\ \text{COMPS} \langle \left[ \begin{array}{l} \textit{canonical} \\ \text{HEAD}/[1] \\ \text{MARKING} \textit{unmarked} \end{array} \right] \rangle \\ \text{COMPS} \langle \rangle \end{array} \right]$$

[CL +] indicates that P are clitics. The feature MARKING has an underspecified *marking* value, which will be replaced by a more specified one (see the value set in (32)). The feature COMPS indicates P’s complement: it is a non-empty (*canonical*) phrase (COMPS < >). [MARKING *unmarked*] is added in order to forbid a P to appear after a marking P. P share the complement’s HEAD values, which is represented by identifying their notation. / means sharing by default: P share the value but they override it by their own value, if there is one.

The feature structure of 3 subtypes can be obtained, if we add feature-values appropriate to each type to the description in (41):

- (42) a. marking P → P & [MARKING *marked*]  
b. oblique P → P &  $\left[ \begin{array}{l} \text{HEAD} \textit{CASE oblique} \\ \text{MARKING} \textit{unmarked} \end{array} \right]$   
c. semantic P → P & [MARKING *unmarked*]

And P items will have following feature structures including values defined by each of them:

- (43) a. *-i/ga* → marking P & [MARKING *ga*]  
 b. *-(l)eul* → marking P & [MARKING *leul*]  
 c. *-ege* → oblique P  
 d. *-(n)eun* → marking P & [MARKING *v-marked*]  
 e. *-kkaji* → semantic P

#### 4.2 Mother phrase's feature structure

P take the host phrase as complement in our analysis. They combine with each other following the syntactic rule HEAD-COMPLEMENT<sup>6</sup>:

$$(44) \begin{bmatrix} \text{HEAD}[2] \\ \text{COMPS} \langle \rangle \end{bmatrix} \rightarrow [\text{SYNSEM } [1]] , \begin{bmatrix} \text{HEAD}[2] \\ \text{COMPS} \langle [\text{SYNSEM } [1]] \rangle \end{bmatrix}$$

P share the complement's HEAD value and percolate it to the mother phrase according to the HEAD FEATURE PRINCIPLE:

$$(45) \begin{bmatrix} \text{HEAD}/[2] \\ \text{COMPS} \langle \rangle \end{bmatrix} \rightarrow [\text{HEAD}[2]] , \begin{bmatrix} \text{HEAD}/[2] \\ \text{COMPS} \langle [\text{SYNSEM } [1][\text{HEAD}[2]] \rangle \end{bmatrix}$$

Let's see some examples. If the complement is an NP, P constitute a direct or oblique NP with a specified MARKING value:

$$(46) \text{ a. Paul-i 'Paul-nom'} \begin{bmatrix} \text{HEAD}[2] \\ \text{MARKING}_{ga} \end{bmatrix} \rightarrow$$

$$\text{Paul } [1] \begin{bmatrix} \text{HEAD}[2] \begin{bmatrix} \textit{noun} \\ \text{CAS}_{direct} \end{bmatrix} \\ \end{bmatrix} , \quad \text{-i} \begin{bmatrix} \text{HEAD}[2] \\ \text{MARKING}_{ga} \\ \text{COMPS} \langle [1] \rangle \end{bmatrix}$$

$$\text{ b. doseogwan-eseo 'library-loc'} \begin{bmatrix} \text{HEAD} \begin{bmatrix} \textit{noun} \\ \text{CASE}_{oblique} \end{bmatrix} \\ \text{MARKING}_{unmarked} \end{bmatrix} \rightarrow$$

$$\text{doseogwan } [1] \begin{bmatrix} \text{HEAD}[2] \begin{bmatrix} \textit{noun} \\ \text{CAS}_{direct} \end{bmatrix} \\ \end{bmatrix} , \quad \text{-eseo} \begin{bmatrix} \text{HEAD}[\text{CASE}_{oblique}][2] \\ \text{MARKING}_{unmarked} \\ \text{COMPS} \langle [1] \rangle \end{bmatrix}$$

*-i* in (46a) constitute a direct NP, sharing the complement's HEAD value and percolating its MARKING value. *-eseo* in (46b) shares the category value but percolates its own CASE value, which gives an oblique NP.

P form an AdvP or a VP, if they combine with an AdvP or a VP:

$$(47) \text{ a. ppalli-man 'fast-only'} \begin{bmatrix} \text{HEAD}[2] \\ \text{MARKING}_{unmarked} \end{bmatrix} \rightarrow$$

<sup>6</sup> The rule places the complement before the head, reflecting the order in Korean.

$$\begin{array}{l}
\text{ppalli [1] [HEAD[2][adverb]],} \quad -\text{man} \left[ \begin{array}{l} \text{HEAD[2]} \\ \text{MARKINGunmarked} \\ \text{COMPS}<[1]> \end{array} \right] \\
\text{b. masi-go-leul 'drink-Comp-acc'} \left[ \begin{array}{l} \text{HEAD} \left[ \begin{array}{l} \text{verb} \\ \text{VFORM } ji \end{array} \right] \\ \text{MARKINGleul} \end{array} \right] \rightarrow \\
\text{meog-go [1] [HEAD[2] \left[ \begin{array}{l} \text{verb} \\ \text{VFORM } ji \end{array} \right] ],} \quad -\text{leul} \left[ \begin{array}{l} \text{HEAD[2]} \\ \text{MARKINGleul} \\ \text{COMPS}<[1]> \end{array} \right]
\end{array}$$

*-man* in (47a) combines with an AdvP complement and forms an *unmarked* AdvP, while *-leul* in (47b) composes an *leul*-marked VP.

2 or more P can attach to a phrase by successive combinations following the HEAD-COMPLEMENT rule. For example, *bang-e-leul* ‘room-loc-acc’ is composed in 2 steps, as follows:

$$\begin{array}{l}
(48) \text{ a. } \text{bang [1] } \left[ \begin{array}{l} \text{HEAD[2] \left[ \begin{array}{l} \text{noun} \\ \text{CASE direct} \end{array} \right] } \\ \text{MARKINGunmarked} \end{array} \right], \quad -\text{e} \left[ \begin{array}{l} \text{HEAD[CASE oblique]/[2]} \\ \text{MARKINGunmarked} \\ \text{COMPS}<[1]> \end{array} \right] \\
\rightarrow \text{bang-e} \left[ \begin{array}{l} \text{HEAD} \left[ \begin{array}{l} \text{noun} \\ \text{CASE oblique} \end{array} \right] \\ \text{MARKINGunmarked} \end{array} \right] \\
\text{b. } \text{bang-e [3] } \left[ \begin{array}{l} \text{HEAD[4] \left[ \begin{array}{l} \text{noun} \\ \text{CASE oblique} \end{array} \right] } \\ \text{MARKINGunmarked} \end{array} \right], \quad -\text{leul} \left[ \begin{array}{l} \text{HEAD[4]} \\ \text{MARKINGleul} \\ \text{COMPS}<[3]> \end{array} \right] \\
\rightarrow \text{bang-e-leul} \left[ \begin{array}{l} \text{HEAD} \left[ \begin{array}{l} \text{noun} \\ \text{CASE oblique} \end{array} \right] \\ \text{MARKINGga} \end{array} \right]
\end{array}$$

#### 4.3 Verb's feature structure

Finally, we show how phrases headed by P are realised in a sentence and how they are restricted by verbs. Let's look at first the basic case that they appear as an argument of a verb:

- (49) Paul-i      seonmul-eul    Mary-ege    bonae-ss-da.  
Paul-nom    gift-acc            Mary-dat    sent.  
Paul sent a gift to Mary.

The verb selects 3 arguments: 2 direct NP for subject and direct object and an oblique NP. It allows the subject and the direct object to be followed by a marking P: *-i* and *-eul*, respectively. These marking P can be omitted and be replaced by *-(n)eun* or *-do*. But they can't replace each other. The oblique object accepts also some marking P:

- (50) a. Paul-(i) seonmul-(eul) Mary-ege bonae-ss-da.

- b. Paul- $\{i, *eul, eun, do\}$  seonmul- $\{*i, eul, eun, do\}$   
 Paul- $\{nom, *acc, top, also\}$  gift- $\{*nom, acc, top, also\}$   
 Mary-*ege*- $\{*ga, leul, neun, do\}$  bonae-ss-da.  
 Mary-*dat*- $\{*nom, acc, top, also\}$  sent.

So the verb has a feature structure concerning its arguments and syntactic restrictions it imposes on them, as illustrated in (51):

$$(51) \text{bonae-ss-da 'sent'}$$

$$\left[ \begin{array}{l} \text{SUBJ} < \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } direct \\ \text{MARKING}[1]:[1] \leq ga \text{ or } unmarked \end{array} \right] > \\ \text{COMPS} \left\langle \begin{array}{l} \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } direct \\ \text{MARKING}[2]:[2] \leq leul \text{ or } unmarked \end{array} \right] \\ \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } oblique \\ \text{MARKING}[3]:[3] \leq leul \text{ or } unmarked \end{array} \right] \end{array} \right\rangle \end{array} \right]$$

The MARKING values are described in a complex form but they show the range of possible values on the value set in (32). For example, “[1]:[1] ≤ *ga* or *unmarked*” of the subject NP means: it may have an *unmarked* value or a value equal or superior to *ga* (i.e. *ga* or *v-marked*).

If we replace the verb *bonae-ss-da* ‘sent’ by another verb *ju-eoss-da* ‘gave’, the restrictions on the arguments may change:

- (52) a. Paul-(i) seonmul-(eul) Mary-(ege) ju-eoss-da.  
 Paul-*nom* gift-*acc* Mary-*dat* gave.  
 Paul gave an/the apple to Mary.

- b. Paul- $\{i, *eul, eun, do\}$  seonmul- $\{*i, eul, eun, do\}$   
 Mary-*ege*- $\{*ga, leul, neun, do\}$  ju-eoss-da.

- c. Paul-*i* seonmul-*eul* Mary- $\{*ga, leul, neun, do\}$  ju-eoss-da.

The restrictions on the subject and the direct object doesn’t change: their marking P can be omitted and replaced by *-(n)eun* and *-do*. But the oblique object has different restrictions: the oblique P may be omitted. So the verb has a different description for it<sup>7</sup>:

$$(53) \text{ju-eoss-da}$$

$$\left[ \begin{array}{l} \text{SUBJ} < \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } direct \\ \text{MARKING} [1]:[1] \leq ga \text{ or } unmarked \end{array} \right] > \\ \text{COMPS} \left\langle \begin{array}{l} \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } direct \\ \text{MARKING} [2]:[2] \leq leul \text{ or } unmarked \end{array} \right] \\ \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } direct \text{ or } oblique \\ \text{MARKING} [3]:[3] \leq leul \text{ or } unmarked \end{array} \right] \end{array} \right\rangle \end{array} \right]$$

<sup>7</sup> It is of course possible to give 2 descriptions to the verb: one with an oblique complement and the other with 2 direct complements.

The next case is the AdvP with a P that appears as adjunct:

- (34) a. bi-ga manhi-{ga,leul} naeli-eoss-da.  
rain-nom much-{nom,acc} fell.

It rained much.

- b. Paul-i wain-eul manhi-leul masi-eoss-da.  
Paul-nom wine-acc much-acc drank.  
Paul drank wine much.

The AdvP can be followed by *-i/ga* and *-(l)eul* in (34a) but only by the latter in (34b). It can appear alone or with *-(n)eun* or *-do* in both cases:

- (54) a. bi-ga manhi-(ga,leul,neun,do) naeli-eoss-da.  
b. Paul-i wain-eul manhi-(\*ga,leul,neun,do) masi-eoss-da.

So the verbs in (34) impose different restrictions on the adjunct's MARKING value. Then they must include the adjunct in their description, even though it is not argument. We put it in their COMPS, as follows:

- (55) a. naeli-eoss-da

$$\left[ \begin{array}{l} \text{SUBJ} < \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } direct \\ \text{MARKING}[1]:[1] \leq ga \text{ or } unmarked \end{array} \right] > \\ \text{COMPS} \langle \text{AdvP}[\text{MARKING}[3]:[3] \geq v\text{-marked or } unmarked] \rangle \end{array} \right]$$

- b. masi-eoss-da

$$\left[ \begin{array}{l} \text{SUBJ} < \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } direct \\ \text{MARKING}[1]:[1] \leq ga \text{ or } unmarked \end{array} \right] > \\ \text{COMPS} \langle \text{NP} \left[ \begin{array}{l} \text{HEAD|CASE } direct \\ \text{MARKING}[2]:[2] \leq leul \text{ or } unmarked \end{array} \right], \text{AdvP}[\text{MARKING}[3]:[3] \leq leul \text{ or } unmarked] \rangle \end{array} \right]$$

The verb in (55a) allows the AdvP to have an *unmarked* value or a value equal or inferior to *v-marked*, i.e. *v-marked*, *ga* or *leul*. But the adjunct may have an *unmarked* value or a value equal or superior to *leul*, i.e. *leul* or *v-marked* when it combines with the verb in (55b).

The final case is the example in (24b):

- (24) b. gongbuha-gi-neun doseogwan-eseo-\*(ga) joh-da.  
study-nominalizer-top library-loc-\*(nom) is good.  
the library is a good place to study in.

*-i/ga* after the oblique NP is not optional. It may be replaced by *-(n)eun* and *-do*, as shown in (26), while the verb refuses *-(l)eul*. *-i/ga* become optional again, if the oblique NP is replaced by a direct NP:

- (56) gongbuha-gi-neun doseogwan-(i) joh-da.  
study-nominalizer-top library-(nom) is good.  
the library is a good place to study in.

2 descriptions can be drawn from the observation:

(57) *joh-da*

- a.  $\left[ \begin{array}{l} \text{SUBJ} < \text{NP} \left[ \begin{array}{l} \text{HEAD} | \text{CASE } \textit{oblique} \\ \text{MARKING}[1]:[1] \leq \textit{ga} \end{array} \right] > \\ \text{COMPS} < \text{NP} \left[ \begin{array}{l} \text{HEAD} | \text{CASE } \textit{direct} \\ \text{MARKING}[2]:[2] \leq \textit{ga or unmarked} \end{array} \right] > \end{array} \right]$
- b.  $\left[ \begin{array}{l} \text{SUBJ} < \text{NP} \left[ \begin{array}{l} \text{HEAD} | \text{CASE } \textit{direct} \\ \text{MARKING}[1]:[1] \leq \textit{ga or unmarked} \end{array} \right] > \\ \text{COMPS} < \text{NP} \left[ \begin{array}{l} \text{HEAD} | \text{CASE } \textit{direct} \\ \text{MARKING}[2]:[2] \leq \textit{ga or unmarked} \end{array} \right] > \end{array} \right]$

The verb in (57a) takes an *oblique* NP as subject and requires that it have a value equal or superior to *ga*. In contrast, the verb in (57b) allows an *unmarked direct* NP to appear as its subject.

The verb allows also an AdvP to appear in this position and requires that it be followed by a marking P:

- (58) *gongbuha-gi-ga*                      *honja-\*(ga,neun,do)*    *joh-da*.  
 study-nominalizer-nom    alone-\*(nom)                      is good.

Being alone is good to study.

From the data, we can infer the reason why marking P may be omitted in (56) but not in (24b) and (58). *joh-da* originally selects a *direct* NP for subject. But, it allows also an *oblique* NP or non nominal phrase subject and requires that it have a specified marking value. In other words, the *direct* case value is required first by the verb and, if this requirement is not satisfied, a specified marking value is required as the second condition. Therefore, marking P can't be omitted, if an oblique NP or an AdvP appear as subject.

## 5. Conclusion

We proposed an analysis of Korean P and showed its description in HPSG.

In our analysis, P are weak syntactic heads taking the preceding phrase as their complement and sharing its syntactic properties. They are clitics attaching to its last word in the phonology. They are divided into 3 subtypes: marking P, oblique P and semantic P. To justify our analysis, we showed 1) differences between P and suffixes and possible accounts for P's suffix-like behaviors, 2) P's head properties and their differences from ordinary heads, and 3) P's distribution inside the phrase and the mother phrase's distribution in the sentence.

For the description in HPSG, we introduced CL and MARKING features to P's

feature structure and adopted the previous analyses of weak syntactic heads. Then P percolate not only shared feature values but also their own feature values, if there are any, up to the mother phrase. So the latter has similar properties to the complement and shows different behaviors also.

We revised also certain factors. Case values are reduced into 2: *direct* and *oblique* while MARKING feature is introduced to P's analysis and its values are specified. And we revised P's classification into 3 subtypes: marking P, oblique P and semantic P. The first P have the MARKING feature with a *marked* or more specified value. The second P have the CASE feature with an *oblique* value. The third P don't have specified values for syntactic features.

# The Interrelationship between Grammatical and Semantic Properties of Adjectives

KyoungNam Lee

Kangwon National University

kynalee@kangwon.ac.kr

Lee, KyoungNam, 2008. **The interrelationship between grammatical and semantic properties of adjectives.** *CIL* 18. The purpose of this paper is to investigate the interrelationship between semantic and grammatical properties of adjectives from a pedagogical perspective. The following respects—semantic difference according to position, meaning types and grammatical properties, distinguishing indicators between participial adjectives and verb participles, and syntactic and semantic characteristics according to adjectival complementation types—are dealt with in this study. As a result, it should be noted that we need to recognize the importance of the interaction between grammar, meaning, and lexical idiosyncrasy. The discussion of grammaticality without considering the lexical and semantic properties of adjectives has limitations that lead EFL learners to gain a very poor understanding of the category of adjective.

**Key words:** interrelationship, pedagogical, position, meaning types, grammatical, participial adjectives, complementation

## 1. Introduction

Adjectives are, when used as predicative complements or objective complements, an obligatory element of a sentence. When they are used as modifiers, they are optional elements. According to Altenberg(1993, cited in Kennedy (2003, p. 126), when the complement was an adjective, SVC type accounted for 45.6% of the 5,004 examples and SVOC type 1.5% in an investigation of the relative frequency of use of clausal patterns in 5,004 examples of the recurrent word sequences extracted from the *London-Lund Corpus of Spoken British English*. Additionally, another main function is as a modifier, typically realized more frequently in written genres than in spoken English (Kennedy, 2003).

In spite of such high frequency, this category tends to be touched on comparatively lightly with regard to teaching grammar or in EFL textbooks. As a result,

EFL learners are likely to have only a superficial knowledge, which leads to a narrow understanding and the misuse of adjectives. However, the use of adjectives in our language provides more detailed information and vivid descriptions. When adjectives are used as complements, furthermore, they determine the number of arguments by playing a role of predicate in logic. Accordingly, EFL learners need to be concerned with the proper understanding and appropriate use of this category.

In particular, the problem of appropriateness presumes the connection between form and meaning in discussing linguistic phenomena. In this case, grammar and lexicon could be conceived as "opposite poles of one continuum" (Celce-Murcia & Larsen-Freeman, 1999, p. 29) and certain grammatical constructions are closely connected with the idiosyncratic characteristics of certain words. Thus, the proper understanding of a given word implies that we can acquire the correct information about its syntactic and semantic features and co-occurrence restrictions.

Thus, the purpose of this paper is to investigate the interrelationship between the semantic and grammatical properties of adjectives from a pedagogical perspective and to help EFL teachers and learners understand the properties of adjectives better and use them correctly and appropriately. The discussion of grammaticality without considering the lexical and semantic properties of adjectives has limitations that lead EFL learners to gain a very poor understanding of the category of adjective. With this focus in mind, this paper will deal with the following problems: the semantic difference according to the position of adjectives, the interrelationship between meaning types of adjectives and grammatical properties, distinguishing indicators between participial adjectives and verb participles, and the syntactic and semantic characteristics according to adjectival complementation types.

## **2. The semantic difference according to the position of adjective**

In terms of position, adjectives occur attributively and predicatively. When they occur attributively, they are used as premodifiers (e.g. *useful* advice) or postmodifiers (e.g. something *useful*). In contrast, when adjectives are used predicatively (e.g. Your advice is *useful*., He makes her *happy*.), they function as subject complement or object complement and in such clause types as SVC or SVOC, predicative adjectives are obligatory elements. In this case, there is a copular relationship between subject and subject complement and between object and object complement.

Generally, with regard to the uses of adjectives, there are criteria for establishing

adjective classes and some examples are given below (Quirk et al. , 1985, p. 404).

- (1) # criteria  
 (a) attributive use  
 (b) predicative use after the copula *seem*  
 (c) premodification by *very*  
 (d) comparison

# examples	(a)	(b)	(c)	(d)	
<i>hungry</i>	+	+	+	+	central
<i>infinite</i>	+	+	-	-	
<i>old</i>	+	-	+	+	peripheral
<i>afraid</i>	?	+	+	+	
<i>utter</i>	+	-	-	-	
<i>asleep</i>	-	-	-	-	

Criteria (c) and (d) are determined by the semantic feature, gradability. The ability of functioning both attributively and predicatively is considered to be a central feature of adjectives. Many adjectives can occur in both positions, but certain adjectives must appear either prenominal or predicatively. According to the position, morphological properties of some adjectives are realized differently as shown in the following examples.

- (2) a. \*Either the driver fell asleep or he was *drunken*.  
 b. Either the driver fell asleep or he was *drunk*.  
 c. Groups of *drunken* hooligans smashed shop windows.

However, we still have a puzzling problem in that the morphological distinction is not always clear-cut because such compounds as *drunk driver* and *drunk driving* are listed in the dictionary.

According to Celce-Murcia & Larsen-Freeman (1999, pp. 382-383), the meaning types of adjectives which occur only in the attributive position are classified into eight categories and certain adjectives which can only be predicative are classified into three categories as follows:

(3) # Attributive adjectives

- ① Those adjectives that show the reference of the head noun has already been determined: *the **very/particular/same/self-same/exact** man I was seeking*
- ② Those adjectives that show us the importance or rank of the head noun:  
*their **main/prime/principal/chief** faults*
- ③ Those adjectives that show the head noun is recognized by law or custom:  
*the **lawful/rightful/legal/true** heir*
- ④ Those adjectives that identify the reference of the noun itself—that is, they tell us (in part) what the noun means—and that may not occur after the copula *be*:  
*a **medical** doctor      \*a doctor is medical,*  
*an **atomic** physicist, a **reserve** officer*
- ⑤ Those adjectives that qualify the time reference of the noun:  
*the **future** king, the **former** chairperson, the **present** monarch,*  
*the **previous** occupant*
- ⑥ Those adjectives that qualify the geographical reference of the noun:  
*a **Southern** gentleman, the **urban** crisis, a **rural** mail carrier*
- ⑦ Those adjectives that intensify or emphasize the head noun:  
*a **total** stranger, a **mere** child, **sheer** fraud, **utter** nonsense*
- ⑧ Those adjectives that show the uniqueness of the head noun:  
*the **sole** survivor, the **only** nominee, a **single** individual*

# Predicative adjectives

- ① Adjectives that begin with an *a*-prefix:  
*The boy is **asleep**. \*the asleep boy*
- ② Health adjectives: *Larry feels **faint**. / He is not **well**.*
- ③ Adjectives that must be followed by prepositional phrases or infinitives:  
*He's **bound** for China. / Debbie seems **inclined** to agree.*

Here, adjectives beginning with *a*- are generally used predicatively, but only a few can be freely used attributively. According to Quirk et al. (1985, p. 408), “*a*-adjectives vary as to whether they can be attributive. Most *a*-adjectives are only marginally acceptable in attributive function, unless they are premodified:”

- (4) a. ?an *afraid* look / ?an *alive* eye  
b. an *aloof* character / an *alert* manner

- c. a *somewhat afraid* soldier / the *fast asleep* children /  
a *really alive/lively* student / the *wide awake* patient

“Some *a*-adjectives freely take premodification by *very* and comparison (e.g. *afraid, alert, alike, aloof, ashamed* and *awake*). Others do so marginally (e.g. *asleep* and *awake*)” (Quirk et al., 1985, p. 409). This shows that linguistic phenomena are a problem of relative tendency and thus we also need a lexical approach.

Especially when adjectives are used postpositively, there are some restrictions. In the cases of compound indefinite pronouns and adverbs ending in *-body, -one, -thing, -where* or several institutionalized expressions (mostly in official designations and in certain fixed expressions mainly borrowed from French), the adjective is postpositive as shown in the following examples.

- (5) a. something *terrible*, somebody *important*  
b. attorney *general*, heir *apparent*, president-*elect*, notary *public*

Usually adjectives ending in *-able* and *-ible* can occur in either attributive or postpositive position like the following examples.

- (6) a. the best *possible* use ~ the best use *possible*  
b. the best *available* person ~ the best person *available*

However, "some postpositive adjectives, especially those ending in *-able* or *-ible*, retain the basic meaning they have in [the] attributive position but convey the implication that what they are denoting has only a temporary application (Quirk et al., 1985, p. 419)" as shown in the following examples.

- (7) A. a. the *visible* stars (a category of stars that can (at appropriate times) be seen)  
b. the stars *visible* (stars that are visible at a time specified or implied)  
B. a. the *navigable* river (permanent characteristic)  
b. the river *navigable* (temporary state)

This phenomenon can be found in some other adjectives. Let's focus on adjectives which cause a change in meaning according to their positions. Consider the following examples.

- (8) a. The *stolen* jewels
- b. The jewels *stolen*
- (9) a. The *guilty* people
- b. The people *guilty*
- (10) a. These jewels are stolen.
- b. These people are *guilty*.
- c. The river is *navigable*.

In (8a) and (9a), the adjectives are used attributively, so they describe something semantically more permanent or characteristic about the premodified nouns, while in (8b) and (9b), the adjectives are used postnominally and tend to reflect temporary states or specific events, according to Bolinger (1967). However, the adjectives are used predicatively in (10) and here, "predicative adjectives are potentially ambiguous, since we cannot tell whether the adjective is being used to describe something that is permanent and characteristic of the subject noun or something that is temporary or occasional " (Celce-Murcia & Larsen-Freeman, 1999, p. 388).

Such semantic tendencies of attributive adjectives can be found in the semantic comparison of the following constructions.

- (11) The house was *pink* in the sunset  $\neq$  The *pink* house
- (12) a. He is *sick*.
- b. He is a *sick* person.

Example (11) shows that attributive positions tend to reject the temporary and the occasional. Also, (12a) describes his present health condition, whereas in (12b) the quality seems to be much more enduring.

According to Celce-Murcia & Larsen-Freeman (1999, p. 389), other languages like Spanish use adjective position to mark meaningful differences as shown in the following examples.

- (13) a. El viejo amigo (a friend you have had a long time)
- b. El amigo viejo (a friend who is elderly)

In this section, the data related to the position was investigated and the following was found: 1) Some adjectives can occur prenominally and postnominally but their

implication or meaning can be different according to their position. Usually, the prenominal position conveys permanent or characteristic properties of the referent, whereas the postnominal position conveys a temporary attribute or state. 2) Some adjectives can occur attributively and predicatively, but other adjectives can occur only in one position. In this case, their meaning types or morphological characteristics can affect their distribution, but in some cases, lexical idiosyncrasy is an affecting factor. This complicated interrelationship needs to be understood by EFL learners.

### 3. The interrelationship between meaning types of an adjective and grammatical properties

The interrelationship between grammar and the polysemous characteristics of a word is another puzzling area for EFL learners. Let's look into the examples relevant to these characteristics.

- (14) a. the *conscious* patient ~ The patient is *conscious*. [= 'awake']  
b. He is *conscious* of his faults. [= 'aware']
- (15) a. I tried to reach him, but the line was *busy*. [= 'engaged']  
b. He is *busy*. [= 'hectic, preoccupied']
- (16) a. a very/rather *criminal* attack (gradable adjective)  
b. *criminal* law (classificatory adjective, 'law relating to crime' cf. civil law)  
c. a *criminal* lawyer (ambiguous, 'a lawyer specializing in criminal law / a lawyer who is criminal')

Here, we can see that an adjective can have various meanings. These polysemous characteristics affect the distribution of an adjective in a sentence. This study will investigate the interrelationship between polysemous characteristics and grammatical properties by classifying the relevant meaning types into the following four categories: 1) inherent vs. noninherent 2) amplifier vs. emphazier 3) gradable vs. non-gradable 4) dynamic vs. stative.

#### 1) inherent vs. noninherent

Consider the following examples (Quirk et al. 1985, pp. 428-429).

- (17) a. an *old* woman ('aged', contrast with a young woman) ~ That woman is *old*.

- b. an *old* friend of mine (a friend whom I have had for a long time) ~  
 \*My friend is *old* (if the meaning of *old* is the opposite of *new*)

In (17a), *old* with the meaning 'aged' can occur in attributive and predicative positions, while if the word means 'long-standing, not new', it is used only in attributive position, not predicative position. To distinguish them, Quirk et al. introduce the terms INHERENT and NONINHERENT. Inherent adjectives characterize the referent of the noun directly like (17a) and they can occur in both attributive and predicative positions, whereas noninherent adjectives can be said to be an extension of the basic sense of the noun and they can occur only in the attributive position, as shown in (17b).

However, this distinction is not absolute because some noninherent adjectives can be used predicatively according to the kind of modified referent like the following examples.

- (18) a. a *new* student, a *new* friend (noninherent 'new')  
 b. That student is new.  
 c. \*My friend is new.

The possibility of such a paraphrase sometimes depends on the semantic relationship between the modifier and the referent. This distinction between inherent and noninherent properties can apply to the difference in grammaticality of the following paraphrases. In other words, if an adjective is inherent, it is often possible to derive a noun from it (Quirk et al., 1985, p. 436).

- (19) a. a *true* report ~ the *truth* of the report (inherent)  
 b. a *true* scholar ~ \*the *truth* of the scholar (noninherent)

However, there is an exceptional case as shown in the example; a ***wooden*** actor (noninherent) ~ the ***woodenness*** of the actor. This case also shows lexical idiosyncrasy.

## 2) amplifier vs. emphasize

Some adjectives can be used to intensify the meaning of the referent. These are called intensifying adjectives and tend to occur in the attributive position. They can be divided into amplifiers (scaling upwards from an assumed norm) and emphasizees (with a general heightening effect) according to the semantic effect on the referent. This difference affects their grammatical properties. With regard to this point, compare the

following sets of expressions (Quirk et al., 1985, pp. 429-430).

- (20) a. a *complete* victory ~ The victory was *complete*.  
b. a *complete* fool ~ \*The fool is *complete*.
- (21) a. *total* destruction ~ The destruction was *total*.  
b. *total* nonsense ~ \*The nonsense was *total*.
- (22) a. I drank some *pure* ['clean'] water. ~ The water is *pure*.  
b. That is *pure* ['sheer'] fabrication. ~ \*The fabrication is *pure*.

In (20a), the meaning type of 'complete' belongs to an amplifier. If this adjective is used inherently in terms of its semantic effect on the referent, it can be classified as a central adjective. Thus, this construction can be paraphrased as SVC type. However, in (20b), although the adjective is used as an amplifier, it shows a noninherent property in relation to the referent, and as such is only attributive.

A similar contrast is also shown in the example (21). While 'total' is used as an amplifier in (21a), it is used as an emphasizer in (21b). When this adjective is used as an emphasizer, it is also only attributive. This explanation applies to the contrast in (22) as well. In (22a) 'pure' means 'clean', so it can occur both attributively and predicatively. On the other hand, in (22b) the adjective is used as an emphasizer, so it is used only attributively. The above-mentioned examples show us the polysemous characteristics of a word and their influence on syntactic properties. When we paraphrase such constructions in SVC type, we need to consider the relationship between the referent and the adjective in terms of meaning type.

### 3) gradable vs. non-gradable

Generally, it is thought that adjectives can take comparison, but when we teach the category of adjective, we need to make learners notice that every adjective cannot always take comparison and that it depends on gradability, a semantic characteristic of an adjective. In Collins Cobuild (1990), adjectives are divided into two main types, qualitative and classifying, on the basis of gradability. Qualitative adjectives are gradable but classifying adjectives are non-gradable. While gradable adjectives can take comparison and be modified by degree adverbs, non-gradable adjectives cannot, as shown in the following examples. Here, these non-gradable adjectives are subclassified.

- (23) a. reference or denominal adjectives: \* *the very former senator*  
\* *an atomicer scientist*

- b. adjectives with an absolute meaning: \**a very **perfect** copy of the original*
- c. adjectives of nationality: \**She is very **British**.*
- d. material adjectives: \**a very **wooden** table* (cf. *She is a very **wooden** actress.*)

Polysemous characteristics of an adjective can often confuse EFL learners about their grammatical property. In the case of (23c), the relevant word *British* can mean either nationality or some aspect of behavior. If the meaning refers to the latter, it can be modified by an intensifier (e.g. *She is very British.*). Likewise, the difference in grammaticality of the constructions in (23d) is also related to the polysemous characteristics of the adjective, and in the latter case the relevant meaning is ‘natural’ and so it can be modified by a degree adverb.

Now, this study will look into syntactic properties which are influenced by the interrelationship between gradable adjectives and polarity. Some gradable measure adjectives consist of a pair of opposite words and they show a contrast in polarity, which refers to positive and negative contrasts in meaning. The adjectives with positive polarity are unmarked because they are used typically in neutral contexts where we ask about something, while the opposite words with negative polarity are marked and are used less frequently. The following examples show this point.

(24) <old, young>

Positive polarity: ex. How *old* is he? [unmarked and general question]

Negative polarity: ex. How *young* is he? [marked and reserved for unusual contexts]

Thus, when we try to explain the difference in grammaticality or acceptability by using a meaning type such as gradability, it would be helpful for EFL learners to have a deeper understanding of the property of adjectives.

#### 4) dynamic vs. stative

Here is another contrastive meaning type. Adjectives are characteristically stative and they do not usually take the progressive form or the imperative. In spite of this fact, many adjectives can be seen as dynamic. In particular, most adjectives that are susceptible to subjective measurement are capable of being dynamic. A general semantic feature of dynamic adjectives seems to be that they denote qualities that are thought to be subject to control by the possessor and hence can be restricted temporally. These dynamic adjectives “can be used predicatively to refer to a temporary state, a change in progress, or something immediate (Celce-Murcia & Larsen-Freeman, 1999, p.

590).” We can see the difference in grammatical behavior of stative adjectives and dynamic adjectives in the following examples.

(25) a. stative adjectives: *tall, old, black, wide, pretty* etc.

*\*He’s being tall. / \*Be tall.*

b. dynamic adjectives: *careful, jealous, obstinate, brave, shy* etc.

*He’s being careful. / Be careful.*

#### 4. Distinguishing indicators between participial adjectives and verb participles

In terms of morphological properties, participial adjectives ending with *-ing* or *-ed* and verb participles have the same forms, but their grammatical properties are obviously different. Such participial adjectives are frequently used in written genres. As Kennedy (2003, p. 234) mentioned, it is difficult to tell the difference between participial adjectives and verb participles and learners of English often find participial adjectives confusing and sometimes interpret them as verbs. As a way of avoiding such confusion, we can use an intensifier test such as *very* or *extremely* before the relevant word or replace *be* by *seem* in SVC type.

(26)	adjectives	verb participles
a.	Her views were very <i>alarming</i> .	*Her views were very <i>alarming</i> his audience.
b.	I was extremely <i>relieved</i> .	*I was extremely <i>relieved</i> by another teacher.
c.	She is very <i>calculating</i> .	She is <i>calculating</i> our salaries.
	→ She seems very <i>calculating</i> .	→ * She seems <i>calculating</i> our salaries.

As shown in (26a, b) we cannot put such intensifiers before participles that are used as verbs, and in (26c) the replacement by *seem* is not allowed before a verb participle. Greenbaum & Quirk (1990) refer to ‘verbal force’ as helping determine whether to interpret the words ending with *-ing* or *-ed* as an adjective or a participle.

These participial adjectives can be used predicatively or attributively as follows.

- (27) a. His views were very *surprising*. / his *surprising* views  
b. The man seemed very *offended*. / the *offended* man  
c. The results were *unexpected*. / the *unexpected* results  
d. All his friends are *talented*. / his *talented* friends

While (27a) and (27b) show that their participial adjectives are rooted in the corresponding verbs (*to surprise, to offend*), there are no corresponding verbs of participial adjectives in the cases of (27c) and (27d) (*\*to unexpect, \*to talent*). Thus, Quirk et al. (1985, p. 413) argue that "when there are no corresponding verbs, the forms are obviously not participles." However, we need to notice that some participial adjectives can be used only predicatively as shown in the following examples.

- (28) a. ??the *faded* curtains / ??the *retired* manager  
 b. The curtains are *faded*. / Her father is now *retired*.

Sometimes, even though there is a corresponding verb, they have different meanings, which can cause ambiguity according to whether the word is used as a participle or a participial adjective (Quirk et al., 1985, p. 414).

- (29) a. ADJECTIVE: She is (very) calculating (but her husband is frank).  
 PARTICIPLE: She is calculating (our salaries).  
 ['. . . so don't disturb her while she is doing the arithmetic.']  
 b. ADJECTIVE: They were (very) relieved (to find her at home).  
 PARTICIPLE: They were relieved (by the next group of sentries).

As shown in the above-mentioned examples, participles and participial adjectives are not distinguishable morphologically, so premodification by the intensifier *very* or the replacement of *be* by *seem* can be used as an indicator to distinguish between them.

However, when there is no such indicator as shown in the following sentence, '*The man was offended*!', the status of the participle form is indeterminate, which means that the sentence can be ambiguous. According to Quirk et al. (1985, p. 415), the participle interpretation focuses on the process, while the adjective interpretation focuses on the state resulting from the process.

To avoid such confusion, there are some verbs which have different participle forms for verbal and adjectival use, as shown in the following examples (Quirk et al., 1985, p. 416).

- (30) a. You have *drunk* too much. ~ *drunk(en)* driving/driver  
 b. Have you *shaved*? ~ a *clean-shaven* young man  
 c. The shirt has *shrunk*. ~ a *shrunk* shirt

Another problem for EFL learners is the use of participial adjectives derived from emotive verbs such as *amuse, annoy, bore, confuse, embarrass* etc. As Celce-Murcia & Larsen-Freeman (1999) and Yule (2000) point out, there is a tendency for EFL learners to overgeneralize the *-ing* participle or confuse the use of adjectives ending with *-ing* and *-ed* forms, as shown in the following examples.

- (31) A. a. \*I am *interesting* in movies.  
 b. I am *interested* in movies.  
 B. a. \*She is *embarrassing* about that question.  
 b. She is *embarrassed* about that question.  
 c. \*The question is *embarrassed*.  
 d. The question is *embarrassing* to me. (adjective)  
 e. The question is *embarrassing* me. (verb participle)

In this case, if we explain that *-ing* adjectives are related to the causer and *-ed* adjectives are related to the experiencer by using the semantic roles ‘experiencer’ (the one experiencing the emotion) and ‘causer’ (the one to refer to the cause or source of the experience), it will be helpful for EFL learners to understand the semantic and grammatical properties of these adjectives more easily.

Now, the relationship between intransitive verbs and their adjectival derivation will be examined. We can divide intransitive verbs into unergative verbs (those whose subject is generated external to the verb phrase) and ergative verbs (those whose subject is generated in the structural object position of the verb phrase). Likewise, Cinque (1990, p. 231) argues that "a comparable distinction must be recognized for [the] class of intransitive adjectives, despite the fact that adjectives morphologically related to 'ergative' verbs are not themselves 'ergative'."

With regard to this point, we will look into the following examples given in Kearns (2000, pp. 248-9).

- |                            |                  |
|----------------------------|------------------|
| (32) A. his tent collapsed | a collapsed tent |
| the milk has curdled       | curdled milk     |
| the leaves have fallen     | fallen leaves    |
| the ankles have swelled    | swollen ankles   |
| the flowers have wilted    | wilted flowers   |
| the shirt had wrinkled     | a wrinkled shirt |

the puddles had frozen	frozen puddles
B. people have talked	* recently talked people
the patient had coughed	* a coughed patient
the light has flashed	* a flashed light
several competitors have run	*several run competitors
children had played	*played children
a patient had sneezed	* a sneezed patient
the bull had charged	* a charged bull

These examples show that the past participles of intransitive verbs can sometimes be converted into adjectives, and sometimes cannot. How can we explain this difference? As Cinque suggested, the distinction of intransitive verbs between unergative verbs and ergative verbs is helpful to explain this difference. The examples of (32A) belong to ergative verbs. Their subjects are generated in the structural object position of the verb phrase, and thus their thematic roles are 'themes'. In contrast, those of (32B) do not belong to ergative verbs. Their subjects are generated external to the verb phrase, and so the thematic roles of most of these verbs are 'agents'. Such differences help explain the possibility of converting a past participle into an adjective.

#### 5. Syntactic and semantic **characteristics according to adjectival complementation types**

When we consider the category of adjective, we are likely to think of only the functions of modifier and predicate complement and to neglect the fact that they can take their own complements. However, some adjectives can take complements of their own to elaborate their meaning, an operation called adjectival complementation. There are four types in this complementation: Adjectives may be followed by a prepositional phrase, a finite clause, a non-finite *to*-infinitive or an *-ing* participle clause as shown in the following examples.

- (33) a. I'm grateful for your help.  
 b. I'm sorry that you failed in the examination.  
 c. I was sorry to hear that news.  
 d. She was busy doing homework.

When adjectives are followed by a prepositional phrase, particular adjectives are combined with particular prepositions as shown in (34), and also some adjectives can be combined with more than one preposition according to the intended meaning like in (35).

- (34) a. They're *dependent on* each other.  
b. They are *sure of* their success.  
c. I'm *sorry about* what's happened  
d. Most people are too *busy with* their own troubles to give much help.
- (35) a. I'm not very *good at* dancing. (skillful and successful at doing something)  
b. Rain water was once considered to be *good for* the complexion. (benefit)  
c. My receptionist is very *good with* people. (skillful at using something or dealing with someone)  
d. Her mother was *good to* me. (an expression meaning kind to someone)

This shows us polysemous characteristics of a word and the choices of different prepositions according to different meanings. Thus, we need to notice the interaction between adjectives and prepositions and acquire these lexical units as collocations.

Now, consider another group of sentences with regard to *to*-infinitive adjectival complementation. Here, we can find some interesting linguistic phenomena.

- (36) A. a. He is wont to be late.  
b. \*He is wont.  
B. a. Max is averse to games.  
b. \*Max is averse.  
C. a. She is sure to win = It is certain that she will win  
b. She is sure = She is not in any doubt.  
D. a. She is eager to win.  
b. She is eager.

(36A) and (36B) show that in 'wont' and 'averse' types the complement is obligatory. However, in (36C), there is a change in the meaning of the adjective according to whether the adjective takes a complement or not, while there is no change in the meaning of the adjective without regard to the complementation in (36D).

Furthermore, when adjectives are followed by *to*-infinitive clauses, we need to distinguish a direct complement licensed by the adjective lexeme itself from

superficially similar constructions. Compare the following examples (Huddleston & Pullum, 2002, p. 1256).

- (37) a. You are [free to leave when you want].
- b. She's [too young to go to school].
- c. She's [young] to be going to school.
- d. I was [mad] to volunteer.
- e. It would be [foolish] to ignore them.

Among the examples given in (37), a real complement licensed by an adjective is (37a). In the case of (37b), the *to*-infinitive clause is licensed by *too* rather than by the adjective *young*, so this infinitival is an indirect complement. In the cases of (37c) and (37d), the infinitival is used as an adjunct, not a complement, which means that it is not lexically licensed. According to Huddleston & Pullum, the syntactic difference between a complement and an adjunct is shown in such ungrammatical constructions as *\*She is one of those young to be going to school* and *\*Anyone mad to volunteer can't expect much sympathy*. Therefore, the infinitival here does not form part of the adjective phrase. The infinitival in (37e) is not a complement of the adjective but is an extraposed subject, so the relevant sentence without extraposition is *To ignore them would be foolish* and as such is not part of the adjective phrase.

When we look into non-finite complements of adjectives, we need to distinguish syntactic differences in derivation according to the types of adjectives. Compare the following examples (Huddleston & Pullum, 2002, pp. 1257-8).

- (38) a. Their argument was [impossible [to follow \_ ]].
- b. Kim was [anxious [to follow the argument]].
- (39) a. Liz was determined to convince them.
- b. Liz was likely to convince them.

The sentences given in (38) and (39) superficially seem to be similar, and the infinitival complements are all licensed by the head adjectives. However, there are syntactic differences between them. In the case of (38a), although the syntactic subject is 'their argument', it is derived from the object position of the *to*-infinitive verb 'follow' and it is not a logical subject of the predicate 'impossible'. Normally such clauses as (38a) have a gap in some non-subject function, that is, object of a verb or preposition in the infinitival complements. On the other hand, the subject of the sentence (38b), 'Kim',

is a logical subject of the predicate 'anxious' and also a covert subject of the *to*-infinitive verb 'follow'. Thus, we need to classify non-finite complements of adjectives into different types. Huddleston & Pullum calls cases like (38a) 'hollow infinitivals' and cases like (38b) 'ordinary infinitivals'. The following adjectives can take 'hollow *to*-infinitivals': *awkward, bad, boring, convenient, dangerous, desirable, difficult, easy, embarrassing, essential, hard, impossible, odd, pleasant, tough, useful, wonderful* (Huddleston & Pullum, 2002, p. 1246).

Now, the structural property of (39) will be examined. (39a) is an example of a non-raising adjective construction, while (39b) is an example of a raising adjective construction. In (39a) and (39b), the adjectives 'determined' and 'likely' commonly function as predicative complements and take an infinitival complement, so their constructions look similar superficially. When considering their logical relationship of argument and predicate, however, there are some grammatical and semantic differences between them. In (39a), *Liz* is an argument of 'determined to convince them', but in (39b) the likelihood applies to the situation of '*Liz*'s convincing them', not to *Liz*. Therefore, we can respectively paraphrase (39a) as '*Liz*<sub>i</sub> was determined that she<sub>i</sub> would convince them.' and (39b) as 'It was likely that *Liz* would convince them.'

Adjectives belonging to the same type as 'determined' take an animate subject but adjectives such as 'likely' do not have a direct semantic relation to their subjects. Adjectives taking a raised subject are as follows: *about, apt, bound, certain, due, fated, liable, set, sure, wont*. In contrast, adjectives taking ordinary subjects are much more numerous (Huddleston & Pullum, 2002, p. 1258).

Now, consider adjective complementation by *that*-clauses. As shown in the following examples, we can divide *that*-clauses following an adjective into three types: (Quirk et al. 1985, p. 1222)

- (40) a. indicative verb: *I am sure (that) he is here now.*
- b. subjunctive verb: *They were insistent (that) we be ready.* <formal>
- c. putative should: *I'm sorry (that) he should have left.* <formal>

The indicative *that*-clause refers to an established fact. On the other hand, mandative subjunctive can be used with adjectives whose meaning contains semantic conditions such as 'demand, recommendation, proposal, resolution, intention, etc'. The relevant examples are as follows: *advisable, desirable, fitting, imperative* (Quirk et al. p. 157).

The putative *should* construction has nonfactual bias and can often be used after

adjectives with the meaning of such emotion as *sorrow, joy, displeasure, surprise, wonder*, etc. There is a tendency to prefer this construction in nonassertive contexts, or where the adjective has negative or unfavorable association (Quirk et al., 1985, pp. 1222-3).

Quirk et al. classify adjectives with an 'experiencer' as subject into the three types as follows.

(41) (i) *That*-clauses with indicative verb only.

These adjectives express degrees of certainty or confidence:

*aware, certain, confident, sure.*

(ii) *That*-clause with putative *should*, or subjunctive verb.

The three principal adjectives in this class are *anxious, eager*, and *willing*.

(iii) *That*-clause with indicative verb or putative *should*.

These adjectives express emotions: *afraid, hopeful, angry, proud, alarmed, disturbed, pleased, shocked, upset* etc.

With regard to gerund-participial complements, there are only a few adjectives licensing such a form: *busy* and *worth/worthwhile*. In this case we can also divide adjectives into various types in terms of the logical relationship between the subject and predicate adjectives as in the adjectives taking infinitival complements: ordinary, hollow, and impersonal, as shown in the following examples (Huddleston & Pullum, 2002, p. 1259).

(42) a. She was busy [preparing her report]. [ordinary]

b. These objections; aren't worth [bothering about \_i]. [hollow]

c. It isn't worth [taking the matter any further]. [ordinary; impersonal]

In the cases of such adjectives as *too, enough*, and *sufficient*, infinitival complements are indirectly licensed by them. "The licensors indicate degree relative to some need, purpose, desire, etc." (Huddleston & Pullum, 2002, p. 1263).

## 6. Conclusion

What I have tried to show in this paper is that we need to recognize the importance of the interaction between grammar, meaning, and lexical idiosyncrasy in order to

understand linguistic phenomena relevant to the category of adjective properly. For the purpose of teaching and learning English, in particular, the interface between grammar, meaning, and lexical idiosyncrasy must be dealt with carefully. With this focus in mind, the interrelationship between grammatical and semantic properties of adjectives has been investigated in the following respects.

With regard to the factor of the position of adjectives in a sentence—prenominal, postnominal and predicative—this study shows that there are some differences in meaning according to the position and that in some cases morphological properties or lexical idiosyncrasy can affect their distribution.

In respect to the interrelationship between meaning types of adjectives and grammatical properties, this study shows that the polysemous characteristics of a word are determining factors, that we need to consider the meaning types of a given adjective in relation to its modified noun referent and that according to meaning type the relevant grammatical behavior is affected.

Learners of English often find it difficult to distinguish between participial adjectives and verb participles. Indicators to distinguish them, like the use of an intensifier test and the replacement of *be* by *seem* in SVC type, prove to be effective. Additionally, in some cases, there are semantic or morphological characteristics according to the function as a participial adjective or as a verb participle. The distinction between ergative and unergative intransitive verbs can also be helpful in explaining the possibility of converting a past participle into an adjective.

Lastly, with regard to adjectival complementation, it should be pointed out that in teaching or learning English, we tend to emphasize only the main functions of adjectives as modifiers and predicate complements while neglecting the fact that they can take their own complements. However, adjectives can be followed by a prepositional phrase, a finite clause, a non-finite *to*-infinitive or an *-ing* participle clause. In relation to such complementation, polysemous characteristics and collocation have to be considered. In the case of a *to*-infinitive complement, furthermore, it is important to distinguish a direct complement licensed by the adjective itself from superficially similar constructions and to notice that there are ‘hollow infinitivals’, ‘ordinary infinitivals’, ‘raising adjective constructions’ and ‘non-raising adjective constructions’ according to each one’s syntactic and semantic properties. When adjectives take a *that*-clause or a gerund participial complement, it must be emphasized that syntactic differences are related to the semantic properties of the relevant adjectives

# Democratization and Language Policy Changes in Spain and Paraguay

**Kyunghee Kim**

Spanish Department of Hankuk University of Foreign Studies  
270 Imun-Dong, Dongdaemun-Gu  
moaikim@hufs.ac.kr

## **Abstract**

Hypothetically, we could suppose that a dictatorial regime justifies a highly centralized language policy while a democratic regime requires a decentralized language policy that might respect the language rights of all citizens and their linguistic freedom. In this paper, we examine Spain and Paraguay because they are countries well-known for their language policy changes in transition to democratization after more than 35 years of dictatorship. We investigate whether the type of government directly influenced the choice of type of language policy in these countries.

From the comparative analysis, we conclude that the type of political regimes (i.e., dictatorship or democratization) does not have a direct relationship with centralization of language policies, though the transition from one political regime to another could provoke crucial changes in language policy just as in any other aspect of society.

**Keywords:** language policy changes, centralized language policy, decentralized language policy, Spain, Paraguay.

## **1. Introduction**

It makes sense to hypothesize that a dictatorial regime would justify a highly centralized language policy but a democratic regime would require a decentralized language policy, respecting all citizens' language rights and linguistic freedom. Schiffman (1996:1), for example, proposes a continuum of language policies, from the autocratic centrist policy of France to the multilingual accommodationist policy of India, with the USA somewhere in between. According to this kind of classification, the typology of language policies not only depends on the kinds of political regimes but also on historical changes.

In this paper, we choose Spain and Paraguay, because they are well-known for their language policy changes in their transition to democratization after more than 35

years of dictatorship. We investigate whether government type directly influenced these countries' language policies, analyze the principle factors which caused language policy changes, and observe what has happened after their application. For this purpose, we consider the case of Spain in part 2 and the case of Paraguay in part 3. Finally, we conclude by comparing the two cases.

## **2. Spain**

### *2.1. Centralized Language Policy during Franco's Dictatorship*

The Castilian language was renamed as Spanish language in 1923 by the dictator Primo de Rivera (1923-30), though the Castilianization begun in the 18<sup>th</sup> century during the regime of Felipe the 5<sup>th</sup>. During the Franco period (1939-75), his model of Spain was of a totally unified nation with one single, unchallenged, centralized regime, and with one Spanish identity. For this purpose, the use of one single unified language was fundamental. The regions with their own proper languages could not be respected. The Castilianization process was accelerated and any deviation from this was oppressed.

At the beginning of the regime, the use of the regional languages was very heavily punished. Their public use, including teaching, was prohibited. Disobeying this prohibition was sanctioned with fines and even prison sentences. But by the end of the regime, this prohibition had weakened considerably. The use of regional languages was tolerated in more trivial activities, and they were considered dialects which might be dominated by Spanish in the linguistic hierarchy. Many of the speakers of regional languages were still able to transmit these languages to their children, but they did not, because they felt guilty doing it, and thus there was no development and full acquisition of the regional dialects by the younger generation due to the lack of teaching to consolidate and reinforce their use and learning (Mar-Molinero 2000: 84).

The regional languages were rapidly losing, but the regime's clever propaganda drive to promote the Castilianization made one costly mistake as mentioned by Mar-Molinero (2000: 85): "The rejection and even ridicule of the minority languages became so closely associated with the ideology of the Franco regime that it also served as a point of reference around which to build the opposition to it. Language became a symbolic standard bearer for and against the regime."

In any case, because of this Spanish monolingual language policy, the bilingual population decreased considerably and the whole population of Spain could speak Spanish. But as a reaction against this Castilianization policy, the regional languages began to be recognized by the oppressed people as a major symbol of their identity against the dictatorship. The recovery of linguistic rights was considered an essential point of democratization.

## *2.2. Decentralized Multilingual Policy through Democratization*

The end of the Franco dictatorship in 1975 initiated the democratization of the nation and the 1978 Constitution consolidated the transition to democracy. On the basis of this constitution, Spain changed from a highly centralized political regime to one of the most decentralized in the world through the recognition of the autonomy of the regional communities. At the same time it declared multilingualism and the protection of linguistic rights, though the official use of Spanish language nationwide continued to be a legal obligation for its people. This means that the realization of multilingualism is dependent ultimately not on the central state policy, but on the individual community's policy. Consequently, as a nation, Spain assumed a partial multilingual policy and the regional communities such as Catalonia, Valencia, the Balearic Islands, Galicia, the Basque Country and Navarra decided to implement multilingual language policies to promote the normalization of their communities' own local languages. Their legal texts regarding language policy are very similar, but their realization is very different because of the distinct language situations and the different economic and social nature of the regions. After the application of multilingualism, the most successful regional language is the Catalan language used in Catalonia, while the less successful language is the Basque language in Navarra.

Before the dictatorship, the Catalan language was used by the majority of the population, and it was considered to be a prestigious language. So the suppression during the dictatorship caused the great desire to recover it. Now, after the democratization, for the official meetings and the administration in the local government it is used officially. The education in Catalan language is obligatory. Sixty percent of classes at the University of Barcelona and 90% of classes at the University of Pompeu Fabra are conducted in Catalan (Siguán 2005: 153).

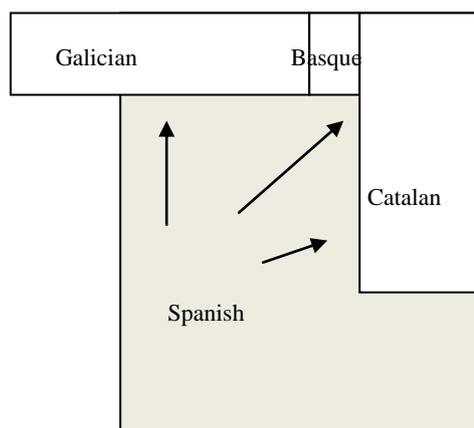

Meanwhile, before the dictatorship, the Galician language was used by the majority of the population, but it was considered to be a less prestigious language.

Therefore, the rejection of Castilianization was relatively weak. Now, after democratization, it is now used for official meetings and local government administration, though education is conducted in Spanish. Twenty percent of classes at the University of Santiago de Compostela are conducted in Galician.

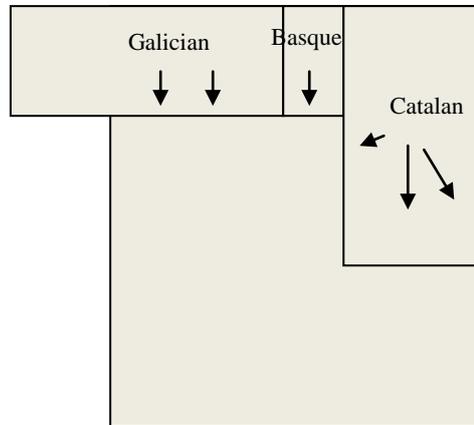

On the other hand, before the dictatorship, the Basque language was used by less than 20% of the population. Due to the lack of a standard writing system, it was difficult to learn Basque, so during the dictatorship, it weakened drastically. Now, for official parliamentary meetings a simultaneous translation system is used. There is an option to be educated in either language, Castilian or Basque. In universities, however, few majors are offered in Basque.

### 2.3. Current Problems in the Application of Multilingual Policy

From the period of the dictatorship, the general Castilianization of the nation was achieved. After democratization, much of the success in promotion of the regional languages in their own territories has also been achieved. The multilingual policy is adapted to each individual community's economic power and the willingness of its people. This has contributed to the balanced development among distinct regions and has become a relevant example of linguistic democratization in the world.

<Figure 1> Castilianization during Franco's Dictatorship

<Figure 2> Current Situation in Spain

In Figure 1 we observe that Castilianization was forced toward the non-Castilian speaking regions, while in Figure 2, that process has been completed, though the extension of the regional languages is now growing. However, there are some serious counter results. First, Spain manifests multilingualism but the central government does not take any responsibility for its realization. It supports Castilianization throughout the whole of Spain to maintain its unity. Spanish can be used anywhere within the territory. The minority languages are not respected outside of their own communities. In other words, the language rights of the minorities still are not respected completely within the Spanish territory.

Second, the majorities of the population in bilingual territories such as Catalonia, Galicia and the Basque Country impose their official local language on minorities who do not have that language as their mother tongue. Spanish-monolingual citizens can actually be excluded from jobs and official positions simply because they do not master the same language as people who speak the language that the regional government imposes. Such enforcement of the regional government is just as unfair as the former imposition of Spanish as the official language for the whole of Spain during General Franco's dictatorship (Kees 2003).

Third, those regional languages are not taught to the citizens in other Spanish territories, while other foreign languages like English and French are taught. With the passage of time, it may deepen the emotional gap among them.

Fourth, the children in bilingual territories are required to learn more languages than others. The EU also supports multilingual language policy and demands for its

citizens to learn two more languages of its member countries. In principle, the children in Spanish bilingual territories are required to learn four languages as EU citizens and this could be an intellectual burden for them.

### **3. Paraguay**

#### *3.1. Language Policy during Stroessner's Dictatorship*

In Paraguay, during the Stroessner period (1954-89), the only official language of the nation was Spanish, though the native languages including Guaraní were not repressed. On the other hand, even though education was carried out in Spanish, it did not promote Castilianization because the Paraguayan investment in this sector was so insignificant that it was the lowest among Latin American countries (Rivarola 2000: 11).

There was other evidence of the fact that the language policy during Stroessner's dictatorship was not centralized. On the one hand, some public processes to promote the use of Guaraní were observed. In 1967, Guaraní was recognized as a national language in the National Constitution. In 1972, the University of Asunción initiated a major in the Guaraní language, giving it a social-educative state for the first time in the country's history. At the level of secondary education, from 1975 it was implemented as a subject of study. In 1983, the transitional model of bilingual education was implanted for the Guaraní monolingual children in elementary school, though thereafter it was considered to have failed (Choi 2004: 244).

On the other hand, Stroessner supported patronage of the Guaraní-speaking peasants. According to Chambers (1999), farms in Concepción, San Pedro, Caaguazú, Caazapá, Itapúa, and Alto Paraná increased dramatically during the seventies. Because of this policy, rural monolingualism in Guaraní was strengthened and bilingualism decreased.

In summary, we could say that during Stroessner's dictatorship there was no centralized language policy as we expected hypothetically. Other factors, including historical and ethnic ones, forced the dictator to maintain a bilingual society.

#### *3.2. Bilingual Education Policy through Democratization*

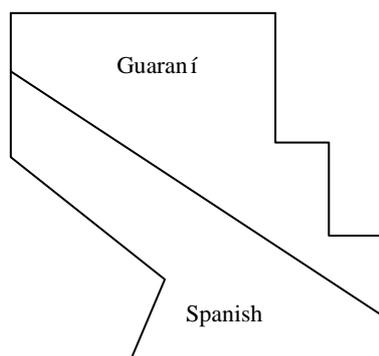

The fall in 1989 of Stroessner's 35-year dictatorship of Paraguay was followed by dramatic changes in Paraguayan language policy. The 1992 Constitution consolidated this transition to democracy. It declared multilingualism and the protection of the linguistic right to receive education through the mother tongue. Spanish remains official, but since 1992, Guaraní has had the same status. Education in Spanish for monolingual Guaraní-speaking children was ineffective, so many of them dropped out and remained illiterate. As a solution to this phenomenon, educating them in their mother tongue, Guaraní, was adopted in spite of some opposition (Gynan 1999).

Since 1994, the current program of bilingual education has begun to produce coordinate bilinguals, that is, individuals capable of using Guaraní and Spanish in any context with equal ability, but maintaining separate system codes. According to this purpose, a child is taught first in his or her mother tongue and the second language is gradually introduced, until in the sixth year when the equilibrium between the two languages is reached. There are two modalities, the Spanish-speaking and the Guaraní-speaking ones (Choi 2004).

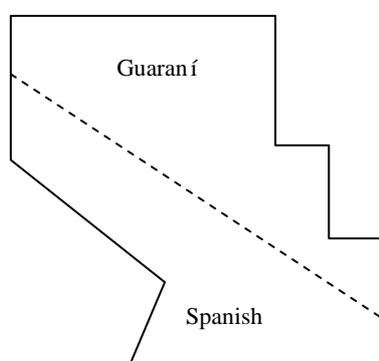

The first modality was applied in urban areas, while the latter was applied in rural areas. In urban areas, Guaraní is learned as a second language and many students say that they use Guaraní most in the classroom. It means that for many of them, Guaraní becomes an academic language, like other foreign languages. Still, there is very low investment in education, so teachers with low salaries have continued to protest and parents think that the Castilian monolingual schools are better than the Guaraní-Castilian bilingual schools for their children (Rivarola 2000).

### *3.3. Current Problems in the Application of Bilingual Education Policy*

In the case of Paraguay, the national government currently insists on centralized language policy focusing on general bilingualism, without considering the economic reality of the nation and the economic gap between urban and rural areas. This has caused an unbalanced development of the nation. Paraguay has generated idealized legal texts but does not have enough human and economic resources to realize them. Castilianization and movement toward bilingualism are accelerated in urban areas, while Castilianization is hampered and Guaraní monolingualism is increasing in rural areas.

<Figure 3> Language distribution during Stroessner's dictatorship

<Figure 4> Current language distribution

We observe that in Figure 3, which is a rough abstraction developed by the author, the country was divided into two areas on the basis of the languages and the division was clearly established. Meanwhile, in Figure 4 the division is still maintained, but without such clarity because of the bilingual education. This bilingual education policy has caused some counter results. In rural areas, many Guaraní speaking students had problems with the Guaraní taught in their schools. The Guaraní that they speak is a variant mixed with and influenced by Spanish, which is called *jopara*, but the Guaraní that they have to learn is a pure variant without code-switching, code-mixing and borrowings from Spanish. This variant is quite different from the colloquial variant *jopara*, so their pure Guaraní learned is of a low level and their Spanish learned as a second language is also of a low level. Moreover, many students give up their studies for economic reasons, so in the rural areas, Castilianization is obstructed. Another reason for the increase of monolingualism in Guaraní in rural areas is the increasing immigration from rural to urban areas because of the collapse of agriculture. There are

higher rates of migration among bilingual populations than among monolingual Guaraní so the monolingual Guaraní remains in rural areas (Gynan 2001). These phenomena deepen the monolingualism in rural areas and extend the linguistic gap between rural and urban areas.

#### **4. Conclusion**

Spain and Paraguay have one thing in common: in both countries the long dictatorship promoted the public desire for democratization and respect for language rights. Both countries established the legality of the multilingual language policy through the modification of their constitution at the beginning of democratization. However, the results of that decision are quite different in each case.

Spain is a partially multilingual country. The citizens of the bilingual regions are expected to be bilingual, though many of them are not. The central government enforces Castilianization throughout the whole of Spain to maintain its unity. Spanish can be used anywhere within the Spanish territory, while the minority languages are just used in their own communities. The language rights of Spanish monolinguals are not respected within the bilingual communities, while those of minority language speaking people are not respected outside of their communities.

In the case of Paraguay, the government currently insists on centralized linguistic policy focusing on general bilingualism, without considering the economic reality of the nation and the economic gap between urban and rural areas. In Paraguay, there is a great difference between the policy as stated and the policy as it really works at the practical level. This has caused an unbalanced development of the nation. Paraguay has created an idealized legal text but does not have enough human and economic resources to realize its goals. Castilianization and bilingualism are accelerated in urban areas, while Castilianization is prevented and Guaraní monolingualism is increasing in rural areas.

In this research comparing the cases of Spain and Paraguay, we conclude that the types of political regimes such as dictatorship or democratization do not have a direct relationship with centralized or decentralized language policies, though the transition from one political regime to another could provoke crucial changes in language policies just as in any other social aspect.

# A preliminary study of metaphor use by Hong Kong university students

Li Lan

Department of English, Hong Kong Polytechnic University  
eglilan@polyu.edu.hk

## Abstract

Metaphoric competence – the knowledge of and ability to use metaphor appropriately and effectively – contributes to all aspects of communicative competence, and is therefore ‘highly relevant to second language learning, teaching and testing.’ (Littlemore & Low, 2006: 268). This paper reports an investigation into the use of metaphor by Hong Kong university students who are advanced learners of English. There were two parts to the study: data mining of a learner corpus which comprised communicative and argumentative writing, and analysis of a metaphor elicitation test. The discussion focuses on the frequency and types of conceptual metaphors produced in different contexts. It is argued that students’ metaphoric competence should be enhanced because metaphors can make communication more effective and impressive.

**Key words:** metaphor, cognitive ability, linguistic competence, ESL/EFL

## 1. Introduction

Metaphoric meaning arises from the interaction between words and their discourse context. Most metaphor studies have focused on identifying, describing and explaining metaphorical language in published and professional discourses such as politics, business, and education. For example, Charteris-Black (2005) analysed the political speeches of Winston Churchill, Martin Luther King, Margaret Thatcher, Tony Blair and the Bushes. Results showed that figurative language was used frequently with about six metaphors produced in every hundred words. Metaphor mapping revealed conceptual metaphors of journey, health, morality, life, death, and animals. Charteris-Black argued that metaphor plays an essential role in the persuasiveness of political rhetoric, that it contributes to the construction of political identity, and that without it ‘politicians would lack hallmarks of charismatic leadership such as passion, energy and conviction’ (Charteris-Black, 2005: 198). The use of metaphor as a tool for persuasion has also been identified in business discourse (e.g., Elwood, 1995; Rohrer, 1995; Boers, 1997; Clancy, 1999; Li & Bilbow, 2000; Henderson, 2000; Koller, 2004). A number of figurative expressions are frequently used. For example, money transfers constitute *cash flow*, new firms are *infant companies*, firms may *collapse*, banks may *sink*, stock markets may *crash*, economic forecasts may be *gloomy*, and currencies may be *weak*, *strong* or *stable* (Henderson, 1986; Boers, 1997; Eubanks, 1997; Li & Bilbow, 2002, 2004; Koller, 2004). Metaphors are also frequently encountered in educational discourse. For example, teaching and learning have been described as *gardening*, *a journey*, *scaffolding*, *mining*, *a bridge* and *movement of water* (Munby, 1986; Cortazzi, 1991; Scott, 1994; Cortazzi & Jin, 1999; Cameron, 2003).

Metaphor is not a linguistic peculiarity restricted to specialized discourse, however, but is pervasive throughout language (Lakoff & Johnson, 1980; Cameron & Low, 1999; Deignan, 2005) because it is inextricably intertwined with thought. On the one hand, metaphors ‘allow us to think about and organise chaotic reality’ (Gannon 2001: 1) and can be used as a linguistic device to express difficult-to-talk-about abstract concepts in terms of concrete entities (Lakoff, 1993; Lakoff & Johnson, 1980). On the other hand, ‘metaphor influences our beliefs, attitudes and values’ (Charteris-Black 2005: 13). Furthermore, experimental research suggests that exposure to certain metaphors can improve cognitive reasoning ability (Gentner & Gentner, 1983), increase understanding of certain concepts (Smith, 1995), and develop critical thinking

(Boers, 1997). This is perhaps because metaphor comprehension requires cognitive effort to link the target and source domain (Cortazzi & Jin, 1999: 154). Metaphor is therefore a fundamental component of overall language proficiency, a potentially useful educational tool, and of considerable relevance for second language learners. However, although a number of studies have identified, described and explained metaphorical language in published discourse, little research has considered the use of metaphor by ESL/EFL learners.

Chateris-Black (2002: 114) proposed a six-type cross-linguistic metaphor classification system which takes account of a metaphor's surface linguistic structure, the underlying concepts which are expressed, and whether the metaphor is culture specific (opaque) or universal (transparent). Table 1 shows the six types. Such a model is useful in ESL/EFL research because for second language learners linguistic, conceptual and cultural differences in metaphor use between their first (L1) and second (L2) languages may result in inappropriate cross-linguistic transfer (Deignan, Gabrys, & Solska, 1997; Irujo, 1986). Alternatively, learners may avoid using words metaphorically in their L2. For example, two small scale studies investigating English language use in a free composition exercise by Italian (Danesi, 1995) and Malay (Chateris-Black, 2002) second language learners of English showed that the metaphors used were those which could be directly translated (both linguistically and conceptually) from the learners' L1.

Table 1. Cross-linguistic model for metaphor use (source: Chateris-Black, 2002: 114)

Category	Linguistic form	Conceptual basis
Type 1	=	=
Type 2	~	=
Type 3	=	#
Type 4	#	=
Type 5	#	# + transparent
Type 6	#	# + opaque

= equivalent; # different; ~ similar

In recent years metaphor research has been dominated by the cognitive linguistics approach, which is underpinned by the assumption that language reflects thought. Two levels of metaphor can be distinguished: conceptual metaphors and linguistic metaphors. The term 'conceptual metaphor' is used to refer to a connection between two semantic areas at a cognitive level. ANGER is HEAT is a conceptual metaphor reflecting the cognitive connection that seems to exist between anger and fire for speakers of many languages (Lakoff 1987). The target (ANGER) is the conceptual domain that is the focus of the investigation; the source (HEAT) is the conceptual domain from which metaphorical expressions can be drawn. Linguistic metaphors are the linguistic realizations of a conceptual metaphor. In the case of ANGER is HEAT, one example is 'She's got a *fiery* temper'. A specific aim of cognitive linguistics is the analysis of linguistic metaphors to make inferences about underlying conceptual metaphors which are then used to make inferences about thought (Cameron & Low, 1999: 18). The approach relies largely on researcher intuition, using examples as necessary which are often decontextualised. Although cognitive linguistics has had a significant influence on metaphor theories (e.g., Gibbs, 1994; 1992; Kittay, 1987; Lakoff, 1987; Lakoff & Johnson, 1980), critics argue that metaphor must be considered in its natural context (e.g., Cameron, 1999, Deignan, 2008). Importantly, the use of single examples can result in important generalizations being missed or in the formation of mistaken assumptions that selected examples of metaphor

accurately reflect all aspects of metaphoric language (Gibbs 2000: 30).

Corpus linguistics is the study of authentic language in context. The approach enables claims about language use to be made from real-life data rather than relying on intuitions which are unreliable (Sinclair, 1991; Teubert, 2005: 1) or on data that is experimentally elicited in psycholinguistic studies and which may be atypical (Deignan, 2008). Computerised methods for data analysis have contributed to its position as one of the most useful and popular methodologies within applied linguistics.

By incorporating both quantitative and qualitative analyses, corpus linguistics offers a way to investigate students' spontaneous metaphor use and to compare metaphor use between different text types. Metaphors can be described in terms of their frequency, proportion (relative to literal use), collocations, underlying concepts, and semantic prosody (whether the metaphor conveys a positive or negative meaning in context).

The aim of the present research is to investigate Chinese students' English metaphor use by analyzing the spontaneously produced metaphors in a corpus of learner English, and the metaphors produced in a metaphor elicitation test.

## **2. Research methodology**

There were two parts to the current research. In the first part a corpus approach was used to examine spontaneously produced metaphors in different types of student writing. The second part was a metaphor elicitation test.

### *2.1. Investigating spontaneously produced metaphors*

#### *2.1.1. Learner written corpus*

The learner corpus used in the project was from the PolyU Language Bank, a collective database consisting of various texts collected between 1999 and 2005 by staff members in the Department of English at the Hong Kong Polytechnic University. Two types of writing were considered, argumentative and communicative. The argumentative writing totals 780,300 words and includes essays for writing competitions, travelogues, and creative pieces. The communicative writing totals 1,080,000 words and largely comprises simulated business letters and memos, minutes and reports. It also includes samples of student MSN messages and blogs.

#### *2.1.2. Corpus analysis*

The analysis broadly followed the three stages of Critical Metaphor Analysis (Cameron 2003): identification, interpretation, and explanation. The writing was initially examined qualitatively to identify metaphors commonly used to describe integral aspects of students' university lives. These metaphors were then mapped according to their source domain – the concepts that they reflect.

For the purposes of the present study 15 words with potential metaphoric meaning were then identified for further quantitative analysis. The words were examples of Goatly's (1997) 'general reifying', 'specific reifying' and 'personification' metaphors. Examples included nouns representing entities, verbs realizing states and process, adjectives representing the properties of entities, and adverbs representing the properties of processes. A wordlist was generated from the corpus and lemmatized. The word list was searched for the presence of the 15 key words, and then the Key Word in Context (KWIC) method was used to judge whether the words were used

metaphorically. It is important to evaluate the metaphoricity of words in context because metaphoric meaning can only be established through an interaction between the word and its context. For example, when ‘grow’ collocates with abstract nouns such as ‘knowledge’, ‘crime rate’, and ‘sales’, it is metaphoric. When the agent is a living entity, such as ‘flower’, ‘plant’, and ‘children’, ‘grow’ typically conveys a literal meaning, although children’s growth is sometimes metaphoric. The phrasal verb ‘grow up’ may convey a literal or a metaphoric meaning.

## 2.2. Investigating experimentally elicited metaphors

The second part of the study was conducted to investigate how metaphors reflect students’ thinking about various topics, using a paradigm which has been previously used (Cortazzi & Jin 1999). Four target words were selected for inclusion in the experiment: ‘internet’, ‘computer’, ‘learning’ and ‘teacher’. ‘Internet’ was specifically selected because it has become an integral part of modern day human life, but yet the nature of the World Wide Web is unfamiliar to most people (Ratzan, 2000). Previous research has documented internet metaphors used pervasively by the on-line community and discussed how they help users’ understanding of the internet. The other three words also reflect important aspects of university life. A group of 201 Hong Kong University students (151 BA students; 50 MA students) were asked to complete sentence stems of the following format:

The TARGET is \_\_\_\_\_ because \_\_\_\_\_.

Students were encouraged to produce metaphors. The metaphors which were produced were mapped according to their source domain – the concepts that they reflect.

## 3. Results and discussion

### 3.1. Discussion of findings of spontaneous metaphor use

The qualitative analysis of the learner corpus revealed that students produced both dead and creative metaphors. Dead metaphors are those which have been used so frequently over time that their meaning has been assimilated into language so that the transferred meaning is not present and not considered by the language user. Dead metaphors include metaphoric clichés. Active metaphors convey incongruity between a focus term and its surrounding discourse. Students used metaphor to describe a number of different aspects of their academic lives. Table 2 shows examples.

Table 2. Examples of metaphors produced spontaneously to describe different aspects of academic life.

TARGET DOMAIN	SOURCE DOMAIN	Examples
INTERNET	JUNGLE/SEA	network, surf
LEARNING	JOURNEY	start, end, milestone, bridge, passport, pave the way
UNIVERSITY	HOME/FAMILY	brother, sister, parents
	HUMAN BODY	head, heart, hand, arm, brain
UNIVERSITY LIFE	WEATHER	cold, hot, storm, sunshine

<b>KNOWLEDGE</b>	SEA	get lost, drawn, sail
<b>STUDENT</b>	PLANT	grow, root, cultivate, seed, branch, harvest, blossom

Students used personification to provide a concrete and accessible framework for certain descriptions. For example, ‘university’ was described as ‘a brother’, ‘a sister’, and as ‘parents’. Personification was also used to help students convey emotion towards that entity. For example:

(1) *I consider every meeting has its good and evil side.*

In addition to metaphoric personification, students also used personification in similes – comparisons that show how two things that are not alike in most ways are similar in one important way – to make their writing more interesting and entertaining. For example:

(2) *To me, Shanghai sounds familiar yet strange; it is like a face covered with a veil.*

(3) *Actually, the city is like a beauty.*

The learner corpus was examined for the presence of 15 potential metaphors, selected *a priori* as examples of Goatly’s (1997) ‘general reifying’, ‘specific reifying’ and ‘personification’. Table 3 shows the occurrence of the 15 target words in the two types of writing. The frequency of literal and metaphoric uses of the metaphoric candidates differs between the types of writing. For example, ‘deep’ as a metaphor occurs more frequently in communicative than in argumentative writing. Literal uses of ‘deep’ can be observed in communicative writing, but metaphoric uses are more common. In argumentative writing ‘deep’ always occurs with a metaphoric sense.

Table 3. Comparison of the occurrence of the 15 target words in communicative and argumentative writing, shown as overall frequency, and the frequency and proportion of times that the word is used metaphorically.

Word	Word frequency		Frequency with which word is used metaphorically		Proportion of times word is used metaphorically (%)	
	Communicative (780,300 words)	Argumentative (1,080,000 words)	Communicative (780,300 words)	Argumentative (1,080,000 words)	Communicative (780,300 words)	Argumentative (1,080,000 words)
bridge	18.0	20.0	0.0	5.0	0.0	25.0
core	7.0	12.0	3.0	12.0	42.9	100.0
cultivate	7.0	6.0	6.0	6.0	85.7	100.0
dance	8.0	2.0	1.0	2.0	12.5	100.0
deep	41.0	28.0	37.0	28.0	90.2	100.0
flavour	8.0	3.0	1.0	2.0	12.5	66.7
flaw	3.0	4.0	3.0	4.0	100.0	100.0
flow	38.0	22.0	35.0	20.0	92.1	90.9
grow	46.0	56.0	22.0	26.0	47.8	46.4
handle	46.0	152.0	45.0	152.0	97.8	100.0
hole	6.0	2.0	1.0	2.0	16.7	100.0
journey	63.0	15.0	2.0	2.0	3.2	13.3
root	30.0	5.0	30.0	5.0	100.0	100.0
shape	15.0	4.0	1.0	1.0	6.7	25.0
war	7.0	12.0	2.0	0.0	28.6	0.0

Observation of the table shows that students did use many of the 15 target words metaphorically. For example, they described knowledge in terms of ‘growth’, they referred to ‘core’ issues, they discussed ‘handling’ a problem, and they considered ‘flaws’ in plans. However, differences were observed in the use of metaphor between the two types of writing, as can be seen with the example of ‘core’. Figures 1 and 2 show the concordance of ‘core’ in the two types of writing. In communicative writing, ‘core’ was used metaphorically less than half of the time (Figure 1, lines 1, 2, and 3), whereas in argumentative writing ‘core’ always occurred with a metaphoric sense (Figure 2).

14 foreign companies are attracted to locate their businesses core in Hong Kong, especially in logistic and finacial sector

Figure 2. Concordance of ‘core’ in argumentative writing.

A number of researchers have studied universality and cultural specificity of metaphors (e.g., Eubanks, 1997; Cameron & Low, 1999; Cortazzi & Jin, 1999). Analysis of the 15 words reported in the paper did not reveal any specific influence of the Chinese culture on English metaphoric use. However, previous analyses of business metaphors in Hong Kong have demonstrated an influence of culture on the metaphoric use of body parts and colour terms (Li & Bilbow, 2004). Future work with the present corpus will therefore analyse a larger set of words which includes body parts and colour terms in the two types of writing.

### 3.2. Discussion of findings from the metaphor elicitation experiment

Table 4 shows the results from the metaphor elicitation experiment. Responses for the targets have been grouped into clusters according to the source domain of the elicited metaphor. Many different metaphors were produced by the 201 students for each of the targets. Metaphor mapping demonstrates the use of various source domains, which reveals the ways in which the targets were conceptualized by the students.

Table 4. Number and percentage of students producing metaphoric descriptions for each of the targets, and the reasons. Results are grouped according to the source domain of the metaphor (the underlying conceptualization).

TARGET DOMAIN	SOURCE DOMAIN	Reason	Frequency	Percentage
<b>INTERNET</b>	NICE PERSON	helpful, supportive, obedient	22	11.0
	BAD PERSON	cheating, unreliable	3	1.5
	SOURCE OF KNOWLEDGE	informative, including all	43	21.4
	TOOL	useful and efficient	6	3.0
	LINK	connecting people worldwide	11	5.5
	BODY OF WATER	vast amount of information, easily drawn	23	11.4
	DRUG	can be helpful and harmful	8	4.0
	CONTAINER	including too much stuff	8	4.0
	JUNGLE	confusing, hard to find something	4	1.9
<b>COMPUTER</b>	NICE PERSON	helpful, knowledgeable, obedient	81	40.3
	FRIEND	ready to help	17	8.5
	EVIL PERSON	making trouble, harmful	7	3.5
	BRAIN	clever, informative	14	7.0
	DRUG	captivated, addicted	14	4.5
	CONTAINER	spacious, cramped	7	3.5
	TOOL	versatile	8	4.0
	HUMAN BODY	indispensable, useful	11	5.5
<b>LEARNING</b>	JOURNEY	long, endless	27	13.4
	ROAD	having to go step by step	8	4.0
	SPORTS	competitive, exciting	18	8.9
	INVESTMENT/BUSINESS	getting what is paid for	15	7.5
	LIFE	in different stages	14	6.9
	COOKING	mixing ingredients	7	3.5
<b>TEACHER</b>	BOOK	knowledgeable	24	11.9
	FRIEND	ready to help	10	4.9
	LIGHT	leading the way	25	12.4
	FAMILY	showing care, closeness	23	11.4
	CARETAKER	considerate	14	6.9
	AUTHORITY	tough control	4	2.0
	GARDENER	growing plants	13	6.5
	ANIMAL	hardworking	6	3.0
	BOSS	bossy	4	2.0

Following the conceptual mapping, the metaphors were additionally grouped according to whether they conveyed positive or negative meanings. The responses to ‘internet’ were both positive and negative. The positive responses included:

1. The internet as a PERSON: *teacher, guide, friend, doctor, assistant*
2. The internet as a SOURCE OF KNOWLEDGE: *encyclopedia, Wikipedia, book, dictionary*
3. The internet as the WORLD: *universe, world, globe*
4. The internet as a TOOL: *tool, screw driver, wireless phone*
5. The internet as a LINK: *link, hook, net, bridge*
6. The internet as a BODY OF WATER: *sea, ocean, pool*

The negative responses included:

1. The internet as a BAD PERSON: *monster, big liar*
2. The internet as a DRUG: *drug, poison, virus, poisonous, addictive, infectious, suffering*
3. The internet as a CONTAINER: *rubbish bin, dust bin, dye vat*
4. The internet as a JUNGLE: *puzzle, maze, jungle*

Metaphors were classified according to Chateris-Black's (2002) model (see Table 1). Most of the elicited metaphors of internet were of Type 1 meaning that the same conceptual metaphor and an equivalent linguistic expression exist in Chinese. The examples are INTERNET as BRAIN, as NET, as SEA, as JUNGLE, as BRIDGE and ADDICTIVE.

An example of a Type 3 metaphor is TEACHER as COW, which has also been observed in previous research (Cortazzi & Jin, 1999). The connotations of 'cow' in Chinese are commitment, devotion, hardworking and asking nothing in return and it is therefore used positively as a description of a teacher. However, in western culture 'cow' may mean slow, old-fashioned and unenergetic and is used as an insult.

An example of a Type 6 metaphor, meaning that both the concept and linguistic expression are different in Chinese is 'dye vat' which was used by one student to describe the internet: *'the internet is a dye vat because its stuff has bad influence on children'*. The source domain *dye vat* (*rangang*, 染缸) is a high-frequency metaphor used in the Chinese language. A google search resulted in 562,000 hits and few of them refer to the literal meaning of dying cloth in a big vat. To Chinese people, the metaphor has negative connotations which can be transferred to the entertainment business, society, the internet, and blogs. However, the use of 'dye vat' as a metaphor is not part of Western culture. Other examples of Type 6 metaphors are descriptions of TEACHER as CANDLE, as LADDER, and as STEPPING STONE. These metaphors convey the way in which teachers' dissemination of knowledge requires self sacrifice and lack of regard for personal gain. The metaphor reflects the Chinese cultural value of placing greater importance on society as a whole rather than on the individual, and demonstrates how the cultural background of students can impact on their linguistic constructions in a second language.

#### 4. Conclusions

Hong Kong Chinese students have little difficulty expressing concepts metaphorically in English, at least when explicitly asked, although there was some indication of interference of the Chinese culture. The variety of metaphors produced in the elicitation experiment demonstrates students' ability to use English figuratively when specifically encouraged and indicates that students do have metaphoric awareness. Conceptual mapping of the metaphors offer some insight into the way particular objects are conceptualized. Furthermore, the findings from the metaphor elicitation test are compatible with the possibility that the low metaphorical use in spontaneous writing is not a result of a lack of metaphorical understanding, but reflects a failure to utilize metaphoric awareness in production.

Students' metaphoric competence should be enhanced by incorporating metaphor training into second language teaching. Possible training methods include engaging students in tasks such as the experimental metaphor elicitation test reported in the present paper. With an increased metaphoric awareness students' spontaneous use of metaphor is expected to increase, which should enhance the effectiveness of their writing.

Future work will examine spontaneous metaphor use in more depth and investigate elicited metaphors produced in context. In addition, the use of metaphor by Hong Kong students will be compared with those produced by native English speakers, as well as those produced by Mainland Chinese students. This will enable more informative claims to be made about students' competence and may reveal more about the influence of linguistic, conceptual and cultural differences between students' L1 and L2 on their metaphor production in a second language.

## **Abstract**

In Asian languages, core arguments (subjects and objects) are normally optional, so in that way they behave as what traditional grammar and any consistent linguistic description would call ‘adjuncts’.

Optionality may then appear as a very unsatisfactory means of classification. But some recent developments in linguistics seem to provide a fresh look into the relative status of sentence constituents, putting emphasis on whether they can be explicitly put in paradigmatic contrast. This paper, focusing on Korean data, aims precisely at showing the difference of behaviour of two kinds of constituents: those able to fall under the scope of the particles *-to* ‘also’ and *-man* ‘only’, and those that are not, thus allowing to distinguish between three different syntactic levels.

**Keywords:** paradigmatic axis, delimiters, micro-syntax, macro-syntax.

## **1. Introduction: Optional arguments and argument-like adjuncts**

It is a general rule, in Asian languages, though not in European languages, that functional equivalents of core arguments – subjects and objects – are optional, i.e. they can be left out without damage to the grammaticality of sentences.<sup>2</sup> Thus, they behave as what traditional grammar would call ‘adjuncts’.<sup>3</sup> One should therefore consider that in those languages, there is no distinction between ‘core arguments’ and ‘adverbial adjuncts’ in terms of syntactic behavior, and that optionality is, for those languages, an ineffective means of classification.<sup>4</sup>

Leaving aside the problem of optionality, I shall distinguish between two types of constituents using the licensing –on those constituents– of particles indicating restriction (‘only’), and addition (‘also’) as a test. Constituents able to fall under the scope of those two particles will be considered either to be arguments, or to be argument-like adjuncts, while those that do not will be seen as proper disjuncts. Doing so, I shall apply tests equivalent to those proposed for Spoken French to Korean, and in line with claims made by a group of French descriptivist linguists, draw first a major demarcation line between two kinds of syntaxes: a micro-syntax corresponding to complements bound to the verb and to the assertive part of utterances, versus a macro-syntax more loosely linked. Then, observing the behavior of collocational sequences with respect to the same diagnostic tests, I shall set up a third syntactic level below ‘micro-syntax’, namely a ‘nano-syntax’.

The method employed is based on tests more that are reliable than the optionality criterium, especially for languages such as Korean, and also gives results that seem to match to a significant extent with structurally similar languages such as Mongolian, as well as for languages very different from Korean, i.e., English or French.

But first let me explain the reasons that led me to use those tests.

### 1.1. Some diagnostic tests for Spoken French (*Groupe Aixois de Recherches en Syntaxe*)

My interest in the restriction test was first aroused by a proposal made by a French research team from Aix-en-Provence (*The Groupe Aixois de Recherche en Syntaxe / GARS*), whose main objective is to describe the grammatical features of a spoken language (Spoken French). Acknowledging that many traditional descriptive notions are ineffective when applied to spoken data, they strived to develop a more suitable means of description. It has to be noted that the perspective of this team is basically descriptive, not theoretical, and it is to their credit that they attach more importance to real data than to any a prioristic discourse on alleged language particulars or universals of structure.

It is worth noting that the traditional criteria of obligatoriness for distinguishing arguments from adjuncts is unsatisfactory. Indeed, if it were really applied, it would lead to count as adjuncts a great number of direct and indirect objects. They observe that arguments, whether obligatory or not, display a set of properties that can be tested. For instance, they are as follows. (see Blanche-Benveniste & al., 1990):

-Properties of arguments (and argument-like adjuncts)

- a. Licensed in cleft constructions: Fr. *C'est ... qui/que ...* ('It is ... who/that')
- b. Licensed under the scope of the negation marker: Fr. *ne (V) pas ...* ('not')
- c. Licensed under the scope of the restriction marker: Fr. *ne (V) que ...* ('only')

Those properties are shared, for example, by the obligatory locative complement of the verb *aller* ('go'), as well as by the optional direct object of *manger* ('eat')<sup>5</sup>:

- (1) *Il est allé {en Allemagne}*. 'He went to Germany.'  
> *C'est {en Allemagne} qu'il est allé*. 'It is to Germany that he went.'  
> *Il n'est pas allé {en Allemagne}*. 'He didn't go to Germany.'  
> *Il n'est allé qu' {en Allemagne}*. 'He only went to Germany.'
- (2) *Il a mangé {une pomme}*. 'He ate an apple.'  
> *C'est {une pomme} qu'il a mangée*. 'It is an apple that he ate.'  
> *Il n'a pas mangé {une/de pomme}*. 'He didn't eat an apple.'  
> *Il n'a mangé qu' {une pomme}*. 'He only ate an apple.'

To make sure that the scope of the restrictive or negative markers is precisely what is intended (here, the complement only), and not wider (for instance including the verb), one should see whether another complement of the same class can be put into contrast with the former, e.g., *Il n'est pas allé en Allemagne, mais en Suisse* 'He didn't go to Germany, but to Switzerland'.

Now, elements that are not usually considered as arguments share the same properties. For instance, locative or temporal adjuncts, such as *en Suisse* 'in Switzerland' in the following sentence, can enter cleft constructions and negative or

restrictive constructions, with the same interpretation as above:

- (3) *Il a pris son petit-déjeuner {en Suisse}*. ‘He had his breakfast in Switzerland.’  
> *C’est {en Suisse} qu’il a pris son petit-déjeuner*.  
‘It is in Switzerland that he had his breakfast.’  
> *Il n’a pas pris son petit-déjeuner {en Suisse}, (mais {en Allemagne})*.  
‘He didn’t have his breakfast in Switzerland, but in Germany.’  
> *Il n’a pris son petit-déjeuner qu’{en Suisse}, (pas {en Allemagne})*.  
‘He had his breakfast only in Switzerland, not in Germany.’

### 1.2. The notion *rection large* (wide government)

As those adjunct constituents behave, save their syntactic optionality, as regular arguments, researchers of GARS have developed the notion *rection large* (‘wide rection/government’) (e.g. Blanche-Benveniste 1990, 2002), which incorporates not only constituents regarded as arguments, but also constituents regarded as adjuncts.

Naturally, this notion is meaningful if and only if other elements in a sentence behave differently. And so are elements that may be called “discourse constituents”, or “disjuncts” as opposed to “adjuncts”. I shall here illustrate with English sentences, manipulating examples from Hasselgård & al. (1999), but French would behave similarly:

-Adjuncts vs. disjuncts:

- (4) *He first met {her in 1982}*. (time adjunct)  
> *It is {in 1982} that he first met her*.  
*He wiped his hands {carefully} on the towel*. (process adjunct)  
> *It was {carefully} that he wiped his hands on the towel*.
- (5) *Apparently, they never received your letter*. (modal disjunct)  
> *\*It is {apparently} that they never received your letter*.  
*John said he couldn’t help me, which is ridiculous*. (comment disjunct).  
> *\*It is {which is ridiculous} that John said he couldn’t help me*.

While time or process adjuncts such as in (4) display argument properties, in terms of behavior with respect to cleft-formation, restriction, or negation, the modal and comment disjuncts do not. Note in addition, those “discourse constituents” are often seen as not “grammatically” integrated, but rather “pragmatically” or “prosodically”, and are the ones usually left aside in grammatical description, especially in syntactic description. Indeed, given the difference in behavior with respect to the basic syntactic transformations used as tests, it may be claimed that those constituents are not governed by syntactic rules. However, with the help of tests, they may be integrated into grammatical description, albeit negatively. The GARS also coined new terminology that makes it clearer that those constituents should also constitute a target of syntactic description, in calling them “macro-syntactic” constituents, as opposed to “micro-syntactic” constituents (those pertaining to the wide government) (Berrendonner 1991;

Blanche-Benveniste 2002). As already mentioned, the distinction can be roughly spelled out in terms of ‘disjuncts’ on the one hand, versus ‘adjuncts’ and ‘arguments’ on the other.

<p><b>“Macro-syntax”</b>          (macro-syntactic constituents)          ≈ <i>Disjuncts/Discourse constituents</i></p>	<p>vs.</p>	<p><b>“Micro-syntax”</b>          (micro-syntactic constituents)          ≈ <i>Adjuncts</i>                      ≈ <i>Arguments</i></p>
---	------------	---

### 1.3. Paradigmatic interpretation

While syntax has long been exclusively concerned with the *syntagmatic axis* (i.e. the question whether or not a given string of segments form a phrase, and if so, whether the syntagmatic structure fits with dependency relations), such approaches explicitly or implicitly highlight the *paradigmatic axis* (Deulofeu 2007). Indeed, the fact that micro-syntactic constituents such as subjects, objects, or place and time adverbials can generally be put into contrast with other constituents by means of negative, contrastive, exclusive, or restrictive markers (also questioned by means of interrogative proforms), shows that those constituents are the result of a paradigmatic choice on the part of the speaker. Discourse constituents, on the other hand, do not display those properties. In pragmatic terms, the distinction between the two kinds of syntax has interestingly, though, again, roughly, been reworded as a distinction between the syntax of assertion (= what results from the online speaker’s choice) and the syntax of presupposition (= what is contextually given).<sup>6</sup>

## 2. Delimiter particle insertion in Korean and the argument/adjunct ~ disjunct opposition

Let’s turn now to an application to an agglutinative language with SOV order: Korean. As mentioned above, tests have been conducted with two particles, called ‘delimiters’, expressing restriction and addition: particles *-man* ‘only’ and *-to* ‘also’. Both, where they are licensed, are supposed to indicate a ‘paradigmatic slot’, so that they are expected to give a basis for the macro-/micro-syntax distinction. However, given that only the first particle has a functional equivalent among the tests proposed for French, it has to be explained why those two particles have been selected, while tests relying on cleft formation and negation have been excluded.

G.A.R.S. researchers use three main tests for stating the macro- or micro-syntactic nature of constituents: pseudo-cleft formation, negation, and restriction. But it should be noted that those three constructions are not mutually incompatible, as illustrated in the following example:

- (6) *Ce n’est pas que lui qui est venu.*  
 ‘It is not only him/he who came.’

Cleft formation has scope over negation which itself has scope over restriction.

The order of application can be hierarchically represented as:

CLEFT [ NEG [ REST [*lui*] ] ]

In order to preserve the homogeneity of tests (thus, hopefully, the homogeneity of results), it is better to choose constructions that are mutually exclusive, in this case, choose one out of the three possibilities. I shall exclude first cleft formation because it is much more restricted in Korean than in English or French (see Cho S.Y. (1991), Choi-Jonin I. (2003) for contrastive accounts with respectively English and French). Negation formation is naturally available, but its use as a test can easily be a delicate matter, because negation can receive a metalinguistic interpretation. Also, it can lead to build long and complex test sentences that often sound unnatural.

Eventually we have the use of the restrictive marker. As it can be expressed in many languages as a phonologically light particle, its insertion does not imply much change or unnaturalness in tested sentences. Also, together with the additive marker, with which it is mutually exclusive, it is widely used. In addition, at least in Korean, Japanese, and Mongolian, both particles are less constrained than other particles of the same paradigm. All those properties make tests easier to conduct, and guarantee more homogenous results.

Note that these particles do not always imply a paradigmatic variation in the position of the constituent they attach to. Such is the ‘idiomatic use’ of Kor. addition particle *-to* (as Japanese *-mo*) marking exclamatory utterances, a use that I shall therefore not consider as relevant for the tests conducted:

- (7) *Onul pam.un tal.to palk.kuna* (오늘 밤은 달도 밝구나)  
*Konya.wa tsuki.mo akarui.nee* (今夜は月も明るいねえ)  
‘Tonight the moon is so bright!’ (vs. ‘Tonight the moon is bright too’)

### 2.1. Nominal functions

What is relevant here is to show that the restriction and addition delimiters can attach to regular arguments or argument-like adjuncts with their expected meanings: putting –explicitly or implicitly– the element they attach to in association with other elements of the same paradigm. To ensure that restrictive or additive markers have scope over the tested element only, and not over some larger phrase, it has been inquired whether other elements belonging to the same class can explicitly be added as units contrasting with the first argument. In each case below, informants could interpret the nouns under scope in contrast with other nouns belonging to the same paradigm. This holds for arguments, e.g.: *Myengsik* vs. *Chelswu* (8: e.g. ‘Only Myungshik spoke in Korean, Chelswu did not’); *doctor* vs. *nurse* (9); *book* vs. *paper*; *student(s)* vs. *teacher(s)* (10), *I* vs. *other people* (11), as well as for a locative complement, e.g.: *Seoul* vs. *Busan* (12). Example (13) gives an illustration drawn from real data (a song’s lyrics) showing a beneficiary complement marked with *-man*: the implicit paradigmatic contrast should not be questionable.

- (8) *{Myengshik}.man/to hankwukmal.lo malhayssta* (명식만/도 한국말로 말했다.)  
'{Myungshik} spoke in Korean.' vs. {Chelswu, etc.}
- (9) *{Uisa}.man/to philyohata* (의사만/도 필요하다.)  
'(I) need {a doctor}.' vs. {nurse, etc.}
- (10) *Senseyngnim.un {hakseyng}.ekey.man/to {chayk}.man/to cwuessta* (선생님은 학생에게만/도 책만/도 주었다)  
'The teacher gave {books} to {the students}.' vs. {papers, etc.} / {other teachers, etc.}
- (11) *{Na}.lang kathi (nolay.lul) pwuluca* (나랑만/도 같이 (노래를) 부르자)  
'Let's sing together {with me}.' vs. {him, etc.}
- (12) *{Sewul.ey}.man/to pom.i wassta* (서울에만/도 봄이 왔다)  
'Spring came {in Seoul}.' vs. {Busan, etc.}
- (13) *Oloci {na.lul wihayse}.man salanghaycwul yeca.* (오로지 나를 위해서만 사랑해줄 여자) (가야랑, 수리수리마수리)  
'A woman able to give her love solely {for me}.'

Delimiters here naturally have a narrow scope interpretation, which means that the most natural way of interpreting complements marked by *-to* or *-man* is to draw them out of a set of other possible elements belonging to the same paradigm. Such complements may be said to pertain to the wide government, or to the micro-syntactic part of grammar.

## 2.2. Adverbial functions

If a temporal adverb such as *ecey* 'yesterday' behaves as expected in (14) (possible contrast with *onul* 'today'), modal adverbs of the comment type, as in (15) or (16), even if they can occasionally attach the additive marker (15), do not lend their slot open to paradigmatic variation (i.e. the insertion of *-to* is not interpreted as an additive process). There is no possibility to retrieve a set of elements contrasting with *tahayngghi* 'fortunately', or *mullon* 'of course':

- (14) *{Ecey}.man/to sicang.ey kassta* (어제만/도 시장에 갔다)  
'{Yesterday} I've been to the market.' vs. {today, etc.}
- (15) *Tahayngghi.(to) ppye.nun pwulecici anhassta* (다행히(도) 뼈는 부러지지 않았다)  
'Fortunately, he had no bones broken.' vs. {Ø}
- (16) *Mwullon. \*(to/man)* (물론\*(도/만))  
'Of course.' vs. {Ø}

Adverbial clauses may display a different sensitivity to delimiter particles. For instance, the purpose clause in (17) may attach both, with the expected restrictive and additive meanings, but conditional clauses with the suffixes *-myen* or *-ketun*, as well as causal clauses with *-se* or *-nikka* cannot directly attach the particle on their right end. Thus, (18) and (19) are ungrammatical:

- (17) *{Na.nun yeki.ey chayk.ul chac.ule}.man/to on keieyyo* (나는 여기에 책을 찾으러 온 거예요.)  
 ‘I went her {to buy a book}.’ vs. {to see you, etc.}
- (18) *{Ttattushayci.myen}.\*man/\*to, wuli.nun kongwen.ey kakeyssta* (따뜻해지면, 우리는 공원에 가겠다.)  
 ‘{If it gets warm}, we’ll go to the park.’ vs. {Ø}  
*{Cey.ka cip.ey eps.ketun}.\*man/\*to samwusil.ey cenhwahaycwuseyyo* (제가 집에 없거든 사무실에 전화해주세요.)  
 ‘{If I am not at home}, please call at my office.’ vs. {Ø}
- (19) *{Chwuw.ese/chwuwu.nikka}.\*man/\*to pakkulo an nakasse.* (추워서/추우니까 밖으로 안 나갔어)  
 ‘I didn’t go outside {because/since it was cold}.’ vs. {Ø}

In order to get acceptable sentences, one has to attach the delimiters to the root of the main verb in the adverbial clause, then attach the conditional or causal connector to the anaphoric verb *ha-* (‘do’). E.g.: *ttattus.man hayci-myen*, [...] ‘only if it gets warm, [...]’.<sup>7</sup>

The peculiarity of such a construction, in contrast with the direct attachment of the suffix to purpose clauses, may indicate that conditional and causal adverbial clauses stand at the border between the syntax of assertion and the syntax of presupposition. It is worth noting that in languages such as English or French, while purpose clauses are always licensed in cleft constructions and acceptable under the scope of restrictive or negative markers, *if*-clauses do not always sound natural in the same contexts (e.g.: *?It is if you go that I’ll go*), while some causal markers never pass the paradigmatic tests (Eng. *since*, Fr. *puisque*).<sup>8</sup>

One step further past the border of assertive syntax, and towards a contextually-bound syntax (i.e. linked with presupposed knowledge), you may find concessive clauses. In Korean, as in Japanese or Mongolian, the additive particle can mark the concessive meaning. But there is no implication of a paradigm. Naturally, it can be argued that there is another element in contrast, that is, the contradictory proposition, for instance “it snowed” vs. “it didn’t snow”, and this may be the explanation why an additive particle appears here, but as contradictory elements, they also cannot coexist in the same paradigmatic set. Moreover, the additive particle can never be substituted for the restrictive one:

- (20) *Nwun.i wa.to/\*man cip.ey issesseyo* (눈이 와도 집에 있었어요.)  
 ‘Also (= even though) {it snowed}, we stayed at home.’ vs. {Ø}

Concessive clauses clearly refer to contents that defy any attempt of explicit paradigmatic variation,<sup>9</sup> and accordingly should be considered as macro-syntactic constituents.

### 2.3. Negative proforms

Another striking similarity concerning the additive particles in Korean, Japanese and Mongolian, is its use in forming negative nominal or adverbial proforms. As in the previous case, the insertion of, respectively, *-to*, *-mo* and *ch*, is not interpreted as an additive process:

- (21) *Amu.to/\*man kaci anhassta* (아무도 오지 않았다.)  
*Dare.mo/\*dake konakatta* (誰も来なかった。)  
*Xen ch/\*l ireegüi* (Хэн ч ирээгүй.)  
 ‘Nobody came.’ vs. {Ø}  
*Amu kes.to/\*man poici anhnunta* (아무 것도 보이지 않는다.)  
*Nani.mo/\*dake mienai* (何も見えない。)  
*Yuu ch/\*l üzexgüi* (Юу ч үзэхгүй.)  
 ‘(I) can’t see anything.’ vs. {Ø}

In paradigmatic terms, and this not surprising, there is no conceivable element that could be contrasted to ‘nobody’ or ‘nothing’ in the set of persons or the set of things referred to respectively. In addition, there is no possibility to substitute *-to* for *-man*. Negative proforms, together with other proforms (indefinite and interrogative) should be given a very specific status here, whatever their function, given that they occupy micro-syntactic slots without having micro-syntactic properties. They have an outsider status, and so are elements that may serve as tests for the macro-/micro syntax distinction (e.g. the negative, restrictive markers themselves): in the same way, indefinite and interrogative proforms are hints that some parts of grammar allow the construction of paradigmatic sets, even if they are empty.

They also point to the fact that the macro-/micro-syntax distinction made here relies on semantic factors, because they show that knowing the function of a given constituent is not sufficient to determine its macro-/micro-syntactic status, in other words, it is not true that functions such as subjects or objects necessarily have the properties of micro-syntactic constituents. This assumption is important, and more, must be emphasized, insofar as it extends to a great deal of *non pronominal* constituents having regular nominal or adverbial functions, which are even so numerous that one is led to posit not less than another syntactic tier.

## 3. Fake arguments in compounds and collocations

### 3.1. Introduction: classic diagnostic tests for compounding

If one really tries to apply tests to all possible elements of a sentence, there is not

much choice left but to acknowledge that there is another syntactic level below which elements cannot be under the scope of delimiters. That level, which could therefore be named ‘nano-syntax’, includes constituents below the word level (morphemes) as well as most constituents belonging to noun or prepositional phrases. It can be recalled here that insertion of the Jap. particle *sae* ‘even’ has been used by Kageyama (1999) for testing the lexical integrity of compounds. In a similar vein, Spencer (2005:78) notes that “it is generally agreed that displacements which realize information structure, such as topicalization/focussing, scrambling, wh-movement and so on cannot affect parts of words”. Here are some Eng. examples quoted in Kageyama (1999:299):

- (22) ?*What do you like (...)ball? > Base(...).*  
 (23) ?*It is not base(...), but volley(...) that I like (...)balls.*  
 ?*Talking of (...)balls, I only like base(...).*

But Spencer goes on observing that *productively formed* noun-noun “compounds” like *morphology lecture* in *She would never give a morphology lecture* are also “immune from such processes”. The list should not end here: many other parts of phrases such as determiners, attributive adjectives, and relative clauses, as well as the head itself, cannot either be *it*-clefted, at least in English (24):

- (24) \**It is {a} that I met young girl.*  
 \**It is {young} that I met a girl.*  
 \**It is {who was wounded ... } that I met another man.*  
 \**It is {girl} that I met a young.*

Compare now a set of classic criteria for compounding (cleft-formation, topicalization and coordination) applied to *morphology* in *morphology lecture*, which was argued to be a compound, with the same set applied to *young* in *young girl*:

- (25) \**It is morphology that he gave a lecture.*      \**It is young that I met a girl.*  
 \**Morphology, he gave a lecture.*                      \**Young, I met a girl.*  
*He gave a morphology and syntax lecture.*      *I met a young and pretty girl.*

What these and other syntactic tests may tell us is simply that elements such as constituents of noun phrases behave in a similar way with respect to some syntactic rules, but they are by no way conclusive on the lexicon/syntax distinction. To make this point clearer, let us take an example of another Adj + N sequence, say *green house*. In one interpretation, it depicts a house that is green (syntactic formation, with a compositional meaning), while in another, it refers to a building designed for growing plants, in which case, the sequence is seen as a lexical formation. But from *I have seen a green house*, neither topicalization nor clefting can be used to distinguish one structure from the other, because they give the same negative results whatever the intended interpretation is:

- (26) \**It's green that I have seen a house.*  
 \**Green, I have seen a house.*

It should be clear then that most syntactic tests used as criteria for compounding do not distinguish lexical units from 'syntactically formed units' such as noun phrases. Naturally, those tests that also serve for the macro-/micro-syntax distinction cannot either be interpreted in terms of syntax vs. lexicon. In the present case as well, it makes more sense to speak of another sort of syntax, namely a 'nano-syntax'. This syntactic level below 'regular syntax' will be illustrated further in collocational sentences.

### 3.2. Fake arguments in collocational sequences

It will be shown here that some constituents that are (1) not to be considered as parts of compounds, and can (2) be marked as regular verb arguments –whatever their function– do not actually behave as regular arguments. Specifically, even though they can attach a delimiter, their actual scope is not solely the noun phrase, but the whole [noun+verb] complex. Thus, when asked to retrieve elements in contrast, informants cannot give contrasting nouns, but they rather give contrasting complexes, with a different noun and a different verb (this option is possible also with regular arguments). The sharp sign (#) in examples (24-31) indicates when the most likely interpretation of the sentence involves a wide scope contrast. Let look first at expressions involving a subject.

In (27), the restrictive particle *-man* was rejected by my first informant on the subject of the expression 'eye-got\_blind = be blind'. Choi E-J. (p.c.) found it however fine in opposition with e.g. 'be healthy', 'be great', etc. *-to* 'also' is licensed only with the metaphorical interpretation of the sequence, i.e. 'lose one's reason', and thus can stand in paradigmatic contrast with other misdeeds (*topak.to heyssta* 'gambled', *mayak.to hayssta* 'took drugs', etc.). (28) and (29) accept both the restrictive and additive particles on the subjects belly and throat, and typically stand in contrast with each other ('I am only hungry, I am not thirsty'), and there is no contrasting subject available for a same predicate, in other words nothing else than (somebody's) belly that could be hungry, or than (somebody's) throat that could be dry. The subject *palam* 'wind' in (30), 'wind is blowing' can have *-man* attached. The sentence, not so natural for my informant, could however be uttered as a reply to someone worrying about a sound, and it would be understood with a wide scope interpretation ('It's only wind that is blowing').<sup>10</sup> *-to* instead of *-man* would also get a wide scope and mean 'And on top of this, it's also windy' (not only does it rain...).

Finally, the example in (30) is one of the most micro-syntactic-like sequence, in that its subject can contrast with other potential strong characteristics, although it most naturally goes along with other collocations, such as 'be smart'.

- (27) *X nwun. \*man/#to melessta* (X 눈\*만/#도 멀었다)  
 X eye.only/also got\_blind 'X is blind.' vs. {??}

- (28) *X pay.#man/#to kophuta* (X 배#만/#도 고프다.)  
X belly.only/also hungry ‘X is hungry.’ vs. {be thirsty, tired, etc.}
- (29) *X mok.#man/#to maluta* (X 목#만/#도 마르다.)  
X throat.only/also dry ‘X is thirsty.’ vs. {be hungry, etc.}
- (30) *Palam.#man/#to pwulko issta* (바람#만/#도 불고 있다.)  
Wind.only/also be\_blowing ‘Wind is blowing’ vs. {??}
- (31) *X him.(#)man/(#)to seyta* (X 힘(#)만/(#)도 세다.)  
X energy.only/also strong ‘X is strong.’ vs. {be smart}

Similar answers were obtained in:

- (32): an object like ‘tobacco’ in ‘smoke tobacco’ (e.g., with *-man*: X does nothing else than smoking (tobacco is implied); with *-to*: exclamation or contrast with ‘drink alcohol’),
- (33): the locative complement ‘outside’ in ‘go outside’ (*-man* is strange, since there is no other choice than going outside, but possible if meaning ‘I did nothing else (e.g. I didn’t hit him) than going outside; *-to* would be acceptable in the context ‘I looked for it inside and I also went outside’)
- (34): the object ‘study’ of the support verb construction ‘do study’ (e.g., contrast with ‘watch TV, play games, etc.’).

- (32) *X tambay.#man/#to phiunta* (X 담배#만/#도 피운다.)  
X tobacco.only/also smoke ‘X smokes tobacco.’ vs. {drink alcohol, etc.}
- (33) *Pakkuro.#man/#to nakassta* (밖으로#만/#도 나갔다.)  
Outside.only/also went\_out ‘I went outside.’ vs. {look for something inside}
- (34) *Kongpwu.#man/#to hay.la.* (공부#만/#도 해라.)  
Study.only/also do.IMP ‘Study!’ vs. {watch the TV, play games, etc.}

Even though the nominal constituents of those example sentences display the functions and marks of regular arguments, they do not behave like micro-syntactic constituents, because they are not in a slot where paradigmatic variation is allowed. Even if they attach delimiters, those have (or, in some cases, tend more naturally to have) a wide scope interpretation: the only possible contrast holds with other verb complexes or collocational sequences. Indeed, any attempt to put another argument in contrast would lead to a semantic incongruity close to what is otherwise known as a figure of speech, namely a **syllipsis**. Examples of syllipsis, as in (35), show that the sole fact that a given verb accepts various complements does not imply they belong to the same set. So the cause for the semantic clash in (35) is not of syntactic nature, but is due to a paradigmatic weirdness. The reason for the awkwardness of coordination in (35) is the same as that of contrast in the previous test sentences.

- (35) *Mr Jones took his coat and his leave.*                      \*take {coat, leave}

*You held your breath and the door for me.* \*hold {breath, door}

A generalized ‘syllepsis principle’ could be called upon here that would account for the ungrammaticality or unnaturalness of sequences where the governing word is somehow forced to accept paradigmatic variation in a complement slot that do not constitute a proper set.

The process at work here is very close to what Halliday (1967:59), speaking of cognate objects, termed a ‘mutual expectancy of collocation between the noun and the verb involved’:

Cognateness is best thought of as ‘extension inherent in the process’ leading to a mutual expectancy of collocation between the noun and the verb involved. (Halliday, 1967:59)

As a matter of fact, cognate object constructions only accept a wide scope contrast when they attach a delimiter.<sup>11</sup> Let us give here another attested utterance:

- (36) (kids.hankooki.com/lpage/entertain/200412/kd2004120915540643540.htm)  
밤늦게까지 먹고 마시면서 ...  
*Pam.nuckey.kkaci mek.ko masi.myense ...*  
night.late.until eat.and drink.while ...  
... 노래도 부르고 춤도 했습니다.  
... *nolay.to pwulu.ko chwum.to chw.ess.supnita*  
... song.also sing.and **dance.also danse**.PAST.ST  
‘Until late at night, while eating and drinking, we sang songs and danced (dances).’

In (36), no noun other than the cognate object *chwum* ‘dance’ can be retrieved as a potential additive object of *chwuta* ‘to dance’, despite the presence of the delimiter –to ‘also’. There is indeed an additive meaning, but bearing on the whole cognate object construction, that is ‘dance dances’ in addition to ‘sing songs’.

There is no doubt that numerous verb-argument constructions would fall under the ‘syllepsis principle’, and among them one should expect many support verb constructions, synthetic compounds or pseudo compounds, cognate object constructions, and even meteorological clauses. Korean facts presented here should not be surprising since it would not be difficult to find similar phenomena in European languages, and test again the licensing of paradigmatic variation.

- (37) *Bill kicked the bucket.*  
→ \**It is the bucket that Bill kicked.*  
→ \**Bill kicked the bucket only, not ...*  
→ \**Bill did not kick the bucket, he kicked ...*  
(see also question formation: \**What did Bill kick?*)

#### 4. Concluding remarks

Specialists of collocations know and have been using these tests for a long time, but it has to be emphasized (1) that collocations are by no means exceptional in their resistance to paradigmatic variation (i.e. they are not singled out from other kinds of word combinations); (2) the obvious cross-linguistic applicability of those tests, with respect to collocations as well as to other elements, should not be overlooked by descriptivist grammarians, because they provide a useful, reliable, and typologically friendly means of classification of elements in a sentence.

Now I would like to add some of the data that were elicited from Korean, and, for the sake of comparison, Mongolian, a language that shares many structural features with the former. It aims to point out some differences in the use of delimiters<sup>12</sup> but can also lead to the conclusion that the results match to a significant extent for what regards the micro-syntax and “nano-syntax” distinction. The detailed answers provided by my informants<sup>13</sup> cannot be reproduced here, so that the chart displays only the main information, that is whether the delimiter is licensed on the constituent in curly brackets, and with what scope interpretation when put explicitly in contrast: narrow scope, i.e. on the constituent only (+), or wide scope (‘wide’). A ‘Ø’ indicates that the answer was not available because of structural particulars of the language investigated).

	Korean		Mongolian	
	만 -man	도 -to	Л -l	Ч -ch
<b>Subjects</b>				
{M.} spoke in English	+	+	+	+
(To) me {doctor} is needed ‘I need a doctor’	+	+	+	+
(To) me {two books} exist ‘I have two books’	+	+	Ø	Ø
{Wind} is blowing	wide	wide	wide/+	wide

<i>Allative</i> : I want to go {to Mongolia}	+	+	+	+
<i>Comitative</i> : Sing {with me}	+	+	+	+
<i>Instrumental</i> : X spoke {in English}	+	+	+	+
<i>Location</i> : Spring came {in London}	+	+	(+)	+
<i>Comparative</i> : T. is taller {than M.}	+	(+)	+	+
<b>Temporal/aspectual adverbs</b>				
{Yesterday} I went to the market	+	+	+	+
{Sometimes} I go to the market.	-	-	(same meaning)	(wide)

<i>Nominalized clause</i> A book hard {to understand}	+	wide/(+)	+	+
<b>Purpose</b> I went here {to take books}				
Kor. <i>-le</i>	+	+	∅	∅
Mong. <i>-xaap</i>	∅	∅	+	+
<b>Cause</b>				
Kor. <i>-se / -nikka</i>	(+)	(+)	∅	∅
Mong. <i>-xoops / yчpaac</i>	∅	∅	+	(+)
<b>Conditional</b> {If (the weather) gets warm}, [...].				
Kor. <i>-myen / -ketun</i>	(+)	(+)	∅	∅
Mong. <i>-bol</i>	∅	∅	+	(+)
<b>Concessive</b> Also (= ‘even if’) {it snowed}, I stayed at home.	-	∅	-	∅

As can be seen from the chart, the overlap of identical answers for structurally similar constructions is striking. But if we were to take into account the optionality of the complements involved in some collocations, we would get a very different picture. For instance, the subjects ‘belly’ and ‘throat’ in Korean expressions for respectively ‘being hungry’ and ‘being thirsty’ (lit. ‘belly-hungry’ and ‘throat-dry’) are rarely omitted, therefore are not normally optional, while in Mongolian, they are. If one were consistent with the criterium of optionality, one would consider that ‘belly’ or ‘throat’ in those collocational sequences are arguments in Korean but adjuncts in Mongolian. Moreover, emphasis on the non-optionality would lead to the conclusion that in Korean, ‘arguments’ involved in collocational sequences are more argument-like than ‘arguments’ in free sequences, because the former are usually optional while the latter are not. Usually, when one has to say that he is hungry in Korean, there is no need to express the first person; the order and optionality of the constituents in such a sentence could be pictured as follows:

(I.Top/Subj) belly.(Subj) hungry.

Using here the labels ‘adjunct’ for the first, optional, subject, and ‘argument’ for the second, (quasi) obligatory subject, would, from my point of view, be quite misleading, mainly because it would fail to recognize the collocational nature of the relation between Subj2 and the predicate, as opposed to the free combinatorial nature of Subj1. In other terms, fail to pinpoint the domain where the speaker has a real choice in combining units, which is beyond doubt, what underlies our implicit conception of what syntax is designed for.

Now, units belonging to ‘nano-syntax’ can still be described as displaying some sort of syntax, not only because their apparent output is often very similar to that of micro-syntax, but also because there are (i) placement rules and (ii) selection restrictions (as in morphology proper).

The same claim can be made for discourse elements, although a thorough investigation of their placement rules and, above all, of their selection restrictions, has still to be undertaken.<sup>14</sup>

So I am likely to support a three-leveled syntax whose three main typical domains of application would be: (1) the ‘core syntax’ with the verb and its arguments and argument-like adjuncts, (2) the syntax of various discourse and context-bound

elements, (3) the syntax of collocational sequences and compounds (possibly covering morphology as well).

	<b>Disjunct syntax</b> = ‘macro-syntax’	<b>Core syntax</b> = ‘micro-syntax’	<b>Collocational syntax</b> = ‘nano-syntax’
<i>Typical domain of application</i>	Modal disjuncts Comment disjuncts	Verb + (free) arguments Verb + (free) adjuncts	Compounds Collocations

As a final remark, In opposition to micro-syntactic constituents, discourse elements and elements of collocations have the same property of not being able to be explicitly or implicitly contrasted. Why? Does this mean that they share a common feature? The main reason, as the tests used, is certainly to be formulated in negative terms: they do not belong to the assertive part of the utterance. Discourse elements, as already mentioned, are linked to contextual presupposed knowledge, while elements of set expressions, not to speak of the internal components of words, most certainly belong to a common mental lexicon (in a wide sense, because it can also involve combinations of words) shared by the speakers of a given community. So that, when a speaker takes its turn, the informational content implied by those elements is already decided.

<sup>1</sup> This paper is one outcome of research that was achieved in Korea (Seoul National University) thanks to the generous support of the Korea Foundation 2008 Field Research Program. I am also grateful to the many valuable comments provided at various stages of my work by Pr. Kim Changsup, my research advisor at Seoul National University, and Choi E-jung (Ewha Womans University), among others. My ‘Frenghish’ has been kindly checked by Douglas Vautour (Seoul National University), but all remaining errors are mine.

<sup>2</sup> There are in fact exceptions.

<sup>3</sup> See Park C.W. (2002) for a treatment of adjuncts.

<sup>4</sup> Not satisfying either for European languages as well. For instance, many, if not most, transitive verbs in those languages also have intransitive uses. The other way round, a great deal of intransitive verbs may ‘lose’ their intransitivity, e.g. in so-called ‘cognate object’ constructions.

<sup>5</sup> Curly brackets (‘{ }’) in example sentences indicate a slot allowing paradigmatic variation. See below.

<sup>6</sup> On this topic: Berrendonner (1983), Danon-Boileau & al. (1991). See also Givón (1975).

<sup>7</sup> Example kindly provided by Choi E-jung (Ewha Womans University).

<sup>8</sup> Contrast the well-known behavior of *because* vs. (causal) *since* with respect to contrastive focalization through clefting: *It is not {because the truth is too difficult to see} ; that we make mistakes, we make mistakes {because the easiest and most comfortable course for us is to seek insight where it accords with our emotions – especially selfish ones} ;* (Alexander Solzhenitsyn) vs. *\*It is not since the truth is too difficult...*

<sup>9</sup> Compare for instance with the behavior of the Eng. concessive marker *although*: *\*It is although it snowed that we stayed at home; \*We did not stay at home although it snowed, but although we were tired, etc.*

<sup>10</sup> Choi E-jung (p.c.) judges it natural however in various contexts.

<sup>11</sup> All things being equal, when they do not have an attributive extension, in which case, the scope may be narrower thanks to the attribute: e.g. *dream only bad dreams. / live only one’s life*. Such constructions thus recover their expected micro-syntactic properties (see also focalization, question formation, etc.) and have to be differentiated from cognate object constructions where the object is normally not otherwise expanded (cf. Kor. *kkwum kkwuta* ‘dream’, *chwum chwuta* ‘dance’).

<sup>12</sup> The most commonly used restriction and addition markers are respectively Kor. *-man* (만), Mong. *-l* (л), and Kor. *-to* (토), Mong. *-ch* (ч). They are to be considered as clitics, attached at the end of words

---

(but they are written as separate words Mongolian). Quite often, they are used together with lexemes having the same meaning, as Kor. *yoksi* and Mong. *bas*, both meaning ‘also’. Also, it is irrelevant here whether, and in which order they may combine or not with case particles (in Mongolian, delimiters always follow case markers). See Kang S. (2004) for a contrastive account.

<sup>13</sup> The data were collected thanks to: Lee Jaymin (Korean) and Turtogtoh Janar (Mongolian), both good informants and good friends.

<sup>14</sup> For instance, it has been noted that interaction adverbs may be restricted to some sentence types and excluded from others. See for instance *frankly*: \**Frankly, come with me.*

## **Abstract**

This research examines written data extracted from local English newspapers from three countries: Malaysia, Singapore, and Pakistan. This research aims at examining the written words used by writers in the news articles and the extent of the use of these words in the local varieties of English. The papers examined are 'The New Strait Times' and 'The Star' from Malaysia, 'The Straits Times', 'Sunday Times', 'Today' and 'The New Paper' from Singapore and 'The Nation' and 'The News' from Pakistan. The borrowing and assimilation of a large number of lexical items identified are then analysed and categorized. The categorization across the countries will be discussed. Such informed knowledge truly makes English an Asian language.

**Keywords:** nativisation, lexical items, newspapers, code switching

## **Introduction**

Despite being an international language that is spoken and used by many speakers in many countries, English is not universally understood. Not everyone who speaks English can understand each other as precisely as it ought to be understood. Due to the existence of various variables like region and location, ethnic landscape, social class, gender, occupation, education, religion, physical environment, age, gender and needs, the way English is used by one group of speakers may differ from the way it is used by another speech community. Each group and its sub-groups have specific characteristics and these characteristics are reflected in the variety of English that they use. Such cultural traits reflected in the way English is used have been discussed by Anna Wierzbicka (1995) who writes about the cultural specifics of the Polish language which result in the inability to explain certain concepts with adequate English lexical items.

How language is used by a particular society or community is a reflection of that society. Language reflects identity, culture, mood, and power and politeness are displayed through language. Differences in how English is used and spoken by people

can be detected in accent, pronunciation, tone, vocabulary and syntax. The English language has been evolving over centuries, moving from old English to Medieval English to Modern English. In the same way, the variety of English used by speakers in Indonesia is different from the variety used by people in Taiwan. The English language, like fashion is constantly evolving and changing. Linguistic change is tangible and can be seen from the way words from local languages are borrowed and assimilated into regional Englishes. This adds a new dimension to the variety of English used in any one locality or region and this has enriched regional Englishes

One of the major tools of communication the world over is the print media. In Malaysia, and Singapore there are four main English dailies and in Pakistan, there is no less than fourteen daily English language newspapers. This study reveals a large number of local lexical intrusions in all the newspapers selected for research.

### **Aim of study**

As the focus of this study is on the nativisation of English, we focus on how words from local languages are used in English language newspapers. In identifying these words we aim to highlight the extent of the process of nativisation of English that has occurred in these three countries.

### **Corpus of data**

This study is based on the collection of data which has been extracted from the newspaper articles in local English newspapers. In Malaysia, the selected English dailies were the “New Straits Times” and the “Star”. Extracts were collected from January 31, to May 12, 2004. In Singapore data from “The New Paper” was collected from February 21, to May 4, 2007; “Today” from February 8, to March 22, 2007; “The Straits Times” from March 4, 2007 to May 4, 2007 and from “The Sunday Times” dated March 18, 2007. In Pakistan, the selected Pakistani dailies were “The Nation” and “The News”. “The Nation” was randomly selected from February 6, 2005 to July 31, 2005, while “The News” was randomly selected from June 1, 2005 to August 31, 2005. This study focuses only on articles written in these newspapers and not on headlines or advertisements.

### **Methodology**

Due to the massive entries of code-switches (and code-mixes) which seem to occur almost daily in these newspapers; random selecting from the data occurring over a period of time would help show that code-switches are a natural phenomenon and occur frequently. Code-switches used by writers were identified and highlighted. Such words had to be words that were not found in British or American dictionaries. To gain a general idea of how much the English of these three countries had been nativised by

lexical items from local languages, the code-switches identified were then categorized. Before moving on to the analysis definitions of certain terms is apt.

### **Nativization**

The Collins English Dictionary (1996, 2006) defines the term, ‘going native’ as to adopt the lifestyle of the local population. By the term nativisation, we mean a variety of English that has borrowed from local languages. For instance, the interaction of two co-existing languages like English and Urdu in Pakistan, English and Malay, English and Chinese (Mandarin and the sub-dialects), or even English and Tamil in multilingual Malaysia and Singapore facilitate multilingual speakers to select words which are culturally associated with certain concepts and situations. This process of nativisation, irrespective of geographical location, does in no way make the particular variety of English more superior or inferior to standard English. In fact, such specific usage results in a specific variety of English with a linguistic identity and culture of its own. The nativisation of English both in Malaysia and Singapore is not very different as the two countries have common languages like Malay, English, Tamil, Mandarin and other dialects of Chinese.

### **Code-switching**

Haugen defines code-switching as the “alternative use of two languages,” and Marasigan (1983) refers to it as the use of two languages in the same sentence or discourse. Gumperz (1982) terms code-switching as being addressee specific, while Fishman (1996) argues that the choice of codes is based on domains. David (2001, 2003) and Kow (2003) demonstrate that code-switching have multiple functions while Kuang (2007) suggests that code-switching in a young child’s writing occurs because the child only has that concept in that particular language. In another study Kuang and Ng (2007) examined how students writing in Malay used English words but maintained Malay syntax.

The mass media in the globalised world is experiencing code-switches. Daniel Hernandez (2004) in an article published in the Boston Globe said that ‘Spanglish’ (Spanish and English) is becoming more and more prominent among US-born Hispanic communities in America, and the mass media is catering to their codes.

Code switching and lexical borrowing is a natural linguistic process in language contact situations. Malaysian, Singaporean and Pakistani varieties of English have moved beyond the stage of lexical borrowings alone. Hybridized and grammaticised mother tongue lexical items are prevalent in English language dailies and have become an integral part of the English lexicon in these countries.

### **Discussion and analysis**

For the analysis of data, the code-switching instances are first identified and highlighted in the English newspapers after which they are categorized into 11 classes. The analysis is organised in the 11 classes listed under a., b. and c. which are used to highlight the respective countries of Malaysia (a.), Singapore (b.), and Pakistan (c.). The 11 classes are as follows:

(1) People (Titles and Honoraries)	(7) Arts and Films
(2) Events	(8) Food
(3) Cultural activities (and physical items)	(9) Clothes
(4) Places	(10) Quotations
(5) Political movements and government	(11) Conceptualising local concepts
(6) Religion	

### **(1) People (Titles and Honoraries)**

All human experiences are, to some extent, mediated through culture and language. Objects and forces in the physical environment become labeled in language only if they have cultural significance. In other words, they take up the attention of the community. Such words or objects or activities become culturally significant.

As a former appendage of Malaysia before 1968, Singapore is not totally unlike Malaysia where titles and honoraries may resemble each other. In Malaysia titles conferred by state governments and by the king are used before the name of the person. Titles like *Datuk*, *Tan Seri*, *Puan Seri*, etc. are often seen in English dailies.

As both Pakistan and Malaysia share a common Islamic tradition certain religious terminology in both Pakistani and Malaysian English dailies emerge. For instance, anyone who has performed the holy Pilgrimage or *Haj* is called a *Haji* and is allowed to use this term before his name. In Pakistan, *Mullah*, *Maulana*, *Hafiz* and *Qari* are all words which refer to persons associated with the religious fraternity.

From the data which follows it is clear that in hierarchical societies like Malaysia, Pakistan and Singapore, titles of respect for heads of organizations, tribal chiefs and religious scholars are used in the English dailies. These titles originate from the local languages and there are no such equivalents in English.

#### **(1) a. People, titles and honoraries in Malaysian dailies**

“As *Datuk Seri* Abdullah Ahmad Badawi has mentioned, we want a closer relationship between the races. We want to feel like one *Bangsa* Malaysia.”(New Straits Times. (2004). April 7, 2004: 11)

Thumbs up were given to these professionally-administered schools not only by those who called themselves “*Anak Johor*” (those who were born and live in the State), but also by people from other states who moved and work here.(Sayuthi, Shahrum. February 28, 2004: 15)

“The move by Selangor *Menteri Besar Datuk Seri* Dr Mohd Khir Toyo to send civil servants who do not buck up to reform school will send a clear message that a certain...(Ganeshadeva, M. February 24, 2004: 11)

**(1) b. People, titles and honoraries in Singapore dailies**

While Muslim law allows a bride’s father to perform the marriage solemnization in the presence of two witnesses, he risks getting jailed if caught doing so without the *kadi’s* (marriage solemniser’s) presence, said Mr Pasuni. Arlina Arshad: The Sunday Times, 18/03/2007, pg 27

Hundreds of people – many with children in tow – were at the *Pasir Ris* resort to see what “*Guru*” Zareena N. Ban had to offer at the Laughter Day event, organized by the NTUC club. Ho Ai Li: The Straits Times, 02/04/2007, pg H2

The tall, well-built bachelor grins mischievously as he says: “When I go on to *Geylang Serai*, some of the ‘*mak cik*’ (Malay aunties) recognize me and shake my hand. I have to watch what I wear now.” Lee Sze Yong: The Straits Times, 02/04/2007, pg Life! People 5

**(1) c. People, titles and honoraries in Pakistani dailies**

Former Foreign Minister *Sardar* (Chief of tribe) Assif Ahmad Ali Saturday said..... (The News 24-07-05)

Other speakers on the occasion including *Maulana* (Religious scholar) *Irshad-ul-Haq* emphasized that Islam is a religion of peace. (The News 24-07-05)

They were *Hafiz* (One who has memorized the Quran) Muhammad Nawaz and Qari Shabir Ahmad. (The News 24-07-05)

This was informed by Pakistan Commissioner for Indus Waters Treaty *Syed* (Revered caste) Jamait Ali Shah .....carrying out inspection of the project along with Indian officials. (The News 31-07-05)

.....tribal notable *Haji* (One who has performed Haj) Ali Mardan, all of them were abducted at gunpoint near Sui by unknown armed men..... (July 24th, 2005)

*Imam* ( One who leads the prayers in the mosque) doubts terrorist link to Pak-American men. (July 24th, 2005)

The group of *Yatrees* (Pilgrims who come to visit holy sites) arrived here on June 21st on ten day visit to participate in 166th death anniversary of Maharajja (Great king) Ranjeet Singh. (The News 01-07-05)

**(2) Events, Ceremonies and Rituals**

Speakers give names to important entities and events in their physical and social worlds, and once named these lexical items become entrenched. Words associated with

ceremonies and rituals relating to birth, marriage and death are generally borrowed from the local languages. Words like *nikah* (both in Malaysia and Pakistan) ,and *shadi rasm-i-hina* (Pakistan) refer to various ceremonies related to weddings. Similarly words like *qul*, *chehlum* and *barsi* (Pakistan) are related to rituals associated with death. Then there are certain words in all three countries which have been accepted in English due to continued usage e.g. bazaar. In the Singaporean context, words like *yusheng*, *gong xi fa cai*, and *chingay* from Chinese were noted. Examples follow:-

### **(2) a. Events, Ceremonies and Rituals in Malaysian dailies**

“He is especially touched when the boys *cium tangan* (kiss his hand as a sign of respect)...a basic *salam* will do...” (Aljunid, Sharifah Sakinah, May 8, 2004: L7.)

The nature of such gatherings is a combination of edutainment, networking, *gotong royong* – whatever you care to call it. (Bajunid, Ibrahim Ahmad, April 18, 2004: 8)

### **(2) b. Events, Ceremonies and Rituals in Singapore dailies**

Reading how Blackie has made alive the endangered “*kampong spirit*”, I can feel a ray of hope for our future. Dr Tan Chek Wee: The New Paper, 25/02/2007, pg 4

Okay, lah, also, *gong xi fa cai*! Peter H L Lim: The New Paper, 21/07/2007, pg 18

If, like me, you’re used to the milder version at neighbourhood *pasar malams*, you may want to avoid ordering it here. Lee Pei Qi: The New Paper, 21/07/2007, pg 26 & 27

Road closure for the *Chingay* Parade preview today will affect 22 SBS Transit bus services. The New Paper, 23/02/2007, pg 18

### **(2) c. Events, Ceremonies and Rituals in Pakistani dailies**

The *nikah* ((the signing of the marriage contract) ceremony but *valima* (the reception hosted by the boy’s family) or reception that was deliberately passed off The nation,30-7-05)

We are at *Data Saab*( Muslim saint ‘s tomb) no one will say anything to you here. (The News 6-6-2005)

### **(3) Cultural activities**

In the Oxford dictionary of sociology (1998), culture is “a general term for the symbolic and learned aspects of human society...[encompassing] to a learned complex of knowledge, belief, art, morals, law and customs” (p. 137). Cultures are context specific and they are maintained through the sociocultural practises of society (also see Fairclough, 1995). Below are some of the examples of cultural activities which are not found in non-Malaysian and non-Pakistani environments (in this case, newspapers).

### **(3) a. Cultural activities in Malaysian dailies**

Video cameras to keeps tabs on *ceramah*. (talk) (Krishnamoorthy, M. February 26, 2004: 1/4)

“After accepting the job, I treated him to a big *makan* (treat) to thank him” (Ang, Yen Ling, May 4, 2004: 15).

Last Saturday was Workers Day. In the name of workers – an lest we forget, we are all workers – let’s reward them properly before their contribution is forgotten. *Selamat Hari Pekerja!* (happy worker’s day). (Talib, Ahmad A. May 3, 2004: 10)

### **(3) b. Cultural activities in Singapore dailies**

Then, as I grew older, I started to wonder why there were more *gong xi fa cai* (Mandarin for wishing you prosperity) wishes than *xin nian kuai le* (happy new year) greetings during Chinese New Year. Peter H L Lim: The New Paper, 21/07/2007, pg 18

Those with their eye on the goodies will tell you that they are hoping for an early *hong bao* from the Government in the Budget to be delivered one week from now. (Tor Ching Li: Today, 08/02/2007, pg 1)

### **(3) c. Cultural activities in Pakistani dailies**

The 377th annual 3 day *urs* (annual celebration) of Hazrat Baba Shah Jamal will start at Saints *Mazar* (Tomb) in Ichra, Lahore on Thursday. (The Nation 12-05-05)

*Thana culture*. (police station) (The Nation 06-06-05)

### **(4) Places**

Names of places mostly use native expressions and these are retained as such in the English language newspapers. Places, like events and cultural values are contextual ‘items’, and over time, the local languages are assimilated into the matrix language.

#### **(4) a. Places in Malaysian dailies**

I support the *SJK* (Sekolah Jenis Kebangsaan). (Aznam, Suhaini. (2004). Gruelling day on the campaign trail. March 20. 20.)

A couple of years ago, I called Hospital *Universiti Kebangsaan Malaysia* (National University of Malaysia Hospital) for an appointment to have a child...(Teh, B. C., May 8, 2004. StarTwo 27).

The many so-called *rumah tumpangan* (brothel) here ply the flesh trade openly.(Tan Hwee Mui, Margaret. April 9, 2004: 11).

As for Noornadia, Ansara’s assistance would enable her to continue her studies at *Kolej Matrikulasi* Kulim (Kulim Matriculation College) in Kedah.(New Straits Times. May 8, 2004: 12).

“Furthermore, the ministry is taking over *Dewan Bahasa dan Pustaka* (Language and Cultural Centre) because it is very important to teach the young to speak proper Malay,” she added. (Ritikos, Jane. April 22, 2004: 12)

#### **(4) b. Places in Singapore dailies**

Mr Ng said his bakery daily produces about 1,000 loaves of brown bread, supplying *Kopitiam* and Banquet foodcourts. (Teh Jen Lee: The New Paper, 25/02/2007, pg 14)

There are many reasons *Bagus* (“good” in Malay), which opened three years ago lives up to its name. (Teo Pau Lin; The Sunday Times, 18/03/2007, pg L31)

#### **(4) c. Places in Pakistani dailies**

...afternoon at *kamran's baradari* (A verandah with twelve arches) (The News 14-08-05)

*Anarkali Bazaars*. (A shopping centre named after a royal maid servant )

A police post exhibition hall Suma'a hall industrial school for women, library, *langar khana* (a place for dining which gives free food)and *musafir khanas*.(inn offering free lodging) (The News 6-6-2005)

*Bab-e- Pakistan* (The Pakistan Gate) project is being completed on 110 Acres of land. (The News 14-08-05)

A low of profile politician, invited me to his sprawling *Lal Havel*. (The News,1-7=05)  
The *Lari Adda* (Bus stop) police said..... (The News 01-07-05)

#### **(5) Political movements and government**

All political movements are indigenous in origin. Also their success and popularity depend on their appeal that cater to the masses so they carry names in the national language, Urdu. Since a vast majority of the public is not familiar with English, Urdu is used to reach out to the maximum number of people in the country. In the Malaysian and Singaporean data base under study, no such examples were found.

#### **(5) c. Political movements and government in Pakistani dailies**

English is the official language in Pakistan. Most of the written communication is done in English.

There are however, some posts that carry Urdu names and one such post is that of *Nazim* which means administrator. This post occurs as the administrator at the lower level (*tehsil*) or at the higher level (district).

A compound word - *Nazimship* was also recorded (The News, 1-07 -06).

*Khaksar Tehrik* (Movement) Pakistan has announced its support to Ms. Fakhrunisa for that office of Lahore High court Bar association. (The Nation 25-02-05)

MMA, ARD and Pakistan *Tehrik Insaf* (movement for justice)agreed yielding unanimous candidate for the *Nazim* slot against the ruling party in UC-32, Dars Baray Mian, Mughalpura. (July 7, 2005)

President Musharraf will also distribute medals among two hundred *Karkun-e- Tehreek* Pakistan. (Workers of the Pakistan Movement) (The News 14-08-05)

The sources said both the parties in their party meetings discussed in detail the ruling party's strategy to win the seats right from union councils to the district and *Tehsil Nazims*. (Local government administrators)

Ministers would also be eligible for simultaneous *nazimship*. (coinage of a new term) (The News 01-07-05)

Dcos, Tmos replace *nazims*. (The News 01-07-05)

Secretariat will come under the Mohtasib. ( Accountability chief) The News, 6-07-05.

Candidates for union council *nazim* and *naib nazim* (deputy administrator) will file their papers. (1-07-05)

The election commission has fixed September 29th for the elections of district, *tehsils*, *talukas* and / or towns. (The Nation 17-06-05)

## **(6) Religion**

Malaysia and Pakistan share a common state religion- Islam hence, it was not surprising to find that a vast majority of words under this category were found. Names of religious places, religious events and activities are retained in the native form in the English dailies. Examples are words like *masjid*, (place of worship for Muslims); *naat khawani* (recitation of poems in praise of the Holy Prophet Mohammad; *assalamualaikum* (peace be upon him) or Quran *khawani* (recitation of the Holy Quran) . Such instances of code-switches in Singaporean newspapers were not found.

### **(6) a. Religion in Malaysian dailies**

But then, we could not sit together because there would be a non-*halal* section and a *halal* section. (New Straits Times. (2004). Captions. February 1. 2.)

The *mutaah* comprised claims of up to 15 year for alimony (*nafkah*) amounting to RM360,000, clothing and accessories (RM270,000) and maintenance of their four children aged between 13 and 22. The remainder, to be given in movable and fixed assets, was acquired by the couple during their marriage (*harta sepencarian*). Properties given to Nooraini as matrimonial gifts (*pemberian hibbah*) – including a BMW car, a Honda Civic car and a house in Subang Jaya, Selangor – will remain at her disposal. (Othman, M. Husairy. May 12, 2004: 6).

“I am not young anymore, and this is a way for me to earn my *pahala* (spiritual merit for doing good deeds),” she says. Just as Muslims have to attend courses to perform the *umrah* and the haj, Asmah too had attended short courses organised by the State Religious Department, the Health Ministry as well as the *surau* to qualify for the job. (Yusoff, Yuslina. May 12, 2004)

### **(6) c. Religion in Pakistani dailies**

*Chehlum* ( Religious prayer /Condolence Ceremony held forty days after death) of *Chaudhary Faqir* Muhammad will be held on Sunday. (The News 24-07-05)

*Qul*( Religious prayers held on the third day after death) of Razzatullah Khan at Jamia Masjid Ashrafia Sant Nagar Today. (July 24th, 2005)

*Madrassa*( Religious seminary /school) reforms Board meets today. (July 7, 2005)

Quran *Khawani*( Reading of the Quran) for mother of Dr. Nadeem Cheema will be held at..... (July 24th, 2005)

...honor of this *Ummah* ( The Muslim nation) is being sold..... ( July 7th, 2005)

### **(7) Arts and film**

Arts define the properties of culture and is presented in the local language, in order to 'contextualise' the value. Both Malaysia and Pakistan's data base displayed such code-switching but it was not found in the Singaporean data base.

#### **(7) a. Arts and film in Malaysian dailies**

He said the performing arts had also been neglected and the new ministry could revive dying traditional arts such as *wayang kulit* and *mak yong*.(Ritikos, Jane. April 22, 2004: 12)

Jeganathan Ramachandram's art exhibition '*Vaastu – Windows to Time*'...The concept is very much like *feng shui*, but *vaastu* also incorporates the time factor in its application...A musician in his own right, he was also trained as a *veenai* (a traditional Indian stringed instrument) player in South India. (Samat, Hafidah, May 8, 2004: L14).

One child especially was in her element dancing to a *bhangra* tune, and mesmerising the audience with her slick Bollywood moves. (Taib, Shuib. April 29, 2004: CL1).

Pengkalan Kotan candidate Lee Hack Teik of Barisan National kicked off his campaign with a song entitled *Say Kai Tay Ee Theng* (meaning "The World's Bravest" in Hokkien).(Star. March 15, 2004: 4).

#### **(7) c. Arts and film in Pakistani dailies**

Names of movies, plays and theatrical performances are mostly in the local language.

Hmm! While on the one hand we have couples heading for splitsville, we have one dusky *dhamaka* (Explosion) from *Sheikhpura* (name of place) *Meera* desperately trying to create some big bangs across the great divide. (July 12, 2005)

Double *Sawari*. (The Nation 05-09-05)

"*Paoon Ka Zever*". (The Nation 05-09-05)

"*Kareeb Kareeb*" (The Nation 05-09-05)

*Samri jadugar* (The Nation 05-09-05)

*Oh ho ho! Ainak Wala Jin* ( The bespectacled genie) (The Nation 05-09-05)

He revealed that he plans to stage play “*Kaereb Kareeb*”.( name of play) (The Nation 05-09-05)

### **(8) Food**

Like art, food also indicates cultural identity. Names of local dishes, foods, fruits and vegetables are referred to by using words from local languages. The reliance on local names occurred because there are no English equivalents:

#### **(8) a. Food in Malaysian dailies**

According to her niece, Delphine Rane Dawson, who is in her mid 30s, “My aunt’s anchovy and *petai sambal* is unbeatable!”...Her catering business includes doing the weekly cooking for a couple and providing snake packs of fried *meehoon* and *nasi lemak* for the altar boys...Her spicy brinjal *chutney*, fiery chicken *sambal*, crispy fish cutlets, rich cauliflower *kurma* and aromatic *briyani* make her clients come back for more... However, her *dhalca*, mutton varuvel and chicken *briyani* have remained all-time favourites...(Chen, Grace, May 8, 2004: StarTwo 4).

As I recall, it used to be a small, friendly, calm, slow, cheap, serene place with a beach and sea view all the trappings of a port city and a pretty good *nasi kandar* and *char kuay teow*...(Moses, Rajan, May 8, 2004: 11).

Smoking be banned in all restaurants, *teh tarik* stalls and toilets. (J., Peter, May 8, 2004. StarTwo 27).

The owner, a short man who still wears a Pagoda- brand white singlet, knows his order – *kopi kau* (strong coffee with condensed milk). Although the tables are always filled up because of a popular *Hokkien mee*, or prawn mee stall there, the 65- year-old teacher is left undisturbed to read his two English newspapers. At *ceramah*, he tells his listeners he has eaten *kari pooi* (curry rice in Hokkein) – a euphemism for having spent time in prison or a lock-up. (Wong, Chun Wai. March 20, 2004: 8).

#### **(8) b. Food in Singapore dailies**

The thought of *ginseng* in *chawanmushi* made me a little nervous. An added bonus? The ginkgo nut at the bottom of the cup. The *tang gui* flower crab is another dish on offer.(Lee Pei Qi: The New Paper, 21/07/2007, pg 26 & 27)

Halfway through our *ramen* dinner, I popped the question: “Where did the two of you meet?” (Mindy Tan: The New Paper, 23/02/2007, pg 25 & 26)

Especially the dinning bit, what with the array of pineapple tarts, *kueh lapis* and abalone meals. (Mindy Tan: The New Paper, 23/02/2007, pg 25 & 26)

If these bakeries were ever to close down, Singaporeans would feel the loss most keenly when they want to eat *kaya* toast. (Teh Jen Lee: The New Paper, 25/02/2007, pg 14)

Go for the *a la carte* buffet if you have the luxury of time and a good appetite (Goh Mei Yi: The New Paper, 26/02/2007, pg 31)

Inspired by a Thai-style glass noodle dish, I decided to prepare a claypot meal using bean thread noodles (*tang hoon*), tiger prawns and thinly-sliced abalone. (Amy Van: Today, 08/02/2007, pg 50)

The crowd is young and casual, and seems to be as comfortable ordering wood-fired pizzas as they are *briyani*, the city's famous meat-and-rice dish. (Today, 08/02/2007, pg 51)

Try carrying a mountain bike, a box of *bak kua* and Kylie Minogue's perfume onto the MRT. (Neil Humphreys: Today, 17-18/03/2007, pg 12)

Last night, I had a strange dream, in which I was wearing my favourite white wrap shirt tucking into an enormous bowl of *laksa*. (Pearlyn Tham: Today, 17-18/03/2007, pg 20)

After all, the laidback recreation area is more commonly known for affordable family-friendly chow than posh nosh like *foie gras*. (Neo Chai Chin: Today, 17-18/03/2007, pg 22)

I was a tad disappointed with the slipper lobster pasta (\$18), comprising chunks of slipper lobster meat, served with chopped parsley in light cream and *pomodoro* (tomato) sauce. (Eveline Gan: Today, 17-18/03/2007, pg 22)

I opted for the baked chocolate *lava gateau* (\$6) served with vanilla ice cream and strawberries. (Eveline Gan: Today, 17-18/03/2007, pg 22)

The eatery will, for instance, serve an eclectic range of food including *foie gras* fried rice, sweet-potato pancakes with *gula melaka* (palm sugar) and *cempedak* preserves. (Ashraf Safdar: Today, 21/03/2007, pg 39)

Organic *miso*, Korean *chilli* paste, maple syrup, eggs, lots of fruit, salad greens, real butter, my store of Chinese herbal tonics such as sweet and bitter apricot kernels, Chinese dates and chicken soup herbs. And my home-made *kimchi* collection. (Eveline Gan: Today, 17-18/03/2007, pg 22)

My Beijing sister-in-law's *jiaozi* (steamed dumplings), served with aged Chinese vinegar with tender ginger juliennes and a saucerful of *jiucaihua* (pickled flowering chives). (Eveline Gan: Today, 17-18/03/2007, pg 22)

At first sight, this *halal yong tau* foo restaurant in a shophouse unit in Changi Road doesn't look promising. You can even have it with *la mian* (pulled noodles, add \$1), bee hoon or rice (add 50 cents). For example, the best-selling *ikan parang* balls (\$4 for a few balls in soup) are big and bouncy, and you can tell they're handmade because their surfaces are pock-marked. (Teo Pau Lin; The Sunday Times, 18/03/2007, pg .L31)

There was also the monkey guffaw, involving much scratching of heads and armpits, and even a local “*teh-tarik*” laugh. (The Straits Times, 02/04/2007, pg 1)

Here I marry two traditions by spicing up a Mediterranean broth with a sambal which I either make from scratch or put together with the help of a bottled paste. I end up with a full-boiled stew, spiked by *chillies* and *belachan*. 2 slices *batang* fish, cut into at least 6 pieces. 1 tbs tamarine puree (available bottled from Tekka market). Mix in turmeric and *galangal* powders. (Sylvia Tan: The Straits Times, 04/04/2007, pg mindyourbody 15)

Just as special is the unique Saison Sayang, a beer crafted in the European style but with a touch of Asian spices like coriander, Chinese *ba jiao* and lightly spiced with a liquorish anise undertone. (Today, 22/03/2007, pg 46)

Serve the rice with slices of lime, coriander leaves, *chilli padi* and cashew nuts. To prepare this dish, you’ll need to get a bottle of preserved olive vegetables (*kana chai*) packed in brine. (Amy Van: Today, 22/03/2007, pg 52)

No doubt about it, *doujiang* (Chinese salted bean sauce). A really good packet of fried hor fun topped with lots of tasty gravy, slices of shark meat, liver, pork fillets and prawns, all wrapped up in smoky, dried palm leaf (*wuba ye*). So breakfast is now one plain *roti prata* for 60 cents. (Radha Basu: The Straits Times, 03/04/2007, pg 2)

#### **(8) c. Food in Pakistani dailies**

They found a packet of *Chaars* (Marijuana) in it and arrested me. (July 12, 2005)

....are called *simla mirch*. (capsicum). (The News 14-08-05)

....while wave after wave of *falsa* (purple coloured sour berries) lychee, mangoes and plums are visible.” (The News 30-06-05)

“the per acre produces of the *sindhr* ( a variety of mangoes) mangoes is around stones.” (The News 06-07-05)

“Mrs Samira Shahzad’s cooking classes ; *Sheesh Kabab* (meat dish) (The News 06-07-05)

*koftas*. (meat balls) (The News 28-08-05)

“... a few itinerant vendors selling peanuts and *chana jor garam* ( roasted grams)...” (The News 28-08-05)

#### **(9) Clothes**

In the era of globalisation, clothes provide the wearer with an identity. The data indicates that clothings which are native in origin are referred to by using words from the local languages.

#### **(9) a. Clothes in Malaysian dailies**

Male students wear black *songkok*, white baju *Melayu teluk belanga*, black *samping* and white shoes. Female students wear white-and-blue *baju kurung*, white *tudung* and white shoes. Male teachers are required to be dressed with tie and *songkok*, while women wear *baju kurung* with *tudung*. Nowhere in sight is “Arabic” attire such as *jubah* (robes), *ketayap* (skull caps) and *serban* (turbans), which are trademarks of religious schools in other parts of the country. (Sayuthi, Shahrums. February 28, 2004: 15).

Probably the most eye-catching were the Wanita Umno members who were using the “blue wave” to maximum effect – they wore the blue BN flag as their *selendang* with their white and red *baju kurung*. (New Straits Times. February 24, 2004: 2).

Clad in a fuschia *songket baju kurung*, guest of honour Datin Paduka Seri Endon Mahmood was clearly pleased to see the stylish creations. (Manan, Dazman. May 7, 2004: 3).

#### **(9) b. Clothes in Singapore dailies**

For a day out at the zoo or in the urban jungle, dress up your little ones in the Safari designs, which are heavy on flower and camouflage prints and crochet details and come drenched in shades of green, *khaki* and pink. (Pearlyn Tham: Today, 17-18/03/2007, pg 21)

The new rules follow a high-profile court case in which the father of a 12-year-old Muslim girl was last month refused permission by London’s High Court to challenge a school’s ban on her wearing the full-face veil, or *niqab*, during lessons. (Today, 21/03/2007, pg 20)

Outwardly, it appears conservative, with many women in long cloaks and wearing the *hijab* (head scarf), yet it boasts a chic quarter, Al-Jedeida, home to a number of boutique hotels with stylish restaurants. (Tan Chung Lee: The Straits Times, 03/04/2007, pg Life! Travel 2)

Law studies: Former Hong Kong actress-turned-lawyer Yung Ching Ching, the wife of director Lau Kar Leung, has been donning a *tudung* and *mini-kurong* while studying Islamic law in Singapore, reported Malaysia’s *Guang Ming Daily*. (The Straits Times, 03/04/2007, pg Life! Buzz 12)

#### **(9) c. Clothes in Pakistani dailies**

She exhibited her bridal collection of *ghararas* and *saris* made in muslin. (The News 24-07-05)

The kind of work seen on the costume included tapestry ,embroided work like *jaamdani* and *zardozi* work on muslin and pure silk. (The News 24-07-05)

She has stuck to se limits with the exception of a *khaadi* shoot in which she felt she revealed too much. (The News 24-07-05)

That and another shoot in which my *choli* was way too small. (The News 24-07-05)

We need to prove that *kurtas*, sequins and *khussaa* are as much our culture as India's. (The News 24-07-05)

President Musharraf was clad in white *Shalwar Qameez* with a traditional *Khusa*. (The News 16-08-05)

She designed her bridal collection of *Ghararas* and *Saris*. She also showed her interest in *Khussas* and *Kurtas* clothes.

### (10) Quotations

Quotations are frequently used to by journalists so as to emphasise and provide a realistic account. This is done in the language used by the speaker.

#### (10) a. Quotations in Malaysian dailies

“*Apakah sangat teruk kerja sini? Cari duit saja. Bau busuk dah biasa* (what is so bad about working here? It is just to earn money. We get used to the stench),” exclaimed one of the women, who gave her name as Mas and she said she was 48 (Chin, Mui Yoon. April 19, 2004: 2-3)

It was scorchingly hot, but one in the crowd was heard saying: “*Panas lit lit pun tak pa. Semangat tu ada.*” “It doesn't matter how hot it is, the spirit is here.” And in thick Penang patois he added: “*Jangan buat lekeh.*” It means, don't spoil it. (Nadzri, Syed. March 9, 2004: 4)

“*Guane, nok sokong lagi?*” (How? Do you still want to support them?). Another popular slogan is “*Pas molek doh weh, Umno dok rok chetong,*” *Molek* which means elok, and *dok rok chetong* translates as *lekeh* or “not in the same class”, say locals. Where the above slogan is seen, Umno's retort can be found a few telephone poles away: “*Serik doh wehhh.*” (Enough already.) “*Umno bina, PAS musnah*” (Umno builds, PAS destroys) – a catchphrase popular in Setiu and Besut, is answered by “*Umno bina tol, PAS musnah tol*” as you cross the Sultan Mahmud bridge into the state capital. At makeshift huts along the road to Merang it is simply “*Selamat tinggal PAS*” (Goodbye PAS) to which PAS retorts: “*Selamat tinggal Umno, dan jangan kembali lagi*” (Goodbye Umno and don't come back). An Umno banner posted in the vicinity of government offices and quarters in Besut carries the list of political blunders allegedly committed by PAS leaders: “2001 – *Panggil wartawan tupai dan monyet* (Called journalists squirrels and monkeys), 2002 – *Panggil polis syaitan bisu* (Called the police silent devils), 2003 – *Panggil kakitangan kerajaan berkaki empat* (Called civil servants four-legged, implying they were animals). The banner ends with the word “*Guane?*” At the state capital, the messages are more conservative with a giant billboard showing Menteri Besar Datuk Seri Abdul Hadi Awang and the ruling government's main slogan below: “*Terengganu kite, hok kite*” (Our Terengganu, Our right) – a direct reference to the issue of oil royalty allegedly owed to the state by the Federal Government. (Suthakar, K. and Baharom, Farris. March 8, 2004: 19).

### **(10) b. Quotations in Singapore dailies**

The Japanese have a proverb: *Ishi no ue nimo san nen* – which means. After sitting on a cold stone for three years, the stone becomes warm. (Letter from John A Tessensohn in Osaka, Japan: Today, 08/02/2007, pg 26)

In reference to their upcoming concert being named Jump: *Li Kai Di Qiu Biao Mian* (Mandarin for “Jump: Leaving the Face of the Earth”), the band’s guitarist Stone said at a press conference on Friday: “In the physical sense, we hope our fans that come to the concert will join us in jumping to the beat if the music and hence ‘leave’ the earth.” (Winson Teo: Today, 17-18/03/2007, pg 30)

He said: “*Tilam* (mattress in Malay) is a very common item. How you interpret it depends on your mindset. But to many....it means having a home, a personal space, a possession.” Wendy Teo: The New Paper, 05/04/2007, pg 26

Student Lim Aik, 21, says: “I’d fell ‘*paiseh*’ (Hokkien for embarrassed) if there was a line of people waiting for seats.” (Shaan Seth: The Sunday Times, 18/03/2007, pg L10)

### **(10) c. Quotations in Pakistani dailies**

Nazar na lagay. (God save you from the evil eye) (July 12, 2005)

History is repeating itself. Previously Mohsin Khan left cricket and joined the Indian Film Industry. Ultimately he was like a “*dhobi ka kutam na ghar ka na ghat ka*” *Har Qadam Zindagi* ! (life at every step)

### **(11) Conceptualising of local concepts**

Although the above categories have attempted to highlight concepts that were related to religion and culture, the following section illustrates instances of code-switches in Singaporean newspapers. These instances appeared to be using local concepts like the Hokkien ‘*kiasu*’ which means afraid to lose.

Although in *huayu* it’s cool, it’s not so hot in English. Mandarin speakers might say *mai hui lai*, which literally translates to “buy back”. (The Sunday Times, 18/03/2007, pg 42)  
But inversely, when there’s more than plenty and one is still grabby, well, there’s being *kiasu* to the nth degree (meaning to the highest order). (Sylvia Toh Paik Choo: The New Paper, 25/02/2007, pg 27)

Oily rice in today’s *kiasi* (fear of death) mindset is a no-no because it can make you feel sick. (K.F. Seetoh: The New Paper, 25/02/2007, pg 30)

The therapeutic aim of a TCM treatment is to invigorate the kidneys and liver, especially through nourishing the kidney *yin* to restore the inner balance. (Gerard Yeo: The Sunday Times, 18/03/2007, pg L12)

It saves you trouble at the airport counter and gives you more time to trawl through the duty-free shops or sip a *mai-tai* in the lounge. (Jason Hahn: The Sunday Times, 18/03/2007, pg L15)

Journalist who have interviewed her attest to her “*nu ren wei*” or sense of femininity.

When I look at the photo, I was dishevelled and my face like *kena bus langah* (like a bus had hit me). (Judith Tan: The Straits Times, 04/04/2007, pg mindyourbody 4)

## Conclusion

The corpus of data had been compiled from local English newspapers in Malaysia, Singapore and Pakistan and they have been categorised under 11 classes. Although Malaysia and Singapore share many historical facts the study indicates that there were a number of categories of lexical usage that are present in Malaysian newspapers but not in Singaporean newspapers and vice versa. A number of possible reasons leading to this could include strict censorship by the Singaporean government on the usage of English to ensure what may be construed by the government as “pure English”. In contrast there is a need to cater to the food habits of Singaporeans and this has resulted in the emergence of many lexical items from other languages. This study also highlights the fact that Malaysia and Pakistan share many similarities in terms of their hybridization of words found in their respective English newspapers while despite the physical closeness, Singapore appears to be more Chinese as many of the terms identified appear to have a Chinese origin.

This richness of lexical intrusions and assimilation into regional varieties of English makes them truly our English and so we can strongly assert that the colonization process has come full circle with the one time colonies of the British Raj now colonizing and Asianising the Raj's language. English is a global language and more importantly from the perspective of learners of English it has become our language as so many of our lexical items have assimilated and been accepted not only in the regional varieties but globally. Everyone knows what a *kampung* is and what going *amuk* means!

# Korean Locative Adverbs and Politeness

Mee-Jeong Park, Bumyong Choi, Hye Seung Lee

University of Hawaii at Manoa

Honolulu, HI 96822  
meejeong@hawaii.edu

## Abstract

Korean locative adverbs *yeki*, *keki*, and *ceki*, when suffixed with the polite *-yo*, function as attention-grabbing devices demarcating the different degrees of politeness toward addressee(s) whose relationship with the speaker is not intimate or formal enough to opt for the typical options (e.g., first name, social titles, etc). *ceki-yo* is very frequently used in catching someone's attention in a very polite manner, polite enough to be used to seniors. *yeki-yo* is used mostly at places such as restaurants and stores where a customer (i.e., speaker) tries to drag the other party's (i.e., waiter/clerk) attention toward him/herself. *Keki-yo* is not polite enough to be used to seniors and, depending on the context, could sound offensive or rude to the hearer.

**Keywords:** Korean locative adverbs, place deixis, person deixis, politeness

## 1. Introduction

The term deixis comes from the Greek language, which means “pointing” via language. When it comes to the spatial deictic expressions such as locative adverbs (e.g., here, there) and demonstratives (e.g., this, that), the notion of relative “proximity” is considered as playing the central role in their use. In some languages with two-term system (e.g., English, Dutch, etc.), the two expressions are contrasted in terms of proximity to the speaker. For languages with three-term system (e.g., Japanese, Korean, Spanish, etc.), the three expressions are used in terms of proximity to either the speaker or the hearer. In addition, the use of proximal deictic conveys the speaker's increased involvement or empathy, and the distal deictic conveys decreased involvement or empathy. That is, the choice between a proximal and a distal deictic form can also be influenced by the speaker's emotional preference toward an object, namely psychological distance (Brown & Levinson, 1987; Fillmore, 1982; Lakoff, 1974), which

is considered as the truly pragmatic basis of spatial deixis (Yule, 1996).

The aim of this paper is to investigate how some Korean deictic expressions, locative adverbs in particular, are used as address terms, demarcating the different degrees of politeness toward addressee(s) whose relationship with the speaker is not intimate or formal enough to opt for the typical options (e.g., first name, social titles, etc). In other words, distance measured by these locative adverbs in physical space, is being extended to mental dimensions, demarcating the degree of politeness between interlocutors. The locative adverbs of interest are: *yeki* ‘here’, *keki* ‘there’, and *ceki* ‘there’. Each of these three locative adverbs is used according to the spatial relation among the three entities: *speaker*, *hearer*, and the *referent*, as in the following examples.

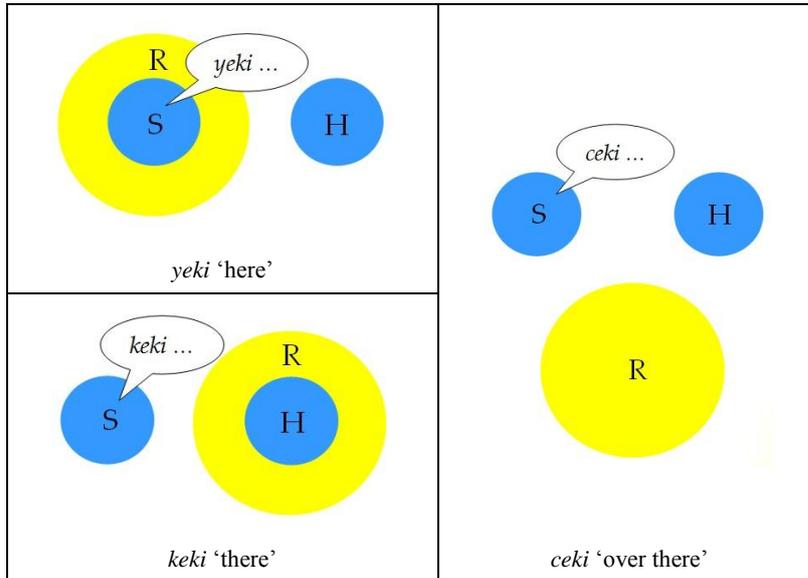

- (1) a. *ku uyca-lul yeki-lo kacjeta cwu-sey-yo*  
that chair-AC here-to bring give-hon-POL  
“(Please) bring that chair over here.”
- b. *i kkoch-pyeng-un keki-ey noh-usey-yo*  
this flower vase-TOP there-on put-hon-POL  
“Put this vase there.” (proximal to hearer)
- c. *i kulim-un ceki-ey kel-e cwu-sey-yo*  
this painting-TOP over there-on hang-give-hon-POL  
“(Please) hang this painting over there.” (distal from both speaker and hearer)

Korean locative adverbs in the example sentences (1)a-c are interpreted in the following ways:

- *yeki* ‘here’
- *keki* ‘there’ (when the referent is distal from speaker but proximal to hearer)
- *ceki* ‘over there’ (when the referent is distal from both speaker and hearer).

It is generally understood that the locative adverb *yeki* ‘here’ refers to a space proximal to the speaker, and this includes the overall space surrounding the speaker. In the similar way, *keki* ‘there’ refers to a surrounding space proximal to the hearer but distal to the speaker. Finally, *ceki* ‘over there’ refers to a space distal from both speaker and hearer. The relation among the speaker, hearer, and the referent shown in these adverbs can be illustrated as in the figure 1 below, where S stands for speaker, H stands for hearer, and R stands for referent.

Figure 1. *yeki / keki / ceki*

Korean speakers use diverse linguistic expressions in addressing others, either to attract their attention or to refer to them, in a spoken discourse. The way in which speakers select these address terms depends largely on the relationship between the interlocutors (e.g., the degree of formality and intimacy) and the social context in which they are engaged during the course of a conversation. In Korean, there are more than one personal pronoun referring to the speaker and the addressee since it reflects a relative social hierarchy between the speaker and the addressee, or the referent (Sohn, 1999). When no particular address term can be selected in addressing the other party, however, speakers often use the locative adverbs to index their rather obscure relationship. These locative adverbs, which function as attention grabbing devices, not only depict speaker-hearer-referent spatial relationship but also the degree of the speaker's politeness toward the hearer. Now, consider the following example sentences.

- (2) a. *yeki, maykcwu twu can chwuka-yo*  
 here, beer two glasses add-POL  
 “Here, please bring two glasses of beer.”
- b. *keki, mwe ha-nun ke-yey-yo*  
 there what do-RT thing-be-POL  
 “There, what are you doing?”

c. *ceki*,        *yeki sicheng-i*        *eti-ey iss-e-yo?*  
over there here City Hall-NM where-at be-POL  
“Excuse me but where is the City Hall around here?”

The locative adverbs *yeki* ‘here’ and *keki* ‘there’ in the examples (2)a and (2)b above illustrate their use as locative deixis as well as attention grabbing devices at the same time. In *ceki* ‘over there’ in (2)c, on the other hand, its function of attention grabbing is predominant over its place deictic function. Furthermore, *ceki* ‘over there’ when used with the polite speech style suffix *-yo*, which accentuate its attention grabbing function, is very frequently used as an address term, such as ‘Excuse me’ in English. In the following sections, the mechanisms through which the distance measured by these place deixis is being extended to mental or psychological dimensions, demarcating the degree of politeness between interlocutors when used as person deixis.

## 2. Method

In order to elaborate such a perplexing relationship among the speaker, hearer, and the referent, a close observation to the context where the speech event takes place is necessary. This study is based on the data collected from TV programs (e.g., commercials, dramas, etc.) in which interlocutors’ spatial and social relationships as well as contextual and situational settings are clearly shown. Excerpts containing the use of the three locative adverbs as person deixis were taken from 112 hours of video materials for careful analysis through a discourse analysis of the speakers and hearers as well as the context within which the interaction occurs from the excerpts.

## 3. Data and Discussion

Excerpts containing the locative adverbs *ceki-yo* ‘there’, *keki-yo* ‘there’, and *yeki-yo* ‘here’ used as person deixis were taken into consideration for this study, and the number of relevant clips is as follows. 9 tokens of *yeki-yo* and 1 token of *keki-yo* were found first. Then, 90 tokens of *ceki-yo* were added to the excerpts to make 100 all together, since the use of *ceki-yo* was endlessly found from the video materials. Because the number of frequency on each token is not the main interest of this paper, we limited the tokens of *ceki-yo*.

**Table 1. Tokens of *yeki* / *keki* / *ceki***

tokens	#	location
<i>ceki-yo</i>	90	various
<i>yeki-yo</i>	9	restaurant/hospital
<i>keki-yo</i>	1	street

*ceki-yo* was predominant among the three forms (see table 1), and all 90 tokens were used in various types of contexts and environments. The 9 tokens of *yeki-yo* were found mostly in restaurant situation where the customer calls the waiter/waitress for assistance. *keki-yo*, on the other hand, was very hard to find as shown in the table, and there was only one instance where this form was used in the street. *ceki* has a unique function of being used as an attention-grabbing device (Park, 2003; Yoon, 2003). However, as shown in examples (2)a and (2)b, the tokens found in this study indicate that not only *ceki*, but *yeki* and *keki* also convey the function of attention grabbing depending on the contexts and situations.

### 3.1. *ceki-yo*

Example (3) below is one of the most typical use of *ceki-yo*. In this excerpt, the speaker and the hearer do not know each other. The speaker (man) is asking for direction to a passerby (woman).

(3) M: *ceki-yo*  
 there-POL  
 “Excuse me!”

W: ...

M: *i kunch-e-y*      *kkochcip-i eti iss-e.yo?*  
 this neighborhood flower shop-NM where be-POL  
 “Where is a flower shop around here?”

In a situation as in excerpt (3), the first thing the speaker would do is to grab the passerby's attention toward himself. The speaker needs to achieve in catching the passerby's attention in an accurate but polite manner. That is, the hearer must recognize whom the speaker is addressing. The Korean second person pronouns such as *ne* 'you' and *tangsin* 'you' are very rude to be used to a stranger, and some other options are such as *haksayng* 'student', *akassi* 'miss', *acwumma* 'mam', and so on often replace the second person pronouns. In excerpt (3), the man could have called the lady by *haksayng* 'student' or *akassi* 'miss', but then he has to make sure to use the right title that goes with her identity, in which case the hearer's identity might be mistakenly assumed by the speaker. In this case, the speaker might have to give up on the politeness toward a stranger. Therefore, in order to avoid an awkward situation, speakers could use an inexplicit expression to grab the hearer's attention, and *ceki-yo*, *yeki-yo*, and *keki-yo* are often used for this purpose.

What is interesting in this excerpt is that the images captured for excerpt (3) show that the speaker (man) is only a 2-3 feet away from the passing-by hearer (woman), yet he chooses to use *ceki-yo* which denotes a distal referent. Therefore, the speaker's selection of the locative adverb *ceki* has nothing to do with the physical distance between the speaker and the hearer. Based on the overall situation, the speaker is the one asking for a favor to the hearer, and therefore an adequate level of politeness is expected from the hearer. The use of *yeki-yo* and *keki-yo* do not fit into the situation very well, not because of the physical distance conveyed within these expressions but rather due to the degree of politeness projected by *yeki* and *keki*. This subtle difference in the degree of politeness is well shown in the next excerpt.

In this excerpt, the speaker and the hearer do not know each other. The boy (hearer) is reading a book, and the girl (speaker) approaches him with an intention of asking him a question

(4) W: *ceki-yo*  
 there-POL  
 “Excuse me.”

M: *ney*  
 yes  
 “Yes?”

W: *ceki, hoksi sikan com iss-u.sey-yo?*  
 over there perhaps time a little be-hon-POL  
 “Well, do you have some time?”

The speaker and the hearer in this excerpt have no acquaintance with each other (students from different schools). The girl approaches the boy to ask if he would be available to go to a school party with her. Therefore, the girl tries to be as polite and pleasant as possible. Similar to the previous excerpt (3), the speaker is very close to the hearer and yet she grabs the hearer’s attention using *ceki-yo*. Therefore, in using one of the three locative adverbs *yeki*, *keki*, and *ceki* with attention grabbing purpose, the speaker does not consider the physical distance between herself and the hearer. When

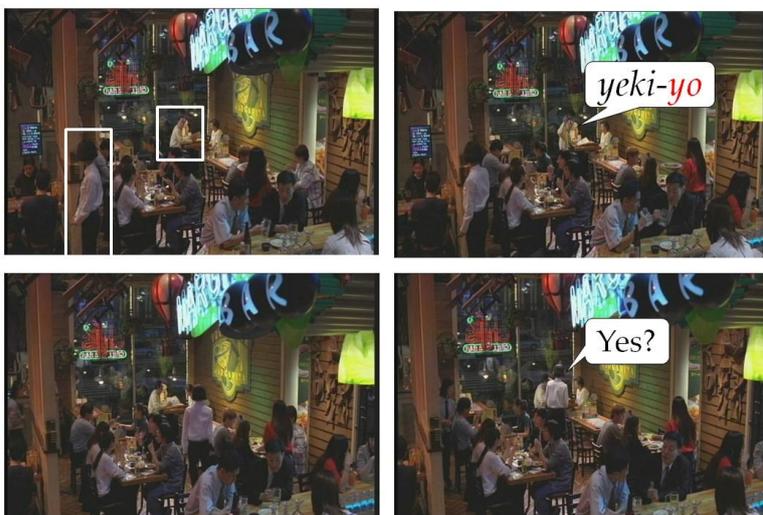

these place deixis are being used as person deixis, the speaker considers the degree of politeness in selecting one out of the three forms.

### 3.2. *yeki-yo*

Now, let us consider the use of *yeki-yo* in the following excerpt. The speaker and the hearer do not know each other, and the speaker is a customer at a restaurant, and the hearer is the waitress. The speaker (customer) calls the hearer (waitress) who is at another table quite distant from his own table in order to request something.

(5) M: *yeki-yo*  
here-POL  
“Excuse me!”

W: (approaching)  
*ney*  
yes  
“Yes?”

The customer, the speaker in this case, calls the waitress, the hearer, who is quite distant (4-5 yards) from his own table, using *yeki-yo*. Once again, the selection of the attention grabbing device is not based on the physical distance conveyed within the locative adverb *yeki* ‘here’. According to other excerpts containing the use of *yeki-yo* show that customers also use *yeki-yo* to call the waiter/waitress who is out of their sight.

By using *yeki-yo*, the speaker (customer) brings the hearer (waitress)’s attention

toward himself. On the other hand, speakers in excerpts (3) and (4) use *ceki-yo* with an intention of reflecting the hearers' attention back to themselves. Going back to the excerpt (5), the speaker (customer) calls the hearer (waitress), being conscious about his identity of being a customer and that of the hearer as a waitress, indirectly manifesting that he deserves the hearer's service and attention. Therefore, when a customer calls a waitress using *yeki-yo*, the speaker induces the hearer's immediate reaction.

Now, look at another instance where *yeki-yo* is being used. In this excerpt, the speaker and the hearer do not know each other; the speaker is a guest in a party, and the hearer is the waiter. The speaker (guest) who is leaning against the table with food calls the hearer (waiter) who is standing at the other side of the table ready to serve wine to the guests.

(6) W: (turning her head slightly toward the back)

*yeki-yo*

here-POL

"Excuse me!"

M: ...

W: (turning her head completely toward the back and looking at the waiter)

*wain han can cwu-sey-yo*

Wine one glass give-hon-POL

"Please, give me a glass of wine."

M: (approaches the woman, and pours the wine in her empty glass)

In this case, the hearer (waiter) is right behind the speaker (guest). The woman turns her head slightly toward the waiter and brings his attention toward herself by using *yeki-yo*. When the waiter looks at her, she now turns her head and shoulder completely toward the waiter and asks him for more wine. Once again, this excerpt shows that the speaker does not consider the physical distance in selecting the appropriate locative adverb, but instead the relationship between herself and the hearer. Some excerpts show that customers use *ceki-yo* instead of *yeki-yo*. In this case, the hearer is usually within a certain boundary to be shared with the speaker. In other words, their respective identities go beyond that of customer-waiter relationship. According to the excerpts, customers generally use *yeki-yo* to call the waiter/waitress but when they have eye contact, customers used *ceki-yo* instead. This implies that customers gain a consciousness on the social relationship between the two parties, and therefore, the customer-waiter relationship gets weakened. Then, the speaker chooses the more polite form *ceki-yo*.

### 3.3. *keki-yo*

The following excerpt shows the use of *keki-yo* which is the only instance of *keki* 'there' found from the video materials. Even in real life situations, any native speaker of Korean would notice that *keki-yo* is rarely used, but instead *keki* without the polite suffix *-yo* is more frequently used.

- (7) M: (looks around after placing the disposal bag on a non-designated area)

W: (realizes what the man is doing)  
*keki-yo*  
 there-POL  
 “Excuse me!”

In this excerpt, a man dressed all black hangs around a neighborhood late at night. He keeps gazing around as if he is trying to avoid being seen by anyone. When he sees no one around, he puts down a bulky parcel in black plastic bag he was carrying next to a garbage can that belongs to someone’s house and tries to leave the place. Right next to the spot where the garbage bag was left, there is a big sign that reads: *Do not place the garbage here*. In Korea, the volume-rate garbage disposal system is strictly kept, and therefore, its violation is directly related to penalty fee. This man in the excerpt is trying avoid the penalty by placing his garbage bag in front of a house in a strange neighborhood. Right in that moment, a woman, the owner of the house, calls the man who is about to flee using *keki-yo*.

The hearer (man), in this case, is getting caught in the middle of a wrong-doing by the speaker (woman) who witnesses his action. When the woman calls the man leaving the place in a hurry, she does it without showing her politeness at the highest degree. Perhaps, the woman uses *keki-yo* to convey her displeasure toward the man. Instead of omitting the polite suffix *-yo*, she uses a different locative adverb *keki* which is not as common as the other two forms. In other words, the woman tries to show the weakest form of politeness toward this man without hurting her own dignity by using the non-polite form to a stranger.

While the person deixis *keki-yo* is rarely used, *keki* without the polite suffix *-yo* is more frequently used both in real life as well as in video materials.

(8) Man: (wearing a white mask passes the gate and enters the campus)

SG: (notices something strange about this guy)

*ya, keki*

hey there

“Hey, you!”

In this excerpt, a security guard working at the main gate of a women’s college sees a strange guy wearing a white mask and carrying a metallic case passing the gate and entering the campus. Then, the guard calls the guy using *keki* without the polite suffix *-yo*. Notice that the guard uses *ya* ‘hey’ with *keki* to call the guy. *keki* itself conveys a low degree of politeness due to its directness pointing at the hearer, but in addition, the speaker drops off the polite suffix *-yo* making this attention grabbing device rude. As a consequence, some sort of rebuke or scolding is expected from the speaker, in this excerpt or any similar situation.

The main reason these locative adverbs are used in grabbing people’s attention is to avoid using inadequate titles in calling people’s attention. However, *keki* somewhat conveys a directness by pinpointing the hearer resulting in an adverse effect in terms of politeness. This is the reason why the polite form *keki-yo* is rarely used, since the connotation of *keki* does not match with the polite suffix *-yo*. As a consequence, it is hard to find excerpts where *keki-yo* is used, and *keki* is usually used instead without the polite suffix *-yo*.

## 4. Discussion

In the previous sections, the semantic extension of locative adverbs *yeki*, *keki*, and *ceki* into their person deixis counterparts *ceki-yo*, *keki-yo*, and *ceki-yo* were detected from different excerpts. Korean speakers use people's names, titles, kinship terms, and so on when addressing other parties. However, when it is hard to find an adequate term to call the hearer, as in vocative case, speakers rather use the locative adverbs *yeki*, *keki*, and *ceki* with deictic function. In this case, the referential meaning left in each of these expressions effectively avoids the directness of pinpointing at the hearer. And the degree of politeness conveyed by each of these three expressions can be accounted for by the physical distance projected through their original locative deictic functions. More detailed analyses of the three expressions are provided in the next subsections.

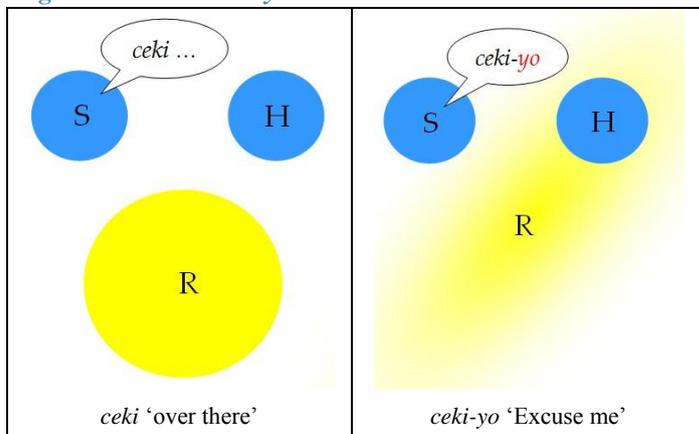

### 4.1. *ceki*

The locative adverb *ceki* 'over there' indicates a reference space that is away from both speaker and hearer. For instance, when a speaker asks a question to a hearer, "What's *ceki*?" without fixing his gaze to a particular point, the hearer would be looking around trying to find something that might catch his attention. However, when *ceki* is used as person deixis as in *ceki-yo*, it denotes the hearer, which is obvious for both parties participating in the talk-in-interaction. In other words, when *ceki* is used with the polite suffix *-yo*, there is no ambiguity at all, and both the speaker and hearer are well aware of this speech context. The polite suffix *-yo* not only increases the level of politeness conveyed within the element it is attached to, *ceki* in this case, but it also functions as an indicator that the expression being uttered contains an addressee's honorific device, and therefore, *ceki-yo* is being specifically addressed to the hearer in a polite manner.

The original meaning of the adverbial *ceki* remains unclear since it points to a vague and abstract space distant from both the speaker and the hearer. The speaker puts his gaze to the hearer and uses the polite suffix *-yo* which clarifies that the speaker is addressing the hearer, and yet, the semantic meaning of *ceki* 'over there' does not point at the speaker nor the hearer. Thus, the speaker achieves an indirectness in addressing the hearer by pointing an invisible finger at any direction other than that of the hearer or the speaker himself. By using *ceki-yo*, the speaker achieves triple indirectness effect in that the denotational meaning conveyed in *ceki* 'over there' puts the focus far away from the hearer; the reference scope depicted by *ceki* 'over there' is vast to figure out which

area the speaker is referring to; and finally, the adverb *ceki* ‘over there’ does not have any referent at all.

Figure 2. *ceki* vs. *ceki-yo*

When *ceki* is used as a locative adverb (see figure 2), the referent (the yellow circle) is a space distant from the speaker and the hearer. Also shown in the graph, *ceki-yo* ‘excuse me’ indicates a vague and abstract space distant from both the speaker and the hearer, but the speaker extends part of the referent (yellow circle) and brings it in until it covers the hearer. So now, the hearer is within this vague reference space. In this way, *ceki-yo* conveys the most indirect expression among the three, and therefore, the degree of politeness conveyed by this indirectness increases, making the expression *ceki-yo* one of the most polite devices in calling people’s attention.

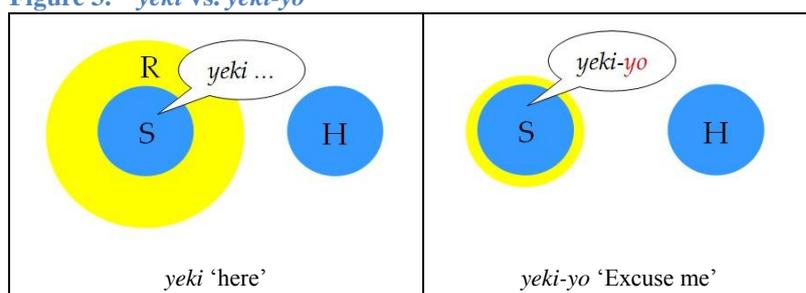

#### 4.2. *yeki*

The locative adverb *yeki* ‘here’ designates a somewhat vast area of reference which includes the speaker himself. For instance, when someone says, “I’m here,” the locative adverb *yeki* ‘here’ can refer to the point where the speaker is standing, the room, the house, the city, and so on. When the polite suffix *-yo* is attached to the spatial deictic *yeki*, it changes into a person deictic, in which case the reference area is relatively smaller compared to *yeki* used as spatial deixis. From excerpt (5), when the customer says *yeki-yo*, he is not implying the entire restaurant but his own table or even just himself, and in addition, the expression is not just referring to the location but rather it is being used to grab the waitress’ attention. This notion is represented in the graphics below.

When *yeki* is used as a locative adverb, its referent space is somewhere near the speaker and its scope extends to all areas surrounding the speaker. The yellow area

surrounding the blue circle with S (speaker) roughly represents the area that could be covered by the locative *yeki*. When *yeki-yo* is used as person deixis with the suffix *-yo*, its scope is diminished from that of the locative *yeki*. Its scope is mostly covered by the speaker himself, leaving some margins surrounding the speaker but not as spacious as in case of the locative *yeki*. Therefore, when speaker uses *yeki-yo* as a person deixis, this device function as attention grabbing, requesting the addressee to put his attention to the speaker himself and not his surroundings. Compared to that of *ceki-yo*, the scope expressed by *yeki-yo* is narrower and more specific since its referent space mostly overlaps with the speaker, and therefore, it directly pinpoints the speaker himself. *yeki-yo* is used to bring the addressee's attention toward the speaker, and therefore, the degree of politeness is slightly lower than that of *ceki-yo*. For this reason, *yeki-yo* is most commonly used in situations such as a restaurant where the speaker (e.g., customer) believes that he deserves to be the center of attention without violating one's cultural norms of politeness.

Figure 3. *yeki* vs. *yeki-yo*

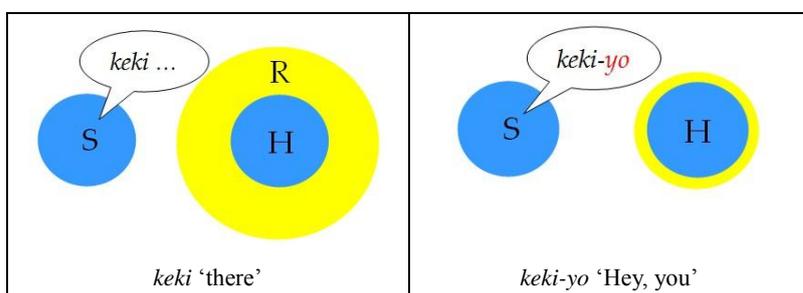

#### 4.3. *keki*

When used as a locative adverb, *keki* includes the hearer and the area surrounding him. For instance, when a speaker in the living room asks a question to a hearer in the kitchen, “Is my car key there?” *keki* ‘there’ refers to the entire kitchen where the hearer is found at the moment of the utterance. On the other hand, when *keki* is used as a person deixis, it refers to the hearer only. For instance, when a high school teacher calls a student passing by the hall using *keki*, it refers to that particular student only. This has an effect of pointing at someone with a finger since it is a very specific and direct way of grabbing the hearer's attention. As seen from the earlier sections, people use the locative adverbs in calling people's attention in order to avoid directness. Yet, due to its directness feature, *keki-yo* is rarely used as person deictic expression. In addition, combining such a direct expression *keki* with the suffix conveying speaker's politeness

toward the addressee *-yo* is such a contradiction.

When used as a locative adverb (see figure 4), *keki* depicts a space surrounding the hearer. This space not only includes the hearer but depending on contexts, it could include an entire city or even country. For instance, in a telephone conversation between someone who has left his own country and his friend back at home, when the friend calls and asks, “How’s everything there?” *there* could imply his friend’s new place, new city, or even his new country. Therefore, the space covered by the locative adverb *keki* ‘there’ could be wider than what’s shown in the graphs. When *keki* is used to refer to people, however, the reference space is smaller and includes mainly the hearer and a small area surrounding him. Targeting the hearer and placing the focus on the hearer alone is such a direct expression that it is like pointing at someone with a finger. Therefore, speakers use *keki-yo* when addressing the hearer with a negative or critical attitude. Since its degree of politeness is very low, *keki* is rarely used with the polite suffix *-yo*. Among the three locative adverbs, *keki-yo* is the least commonly used as person deictic, due to its feature that expresses such a low degree of politeness.

Figure 4. *keki* vs. *keki-yo*

#### 4.4. Summary

So far, we have discussed the use of the spatial deixis as person deixis, focusing on the way in which the denotational meanings conveyed within these spatial deixis are metaphorically extended to different degrees of politeness when used as interactive person deixis. Among the three forms, *yeki-yo*, *keki-yo*, and *ceki-yo*, the last one expresses the highest degree of politeness, whereas the second one expresses the lowest degree of politeness. The degree of politeness expressed through the first one is lower than *ceki-yo*, but higher than *keki-yo*.

*ceki-yo* achieves the highest degree of politeness by referring to a rather vague space that does not include neither of the interlocutors (i.e., speaker and hearer)

‘somewhere over there’. In this way, the speaker achieves the highest degree of politeness by using a rather vague and indirect expression. In case of *keki-yo*, the speaker gives this device an effect of directness in a similar way that a second person pronoun does. Using *keki-yo* to the addressee is almost like pointing at the addressee with the speaker’s finger. Different degrees of politeness conveyed within each form is summarized in the following table.

Table 2. Degrees of politeness: *yeki-yo* / *keki-yo* / *ceki-yo*

token	Referent scope	Degree of politeness
<i>ceki-yo</i>	away from Sp & H	High
<i>yeki-yo</i>	focused on Sp	Midium
<i>keki-yo</i>	focused on H	Low

Speakers of different languages (e.g., Korean, French, Spanish, etc.) avoid using the second person pronoun to the hearer since it is considered too direct and therefore rude. Thus, they either use 3<sup>rd</sup> person pronouns in addressing a hearer or a pronoun designated for the 2<sup>nd</sup> person plural. In similar ways, Korean speakers avoid using *keki-yo* to grab people’s attention for the similar reason they avoid using 2<sup>nd</sup> person pronouns to their addressees. *yeki-yo* places the speaker’s focus to himself, but since the speaker is pointing at himself, it does not convey any rudeness. Since *yeki-yo* try to bring the hearer’s attention toward the speaker, however, this is not as polite as *ceki-yo* which drags the speaker himself toward the hearer.

## 5. Conclusion

The present study has attempted to determine the mechanism in which the semantic extension occurs from locative adverbs (i.e., spatial deixis) to person deixis. The results of the data analysis clearly show that *yeki-yo* ‘here-POL’, equivalent to English “Excuse me,” is used in limited occasions, mostly at places such as restaurants and stores where customers are expected to have a service offered. By using the locative adverbial *yeki*, the speaker tries to drag the other party’s (e.g., waiter, clerk, etc.) attention toward him/herself. *ceki-yo* ‘there-POL’, on the other hand, is very frequently used in catching someone’s attention in a very polite manner, as in English “excuse me,” polite enough to be used to seniors. Among several uses of this locative adverbial, that of the attention grabber is most frequent when used with the polite speech style suffix

-yo. By using the adverbial *ceki* 'there', the speaker catches the addressee's attention by placing the focus on a vague referential point distant from both speaker and addressee.

*Keki* 'there' is sometimes used as a second person pronoun and thus the polite ending -yo is omitted. This form is not polite enough to be used to seniors and, depending on the context, could sound offensive or rude to the addressee. Furthermore, the findings show that among the three locative adverbials, *ceki* is the most polite one. The deictic information of adverbials *yeki* and *keki* diminishes the degree of politeness since they pinpoint either the speaker him/herself or the addressee, which could be impolite or even offensive in Korean culture as if in pointing a finger directly at someone. When using *ceki*, the speaker moves the focus away from the addressee and puts it at a vague referential point onto which the interlocutors' attention is expected to be placed. In conclusion, the distance measured by these locative deictics in physical space, is being extended to mental dimensions, demarcating speaker's degree of politeness toward the addressee.

# The English causal adposition *thanks to*: a grammaticalization perspective

Mikyung Ahn

Hankuk University of Foreign Studies,  
Seoul, Korea  
(E-mail : amk7136@hotmail.com)

## Abstract

This paper describes English complex preposition *thanks to* from a grammaticalization perspective. The semantic change of *thanks to* occurred along the path of [thought > favorable thought, favor > expression of gratitude > indebtedness > cause]. The semantic development from ‘thought’ to ‘favor’ involves narrowing. The semantic extensions from ‘gratitude’ to ‘indebtedness’ and further to ‘cause’ are also based on psychological contiguity of speakers i.e. metonymy. The source meaning of *thanks to* is ‘favor’, and it adheres to the causal preposition. Therefore, the *thanks to* phrases are restricted to the sentences that are semantically compatible with its original lexical meaning, ‘favor’ with the exception of ironical usages. Finally, this investigation analyzes *thanks to* in accordance with speaker involvement degree by using the 100 –million word British National Corpus, and described how the speaker involvement level affected the current usages and the distribution of *thanks to*.

**Keywords:** grammaticalization, semantic change, speaker involvement, semantic persistence.

## 1. Introduction

Causality is an important principle of human perception and a central category in human cognition. The conceptualization of causality is fundamental to the representation of human knowledge and to other cognitive processes. This is well illustrated by numerous cognitive explorations on causality (cf. ‘force dynamics’ (Talmy 1995), Talmy 2000, Sweetser 2000, Matt & Sanders 2000, Noordman & Blijzer 2000). In this regard, without much risk of overstatement it can be claimed that every language has specific linguistic means to express causal relations. When language users want to express causality, they can use causal connectives such as English *because*, *so* and *since*, Korean *kerese*, *keremero*, and *kerekitemune*, or adpositions such as English *because of*, *due to*, and *thanks to*, and Korean *ttaymwuney*, *palamey*, and *tekwuney*. Although all

these linguistic means express causality in one way or another, they seem not to be used interchangeably. Interestingly, however, English causal adposition *thanks to* indicates positive causality such as *khop khun* ‘thanks to’ in Thai, *con el favor de* ‘with the favor of’ in Spanish, and *tekwuney* in Korean. The sentences including *thanks to* comprise a causer and a causee, and a causer largely becomes a benefactor and a causee becomes a beneficiary.

The present investigation is intended to provide a detailed description of grammaticalization of the positive causality marker *thanks to*. English complex preposition *thanks to* is an example par excellence of grammaticalization in many aspects as it shows properties typical of grammaticalization processes. Although the scope of grammaticalization research is wide enough to look at grammaticalization of *thanks to* from many different perspectives, this paper focuses on characterizing the diachronic semantic changes from a grammaticalization point of view. This paper also addresses morphosyntactic changes. In addition, this study discusses different aspects of the current usage as well as the distributional characteristics of this complex preposition by using the 100-million word British national Corpus.<sup>1</sup>

## 2. Grammaticalization of *thanks to*

English complex preposition *thanks to* has developed from the independent relational noun, *thank* designating ‘favor’, accompanied by a preposition *to* (Oxford English Dictionary 1991, 2<sup>nd</sup> ed., OED hereafter). An investigation into the semantic change pattern exhibited by *thank to* reveals that it has undergone a series of semantic change. This is well illustrated in the following examples taken from OED.

(1) ‘Thought’

Gode *þonkes* and monie þewes for te teche fele schrewes. (1300, Prov. Hending i.)  
‘God’s thought and money needed for the technology was not easy to seek’

(2) ‘Favorable thought’, ‘favor’

If thou wilt doe good, know to whom thou doest it, and there shal be much *thanke* in thy good deedes (1609, Bible Eccclus. Xii. I)

---

<sup>1</sup> The British National Corpus is a large corpus of modern English (almost 100 million words) which was designed to be a representative sampling of the language as it was used on the British Isles towards the end of the twentieth century.

The examples above show that *thank*, which was originally used to denote ‘thought’ as in (1), has developed to refer to ‘favorable thought’ or ‘favor’ in (2). This semantic extension from ‘thought’ to ‘favorable thought’ or ‘favor’ involves metonymic transfer, essentially triggered by the contiguity relationship between two entities or events. The metonymization mechanism involved in the semantic change above shows that certain aspects of an event or a state are given a special focus. For instance, in this semantic extension from ‘thought’ to ‘favorable thought’, the particular aspect, i.e. ‘favorable thought’ is selected by metonymization, which is due to the human’s subjective mind. Humans generally tend to recall and focus upon only the best memories from the past, that is, favorable thoughts rather than negative or painful thinking. Furthermore, the human mind appears to have a built-in tendency to erase more painful aspects from its memory, which is also one of human strengths that are strongly tied to happiness. This human propensity to give focus on the favorable thought has been already noted by numerous psychologists. (Seligman 2007)

It is to be noted that this semantic development from ‘thought’ to ‘favorable thought’ also involves narrowing (e.g. *drink* used to mean ‘alcoholic drink’). Narrowing is the case where a word is used to convey a more specific sense than the encoded one, with a restriction of the linguistically-specified denotation (Lakoff 1987, Wilson 2002). As for *thank*, the sense of ‘thought’ changed into the more specified one of ‘favorable thought’.<sup>2</sup> However, given the fact that specific and concrete meanings entering into grammaticalization process become generalized and more abstract, narrowing is not the general outcome of the semantic change.

(3) ‘gratitude, an expression of gratitude for a favor received’

a. Is this the *thanke* which you returne to God? (1642, Rogers Naaman)

b. *Thanks*, Sir: the like to you (1605, Macb. II.)

(4) ‘Thanks being given to’

It *is* no *thanks to* a man to pay that willingly, which he must doe of necessitie.

(1633, Earl Manch)

(5) ‘Indebted to (in debt to)’

*Thanks to* Homer since I live and thrive, indebted to no prince or peer alive

(1737, Pope *Hor. Epist.* II).

---

<sup>2</sup> English prepositions, *between*, *on* also involve narrowing. As for *between*, the sense of ‘area next to two’ changed into the more specified one of ‘intervening space of two.’ The preposition *on* which denoted ‘any point in contact’ means more specifically ‘superior point in contact’ (Rhee 2004).

(6) 'In consequence of'

It is a sight but rarely spied, *thanks to* man's wrath and woman's pride

(1813, Scott Rokeby v.).

The semantic change from 'favorable thought, favor' in (2) to 'gratitude' in (3), (4) relates a shift of perspective. For example, the role of a speaker or a subject changes from *receiving* a favor to *giving* thanks to the favor giver. In other words, as *thank* denotes 'favor', the speaker is the one (i.e. beneficiary) who receives the favor, but when the sense of 'favor' changes into that of 'gratitude', the speaker becomes the one who expresses gratitude for the favor received.

Metonymy, i.e. psychological contiguity of speakers is also the driving force behind the semantic developments from 'gratitude in (3) (4)' to 'indebtedness' in (5) and further to 'cause' in (6). For instance, when a person is 'thankful' for the favor received, he or she may feel 'in debt' to the favor giver. Further, the favor is 'attributed' to the giver. In other words, the favor giver is considered as a causer.

As shown in the examples above, *thanks to* has undergone a series of semantic change. The semantic path can be diagrammatically represented as:

**Figure 1. The semantic path of *thanks to***

[thought > favorable thought (favor) > gratitude for a favor received > being in debt to (a favor giver) > being attributed to (a favor giver) > cause]

Diverse semantic change mechanisms operate over the semantic change such as metonymy and semantic generalization. Of particular importance among these is metonymy, a cognitive mechanism of extension of meanings enabled by the contiguity relationship between the original and new meanings. In the progression of the semantic change, the development of ironical meaning falls outside of the natural way of metonymic inference. The emergence of the ironical meaning may have to do with the strategic use of irony as a figure of speech as seen in (7).

(7) 'Ironical'

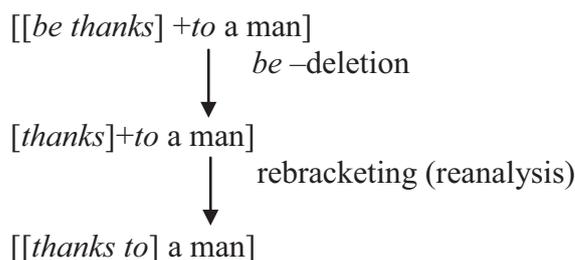

But...now, *thanks to* you, he can't wait to get rid of me (BNC).

As shown in (7), the *thanks to* phrase co-occurs with the subject, *he* which is not a beneficiary. This brings about irony because the source meaning of *thanks to* is 'favor',

and it adheres to the causal adposition, and therefore, the *thanks to* phrase is incompatible with the subject which is not a beneficiary. In other words, the *thanks to* phrases are restricted to the sentences that are semantically compatible with their original lexical meaning, ‘favor’. Nevertheless, the *thanks to* phrases sometimes co-occur with subjects [-beneficiary], which causes ironical meanings as in (7).<sup>3</sup>

In the paths of grammaticalization, morphosyntactic changes, in general, follow the semantic changes. As seen in the examples (4) and (5), the causal complex preposition *thanks to* in (5) has derived from a predicative *be thanks to* in (4). The structural boundary within a construction comprising *[[be thanks] + to a man]* has shifted into a causal construction consisting of *[[thanks to] + a man]*. The rebracketing process can be understood as a process of 'reanalysis'.

Reanalysis has been considered the major factor in morphosyntactic change, and reanalysis is defined as the reinterpreting of old structure (i.e. rebracketing) and is considered one having the effect of redefining constituent boundaries (Traugott and Dasher 2002). The structural evolution of *thanks to* is as follows:

**Figure 2. The structural evolution of *thanks to***

- (15) a. It is no *thanks to* a man to pay that willingly, which he must doe of necessitie.  
 (Manch 1633)
- b. *Thanks to* Homer since I live and thrive, indebted to no prince or peer alive.  
 (Pope 1737)

The complex preposition, *thanks to* in (15b) has also derived from a predicative, *be thanks to* designating ‘be due to’ as in (15a). This change also involves analogy. As the predicative *be thanks to* was used to denote ‘be due to’, the complex preposition, *thanks*

<sup>3</sup> In modern English, the preposition *for* is primarily used to designate advantageous relationship, but it was used to denote ‘disadvantage’ as attested in OED. (Rhee 2007) The emergence of the sense of ‘disadvantage’ is related to the strategic use of irony as a figure of speech, as shown in the following examples in OED

a. I will swinge his jacket for him. (1740, Xmas Entertainm. ii 12)

b. It would have been a mercy if I hadn’t broken some of his bones for him. (1855, Smedley. H. Coverdale Liii)

*to* occurred, following the complex preposition *due to* and omitting *be* as in (14) because of semantic similarities.

### 3. The speaker involvement analysis of *thanks to* and its distributional characteristic

Analyses of the speaker involvement potential inherent to causal complex prepositions in English can not do without systematic corpus analyses. However, there has been scant interest in the causal complex prepositions in English. Hence, we carried out corpus analyses of English causal complex prepositions, *thanks to* and *due to* with the help of the British National Corpus (BNC). For each of these prepositions, we assembled 50 occurrences from BNC.

First, we contrasted the prepositions in terms of the relations they occur in. These relational interpretations are the result of an interaction between the prepositions and the connected discourse segments. We have characterized this contribution in terms of a certain speaker involvement level that is added to the interpretation of its discourse environment. The results for these English causal prepositions are given in Table 1

Causal prepositions	Relation		
	non volitional	volitional	epistemic
Due to	43	12	5
Thanks to	22	9	19

**Table 1. Relational interpretations co occurring with *thanks to* and *due to***

Table 1 indicates that *thanks to* more frequently express epistemic relations than *due to*. With respect to volitional relations, there are not much significant differences between the two prepositions. The causal connective, *due to* has much to do with non volitional relations. Thus, the relational interpretations of the fragments containing a preposition also constitute the area of the speaker involvement scale covered by the prepositions. The relationship between speaker involvement and causal relations can be illustrated as in Figure 3:

*non volitional < volitional < epistemic < speech act*

**Figure 3. Speaker involvement and Causal coherence relations**

In this regard, we can hypothesize that *thanks to* is higher on the speaker involvement scale in terms of relational interpretations than *due to*. To determine the proper level of speaker involvement of the prepositions, we analyzed each occurrence in accordance with these four speaker involvement aspects presented: i) the degree of subjective involvement of a conscious participant, ii) the degree of iconicity of the causal relation, iii) the distance to speaker and speaking time, iv) the degree of explicitness of the participants involved in the causal relation. The combination of these distributional data determines the level of speaker involvement encoded by the prepositions. For each occurrence of a given preposition, we analyzed the related segments for a number of features related to these four aspects. Doing so, we can scale the prepositions *thanks to* and *due to* with respect to each other on the speaker involvement scale.

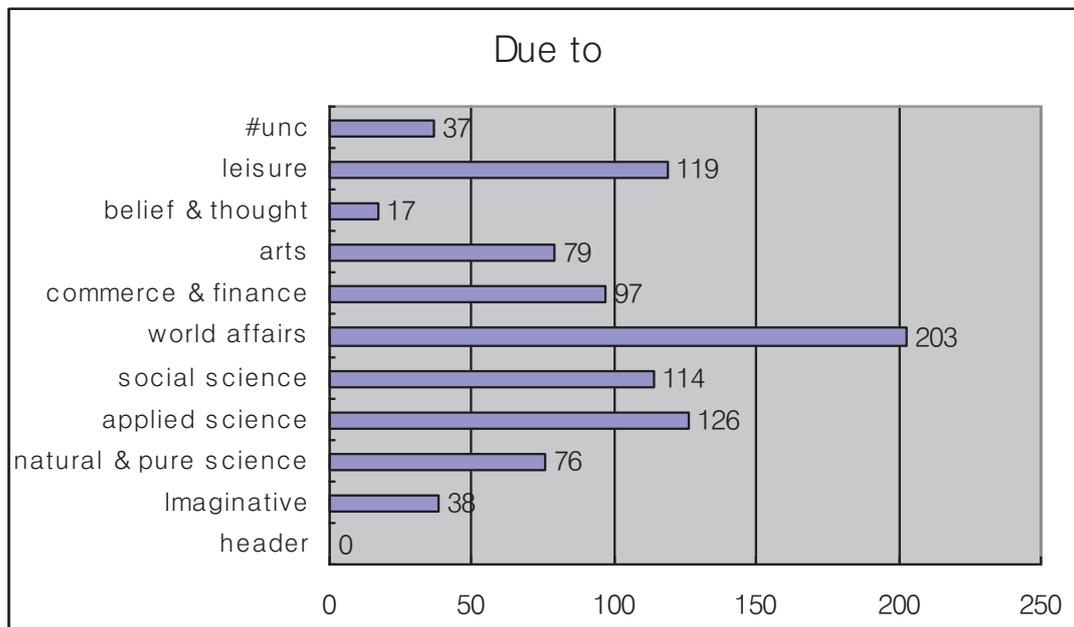

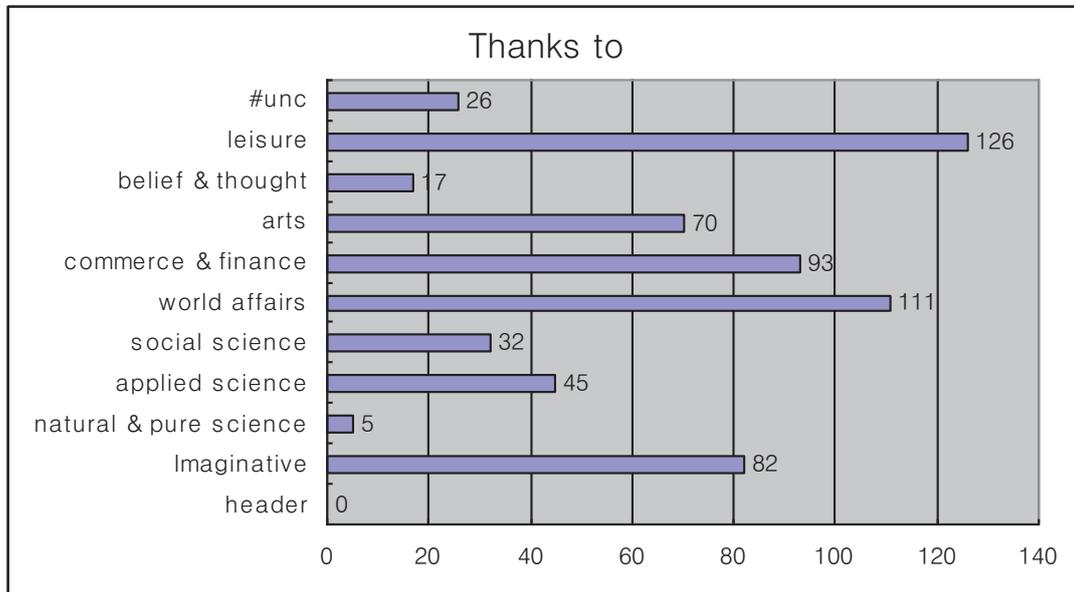

As seen above, there is a significant tendency for *due to* to express causal relations that are isomorphic with real-world causality, i.e. non volitional. The non volitional relations are at a certain distance from speaker and speaking time. These two characteristics place *due to* lower on the speaker involvement scale than *thanks to*. The latter preposition can also express relations that are non-iconic with respect to real world causality, i.e. epistemic relations. Hence, we hypothesize that *thanks to* is higher on the speaker involvement scale than *due to*.

Causal prepositions	Tense	
	present / future	past /present or past perfect
Due to	13	37
Thanks to	22	28

**Table 2. Tense co-occurring with *due to* and *thanks to***

Table 2 shows that speaker involvement increases when the distance between speaking time and causal situation time decreases. *Thanks to* more often comes with the present or future tense than *due to*. If we consider these data in Table 1, 2, we can conclude that *thanks to* is higher on the speaker involvement scale. than *due to*.

**Figure 4. The distribution of the complex prepositions *thanks to* and *due to* over the text domains of the BNC**

As seen in Figure 4, the causal preposition *due to* is frequent in ‘social science’, ‘world affairs’, ‘applied science’, and ‘natural and pure science’ whereas ‘imaginative’ is the category with lower frequency. For the written component of the BNC, a major distinction is made between *imaginative* and *informative* texts. The ‘imaginative’

category comprises texts ‘which are fictional or which are generally perceived to be literary or creative’ (Burnard 200:7). The domain ‘imaginative prose’ comprises samples from novels, drama scripts, short stories, and poetry collections. In this regard, ‘imaginative prose’ is less associated with non volitional (factual) relations than informative prose. Therefore, *due to* which expresses non volitional (factual) relations does not occur frequently in imaginative prose.

The complex preposition *thanks to*, however, have more instances in imaginative texts than *due to* while *thanks to* occurs less frequently in natural and pure science domains than *due to*. This is also in line with the fact that *thanks to* is higher on the speaker involvement scale than *due to*, that is, being more related to volitional and epistemic relations than the preposition *due to*.

#### **4. Meaning development and human cognition**

Semantic change is largely considered far less systematic and general than changes in phonology, morphology and syntax. Nevertheless, recent studies within the field of grammaticalization have provided overwhelming arguments that meaning change is motivated by cognitive principles independent of specific languages. Sweetser (1990: 18) states that in certain semantic domains there is a “deep cognitive predisposition” to turn to specific concrete domains to derive vocabulary for specific abstract domains. Traugott (1985) also has sought to identify over-arching and predictable cross- linguistic regularities in semantic change and have highlighted the extent to which meaning change as well as meaning itself is structured by cognition. The regularity of semantic change in grammaticalization is proposed in the Source Determination Hypothesis (Bybee et al 1994). Likewise, Heine et al. (1993) and Heine and Kuteva (2002) also reveal that there is a compelling reason to believe that there is a close relationship between the source and target meanings.

The semantic nuances of the source construction can also be retained in certain contexts long after grammaticalization has begun (Bybee et al. 1994). Persistence (Hopper 1991) states that when ‘a form undergoes grammaticalization from a lexical to a grammatical function, so long as it is grammatically viable, some traces of its original lexical meanings tend to adhere to it, and details of its lexical history may be reflected in constraints on its grammatical distribution’.

Therefore, the adposition is incompatible with the situation which is not beneficial to the subject or the possessor. That is, as illustrated in (16), the usages of *thanks to* are

restricted to the sentences that are semantically compatible with their original lexical meaning ‘favor’ with the exception of ironical usage. In the example (16), the nominal *my parents* following *thanks to* is a favor giver, and the favor is beneficial to the subject *I*.

(16) Thanks to my parents, I could have college education.

## 5. Conclusion

This paper addressed English causal adposition *thanks to* from a grammaticalization perspective. The grammatical form, *thanks to* is a good instance of a general evolution whereby a lexical item, (i.e. a noun), *thank* turns into the grammatical item, (i.e. a complex preposition) *thanks to*. This evolution is unidirectional, and involves a number of interrelated mechanisms such as desemanticization, decategorialization, and phonetic erosion.

Diverse change mechanisms such as metaphor, metonymy, and generalization operated in the course of semantic changes of *thanks to*. The source lexeme of *thank* is ‘thought’. The semantic change of *thanks to* occurred along the path of [thought > favorable thought, favor > expression of gratitude > cause]. The semantic development from ‘thought’ to ‘favorable thought’ or ‘favor’ regards narrowing which is not the general outcome of grammaticalization. Along the path of grammaticalization, *thank* did not denote the original meaning ‘thought’ but more specifically, ‘favorable thought.’ The semantic developments from ‘gratitude’ to ‘indebtedness’ and further to ‘cause’ are also based on psychological contiguity of speakers i.e. metonymy.

We analyzed the causal complex preposition *thanks to* in accordance with speaker involvement degree by using the 100 –million word British National Corpus, and described how the speaker involvement level affected the current usages and the distribution of *thanks to*. Further, we discussed that the usages of *thanks to* are also restricted by the semantic persistence.

# Head Morae in Tonal Reduction: Interaction of Stress, Mora, and Tone

Mingxing LI

Department of Linguistics and Modern Languages  
The Chinese University of Hong Kong  
mxlistar@hotmail.com

## Abstract

This paper discusses the interaction of stress, mora and tone in two cases of tonal reduction, a kind of tone sandhi where a lexical tone is reduced to approximately half its length in an unstressed syllable. In *Liuyang* dialect, head mora is avoided in unstressed syllable, which leads to the deletion of the first tonal feature and first mora. Contrastively, in *Jiangxiang* dialect, the head mora in unstressed syllable is delicately preserved to such a degree that it loses its link with lexical tone but maintains its ability to attract H tone.

**Keywords:** head mora , tonal reduction, stress, interaction

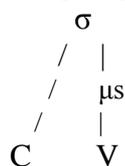

## 1. Head Mora vs. Non-head Mora

### 1.1. Head Mora vs. Non-head Mora

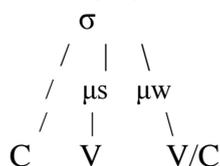

In phonological studies, mora has been argued to be the tone-bearing units (van der Hulst 1984, Hyman 1985, Hayes 1989, etc.), and a finer distinction between head-mora and non-head mora in Shaw (1992, 1993, 1995), Jiang (1996, 1999), etc. The idea goes as (1):

#### (1) Moraic Structure of Syllable

##### a. light syllable

##### b. heavy syllable

( $\mu s$  = nucleus mora= head mora,  $\mu w$  = non-nucleus mora= non-head mora)

---

\* This paper is revised from parts of Chapter 1 and Chapter 2 of my M.A. Thesis (M. Li 2004).

\* I would like to thank the CUHK Postgraduate Student Grants for Overseas Academic Activities 2008-09 for the financial support.

Such a dichotomy throws light on some types of reduplication (Shaw 1992, 1993, 1995, etc.), and certain tonal phenomena in Chinese dialects (Jiang 1996). Below, I will first visit the tonal distribution in Chinese dialects, and review the significance of such a dichotomy in the analysis of tonal inventory..

### 1.2. Prevalence of H Tones across Chinese Dialects

In terms of tonal typology, Jiao (2003) makes a statistics of the distribution of full tones across 40 Chinese dialects, as illustrated in (2):

(2) Distribution of Inventory Tones across 40 Chinese Dialects (Jiao 2003)

Tone Type	Shape	No.	Shape	No.	Shape	No.	Shape	No.
Level Tone	HH	29	MM	19	LL	1	No Level	6
Falling Tone	HL	5	HM	28	ML	20	No Falling	1
Rising Tone	LH	4	MH	27	LM	7	No Rising	3
Concave	HMH	5	MLM	14	Convex	2	MLML	(1)

(No. refers to the number of dialects where the tonal shape on the left is attested.)

From the above statistics, it can be seen that H tone is more frequent in tonal inventory than L and M tone. In a similar style, J. Lu (1999) samples 28 dialects and concludes that high-level tone (HH) show stability in tone sandhi, while low-level tone (LL) undergoes changes in most cases. This *asymmetry* is better accounted for in (1996, 1999). With data of 26 dialects from both South and North Chinese dialects, Jiang (1999) observes that (i) high level tones occurs more frequently than mid-level tones, and low level tones occurs the least, i.e.  $HH > MM > LL$ ; (ii) *half rising* tones (MH, LM) occur more frequently than *full rising* tones (LH); *half falling* tones (HM, ML) occur more frequently than *full falling* tones (HL).

### 1.3. An OT Account

To capture the above asymmetry, Jiang (1996a, b) proposes Tonal Sonority Hierarchy:

(3) *Tonal Sonority Hierarchy* (Jiang 1996, 1999)

$$|H| > |M| > |L|$$

This hypothesis is supported by the facts that (i) the general distribution of high-level tone and its stability in tone sandhi, (ii) the priority of high tone in acquisition to low tone, and (iii) the psychological prominence of high tone (Jiang 1999). Jiang (1996) also proposes the following constraint to capture the distribution of tonal shapes across Chinese dialects.

(4) Tonal Alignment Constraint (TAC) (Jiang 1996, 1999)

a.  $*\mu s/[L]$ : L tone cannot be linked to head mora;

b.  $*\mu s/[M]$ : M tone cannot be linked to head mora;

c.  $*\mu s/[H]$ : H tone cannot be linked to head mora.

Ordering in hierarchy:  $*\mu s/[L] \gg * \mu s/[M] \gg * \mu s/[H]$

Jiang (1999) further argues that within a syllable, non-head mora ( $\mu w$ ) cannot be linked to H tone, with a constraint triplet as follows:

(5)  $*\mu w/[H] \gg * \mu w/[M] \gg * \mu w/[L]$

From (4) to (5), Jiang (1999) captures the distributional asymmetry between H and L *within a syllable*. The idea here can be simplified into (6):

(6) Within a syllable, head mora ( $\mu s$ ) bans L and non-head mora ( $\mu w$ ) bans H.

In the following part, I will demonstrate the effect of the above argument in some particular types of tonal phenomenon in Chinese dialects.

## 2. Neutral Tone in Unstressed Syllables

### 2.1. Neutral Tone

Neutral tone is a special phonological phenomenon in Chinese tonology. It refers to the case where, in the disyllabic sequence like Mandarin *zhuozi* ‘table’, the second syllable is pronounced in a style light and short. In its lexical form, the syllable *zhuo* bears a tonal value 55 and the *zi* syllable bears a tonal value 214 (The numerical figure is a convention of tonal description proposed by Chao (1930), with 5 representing the highest tone and 1 the lowest.). In the disyllabic sequence, *zhuo* is read as 55, however,

zi is read as a low tone, rather than 214, comparatively short and light, like (7)

(7) Neutral Tone in Beijing Mandarin

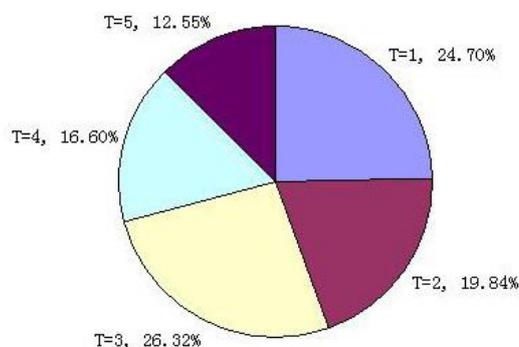

tian. <i>shang</i>	HH.L	sky-up	‘in the sky’
hong. <i>de</i>	LH.L	red-affix	‘red’
jiao. <i>zi</i>	LL.H	dumpling-affix	‘dumpling’
mu. <i>tou</i>	HL.L	wood-affix	‘wood’

Phonologically speaking, neutral tone is characterized by i) the loss of tonal contrast in unstressed syllables, which indicates the loss of tonal features; and ii) the shortening of syllable duration, which indicates the loss of mora. Then, how can we capture this type of phonological phenomenon?

2.2. \*NEUTRAL TONE/H (J. Wang 2002)

With a statistics of 55 Chinese dialects, Li (2004) got the following pattern of neutral tone values among Chinese dialects, as in (8).

(8) Statistics of 55 Chinese Dialects (Li 2004)

In general, this chart shows that in neutral-tone syllables lower tone is preferred than higher tones. With regard to Pulleyblank (1986), J. Wang (2002) proposes a constraint \*Neutral tone-H, which bans H tone in neutral-tone syllable.

(9) \*NEUTRAL TONE-H (J. Wang 2002)

Neutral-tone syllable cannot be linked to H.

This constraint is statistically supported by (8) above. Then, is there a unified account

for both the preference of H tones (as in 1.2) and the dislike of it (as in 2.2)?

### 2.3. *Decomposition of \*NEUTRAL TONE/H*

Li (2004) decomposes Wang's constraint into the following three constraints (10), (12), and (13) respectively.

(10) **NON-HEADSYLLABLE/MONO-MORA (\*σw/μμ)**

Non-head syllable (σw) in a syllabic foot bans two morae.

This constraint is a similar function to Weight-to-Stress Principle (Prince 1983, Prince & Smolensky 1993), where the matching of syllable weight and prominence is highly supported by cross-linguistic evidence.

(11) **Weight-to-Stress Principle (WSP)** (Prince 1983; Prince & Smolensky 1993)

Heavy syllables are stressed.

Neutral tone occurs in unstressed syllable, and the syllable is invariably light than its neighboring normal syllable. Thus, the constraint (10) accounts for why unstressed syllables are short.

(12) **NONHEADMORA-NONHIGH (\*μw/[H])**

Non-head mora bans tonal feature H.

This constraint is consistent with Jiang (1999)'s account of full tones, as well as J. Wang's (2000, 2002a, 2003) claim for neutral tone, and is supported by my statistics of 55 dialects as illustrated in (8).

(11) captures the mechanism above the mora, and (12) captures the tonal configuration below the mora. Then, what is left between the syllable and tone needs explanation. I attribute the relevant function to (13), namely, weak syllable bans non-head mora.

(13) **NON-HEADSYLLABLE/NON-HEADMORA (\*σw/μs)**

Non-head syllable bans head mora.

Thus, the constraint of \*NEUTRAL TONE-H in J. Wang (2002a, b) can be decomposed into the following constraint triplet:

$$(14) \quad *σw/μμ, *σw/μs, *μw/[H]$$

A simple tableau is given below for the selection of optimal candidates. It can be seen that this constraint triplet can predict the unmarked form regardless of the input form. In an OT sense, this is caused by the absence of faithful elements in constraint triplet (14).

(15) a.

Input: σw /\ μ μ	*σw /μμ	*σw /μs	*μw /[H]
a. σw   ☞ μw   L			
b. σw   μw   H			*!
c. σw   μs   H		*!	
d. σw /\ μ μ     t t	*!		

b.

Input: σw   μ	*σw /μμ	*σw /μs	*μw /[H]
a. σw   ☞ μw   L			
b. σw   μw   H			*!
c. σw   μs   H		*!	
d. σw /\ μ μ     t t	*!		

### 3. Tonal Reduction in Unstressed Syllables (I): Head-Cutting Model

Tonal reduction, in this paper, refers to a kind of tone sandhi, in which a normal lexical tone, usually two morae in nature, is reduced to approximately half its length in an unstressed syllable. Below we will examine two cases of tonal reduction in Chinese dialects.

### 3.1. Liuyang Dialect (J. Xia 1989)

Tonal reduction is attested in Liuyang Dialect (Hunan Province), where the last syllable in multi-syllabic sequences is usually read in a slight and short manner. (Xia 1989). (16) shows the configuration of this reduction.

(16) Tonal reduction in Liuyang (Xia 1989)

	Lexical Tone	Reduced Tone
Tone 1	33 (M ↓ )	M
Tone 2	55 (H)	H
Tone 3	24 (LH)	H
Tone 4	11 (L)	L
Tone 5	44 (M)	M

The reduction from normal length (two morae) to half the length is suggestive of the loss of a mora. If so, which mora is deleted, the head mora ( $\mu s$ ) or the nonhead mora ( $\mu w$ )? On the other hand, the reduced tonal form usually changes from a tonal contour to a single tonal feature. Thus, if mora is assumed to be the tone-bearing unit (van der Hulst 1984, Hyman 1985, Hayes 1989, among others), then tonal reduction will involve the deletion of both a mora and, presumably, the deletion of a tonal feature.

### 3.2. Head-cutting Model

Under a closer examination, it can be seen that the deleted mora in Liuyan is unanimously the *head-morae*. If we assume no phonological forms like re-linking has happened, then the single mora and its tone in the reduced form corresponds to the *non-head mora* in the lexical syllable. Figuratively, we can say the lexical-tone syllable has been *beheaded* to satisfy some conditions. This configuration is illustrated in (17)

(17) Head-cutting Reduction in Liuyang dialect

Recall the constraint  $*\sigma w/\mu s$  which bans head mora on a non-head syllable. It can be seen that this “head-cutting” effect can be attributed to the higher ranking of  $*\sigma w/\mu s$  and  $*\sigma w/\mu\mu$  over faithfulness constraint MAX-IO (T), which bans deletion of input tonal features. Note that there is no change of the tonal features in the non-head mora, another faithfulness IDENT-IO (T) is expected to sit at the top of the constraint ranking. However, in Liuyang dialect,  $*\mu w/[H]$  is violated, i.e. H, M, L are all attested for the value of “full-tone-related neutral tone”. Thus, I expect a sandwiching position of  $*\sigma w/\mu\mu$ ,  $*\sigma w/\mu s$  between IDENT-IO (T) and MAX-IO(T),  $*\mu w/[H]$ . The following constraint hierarchy is proposed for tonal reduction in Liuyang dialect:

(18) Liuyang Grammar for Tonal Reduction

IDENT-IO (T) >>  $*\sigma w/\mu\mu$ ,  $*\sigma w/\mu s$  >> MAX-IO (T),  $*\mu w/[H]$

Input: $\sigma w$ $\wedge$ $\mu s \mu w$     M M	ID- IO- T	$*\sigma w$ / $\mu\mu$	$*\sigma w$ / $\mu s$	Max- -IO -T	$*\mu w$ /[H]
a. $\sigma w$ ☞   $\mu w$   M				*	
b. $\sigma w$   $\mu s$   M			*!		
c. $\sigma w$ $\wedge$ $\mu s \mu w$     M M		*!			
d. $\sigma w$ $\wedge$ $\mu s \mu w$     L L	*!	*			
Input: $\sigma w$ $\wedge$ $\mu s \mu w$     L H	ID- IO- T	$*\sigma w$ / $\mu\mu$	$*\sigma w$ / $\mu s$	Max- -IO -T	$*\mu w$ /[H]
b. $\sigma w$ ☞   $\mu w$   H				*	*
c. $\sigma w$   $\mu s$   L			*!		
d. $\sigma w$ $\wedge$ $\mu \mu$     L L	*!	*			
e. $\sigma w$ $\wedge$ $\mu s \mu w$     H M	*!*	*			

## 4. Tonal Reduction in Unstressed Syllables (II): High-Preserving Model

### 4.1. Jiangxiang Dialect (Jiang & Xie 2001)

Jiang & Xie (2001) reports that in disyllabic SN sequences (1 stressed syllable + 1 unstressed syllable), tonal reduction occurs. The reduced tones are short, indicating the existence of one single mora. However, the tonal realization of these reduced forms is related to the lexical tone. Jiang & Xie (2001) summarizes the mechanism into (19):

(19) Tonal Reduction in Jiangxiang (Jiang & Xie 2001):

- i) Reduced tone = H, if H is present in lexical tone;
- ii) Reduced tone = L, if H is absent from lexical tone;
- iii) No change on 5 (H) and 2 (L)

### 4.2. High-Preserving Model

In the reduced form, it is clear that no tonal features occurs as non-existing in lexical (underlying/input) forms, thus (20) is highly considered.

(20) **DEPENDENCY-IO (or DEP-IO)**

Output segments must have input correspondents. (No epenthesis!)

To specify it to tonal faithfulness, I formulate it as **DEPENDENCY-IO (T)** or **DEP-IO(T)**

(21) **DEPENDENCY-IO (T) or DEP-IO(T)**

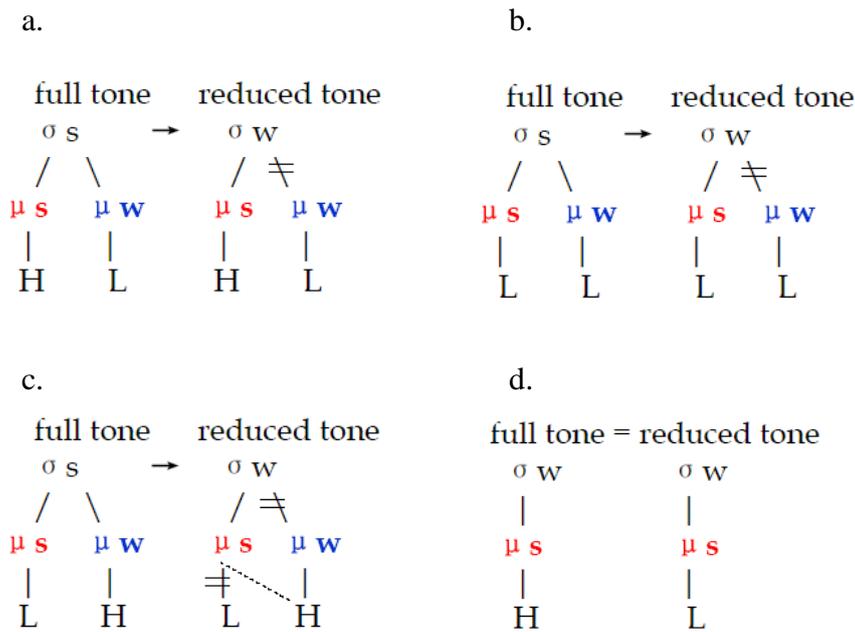

Output tonal features must have input correspondents. (No epenthesis!)

Now let's consider the preference for H Tone. As said in (19), the tonal reduction in Jiangxiang dialect shows preference for H tone, within the limits of faithfulness. Recalling Jiang's account of H preference in full tones, (4) ~ (5), it can be realized that H preference is the property of *head mora* ( $\mu_s$ ), rather than non-head mora ( $\mu_w$ ). Thus, we are justified to postulate that in the reduced form there is (only) head-mora.

Then, what about the unreduced tones (19 iii), which are said to undergo no reduction? Actually, if we assume head-mora is the only mora in the lexical tone (i.e. 5 (H) and 2 (L)), then this will not conflict our analysis above. Namely, the only head mora is consistent with the other reduced form in that its only mora is a 'head-one'.

On the whole, the tonal reduction in Jiangxiang dialect can be illustrated as (22), where the head mora is preserved in the tonal reduction but the head-mora is not bounded to its lexical linking with tone. Rather, when necessary, it de-link with its original tone and goes for a preferred tone, as in (22a), (22b), (22c).

(22) Tonal Reduction in Jiangxiang

From the above analysis, I propose (23) to be the grammar for tonal reduction in Jiangxiang dialect, with tableaux for illustration:

(23) Jiangxiang Grammar for Tonal Reduction

IDENT-IO (T), \* $\sigma$ w/ $\mu$  $\mu$ , MAX-IO- $\mu$ s >> \* $\mu$ s/[L] >> \* $\sigma$ w/ $\mu$ s

5. Conclusions

In this paper, I discussed the interaction of stress, mora and tone in two cases of tonal reduction. In *Liuyang* dialect, head mora is avoided in unstressed syllable, which leads to the deletion of the first tonal feature and first mora. Contrastively, in *Jiangxiang* dialect, the head mora in unstressed syllable is delicately preserved to such a degree that it loses its link with lexical tone but maintains its ability to attract H tone.

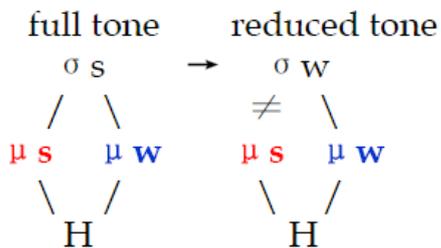

Input: $\sigma$ $\begin{array}{c} \wedge \\ \mu s \quad \mu w \\   \quad   \\ H \quad L \end{array}$	MAX-IO-T	* $\sigma w/\mu\mu$	MAX-IO- $\mu s$	* $\mu s/[L]$	* $\sigma w/\mu s$
a. $\sigma$ $\begin{array}{c}   \\ \mu s \\   \\ H \end{array}$					
b. $\sigma$ $\begin{array}{c}   \\ \mu w \\   \\ L \end{array}$			*!	*	
c. $\sigma$ $\begin{array}{c} \wedge \\ \mu \mu \\   \quad   \\ H \quad L \end{array}$		*!			

Input: $\sigma$ $\begin{array}{c} \wedge \\ \mu s \quad \mu w \\   \quad   \\ L \quad L \end{array}$	MAX-IO-T	* $\sigma w/\mu\mu$	MAX-IO- $\mu s$	* $\mu s/[L]$	* $\sigma w/\mu s$
a. $\sigma$ $\begin{array}{c}   \\ \mu s \\   \\ L \end{array}$				*	
b. $\sigma$ $\begin{array}{c}   \\ \mu w \\   \\ L \end{array}$			*!		
c. $\sigma$ $\begin{array}{c} \wedge \\ \mu \mu \\   \quad   \\ L \quad L \end{array}$		*!			

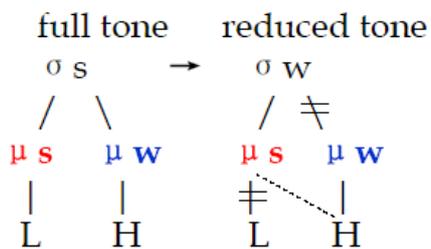

## 6. Residual Issue

In the above analysis about Jiangxiang and Liuyang, one aspect may deserve further consideration, that is the different faithfulness between the mora and its lexically linked tone. In Liuyang dialect (24 a), the above analysis assumes that there is no relinking effect like the Jiangxiang case (24 b).

(24) a

b.

Due to the scale of the current paper, I will not go into discussion on this problem. However, the faithfulness between mora and tone should be an interesting topic to explore.

# Story Co-construction and Establishment of Mutual Consent: Convergences and Divergences between English, Japanese and Korean

Myung-Hee Kim / Yoko Fujii

Hanyang University / Japan Women's University

[mkim@hanyang.ac.kr](mailto:mkim@hanyang.ac.kr) / [yokofujii@nifty.com](mailto:yokofujii@nifty.com)

## Abstract

This paper aims to show similarities and differences in the establishment of mutual consent in problem-solving tasks engaged in by English, Japanese, and Korean speakers. We examined 'Mr. O Corpus', where two people worked together to construct a coherent story by arranging 15 picture cards. We classified all the verbal behaviors into three categories: a) the storyline, b) descriptions about the cards, and c) ordering of the cards. The results show that 82.6% of their total turns by English pairs but only 73.7% by Japanese and 77.2% by Korean pairs belong to the three types of talk. Further analyses show that English speakers tend to be direct and task-oriented whereas Japanese and Korean speakers tend to be interactionally-oriented.

**Keywords:** task-based conversation, interaction, cultural perspective, English, Japanese, Korean.

## 1. Introduction

The present paper aims to show similarities and differences in how English, Japanese, and Korean speakers establish mutual consent in a problem-solving task, and to suggest that the results can be better accounted for by considering the deep-rooted cultural practices of each language users, than by existing frameworks based on western cultures and philosophical assumptions.

The data 'Mr. O Corpus' is part of a cross-linguistic video corpus, consisting of three types of interactions--conversations, narratives, and problem-solving tasks--in American English, Japanese, Korean, and Chinese.<sup>1</sup> The data on which this study is based is the problem-solving tasks, where two people were asked to work together to construct a coherent story by arranging one of the two sets of 15 picture cards. In Story

---

<sup>1</sup> The corpus was collected for the project entitled "Empirical and Theoretical Studies on Culture, Interaction, and Language in Asia" under a Grant-in-Aid for Scientific Research from the Japanese Academy for the Promotion of Science (No. 15320054), directed by Sachiko Ide at Japan Women's University).

I, Mr. O tries to get across a cliff by using a stick, and succeeds in the second attempt but finds himself stuck in an island. In Story II, Mr. O tries to get across a cliff with a help of a bigger guy but the bigger guy jumps off him to the other side of the cliff. Mr. O tries to do the same thing with a smaller guy but ends up crushing him instead. Some of the pictures are shown in Figure 1 below:

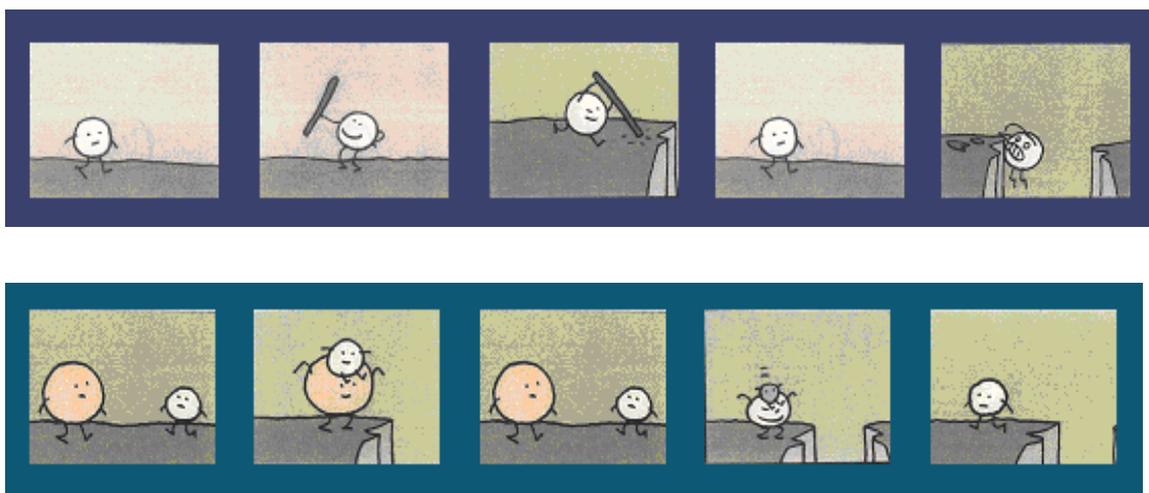

Figure 1. Story I and II

The subjects were all female speakers, with half of them being university students and the other half teachers. Half of the pairs were student-teacher (S-T) pairs and the other half were student-student (S-S) pairs. They were told to make a coherent story by arranging the fifteen pictures but told that there is no “correct” story. All the processes and interactions were videotaped. In total, we examined the data from 22 pairs of American and Japanese speakers and 20 pairs of Korean speakers.

## 2. What Do They Verbalize?

### 2.1. General characteristics of the verbal behavior during the task

First of all, we compared some general characteristics of the three language corpora. We examined the average time to complete the task, the number of turns, and the time spent on each turn. Table 1 summarizes the results.

Table 1. General Characteristics of the Data

	English	Japanese	Korean
No. of Subjects	22	22	20
Average Time (min.)	7.07 (max. 14.28, min. 3.39)	7.55 (max. 13.58, min. 3.53)	7.21 (max. 15.54, min. 3.19)
Average No. of Turns	67	93	86
Turn Duration (sec.)	6.5	5.4	5.0

The result shows that the Japanese pairs spent more time on the task than the American pairs, and that the Korean pairs were in the middle. Compared to the task time spent, however, the American pairs exchanged longer turns than the Japanese or Korean pairs.

## 2.2. *The three types of talk- the amounts of verbalization*

Second, we examined all the verbal behaviors in the data, and classified them into the following three categories: that is, 1) the storyline, 2) the descriptions and comments about the cards, and 3) the ordering of the cards. Examples for each category in the English data are shown in (1)-(3):

- (1) He is walking along, he sees the cliff, and he can't get across...
- (2) These two characters look very similar.
- (3) This is obviously first, right?

They illustrate the storyline talk, description of the card, and ordering of the cards respectively. Each turn might have more than one type of talk, as in (4):

- (4) Then again, this one looks happy also, so I don't know where this one would actually fit in.

In (4), the first part is classified as a description, whereas the second part is classified as an ordering talk.

Table 2 shows the extent to which each group of language speakers verbalize the three kinds of talk in all of the turns:

Table 2. The Percentage of Each Type of Talk in the Total Turns  
by the American, Japanese, and Korean Pairs

3 types of talk	American	Japanese	Korean
Storyline	45.8 %	37.2 %	39.4 %
Description	21.7 %	20.8 %	23.7 %
Ordering	15.1 %	15.7 %	14.1 %
Total	82.6 %	73.7 %	77.2 %

The result shows that 82.6% of the turns by the American pairs, but only 73.7% by the Japanese pairs belong to the three types of talk. Again, the Korean pairs fall in the middle, using 77.2% of their total turns for the three types of talk. It seems that the American pairs explicitly verbalize the three types of talk constantly. On the other hand, the Japanese and Korean pairs have a great tendency not to verbalize their thoughts, depending more on the shared visual information.

Next, we would like to examine the data more in detail to see how the three language speakers depend on verbalization and how they establish mutual consent.

### 3. Establishing mutual consent

#### 3.1. The American way of interaction

Examples (5)-(8) below, which are from a single pair (E14), illustrate a typical American way of constructing a story. First of all, consider example (5):

(5) (E14: 047-075)

01 A: he sees the cliff first[, and then he meets the little per[son.

02 B: [oh! [no, it goes like this, {disagreeing}

03 A: oh, oh, I bet what happens is this guy comes and he says 'I can't get over the cliff', so he bounces, but this guy (actually) bounces over instead[, but he's still stuck on this [hah... {start agreeing} cliff[, so he finds the little guy and tries to do the same thing,[ and it doesn't work[.

[yeah

[Uh-huh

Example (5) shows that in line 1, A proposes the beginning part of the story, but B tries to interrupt to start presenting her way of thinking. Ignoring what B tries to say, A starts explaining a story of her own in line 3. It seems that the interaction of this American

pair is rather direct and straightforward.

(6)

04 B: [Oh... okay, let's do it that way].

05 A: [let's do it this way, okay. [So...

06 B: [I would have done it differently, but I guess because we're working together...

{indirectly expressing disagreement}

07 B: Wait, no, wait, wait...

08 A: So first it's ...=

09 B: =Wait, first he's like...

{start insisting her own idea}

10 A: There's the cliff.

11 B: I think ... okay...

For what A presents, B sounds like she agrees in line 4. However, she shows her opposition in line 6 saying “I would have done it differently, but I guess because we’re working together...” but finally starts trying to insist her way of thinking “wait, no, wait, wait...” and “wait, first he’s like...” in lines 7 and 9. Even though B tries to stop A, A claims her idea by saying “There’s the cliff,” for which B reluctantly agrees saying, “I think... okay....”

(7)

12 A: Then he walks away from the [cliff.

13 B: [No, no... wait, hold on... {expressing disagreement}

14 B: No wait, you're totally messing this up. [{laugh} {disagreeing with blaming}

15 A: [Hah, (I'm( sorry. {apologizing}

16 B: Wait, hold on.

17 A: Okay, so[...oh, I think he meets the yellow person before the grey person. {start again}

18 B: [Okay.

19 B: (Wait...) yeah.

A does not stop presenting her idea, then B again says, “No, no... wait, hold on...” and “No wait, you’re totally messing this up” in lines 13 and 14 while laughing as if it mitigates its negative impact. Finally, A apologizes “I’m sorry,” but B still keeps saying “wait, hold on” on line 16. Then, A starts her rough storyline again in line 17.

(8)

21 B: Okay, wait so he's like... he's like still on this side. {start expressing her idea}

22 A: Uh-huh[. {agreeing}

23 B: [Okay, I think this one's the first one, though, like [totally,  
{expressing an idea}

24 A: [I think that's good.  
{agreeing}

From lines 21 to 23, the leadership changes from A to B, for which A agrees by saying "I think that's good." After this excerpt, they construct a story one by one. While they are doing it, if either one has a different idea, she shows her disagreement by saying, "maybe ... yeah" but when she finds the other one is right, she shows it by saying, "no, I think you're right." Thus, their interaction is rather straightforward.

This short excerpt demonstrates that the American participants tend to express their own ideas in a direct manner. When they do not agree with each other, they rather directly express disagreement and try to convince the partner with explicit verbalization. The American interaction can be characterized as information-oriented, confrontational, and task-oriented, etc.

### 3.2. *The Japanese way of interaction*

Now, we will look at a typical Japanese style of interaction in excerpts (9)-(15) below:

(9) (J16: 043-071)

01 A: *eto, kore, kore-wa nani*= {asking}  
'well, this, what is this?'

02 B: = *sore-wa, naNnaN-deshou-ka* {wondering the same thing}  
'it is, I wonder what it is'

03 B: *a, chiisai-no, de mazu hajimeni yat-te, chousen-shitara tsubure-chat-ta-node, ookii-no*[*de yat-tara, jibun-ga* {proposing an idea}  
'ah, at first, (s/he) tried with the small one and challenged, but since (it) was smashed, (s/he) tried with the big one, then s/he himself/herself'

04 A: [*ah, na?*  
'ah, na?'

In this excerpt, A and B finally have started constructing a concrete story. First of all, A posits a question holding a card and says, “*kore-wa nani* (what is this?)” and B is wondering what it is as well. Then, from lines 3 to 6, B looks like she has a hunch and starts verbalizing a summary of a storyline, looking at the whole cards.

(10)

05 A: *tobe-ta, mitaina, e?* = {proposing a different idea}

‘(s/he) could like jump, eh?’

06 B: = *?e, pechanko-ni na, na, n?, (1.0) a, jibun-wa tobezu-ni*

‘eh?, (it) becomes smashed, although s/he himself/herself could not jump’ {disagreeing}

[pause: 3.0 seconds]

07 B: [*u..n?*

{wondering}

‘nnn?’

08 A: [*a, ja, kore, kore-ga sagashi-te-ta-n-da, (1.0) sagashi-ni it-te, a, kore-janai, saisho, shitara, un?*

{proposing another idea} {wondering}

‘ah, then, this, this was looking for, went to look for, ah, is this the first one, then, nn?’

[pause: 2.0 seconds]

In line 5, however, A gives a different idea about the picture, but cannot get any immediate agreement or response from B, so she expresses her uncertainty in a very small voice as “e?” On the other hand, in line 6, B is surprised with A’s unexpected story so she also expresses her uncertainty with the expression “e?” the instant she hears A’s idea. Then, B continues her idea in line 6, which is an opposite idea to A’s, that is, “(the character) could not jump.” However, since B cannot get any agreement from A either, she pauses a little and shows uncertainty saying “nnn?” on line 7. Overlapping with B, in line 8, A tries to turn their focus on a different card and proposes it as the first card of the story by saying, “is this the first one?” But A says, “nn?” again after not getting any agreement from B.

(11)

09 B: *a, demo, watarou-to-shite at-te, akirame-[te, at-te* {disagreeing, proposing an idea}

‘ah, but, (s/he) tries to jump and meets, gives up,

10 A:

[*un un, at-te*

{agreeing}

‘yeah yeah, (s/he) meets’

11 B: (0.4) *de*

‘then’

12 A: (0.8) *sou sou sou*, [*sou-dayo-ne* {agreeing}  
'right, right, right, that's it, isn't it?'

Without showing any response to A's proposal, but just by saying, "*demo* (but)," B starts her story again. This "*demo* (but)" actually implies that B does not agree with A's proposal of the first card. However, without saying direct opposite expressions such as "no," or "I don't think so," B finds some other cards that will come before A's proposed card. Thus, by proposing her own story, B indirectly shows that the card which A suggested is not the first one. A, then, rides on what B proposes here and from lines 10 to 12, they agree on the storyline by exchanging the verbal signs of agreement, "*un*, *un* (yes, yes)," and "*sou*, *sou*, *sou* (right, right, right)," and the repetition of "meet."

(12)  
13 B: [*a, a, demo kore\_* {wondering}  
'ah, ah, but this'  
14 A: *a*, [*ja, mazu sore-da* {proposing an idea}  
'ah, then, first, that one'  
15 B: [*a, ja kou-[desu-ka* {asking with agreement}  
'ah, then, like this?'  
16 A: [*un un* {agreeing}  
'yeah yeah'  
[pause: 2.0 seconds]

From lines 13 to 16, B picks up a card and wonders "*kore* (this)?" but they both have the same idea at the same time and agree where to put the card by overlapping. While they are saying "then, that one, first," "like this?" "yeah, yeah.", they put the card in order. However, again it is hard for an observer to follow why they agree on the order of the cards.

(13)  
17 B: *komat-te*, [*modot-te* {verbalizing a story}  
'being troubled, returns'  
18 A: [*modot-te \_* {verbalizing a story}  
'returns...'  
19 B: *at-te\_* {verbalizing a story}  
'meets...'

- 20 A: (0.2) *a, to kore at-te\_* { verbalizing a story }  
 ‘ah, .. this, meets...’  
 [pause: 2.0 seconds]
- 21 B: *de\_, sasou?* { asking }  
 ‘then, invites?’
- 22 A: *sasot, -te\_* { verbalizing a story with agreement }  
 ‘invites, ...’  
 [pause: 2.0 seconds]

From lines 17 to 22, they both verbalize the storyline “(the character) is troubled, returns, meets, and invites.” They are saying the storyline together as if they were sharing a mind, which is revealed in the overlapping “returns” in lines 17 and 18, or repetitions of action verbs of “meet” and “invite.”

- (14)
- 23 B: *de [kou* { proposing }  
 ‘then, like this’
- 24 A: [*a, ha, mat-te, kore-kara hajimaru-n-janai, moshikashi[te* { proposing the first card }  
 ‘ah, ha, wait, start from this one? Maybe’
- 25 B: [*a sou-desu-ne, arui-[te-ta*  
 ‘ah, right, walking’ { agreeing }

Then in line 24, A suddenly finds a card saying, “does the story maybe start from this one?” and B, without any hesitation, agrees on A’s proposal in line 25. Again, it is hard for onlookers to know why A judges the card as the first one and why B agrees with her without any hesitation.

- (15)
- 26 A: [*te-tara, watarae-nai, [modot-te, mitukeru* { verbalizing a story }  
 ‘then, can’t go across, returns, finds’
- 27 B: [*modot-te, mituke-te, sasot-[te\_* { verbalizing a story }  
 ‘returns, finds, asks’
- 28 A: [*un, nok-[ke-tara* { verbalizing a story }  
 ‘yes, put him/her on, then...’
- 29 B: [*nok-ke-te, tsubureru* { verbalizing a story }  
 ‘put him/her on, is smashed’

Then, both start verbalizing the story from the beginning from lines 25 to 29 pointing to each card one by one. The frequent occurrence of repetition and overlapping reveals as if A and B are sharing a mind.

The analyses of the Japanese interaction show that they construct a story by agreeing with each other at every step. They try to avoid conflict and seek understanding from the partner step-by-step. Their indirect way of interactions are characterized by their profuse use of repetition, overlapping, co-construction, modality expressions such as *mitai* ‘it seems’ or ‘it looks like’ forms, question or tag-question forms, and final particle *ne* which induces the partner’s agreement. Furthermore, the Japanese verbal interaction deeply depends on the context. They hardly mention, or name the characters in the cards; instead, they often use deictic expressions together with pointing or holding the cards. Thus, compared to the American interactions, the Japanese interactions are interaction-oriented, non-confrontational, and context-based.

### 3.3. The Korean Interaction

Finally, the following excerpts (16)-(21) illustrate how Korean pairs establish their agreement in their task. In this excerpt, the Korean pair explores different parts of the story.

(16) K2: 031-071

01 B: *kurem ceke-n mwue-ya? ah, ceke-n,*

‘Then, what’s that? Ah, that,’

02 A: *un. cal moru-kess-e. kukka, yay-ka iltan honca ka-nun key ceyil cheum i-l ke khat-ay, kuci?*

‘I don’t know. Anyway, looks like the one where this one goes alone is the beginning, right?’

03 B: (cough)

04 A: *ah, anin, a, kuntey ikey mwue-lkka?*

‘Maybe not? By the way, what would be this one?’

In line 2, A proposes the first picture of the story, but when she doesn’t get agreement from B, she backs down and moves to something else in line 4. Notice that speaker A expresses her opinion by using a tag question in line 2.

Korean speakers also use negative questions to seek agreement from their partner, as in line 5 and 7 below:

(17)

05 B: *kukka ike, ike taum aniya? Ttak yay-ka mwue ha-lye, irehkey, irehkey mwue ha-nuntey*

‘Isn’t this after this? When this one is just trying to do something like this, like this,’

06 A: *um*

07 B: *@cay-n ccipwureci-n ke ani-ya, nemwu ccokkumayse, @*

‘Isn’t that one crushed? Because it is too small?’

08 A: *ah: kukka, ike kil-ul ka-taka,*

‘ah:, while this one goes on the road,’

09 B: *uh. ‘Yes.’*

10 A: *kuntey na-nun mwue-nka[ka, ] yayney yayney twul-i manna-n sanghwang-i iss-ko,*

‘By the way, I think something like there’s a situation where this one and this one met, and’

In Line 8, it is hard to say whether A agrees with B’s opinion. She just goes back to the beginning of the story.

(18)

11 B: *[kil-ul, ung]*

‘on the street, yes’

12 B: *ung*

13 A: *yayney twul-i manna-n sanghwang-i iss-cianha.*

‘there’s a situation where these two met, as you know.’

14 B: *ung*

15 A: *kuraykaciko i, kenne-l ttay yay-ka, mence yay-lul wi-ey thaywu-cianha?*

‘And when he crosses over, this one rides this one on top, as you know.’

16 B: *ung*

Speaker A explains the two situations where Mr. O meets two guys by using *cianha* in line 13 and 15, which is an agreement seeker like ‘you know’ in English.

(19)

17 A: *kurehkey ha-nuntey, wey yay-ka irehkey toy-ss-nunci moru-kess-e.*

‘While they do it, I don’t know why this one became like this.’

18 A: *nemeci-ese [yay] kkali-n ke-ci? cak-un ay. @Aninka?@*

‘Isn’t it he fell down and he got sat on? The small one. Is it not?’

19 B: *[ah!]*

20 B: *camkkanman camkkanman ikey na-nun cikum*

‘Just a moment, just a moment, this I now’

21 A: *um*

A shows uncertainty about a picture in line 17 but attempts to her opinion, again in a subtle way using -ci, a weak agreement seeking ending and a negative question in line 18.

(20)

22 B: *irehkey ieci-nun key ani-lkka, irehkey? Ah, ike camkkan. Uh,: hh ani, mwue-ci?*

‘Isn’t it connected like this? Ah, this, just a moment. No, what is it?’

23 A: *## cal moru-kess-ci ?*

‘You don’t know either, right?’

24 B : *ung: camkkanman, taychwung macchwe po-lkka, wuri, hayse,*

‘Yeah. Just a minute, shall we put together roughly?’

25 A: *nangttere-ci-lul manna-se [tasi tolaka-nun kes kath-un-*

‘Seems like (he) meets a cliff and goes back’

26 B: *[manna-se,*

‘meets and’

In line 22, we see B expressing her opinion in a very indirect way. As they try to make a story together, they use repetitions as in line 26, and 28 below:

(21)

27 B: *tolaka-ss-nuntey, tolaka-ss-nuntey, [yeki yay-lul manna?]*

‘(he) went back, went back, and met this one?’

28 A: *[ah, tolaka-taka] yay-lul manna-na?*

‘Ah, when (he) goes back, does he meet this one?’

29 B: *kurem cyay-nun ettehkey hay? Kunikka yay-rang yay-rang nwuka te mence manna-ss-nunya-ka: cwungyoha-nka?*

‘Then, what do we do with that one? I mean, is it important which one of the two he meets first?’

30 A: *ya, ike ieci-nun ke-ci? hana-ci? [iyaki.]*

‘Hey, this is a connected one, right? One story, right?’

31 B: *[ung.] ung.*

The analyses of the Korean interaction show that the Korean speakers are more

like Japanese speakers than Americans in that they use indirect, non-confrontational expressions and seek agreement from the partner constantly. Various question forms and sentence-endings are very useful devices to achieve this goal. Also, they have a greater tendency to depend on the context, using a lot of gestures and deictic expressions.

## 5. Implications of the Findings

So far, this study has demonstrated some differences in interactional characteristics among the American, Japanese and Korean pairs as they were working on a problem-solving task. We would like to illustrate the differences between the American and Japanese/Korean interactions using the *field/ba/cang*-theory (Shimizu 2000). Figures 1 and 2 below illustrate the different patterns of interaction between the American and Japanese/Korean pairs:

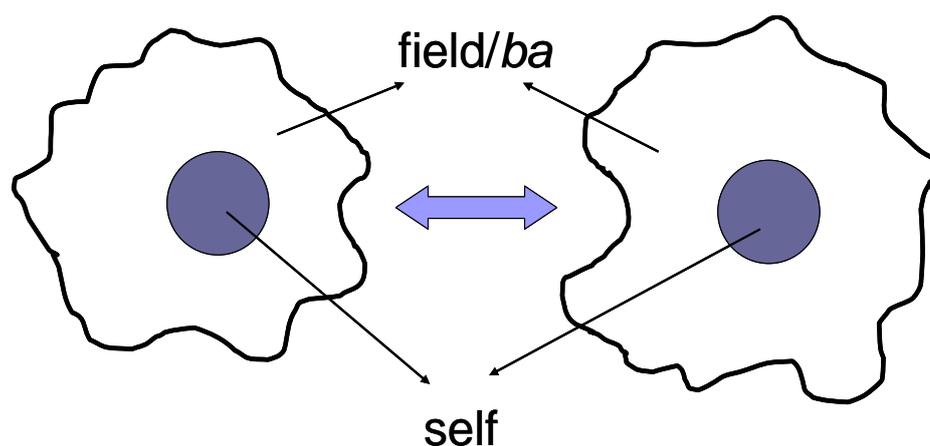

Figure 1. Patterns of Interaction 1: American Interaction

In the American interaction, the participants keep their independent selves of separate fields throughout the interaction. Their interaction mostly consists of the exchange and negotiation of information in order to accomplish the task.

Figure 2 illustrates the Japanese and Korean pattern of interaction:

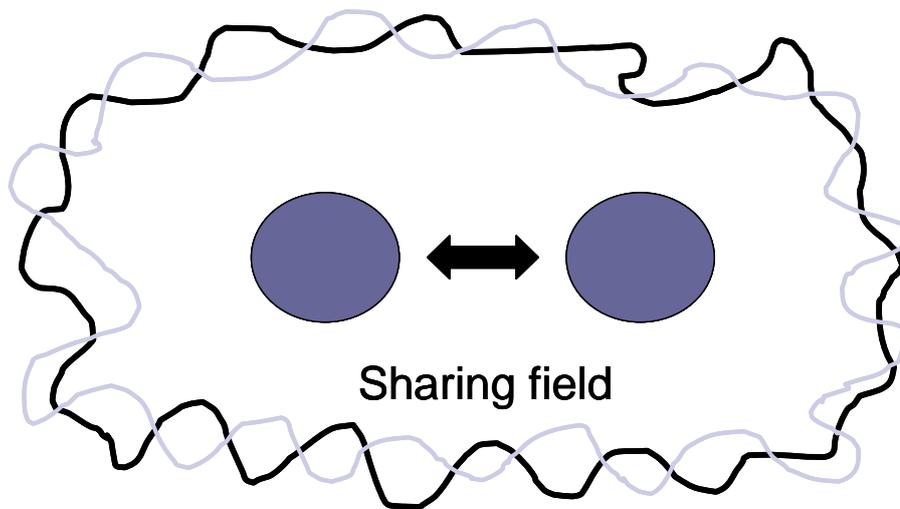

Figure 2: Patterns of Interaction 2: Japanese and Korean Interaction

Figure 2 illustrates the Japanese and Korean pattern of interaction where the participants always concern about the partner's position as well as themselves. Then, they reorient themselves at every moment of the interaction so that their fields/*ba* can merge into one. Then, on the sharing field/*ba*, they work together as if they had a single mind in order to accomplish the task. What this study reveals is that, compared to the English counterpart, the Japanese and Korean interactions show the value of the practice of field/*ba*-dependency over and above the practice of information exchange.

We strongly believe that this field/*ba*-dependency is deeply rooted in the underlying cultural practices in the Japanese and Korean societies, which are based on their rice-farming culture and Buddhism. In rice-farming culture, people inevitably have to settle permanently in one place. In such a society, individuals are closely bound to each other and they form an exclusive social nexus.

Buddhism is also characterized by the recognition of nexus, not only with other people, but also with other beings. Thereby one feels indebtedness to other people that may or may not be relevant to oneself (Ide 2007). These underlying cultural practices make us situate ourselves in the context; that is, participants index their sharing field/*ba* as well as themselves at each moment of interaction.

We would like to conclude our talk by suggesting that we should account for the diversity of patterns in interaction from a wider perspective based on underlying cultural practices. However, at this moment we would like to leave the difference between the Japanese and Korean interactions as an open question.

# New Korean Adjectival Suffix ‘-tic’

Nari Lee

Korea University  
1-5ga, Anam-dong, Seongbuk-Gu, Seoul, Korea  
lee\_nari@yahoo.co.kr

## Abstract

English adjectival suffix *-tic* is increasingly used to formulate new verity of Korean adjectives though there are pre-existing Korean adjectival suffixes. The *-tic* forms are combined with various root words and productively create new types of adjectives. It is worth analyzing the characteristics of the adjectival suffix *-tic*. Three different methods have been applied to illustrate the characteristics of *-tic* forms. Four Korean Internet search engines are used to gather the actual data, a questionnaire is conducted to identify the Korean native speakers’ intuition on the forms, and a substitution check is applied to reveal the relationship between new suffix and pre-existing ones. The findings demonstrate that *-tic* forms are morphologically and semantically similar to the pre-existing Korean adjectival suffixes.

**Keywords:** Korean adjective, derived adjective, adjectival suffix, English suffix

## 1. Introduction

Adjectives can be “verb-like” or “noun-like” with respect to their functions as predicates or modifications (Dixon 2004: 31). There have been many attempts to classify Korean adjectives, but it is still controversial to categorize Korean adjective explicitly as well as noun and verb classes (Sohn 2004).

Plag (2003) states that morpheme can be coined with various word classes and generate many different word categories effectively. One productive way of making English adjectives is by using suffixes. Korean likewise uses several suffixes such as *-sulepta* ‘seem to’, *-tapta* ‘be similar to’ or *-cek* ‘being alike, 的’ to create derived adjectives. Recently Korean has adopted English forms to formulate a new category of words (Yoo 2004; Park 2005). Though Korean already has adjectival suffixes, English suffixes have been increasingly used to make adjectives. The main concern of this study is to analyze the new Korean adjective forms and their preceding stems. Among many

adopted English adjectival suffixes, ‘-*tic* (being alike)’ appears to be the most widely and frequently used form.<sup>1</sup> The following examples show the various usage of -*tic*:

(1) *Sonye-tic-hata*.

girl being alike do  
“(It) seems girlish”

(2) *Chun Yu-ok-tic-hata*.

Chun Yu-ok being alike do  
“(She) is similar to Chun Yu-ok’s character”

(3) *Pwutulewun-tic-hata*.

Soft being alike do  
“(It) is soft”

(4) *Yume-tic-hata*.

humor being alike do  
“(It) is humorous”

(5) *Tulama-tic-hata*.

drama being alike do  
“(It) is dramatic”

(6) *Ccicil-tic-hata*.

pathetic being alike do  
“(It) is pathetic”

These examples are collected from four Korean Internet search engine sites.<sup>2</sup> They show that the English adjectival suffix -*tic* can be joined with Korean common nouns (1), Korean proper nouns (2), Korean native adjectives (3), English nouns (4), English adjectives (5), and even Internet newly coined words (6).<sup>3</sup> It is very simple and systematic to create new adjectives; add -*tic* at the end of the morphemes no matter what their grammatical categories are. One of the most unique phenomena of the examples is (4). Although there is an English adjective ‘humorous,’ some of Korean speakers rather uses -*tic* form with English noun *humour*. It suggests the productivity of

---

<sup>1</sup> Though English adjectival -*tic* should be spelled as -*thik* according to the Yale Romanization System, in this paper, I will use -*tic* to indicate that it originates from English suffix as in *romantic* or *dramatic*.

<sup>2</sup> Four Internet search engines are selected according to the 2006 year report and first quarter of 2008 report of the Acecounter: Naver, Daum, Yahoo! Korea, and Google Korea ([http://www.acecounter.com/report/report\\_list\\_view.html?no=28&pageno=1](http://www.acecounter.com/report/report_list_view.html?no=28&pageno=1)).

<sup>3</sup> Internet newly coined words are created by the netizens, who enjoy using the ellipsis, acronym, misspelled words, and neglecting to space between words (Hwang, 2006).

the *-tic* forms. It is the starting point of the present study; to characterize the morphological and semantic characteristics of the English derived adjectival suffix *-tic*.

The pattern of new Korean adjectives is that English suffixes are coined with Korean root words. It is worth investigating the characteristics of root words to categorize the derived adjectives. Once a root word and the adjectival suffix *-tic* are merged, they subsequently are combined with dummy verb *-hata* (do/be) which is a predicate form, or with dummy modifying suffix *-han* (done/being) which is a modification form. These new adjectival forms are used in a wide range of contexts.

## 2. Literature Review

Adopting English suffixes to create Korean adjectives is the morphological borrowing (Min 1998: 92-102; as cited in Yoo 2004). Park (1999) defines Korean words which contain ‘X-*tic*’ form as compound words; English adjectival suffix *-tic* has been combined with Korean nouns. According to Park’s (2005) claim, it is relatively natural to borrow vocabularies to create new Korean words; however, it is very awkward to adopt grammatical forms such as bound morphemes. Moreover, Yoo (2004) agrees that the borrowing of English bound morphemes to make Korean words is redundant because Korean already has abundant bound morphemes. One of the most widely used Korean adjectival bound morphemes is *-cek* which is derived from Chinese character 的.<sup>4</sup> The study of *-cek* has been accompanied with the study of its stem words; what types of stem words can be coined with the bound morpheme of *-cek*. However, the study of *-tic* forms or its stem words scarcely has been made.

The data with respect to the Korean adjectival suffix *-cek* has been collected and compared with *-tic* form to identify its characteristics. The research on *-cek* has been largely conducted by Kim (1990), Nam (2001, 2002), and Mok (2001).

First, Kim (1990) focuses on the analysis of the ‘preceding stems’ which appear in front of the suffix *-cek*. He reports that the nouns which originate from Chinese language are mostly used for the preceding stems, and the nouns from the native Korean and the loanwords from the western languages are used, respectively. To sum up, most nouns can be coined with the suffix *-cek* and productively produced the adjectives.

Second, Nam (2001, 2002) and Mok (2001) take the morphological analysis of *-cek*. Nam (2001, 2002) questions the effectiveness of the Korean adjective classification. She opposes admitting *-cek* as an adjectival suffix, and suggests *X-cek ita* as one type of

---

<sup>4</sup> Not only Korean but also Chinese and Japanese use *-cek* to formulate adjectives.

the adjective form. Her studies mainly focus on the form of *X-cek ita* rather than *X* (preceding stems) itself. Mok (2001), in contrast, defines *-cek* as the (predicative) noun derivative suffix. He insists that nouns and adjectival stems can be located in front of the suffix *-cek*. Mok's (2001) idea can be compared with that of Kim (1990); Kim asserts that only nouns can be the preceding words of the suffix *-cek*, whereas Mok broadens the scope of the preceding words to nouns and adjectival stems.

In short, the previous studies of *-cek* have been conducted in two different fields: semantic and morphology. The main concerns are defining the range of *X-cek ita* form, and clarifying the characteristics of its preceding stems.

### 3. Method

The data for the empirical component of the present study were collected from the top four Korean Internet search engines in 2006 and 2008. The two keywords were: *tic-hata* (predicate form) and *tic-han* (modification form), and the words which contained *-tic* were gathered from the first three pages of the result in 2006, and the first five pages in 2008. The collected items were sorted by the feature of the root words. Next, the characteristics of the root words are compared semantically and morphologically with the previous studies: the analysis of *-cek*.

For further validation of the research authenticity, a questionnaire was administered to the native speakers of Korean.<sup>5</sup> Participants in 2006 were 13 male university students, their average age was 24, and all of them were majoring computer science. Due to their major, all of them spent more than six hours to access Internet every day. They were familiar with the Internet jargons and the new vocabularies which were created on the web. The number of participants in 2008 was 68, all university students, and most of them were science major.<sup>6</sup> The proportion of male and female was 81% (55) and 19% (13) respectively. Their mean age was 23.3 years old, and their average time of Internet use was 5.6 hours per day. The participants were asked to judge the naturalness/awkwardness of twenty most frequently used derived adjectives with the English suffix *-tic*. They value the items within 5 Likert scale; if the word is natural they are asked to give 5 points, if it sounds awkward then they are asked to give 1 point on the item. The examples used in the questionnaire were selected from the results of the

---

<sup>5</sup> The list of words for questionnaire is on the Appendix.

<sup>6</sup> 66 (97%) were majoring in science such as Computer Science, Biology, Environmental Engineering and so on.

Internet search engines data. Four top most frequently used adjectives from each category were chosen: Korean common nouns, Korean proper nouns, English loan words, and English words.

To verify the relationship between *-cek* and *-tic* form, a substitution check was conducted. The collected *-tic* forms were replaced in the position of Korean adjectives which use pre-existing Korean adjectival suffix *cek-ita* ‘being alike’. It was to examine the possibility of meaning substitution between pre-existing form and new one. The root words from the twenty adjectives, which were used for the questionnaires, had been coined with *-cek* form, and employed in keyword search on top four Internet search engines. For example, the words *yua-tic* (childish) had been changed to *yua-cek* (childish), and the substituted word *yua-cek* (childish) was used for a keyword search.

#### 4. Results and Discussion

The same procedure for collecting data from the Internet search is applied both in 2006 and 2008. Items are gathered through the keyword search and then the overlapped items are deleted. Table 1 shows the number of items collected from the Internet search. The total number of the collected items in 2006 research is 240 but the actual number is 157 after omitting overlapped items; the number of the predicate form (*tic-hata*) is 77 (49%), and that of the modification form (*tic-han*) is 80 (51%). In 2008 research, the total number of collected item is 400 but the actual number of items for the research is 181; the number of the predicate form (n=98, 58%) is more than that of the modification form (n=83, 42%) this time.

Table 1. The number of collected items from the Internet search engines

	<i>tic hata</i> (n (%))	<i>tic han</i> (n (%))	Sum
2006	77 (49%)	80 (51%)	157
2008	98 (58%)	83 (42%)	181

The root words of *-tic* forms are divided into five groups: Korean common nouns, Korean proper nouns, English loan words, English adjectives, and extra. These categories are based on Kim’s (1990) classification, and additional categories are included according to the frequency of the appearance from the Internet search. Kim (1990) analyzes preceding stems of *-cek* and classifies them as Korean nouns derived from Chinese, native Korean nouns, and loan words from western languages. From the

Internet research data, Korean nouns are divided into common nouns and proper nouns such as a name of person, country, video game, movie, book or ideology. English vocabularies are also sorted by English loan words and English adjectives with *-tic*; all of the English loan words are common or proper nouns. The items which are not fit into the four categories are sorted as extra group which are Korean native adjectives, English adjectives except the words containing *-tic* forms, Internet newly coined words, Internet jargons, slang, symbols, and onomatopoeia.

Figure 1 and table 2 show the percentage of the preceding components of *-tic*. Predicate forms (*tic-hata*) and modification forms (*tic-han*) are compared by the year of the research (2006 and 2008). Five categories can be grouped according to the characteristics of the preceding stems. Figure 1 illustrates that Korean common nouns, Korean proper nouns, and loan words are wildly used.<sup>7</sup>

Figure 1. The comparison of the Internet research data

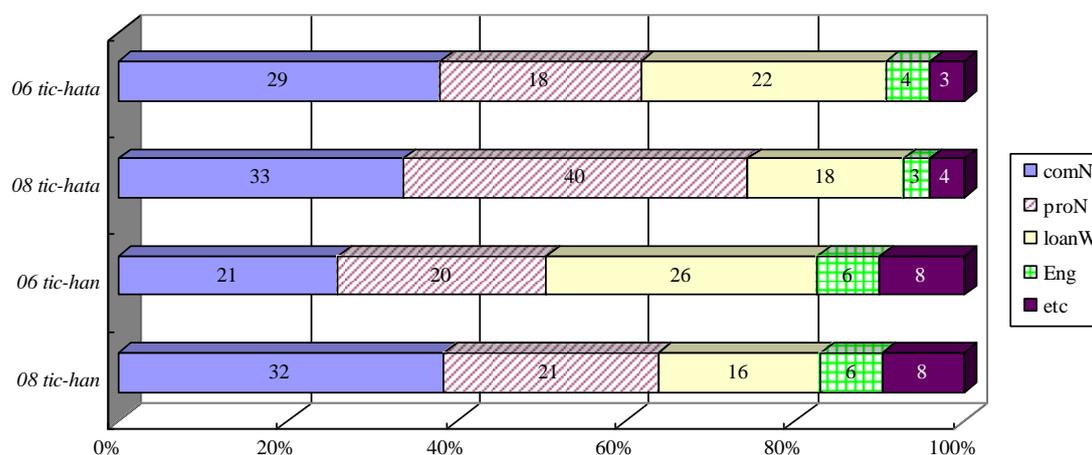

Table 2. The descriptive analysis of the Internet research data (n(%))

	comN	proN	loanW	Eng	etc
06 tic-hata	29(38.2%)	18(23.7%)	22(28.9%)	4(5.3%)	3(3.9%)
08 tic-hata	33(33.7%)	40(40.8%)	18(18.4%)	3(3.1%)	4(4.1%)
06 tic-han	21(25.9%)	20(24.7%)	26(32.1%)	6(7.4%)	8(9.9%)
08 tic-han	32 (38.6%)	21(25.3%)	16(19.3%)	6(7.2%)	8(9.6%)

\*com N: Korean common noun, pro N: Korean proper nouns,  
loan W: English loan words, Eng: English adjectives, etc: extra

<sup>7</sup> Loan word is directly adopted from foreign language and transcribed with Korean alphabet. The examples are *Khenthuli* (country), *imici* (image), *ssaikho* (psycho), and so on.

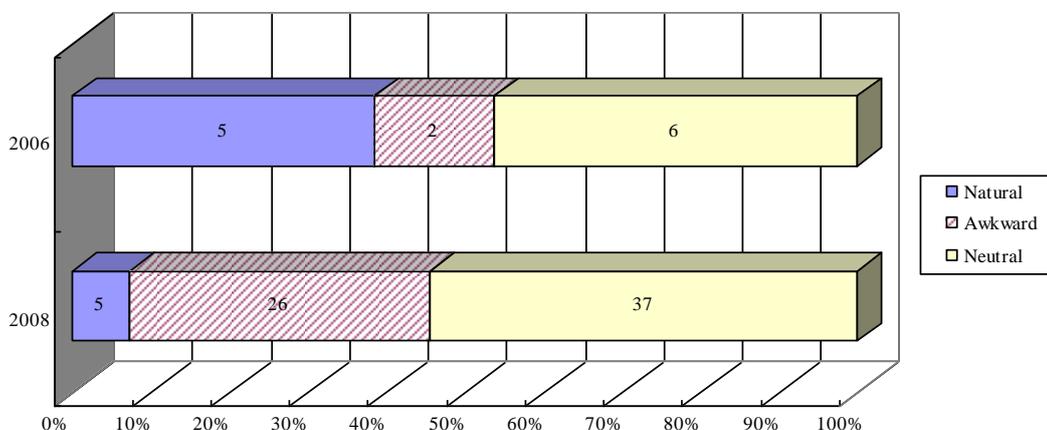

Figure 1 and table 2 suggest that Korean common nouns are the most widely used elements overall. According to the findings, for predicate forms (*tic-hata*), Korean common nouns are popular in 2006 whereas Korean proper nouns are used more in 2008. For modification forms (*tic-han*), loan words are the most frequently combined elements in 2006 but Korean common nouns are used twice more than loan words in 2008 research.

The percentage of Korean proper nouns and the loan words are very similar in predicate forms in 2006. Contrary to the previous research, the ratio of Korean common nouns and loan words are decreased in 2008. The three categories (Korean common nouns, Korean proper nouns, and loan nouns) take up almost 90% of the whole components of the predicate forms (*tic-hata*) both in 2006 and 2008 research.

While the loan words are the most popular preceding stems for the modification form (*tic-han*), Korean common nouns and Korean proper nouns are also largely used in the modification forms in 2006. The use of Korean common nouns increased in the later analysis. The percentage of Korean nouns and loan words in the modification form (*tic-han*) is almost 80% in 2006 and 2008 study.

The total amount of Korean nouns and loan words of figure 1 and table 2 illustrate that *-tic* is a very productive suffix. Even though the percentages of each category which is coined with suffix *-tic* form are vary according to the functions (predicate/modification) and the time (research year), the total percentage of Korean nouns and loan words take up more than 80%. Comparing with the number of English words which contain *-tic*, the new Korean adjectives using *-tic* forms are overwhelmingly massive.

Figure 2. Judgment of Korean native speakers' on the *-tic* forms

Next, figure 2 shows the results of the intuitive judgment on the *-tic* forms by the Korean native speakers. Though the percentage of awkwardness has been increased, more than half of the participants answer that *-tic* forms sound natural or at least, they do not sound awkward. The number of participants in 2006 is small and it might be difficult to generalize the results; however, both results provide the interpretation that almost half of the Korean native speakers are ready to accept new adjectives using *-tic* forms.

Figure 3 and 4 demonstrate the intuition of Korean native speakers on the *-tic* forms in four different categories. In terms of the naturalness, English words are the most natural elements with *-tic-hata/han* forms. Needless to say, it is obvious that English adjectives containing *-tic* form can be the most natural elements because they are the original forms of the words: such as *dramatic*, *romantic*, and *fantastic*. Besides English adjectives, Korean common nouns are the second most suitable preceding stem of *-tic* forms. It is interesting that loan words are not considered as the natural preceding stems for *-tic* forms.

Figure 3. Judgment of Korean native speakers' on the naturalness of *-tic* forms

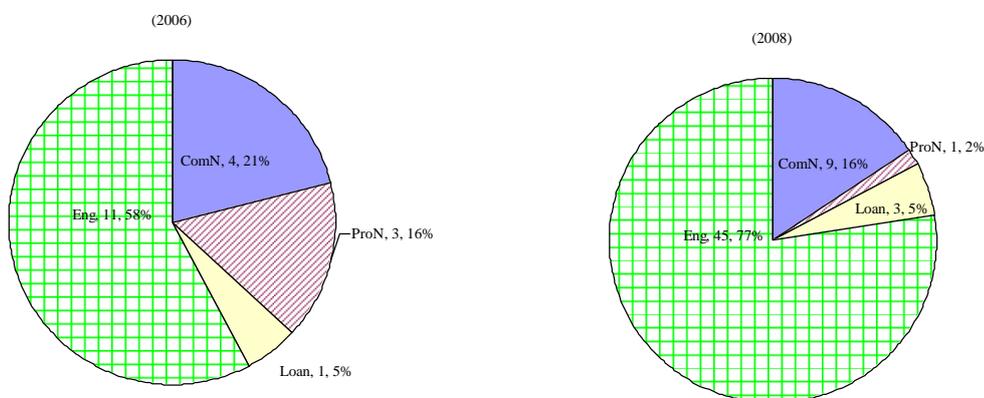

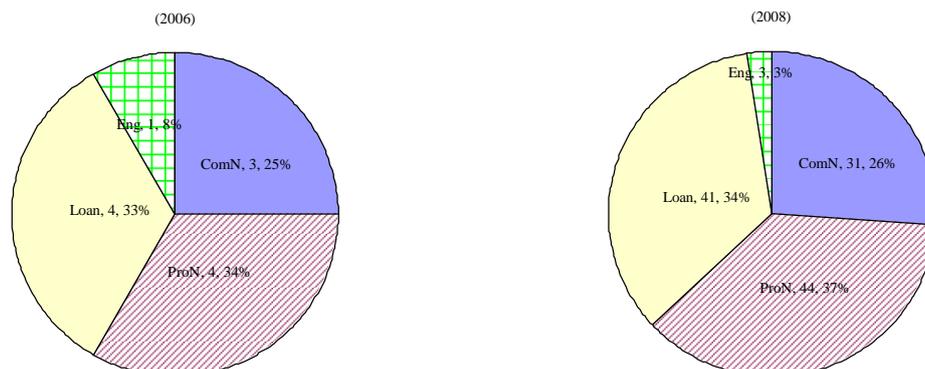

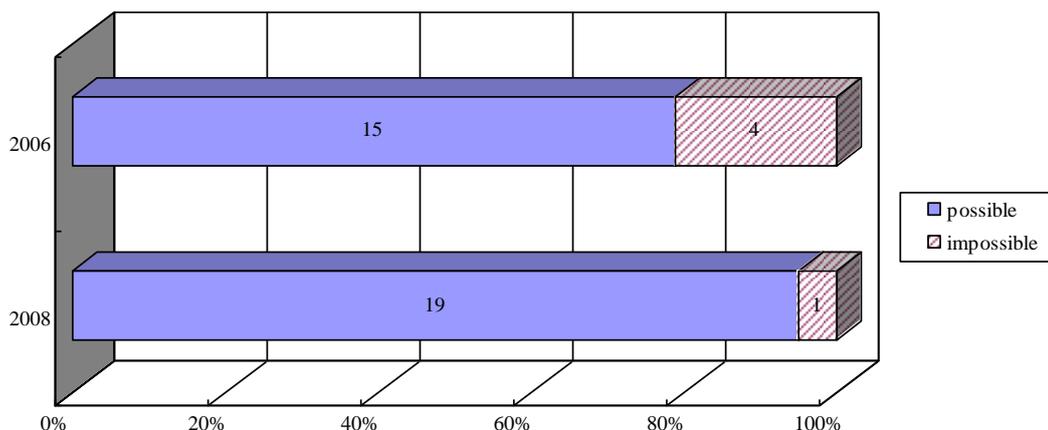

Figure 4. Judgment of Korean native speakers' on the awkwardness of *-tic* forms

On the contrary, in terms of the awkwardness, Korean native speakers judge that Korean common nouns, Korean proper nouns, and loan words are awkward to combine with *-tic* forms. Though participants answer that Korean common nouns can be suitable for stem words of *-tic* forms, their judgment on the awkwardness contradicts the previous findings. It can be interpreted that even Korean native speakers have not obtained full intuition of the new adjectival suffix *-tic*. To be surprised, some participants value English words such as *energetic* is awkward. During the personal communications, they mentioned that the word *energetic* was not familiar to them, and they guessed *energytic* (*energy* + *tic*) is the natural form of it.

The results also reveal the discrepancy between the actual usage and the intuitive judgment. Though loan words are widely used for preceding stems of *-tic* from the Internet research (figure 1), some Korean speakers believe that these words are not appropriate for the preceding stems (figure 4).

Figure 5. The possibility of substitution with *-cek* forms

Last, figure 5 shows the potentiality of the new adjectival suffix *-tic*; both results (2006 and 2008) indicate the high possibility of the substitution. The preceding stems of the *-tic* forms can be replaced with that of pre-existing Korean adjectival suffixes *-cek*. It is interesting that even English root words with suffix *-tic* can be substituted with *-cek* forms. For example, the word “*drama-cek*” which is the converted word for “*dramatic*” is found on the substitution test. The result of the figure 5 proposes that *-tic* forms are easily switched with *-cek* forms regardless of the root word categories. It also implies that *cek-ita* form is morphologically similar to the *-tic-hata* form not to mention of its semantic similarity, and it explains the high potential of the substitution.

## 5. Conclusion

The results of the present study prove that adopted English adjectival suffix *-tic* can be generally joined with many types of Korean root words: nouns, adjectives, loanwords, or English nouns and adjectives. However, the verbs or adverbs are scarcely used for the preceding stems of *-tic* form.

The native speakers of Korean judge that English words are the most natural with the suffix *-tic*, and Korean common nouns are ranked as the second most natural stems for the *-tic* forms. In contrast, in terms of awkwardness, the participants answer that Korean nouns and loanwords do not sound natural with *-tic* forms. Their replies suggest two things: one is their intuitions on the *-tic* forms are not clearly establish, the other is the discrepancy between the actual usage of *-tic* forms and their intuition of the new words.

Morphologically, nowadays, using *-tic* form to create new Korean adjectives is more productive than that of pre-existing adjectival suffix *-cek*. In semantic point of view, most of words which contain *-tic* form have the same meaning with the pre-existing Korean adjectives such as *-cek* form. It is proved by substituting *-tic* forms with those of *-cek* in the sentence from the web sites. Consequently, the morphological and semantic analysis of *-tic* forms reveal that *-tic* can be included in new types of Korean adjectival suffix though the morphological borrowing has not been common in Korean.

# Varying Implicature in Contrastiveness

Osamu Sawada

University of Chicago  
1010 E 59th street, Chicago, IL 60637  
sawadao@uchicago.edu

## Abstract

This paper investigates the varying implicatures in contrastiveness in Japanese and considers how the variability can be accounted for in a principled way. The varying types of implicature in contrastiveness have to do with the following parameters: (i) the presence or absence of uncertainty meaning inside the implicatures, and (ii) whether the contrastive is specific (existential) or universal. As for the first parameter, the notion of strengthening/exhaustivity can account for the variability (e.g. Hara and van Rooij 2007). As for the second parameter, I argue that the contextual domain restriction plays an important role in capturing the variability of implicatures. It will be shown that the narrower the speaker's/ hearer's contextual domain is, the more specific the contrastive becomes.

**Keywords:** contrastiveness, scalar implicature, strengthening, contextual domain

## 1. Introduction

This paper investigates the varying implicatures of contrastive *wa* and tries to explain this variability in a unified way. Let us observe the following dialogue (CT stands for contrastive marker):

- (1) a. Among John, Mary and Tom, who came to the party?  
b. JOHN-wa ki-masi-ta  
    John-CT come-PRED.POLITE-PAST  
    ‘[John]<sub>CT</sub> came.’  
c. ... (interpreting the conversation between A and B)

The sentence in (1b) can have various implicatures, symbolized by  $\rightarrow$  :

- (2)a. → But it is possible that Mary didn't come.  
 b. → But Mary didn't.  
 c. → But it is possible that no one other than John came.  
 d. → But no one other than John came.

The implicatures in (2a) and (2b) contrast the focused element (John) with a specific individual (Mary).<sup>1</sup> That is to say, the implicature of contrastiveness is considered to be binary (Kadmon 2001: 324) and no other comparison class will come to mind except for the set containing precisely these two individuals. In these implicatures, the speaker in (1b) does not care about Tom. (The natural situation for the implicatures is where the speaker in (1b) is indifferent to Tom). It is true that it is difficult for the speaker in (1a) to get these implicatures, but the speaker in (2c) can get implicatures like (2a) or (2b) if he/she knows that the speaker in (1b) does not know about Tom (or he/she knows that the speaker in (1b) is indifferent to Tom). Where (2a) and (2b) differ is in the presence or absence of the meaning of the speaker's uncertainty in implicatures. That is, while (2a) has a possibility modal in its implicature, (2b) does not have such an operator.

Now let us consider (2c) and (2d), which are different from (2a) and (2b) in that the former pair, but not the latter, contrasts John with all of the alternatives. There is no specificity in terms of contrastiveness. As for the difference between (2c) and (2d), we can observe that while (2c) has a possibility meaning (i.e. the speaker's uncertainty), (2d) does not have such a meaning. (2d) is a situation where *dake* 'only' is used. Note that the speaker can naturally say (2a-d) immediately after (1b):

(3) (Among John, Mary and Tom, who came to the party?)

- a. John-wa ki-ta-kedo, Mary-wa ko-na-katta-kamosirenai.  
 John-CT come-PAST-though, Mary-CT come-NOT-PAST-may  
 'John came but it is possible that Mary didn't come.'
- b. John-wa ki-ta-kedo, Mary-wa ko-na-katta.  
 John-CT come-PAST-though, Mary-CT come-NOT-PAST  
 'John came but Mary didn't come.'
- c. John-wa ki-ta-kedo, hokano-minna-wa ko-na-katta-kamosirenai.

John-CT come-PAST-though, other-everyone-CT come-NOT-PAST-may  
 ‘John came but it is possible that no one else came.’

d. John-wa ki-ta-kedo, hokano-minna-wa ko-na-katta.  
 John-CT come-PAST-though, other-everyone-CT come-NOT-PAST  
 ‘John came but no one else did.’

We can summarize the differences of implicature in (2a)-(2d) as follows:<sup>2</sup>

(4) Varying implicatures of contrastiveness

(2a)	(2b)	(2c)	(2d)
$\diamond\exists x[C(x) \wedge x \neq \text{John} \wedge \neg P(x)]$	$\exists x[C(x) \wedge x \neq \text{John} \wedge \neg P(x)]$	$\diamond\forall x[C(x) \wedge x \neq \text{John} \rightarrow \neg P(x)]$	$\forall x[C(x) \wedge x \neq \text{John} \rightarrow \neg P(x)]$
			<i>cf. only</i>

Here, variable C is a contextually determined set of individuals. We can classify the varying implicatures in Table (4) by the following two parameters: (i) the presence or absence of the speaker’s uncertainty concerning the implicature and (ii) whether the contrastive is specific (existential) or universal:

(5)

	+Uncertainty	-Uncertainty
Specific/Existential contrastiveness	(2a)	(2b)
Universal contrastiveness	(2c)	(2d)

The purpose of this paper is to consider how the variability of implicature can be explained in a principled way. We will first introduce the two representative approaches to the implicature of contrastive *wa*—reversed polarity (Oshima 2008) and the scalar alternative (Hara 2005, 2006)—and consider whether these two approaches can explain the variability of implicature. I will claim that both approaches seem to have pros and cons in analyzing the variability of implicatures, but the scalar alternative approach can become a better approach if accompanied by the assumptions that (i) the contextual variable C is fixed by the speaker or the hearer, so the contextual domain may be different

for each of them and (ii) the smaller the contextual domain of C is, the more specific the contrastive meaning becomes.

Finally, I will compare the scalar and non-scalar uses of contrastive *wa* (Sawada in press) and consider whether these two uses are to be understood as special cases of a single meaning (cf. *only*; Beaver and Clark 2008 and references therein). It will be shown that the scalar alternative approach can unify the two uses in principled way.

## 2. Background: Thematic *Wa* vs. Contrastive *Wa*

It is well known that the particle *wa* in Japanese has two kinds of uses, thematic and contrastive:

(6) Taro-*wa* hasi-ttei-ru.

Taro-WA run -PROG-PRES

a. Thematic *wa*: ‘Speaking of Taro, he is running.’

b. Contrastive *wa*: ‘Taro is running (but Hanako is not running.)’

(Kuno 1973a: 207)

In (6a) *wa* marks a constituent that stands for theme as opposed to content. According to Kuno (1972), the theme must be either **generic** or **anaphoric** (previously mentioned). In (6b), on the other hand, *wa* marks the contrastive element of the sentence, and conventionally implies that there is another element that is an alternative to it. Notice that the contrastive element can be generic, anaphoric or neither of the two (Kuno 1972). That is, there is no constraint on the contrastive *wa*. Notice that contrastive *wa* and thematic *wa* are different in terms of phonology as well. Sentence (6) is interpreted as contrastive if we stress the element attached to the particle *wa* (here, ‘Taro’) or *wa* itself.

### 3. Previous Analyses of the Contrastive *Wa*

In this section we will introduce the representative approaches to contrastive *wa* (reversed polarity vs. scalar alternative) and consider whether either approach can explain the variability of contrastiveness.<sup>3</sup>

#### 3.1. Reversed polarity approach

Many researchers agree on the following idea:

##### (7) *Reversed polarity approach*:

The implicature induced by contrastive *wa* has an opposite meaning: ‘*x-wa...*’ implies ‘but it is **not** the case that *y-wa...*’ (Kuno 1973b; Teramura 1991; Noda 1996; Oshima 2008, among others)

Some researchers call this implicature the ‘reversed polarity presupposition’ (e.g. Lee 2006; Oshima 2008). For example, Oshima (2008) argues that an utterance of (8) is felicitous only if **at least one of the alternative propositions** with respect to John, like those listed in (9), is *not* in the common ground C.

##### (8) (Among John, Mary and Tom, who came to the party?)

JOHN-wa ki-mashi-ta.

John-CT come-PRED.POL-PAST

‘[John]<sub>CT</sub> came.’

##### (9) {Mary came; Tom came}

In this analysis the common ground is a contextually determined set of alternative propositions to sentence (8) with respect to John. Oshima’s approach can explain the implicatures in (10b) and (10d) because his felicity condition for contrastive *wa* enables us to use (8) in two situations: where all of the contextually determined persons didn’t come, or where only some of them didn’t come:

(10) Variability of implicature of (8)(=1b)

(a)	(b)	(c)	(d)
$\diamond\exists x[C(x) \wedge x \neq \text{John} \wedge \neg P(x)]$	$\exists x[C(x) \wedge x \neq \text{John} \wedge \neg P(x)]$	$\diamond\forall x[C(x) \wedge x \neq \text{John} \rightarrow \neg P(x)]$	$\forall x[C(x) \wedge x \neq \text{John} \rightarrow \neg P(x)]$
			cf. <i>only</i>

Note that in the above table, I use the variable C to represent a contextually determined set of alternative individuals with respect to John.

The reversed polarity approach is intuitively right, but the problem is how to explain cases (a) and (c) where the speaker's epistemic uncertainty is conveyed.

3.2. Scalar alternative approach

Hara (2004, 2006) claims that a contrastive topic presupposes a particular set of scalar alternatives, namely stronger propositions than the one asserted, and conventionally implies that it is possible that the stronger alternative is false. I will call this approach the scalar alternative approach:

(11) Scalar alternative approach: The contrastive *wa* 'always' induces a conventional Q implicature (Hara 2004, 2006).

She formalizes this idea as follows:

(12) CONTRASTIVE(<B, F>) (B : background, F: the focus-marked elements)

- a. asserts: B(T)
- b. presupposes:  $\exists F'[F' \in \text{ALTC}(F) \wedge B(F') \text{ entails } B(F) \wedge B(F) \text{ doesn't entail } B(F')]$
- c. implicates:  $\forall F'[F' \in \text{ALTC}(F) \wedge B(F') \text{ entails } B(F) \wedge B(F) \text{ doesn't entail } B(F')] \rightarrow \text{Poss}(\neg B(F'))]$

As we can see in (12b), there must be a scalar alternative that *entails* but *is not entailed by* the original assertion. If the presupposition is correct, the sentence with CON conventionally implies that the speaker is considering the possibility that the stronger

alternative is false, as shown in (12c).

Let us apply the above idea to example (13):

(13) a. Among John, Mary and Tom, who came to the party?

b. JOHN-wa ki-mashi-ta.

John-CT come-PRED.POL-PAST

‘[John]<sub>CT</sub> came.’

→ Mary didn’t come, or I don’t know about Mary.

(14) shows the interpretation of (13):

(14) a.  $B = \lambda x. x$  came

F=John

F’={John & Mary, John & Tom, John & Mary & Tom}

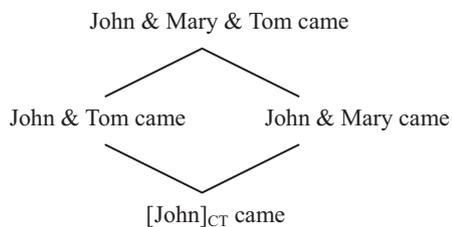

b. assertion: John came.

c. implicatures: the speaker is considering the possibility that ‘every proposition that is stronger than the asserted one is false.’

d. assertion + implicature: the speaker is considering the possibility that no one other than John came.

As we can see in the following figure, the alternatives to the focus-marked element (John came) are {John & Mary came, John & Tom came, John & Mary & Tom came}:

(15)

By negating every proposition that is stronger than the assertion, we get the scalar implicature that ‘it is possible that no one other than John came to the party.’ Now, let us

consider this approach in terms of variability of implicature.

(16) Variability of implicature in (13b) (=1b))

(a)	(b)	(c)	(d)
$\diamond\exists x[C(x) \wedge x \neq \text{John} \wedge \neg P(x)]$	$\exists x[C(x) \wedge x \neq \text{John} \wedge \neg P(x)]$	$\diamond\forall x[C(x) \wedge x \neq \text{John} \rightarrow \neg P(x)]$	$\forall x[C(x) \wedge x \neq \text{John} \rightarrow \neg P(x)]$
			cf. <i>only</i>

Hara's scalar alternative approach corresponds to the implicature in (16c) in the table. Note that the scalar alternative approach can explain (16d) based on the general mechanism of scalar implicature (Hara and van Rooij 2007). Soames (1982) suggests that the epistemic force of scalar implicature arises from the external negation of the Hintikka operator K. Thus, asserting 'some came' will conversationally imply that 'the speaker does not know whether everyone came.' In our case, this corresponds to (16c). However, Soames suggests that this implicature may be strengthened to a particularized conversational implicature that 'the speaker definitely knows that not everyone came' due to an additional assumption (See also Suerland 2004; Schulz and Robert van Rooij 2006 and references therein). Although we are assuming that the contrastive *wa* induces a 'conventional scalar implicature', but not 'conversational scalar implicature', it is natural to think that the same analysis can be applied to implicature of contrastive *wa*. That is, the primary implicature in (16c) is strengthened to (16d) (Hara and van Rooij 2007).

Thus we can conclude that the variability in the level of the speaker's uncertainty can be captured by Hara's approach. Notice that the following example only has a strong implicature:

(17) (Can you speak French and German?)

Fransu-go-wa            hanas-e-masu.

French language-CT    speak-can-PRED.POL

'I can speak [French]<sub>CT</sub>.'

In this context, the natural implicature of (17) will be 'but I cannot speak German,' because the speaker is talking about himself. Things become different, however, if the

speaker is talking about Taro's competence in foreign languages.

The potential problem with the scalar alternative approach is that it may not be able to explain the variability of specificity. Observe the following sentence:

(18) a. Among John, Mary and Tom, who came to the party?

b. JOHN-wa ki-masi-ta

John-CT come-PRED.POLITE.PAST

'John]<sub>CT</sub> came.'

→ But Mary didn't come./It is possible that Mary didn't come.

According to the scalar alternative approach, (18b) makes a scale like (15) and generates the conventional implicatures that 'it is possible that no one other than John came' or 'no one other than John came'. However, the implicature of (18b) can be more specific. For example, it can be binary as in (18). Is there a way to explain this implicature using the scalar alternative approach?

#### 4. Domain Restriction and the Contextual Variable C

I argue that the problem with the scalar alternative approach disappears if we assume that the contextual variable C is fixed separately by the speaker and the hearer, who do not always share the same contextual domain. Let us observe the above example again:

(19) a. Among John, Mary and Tom, who came to the party?

b. JOHN-wa ki-masi-ta

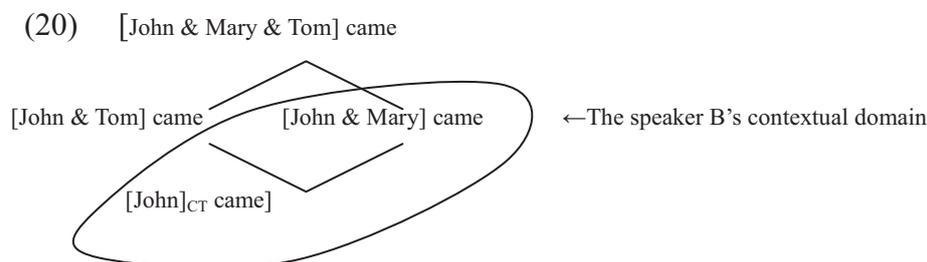

John-CT come-PRED.POLITE.PAST

[John]<sub>CT</sub> came.'

→ But Mary didn't come./It is possible that Mary didn't come.

The implicature in (19b) can be generated if the speaker does not know Tom. The

implicature is generated by narrowing the contextual domain:

In this situation, the speaker knows that John came and Tom didn't, but is not sure whether Mary came to the party. The narrowing of the contextual domain is meaningful in this case, because the speaker can highlight the fact that Mary didn't come. Although the implicature is a scalar implicature with a universal meaning (=21a), since there are only two members (i.e. John and Mary) in the contextual domain, the implicature is construed as a binary contrast whose quantificational force is existential, as shown in (21b).

- (21) a.  $\lambda C \diamond \forall x [C(x) \wedge x \neq \text{John} \rightarrow \neg \text{came}(x)]$  (where C contains John and Tom)  
 b.  $\exists x [x \neq \text{John} \wedge \neg \text{came}(x)]$

I would like to suggest that contrastiveness has the following cognitive principle:

- (22) The smaller the set of alternatives to John is, the more specific (existential) the contrastiveness becomes.

By adopting the idea that the contextual domain can be different between the speaker and the hearer, and that there is a correlation between the contextual domain and the specificity of contrastiveness, we can maintain the scalar alternative approach.

## 5. The Scalar Use of Contrastive *Wa*

Sawada (in press) claims that there are two types of contrastive *wa*: scalar contrastive *wa* and polarity contrastive *wa*. All of the examples belong to the polarity contrastive *wa* (non-scalar use) because intuitively, they do not invoke a scale like <x, y, z, ...> (where x is a focus marked element).<sup>4</sup> The scalar contrastive *wa*, on the other hand, can invoke a scale from the focused element. Sawada argues that scalar contrastive *wa* behaves like a mirror image of *sae* ‘even.’ Observe the following examples:

(23) (Context: Taro participated in an unofficial tennis tournament (=round robin). He competed with an amateur, a semi-professional and a professional.)

- a. Taro-wa    sirooto-ni            {*wa*/ ??*sae*}    ka-tta.  
Taro-TOP   amateur-DAT    CT/    even    win-PAST  
‘(lit.) Taro beat an [amateur]<sub>CT</sub>. /??Taro even beat an amateur.’
- b. Taro-wa    puro            -ni            {??*wa* / *sae*}    ka -tta.  
Taro-TOP   professional -DAT    CT / even    win-PAST  
‘(lit.) ??Taro beat a [professional]<sub>CT</sub> / Taro beat even a professional.’

The good cases in (23) are those in which the scalar contrastive *wa* picks a focused element that is construed as low on a given scale (in this case, the ranking of tennis players in terms of skills), and *sae* ‘even’ picks a focused element that is high on this scale.<sup>5</sup>

## 6. Empirical Facts Concerning the Scalar Use of Contrastive *Wa*

There are several pieces of linguistic evidence to support the idea that there is a scalar use of contrastive *wa*.

### 6.1. Standard of comparison with contrastive *wa*

If contrastive *wa* is attached to *yori*, the standard of comparison is construed as low on a given scale, as shown in (24b):

(24) a. Taro-wa Ziro-yori se -ga takai.

Taro-TOP Ziro-than height-NOM tall

‘Taro is taller than Ziro.’

b. Taro-wa Ziro-yori-*wa* se -ga takai.

Taro-TOP Ziro-than-CT height -NOM tall

‘Compared to Ziro, Taro is tall.’

→ Ziro is short. (Implicature from the standard of comparison)

→ Taro is not definitely tall. (Implicature from the main clause)

Notice that there is another implication as well: that ‘Taro is not definitely tall’ (Sawada 2007).

### 6.2. Predicate with contrastive *wa*

A low scalar value also arises when contrastive *wa* is attached to the predicate of a sentence (i.e. adjective, verb):

(25) Ame-wa furi-*wa* si-ta.

Rain-TOP fall-CT do-PAST

‘It [rained]<sub>CT</sub>.’

→ (Implicature): It didn’t rain a lot. (low amount)

### 6.3. Polar question (negative bias)

Positive questions with minimizers can express a negative bias (Borkin 1971, Ladusaw 1980, Giannakidou 2007, among others):

(26) Did Tom *lift a finger* to help?

(Bias: No, he didn’t.)

Contrastive *wa* can also be used in a positive question with a negative bias.

- (27) X daigaku-ni-wa ukari-masi-ta-ka.  
X university-DAT-CT pass-POLITE-PAST-Q  
'Were you accepted by [X university]<sub>CT</sub>?  
(Bias: I assume that you weren't.)

This fact supports the argument that scalar contrastive *wa* has a low scalar value.

## 7. The Difference between the Scalar and Non-scalar Uses of Contrastive *Wa*

So what can we say about the scalar approach in the end? It seems that the scalar alternative approach can explain the distinction between the scalar and non-scalar uses (e.g. (1)) in a unified way. Both uses construe a focused element as being at the **bottom** (or low) of a scale and generate a conventional scalar implicature (cf. *at least*; Geurts and Nouwen 2007). The only difference between the two uses is whether a scale is created based on logical entailment or pragmatic entailment (Hirschberg 1991). For example, [Tom and Mary came] logically entails [Tom came], but [Tom beat a professional] pragmatically entails that [Tom beat a semi-professional]. (It is possible that Tom beat a professional but he could not beat a semi-professional.) Thus we can say that in principle the implicatures of the scalar and non-scalar uses of *wa* are derived from the same pragmatic mechanism.

## 8. Conclusions

This paper investigated the varying implicatures of contrastive *wa* and tried to explain the variability of its implicatures in a unified way. As for the variability of uncertainty meaning inside the implicatures, it can be captured by the mechanism of the strengthening/exhaustivity (Hara and van Rooij 2007), similarly to the case of a conversational scalar implicature (e.g. Soames 1982; Horn 1989). As for the variability in quantificational force, I argued that the quantificational force of contrast *wa* can change if

the speaker narrows the contextual domain. Furthermore, I proposed as a general mechanism that the smaller the contextual domain is, the more specific the contrastive meaning becomes. I also showed that the scalar alternative approach can explain the behaviors of scalar and non-scalar uses of contrastive *wa* in a unified way. The difference between the two uses is due to the nature of the scale (i.e., whether it is a logical entailment scale or a pragmatic scale).

### Acknowledgements

I would like to thank Anastasia Giannakidou, Tommy Grano, Chris Kennedy, Chungmin Lee, Paul Portner, Harumi Sawada, Jun Sawada, Chris Tancredi, Reiko Vermeulen, and Katsuhiko Yabushita, and the audience at the CIL 18 for their helpful comments and suggestions.

### Notes

1. Of course, there is another implicature similar to (2a) and (2b):

(2a') But it is possible that Tom didn't come.

(2b') But Tom didn't come.

These are fundamentally the same as (2a) and (2b) in that they contrast John with Tom (a binary contrast).

2. Here, since the contrastive marker *wa* attaches to John, the alternatives are variables of type <e>. However, the contrastive *wa* can also target constituents such as verbs and postpositional phrases.

3. There are other approaches as well. For example, Tomioka (2007) proposes a contrastive speech act approach. In this approach, CTs operate at the level of speech acts and contrastive *wa* introduces a set of alternative Speech Acts.

4. It seems that the English only also has both scalar and non-scalar uses. (Beaver and Clark 2008 and references therein):

(i) David *only* wears a bow tie when teaching. (Beaver and Clark 2008:69)

(ii) At the time of the battle of Shiloh, MacPherson had *only* been a lieutenant colonel.

(Beaver and Clark 2008: 69)

Beaver and Clark (2008) take a position that the scalar and non-scalar uses of *only* are understood as special cases of a single meaning.

5. Sawada (in press) uses the ‘unlikelihood’ scale for the scalar contrastive *wa* in order to capture the similarities and differences between the particle and *sae* ‘even’.

k3716@cc.kyoto-su.ac.jp

## Abstract

The purpose of this paper is to introduce several key observations of both middle-age and modern Japanese language by Korean envoys. These observations regarding Japanese grammar, lexicon, dialects, phonetics, and the writing system are prevalent throughout their travel log, *Hae-Haeng-Chong-Jae*. Korean envoys made detailed notes regarding Sino-Japanese words. In particular, they transcribed some words using different Chinese characters, so we can assume the change in pronunciation of Sino-Japanese words. They also made detailed observations regarding the difference between Sino-Japanese words and Sino-Korean words, such as in the phonetic-reading of Chinese characters. In addition, they recorded the exceptional use of Chinese language by their Japanese contemporaries, for example, the semantic-reading of Sino-Japanese words and the Japanese reading method of deciphering Chinese text.

**Keywords:** Korean envoys, Japanese grammar, Japanese lexicon, Japanese dialects, Japanese phonetics, Japanese writing system.

## 1. Data

The text of *Hae-Haeng-Chong-Jae* (海行摠載) is a collection of travel records written by the hands of various Korean envoys, recorded between the end of the Goryeo (高麗) and the end of the Joseon (朝鮮) period.

For example Japanese words for names of places in *Hae-Haeng-Chong-Jae* and the transcription of some words are as follows.

- (1) a. 兩人皆着肩衣 倭音可當其妻。  
b. 倭音謂忠海 謂但多于微。  
c. 橫泊對馬島志志見浦 倭音시시미우라。 <扶桑錄(1655~6)>

This text comprises twenty-four travel logs (see Table 1), among which *Mun-Gyeon-Byeol-Rok* (聞見別錄) and *Hae-Yu-Rok* (海遊錄) are especially noteworthy for their observations regarding the Japanese language of that time.

My purpose is to analyze the nature of this text as a valuable source of knowledge regarding those observations made by the Korean envoys, especially regarding contemporary Japanese language.

*Hae-Haeng-Chong-Jae* in the national library of Korea can be used as research data, because this book is recognized as the closest version of the original text. The *Catalog of Old Books* (古書目錄, 1972) explains this book as follows.

(2) Call number: 한古朝90-2

Title: 海行摠載

Contents: 24 manuscripts, undated, 27.8 cm (height) × 19.2 cm (width), 28 letters in each 10 line.

## 2. Kana

In terms of the Japanese writing system (*Kana*), it is noted that from 47 to 50 letters—simplified versions of Chinese characters—are used by men and women, old and young alike. It was observed that *Kana* was similar to the Korean official reading *Idu* (吏讀) and *Hanguel* (諺文), because *Kana* and *Hanguel* were used with Chinese characters.

- (3) a. 其國以爲生佛。依方言以四十八字。〈海上錄〉(1597-1599, 鄭希得)  
 b. 依方言以四十八字。分作倭諺。 〈看羊錄〉(1597-1600)  
 c. 以倭人不解文字。依方言。以四十八字。 〈海槎錄〉(1636-7)  
 d. 國中所用諺文有四十八字。 〈海遊錄〉(1719)  
 e. 伊呂波四十七字。〈中略〉蓋本梵字十二摩多。三十五體文。而統四十七字。 〈青莊館全書〉(1795, 李德懋)

As for the number of *Kana*, most Korean envoys said that it was comprised of 48 letters.

- (4) 48字: 海上錄, 看羊錄, 海槎錄, 海遊錄  
 47字: 青莊館全書

In the Heian (平安) Period, ㄱ was distinguished into two: [e] and [ye], though [e] and [ye] were merged to [ye] at the end of the Heian period. This is why Korean envoys cited the number of *Kana* as 48 letters first and 47 letters latter. Furthermore the 五十音圖, like present, was figured in *Il-Sa-Jip-Ryak* (日槎集略, 1881) with translated *Hanguel*.

Observations regarding Japanese “home-made” Chinese characters (that is, characters existing only in Japan) can also be found throughout this text. National

there are some faults in (6a) and (6b), such as in character 鶴頂 (←鶴頸), and in pronunciation 海 (由未[jumi]←于未[umi]).

Other examples are observed in *Cheong-Jang-Gwan-Jeon-Seo* (靑莊館全書, 1795). Records of the pronunciation are listed below <Table 2>. When there is a mistake of transcription, I have suggested the accurate pronunciation.

<Table 2> Pronunciation of the Japanese proper word (聞見別錄, 海遊錄, 靑莊館全書)

Original character	Korean transcription of Japanese pronunciation	Original character or phrase	Korean transcription of Japanese pronunciation
山	夜麻 yama	冠	加牟里 kamori
海	由未 yumi(←umi)	烏帽	染浦是/汝甫是 yə <sup>m</sup> bosi/yəbosi
火	噫伊 huii	折烏帽	烏里染甫是/烏里汝甫是 oriyə <sup>m</sup> bosi/oriyəbosi
水	閔注/民註 mi <sup>n</sup> ᄁu/mi <sup>n</sup> ᄁu	振舞	候老麻伊 huromai(←hurumai)
紙	加未 kami	見物之美者	乂伊 yei
筆	侯代 hudəi	不好者	曰伊 wari(←warui)
墨	愁未 sumi	用力之聲	乂沙乂沙 yesə-yesə
硯	愁愁里 susuri(←suᄁuri)	用力之聲	夜沙夜沙 yasə-yasə
殿様	敦于沙麻 donosəma	夫則前者唱	高里臥沙 koriwasə
御前様	烏麻伊沙麻 omaisəma	後者應曰	高里臥是 koriwasi
上様	加美沙馬 kamisəma	徐行則緩聲	伊即于伊 iᄁugui(←isoge)
飯	眠時 myə <sup>n</sup> si	徐行	疏老疏老 soro-soro
鳥	時麻 sima	疾行	何要何要 hwayo-hwayo
肩衣	可當其婁 kata <sup>n</sup> giru	喫	央喝伊 a <sup>n</sup> gari
道袍	老服古 robokko	也, 乎(助動詞)	麻時 masi
唐袴	化可馬 hwakama		

In <Table 2>, there were examples of the noun ‘山 mountain’, adjective ‘良い good’, ‘悪い bad’, and the verb ‘急ぐ hurry’. In addition, an adverb ‘そろそろ slowly’, and the exclamation exchanged between workers such as ‘早早 hwayo-hwayo’ were included. In the case of exclamation, they noted that reduplication was used frequently.

In particular, there are some words transcribed using different Chinese characters.

<Table 4> Special use of Chinese character in Japan (聞見別錄)

	Sino-Japanese or usage in Japan	(corresponding) Sino-Korean or usage in Korea
進上	regardless of political status	the upper classes
臣	regardless of political status	Officials of superior class
Monk	法印	僧侶
A hotel of envoy	御宿	館所
A hotel of the lower classes	御所	處所

For example, 臣 was used for officials of the superior class in Korea, but the word is used regardless of status in Japan. In addition, Korean people used the honorific Chinese character 御 (Korean 'eo', Japanese 'on') exclusively when referring to a king, whereas the Japanese people liberally prefixed this character to anyone of exceptional honor. These differences in the use of Chinese characters resulted in occasional feelings of discontent and misunderstanding among the Korean envoys.

Careful notes were made regarding Chinese terms adopted into the Japanese language not existing in the Korean language.

For example, names of the Pisces are presented as follows.

- (8) 謂大口魚曰鱈。銀口魚曰鯨。道味魚曰鯛。古刀魚曰鮎、或曰鯖。魴魚曰紅魚、或曰鮠。鱧魚曰鮭魚。賊魚曰\*(魚+曷)。乾者曰干。生者曰鮮。沈鹽曰鹽漬。沈糟曰粕漬。 <海遊錄,下>

#### 4. Japanese reading method of deciphering Chinese texts

The Japanese method of deciphering Chinese texts semantically was not something practiced by Korean scholars. Because Japanese word-order is SOV, so Japanese used certain diacritics, such as 上下 (top and bottom), to indicate Japanese word-order and to adjust Chinese word-order to Japanese one.

Korean envoys cited that Japanese people had difficulty in reading the Chinese text, and this tendency resulted in that kind of reading.

- (9) 其爲讀書。不解倒結先後之法。逐字辛苦。下上其指。然後僅通其義。如

馬上逢寒食。則讀逢字於寒食之下。忽見陌頭楊柳色。則讀見字於楊柳色之後。文字之難於學習。又如此。 <海遊錄,下>

Korean scholars were accustomed to reading Chinese texts directly, that is, using the Korean phonetic readings of Chinese characters without changing the word-order of the original text.

For this reason, the Japanese method of reading Chinese texts prevalent at that time must have seemed to these envoys both unique and at the same time strangely inefficient. In this light, the value of this text lies in those observations regarding the differences between the Japanese and Korean language.

Because Korean word-order is SOV like Japanese, when Koreans decipher Chinese texts in their native tongue, it is necessary to change the word-order. But Koreans do not use the Japanese method, but simply read the texts phonetically and attach Korean auxiliary verbs, particles and endings (口訣) to facilitate understanding. Even now this system is maintained in Korea. So, this observation is due to the difference in method of reading the Chinese texts between Korea and Japan.

## 5. Japanese phonetic readings of Chinese character

### 5.1. Japanese pronunciation of the final (韻母)

(10) 日本讀字之音。如東冬陽庚青蒸之韻、則呼以二音。東字曰都于。陽字曰要于。青字曰世伊。江字曰乂伊。 <中略> 其他蕭豪韻及入聲、亦用二音。而時或與我國彷彿。 <海遊錄,下>

The Korean envoys also point out that the Japanese phonetic readings of such Chinese characters as 東, 陽, 青 are pronounced with long vowels, 'tou', 'you', 'sei', where as the Korean pronunciation of these same characters is given a short vowel followed by nasal close, 'dong', 'yang', 'cheong'. In a similar vein the envoys, focusing on the absence of glottal stops in Japanese phonetic readings, noted that while the Japanese pronunciation of 蕭 is 'shuku', two distinct syllables ending with a vowel, the Korean pronunciation is 'suk', a single syllable ending in a clear glottal stop. On the other hand, the Japanese pronunciation of the final (韻母) such as 眞, 文, 元, 先, 寒 and 刪 were noted as being more-or-less similar to the Korean reading.

## 5.2. unvoiced/voiced(清濁) and accent

Regarding the Japanese phonetic readings of Chinese characters, the Korean envoys observed that the Japanese system of pronunciation was purely unvoiced (純清), lacking any noticeable voiced sounds. Shin-Yuhan (申維翰) recorded about the Japanese sound of Chinese character in *Hae-Yu-Rok*, borrowing the words of Amenomori-Hosyu (雨森芳洲, 1668-1755).

- (11) 嘗與雨森東。論音譯異同。東曰。華音多濁。鮮音多清。日本之音。純清無濁。 <海遊錄,下>

Amenomori-Hosyu, a Japanese interpreter for incoming Korean envoys, stated that Japanese pronunciation is not sonant. Shin-Yuhan (申維翰) also commented that there is neither heavy sound nor vocal sound in Japanese pronunciation.

- (12) 然大抵倭人弄舌。本多輕浮而啾噪。語似鳥音。故全清而無濁。有淺聲而無重聲。如我國之於中華。不得其全濁也。 <海遊錄,下>

In like manner, J. F. van Overmeer Fisscher, visiting Japan at the same time as these Korean envoys, notes that the Japanese pronunciation of Chinese characters was completely unvoiced (輕清) making it difficult to understand.

Futhermore Shin-Yuhan (申維翰) noted that the Japanese reading of Chinese characters does not make use of tone, a crucial part of Chinese pronunciation.

- (13) 其爲字音、又無清濁高低。欲學詩者。先以三韻。積年用工。能辨某字高某字低。然後苟合成章。 <海遊錄,下>

However, the fact that contemporary Korean pronunciation of Chinese characters had likewise already abandoned the use of tones suggests that the intellectuals of Korea made such observations not on the basis of their native language but on the basis of Chinese, which was the real language of scholarship at that time.

This theory may be supported by certain records regarding the exchanges of Chinese poems between Korean and Japanese scholars, where it becomes apparent that the latter have great difficulty in making use of correct Chinese rhyme-characters. Therefore, it appears that Korean scholars tended to judge the ability of their Japanese neighbors insofar as they were able to accurately employ rhyme in their composition of

Chinese poems.

Contrary to this, however, Amenomori-Hosyu (雨森芳洲) retorts that it was not a lack of knowledge on the part of Japanese scholars but rather the fact that the Korean governmental-examination contained a section on Chinese rhyme which made the Koreans seem superior in this area.

## 6. Dialect

### 6.1. Vocabulary

A shipwrecked traveler makes various observations regarding certain Japanese dialects, among these one of the more interesting being the Ainu dialect. Exchanging questions and answers with an official interpreter, Korean recorded some words in *Pyo-Ju-Rok* (漂舟錄) of the Ainu dialect.

- (14) 一時歸現於松前太守前。餘在船中日。與書示探識其言語物情。而不盡詳知。問蝦夷通事者曰。蝦夷等。마즈마이云者何言耶。曰謂松前稱也。又問앙그랍에何耶。曰平安也。빌기의何也。美也。악기何也。水也。아비何也。火也。憑以倭語則大相不同。 <漂舟錄, 1. July. 1756>

Observing that the Ainu word for water is ‘akki’ while the word for fire is ‘abi’, they realized that this dialect was completely different from central Japanese.

The Ryukyu dialect appeared in *Hae-dong-je-guk-gi* (海東諸國記).

- (15) 肉시시, 魚이우, 鹿肉카우루시시, 猪肉오와시시, 兔肉우상가시시, 油으 부라, 鹽마시오, 醬미쇼, <中略> 面초라, 眼무, 鼻파나, 口크지, 耳미, 頭가난우, 手데, 足피산, 舌頭시자, 手指頭외빅, 頭髮카시리, 牙齒파, 花파라, 綠으오스, 黑구루스, 靑탄청, 牛우시, 馬우마, 猪우와, 鷄투리, 狗이노, 羊비즈자, 老鼠오야비쥬, 蛇파우, 龍타즈, 象자, 獅시시, 虎도라 <海東諸國記-語音翻譯, 1471>

Eoe-Um-Beon-Yeok (語音翻譯) has 169 words of the Ryukyu of the time.

### 6.2. Impression of dialect

A difference between the central tongue and the local tongue in Japanese language may be seen in comparative length.

(16) 日本方言。亦有京外之別。外方則差緩而實。京則愈輕而簡。馬島之人至江戸。多以言缺見笑。即如我京之於嶺邑也。 <海遊錄,下>

In terms of the differences between central Japanese and the various surrounding dialects, for example Tsushima dialect, the envoys, borrowing the words of Amenomori-Hosyu (雨森芳洲) note that while the former is …“relatively light and terse”, the latter are …“slow and thick”.

## 7. Conclusion

By analyzing this text I hoped to introduce several observations of the Japanese language by Korean envoys of the middle-ages and modern period. I do not here wish to say whether or not these observations are in fact accurate, but rather wish to point out that here in this text we find by far the greatest number of such observations in any given Korean travel log.

Considering that Korean intellectuals of this time were accustomed to the use of Chinese characters and language, it seems understandable why they would make such detailed notes regarding the exceptional use of Chinese by their Japanese contemporaries.

Not only this, but observations regarding Japanese grammar, lexicon, dialects, phonetics, as well as the writing system (*Kana*) are also prevalent throughout the text. It may be possible, through a comparison of this text with similar records left by European visitors, to judge just how far we may trust the accuracy of such observations.

# The Semantics of Cantonese Lexical Quantifier –*saai* ‘all’<sup>1</sup>

Peppina LEE Po-lun & PAN Haihua

City University of Hong Kong  
83 Tat Chee Avenue, Kowloon Tong, Hong Kong.  
[ctpllee@cityu.edu.hk](mailto:ctpllee@cityu.edu.hk); [cthpan@cityu.edu.hk](mailto:cthpan@cityu.edu.hk)

## Abstract

Adopting a syntax-semantics mapping approach, this paper studies quantification with a special reference to Cantonese verbal particle –*saai* ‘all’ which gives a universal meaning to its associated item. As a quantifying particle attached to the verb, –*saai* is categorized as a lexical type of quantification, hence a lexical quantifier under A-quantifiers (Partee 1987, 1991, 1995). Based on the quantificational pattern demonstrated by –*saai*, the paper argues that quantification should be considered as including two independent processes: the selection process and the mapping process. The selection process selects the item for association and should be separated from the mapping process which maps the relevant syntactic structure to the semantic tripartite structure. The quantificational pattern in the lexical quantifier –*saai* supports such a separation, where the selection of a constituent for association is determined solely by a grammatical function hierarchy to be proposed in this paper, which is then followed by the mapping process, determined either by the lexical semantics of the quantifier in question, or by focal mapping, and focal mapping only comes into play when the constituent selected from the hierarchy is in focus.

**Keywords:** syntax-semantics mapping, lexical quantification, selection process, mapping process, grammatical function hierarchy

## 1. The Problem

Partee (1987, 1991) differentiates D-quantification from A-quantification, where D stands for “determiner” and A for the cluster of adverbs, auxiliaries, affixes and argument-structure adjusters. Partee (1995) further divides A-quantification into two subtypes: true A-quantifiers, including both preverbal A-quantifiers and adverbs of quantification (Q-adverbs), along the lines of Lewis (1975) and Heim (1982), and lexical quantifiers which have an operator, quantificational in nature, applying to the verb or other predicate at a lexical level, with (potentially) morphological, syntactic and semantic effects on the argument structure of the predicate.

The distinction between A- and D-quantifiers is significant, as they represent different mechanisms of how surface syntax is mapped to semantic representations. In the case of D-quantification, the tripartite structure is syntactically determined: the determiner (D) as the operator, the noun phrase (NP), the restrictor and the VP, the nuclear scope (the matrix). Hence, we may say that the entire partition of D-quantification is not affected by semantic factors, and relies crucially on syntax. Unlike D-quantification, quantification by adverbials like *always*, *often* is less

---

<sup>1</sup> The results reported in this paper are partially supported by the Strategic Research Grant #7002061 and #7002189 from the City University of Hong Kong and RGC GRF projects (CityU 1501/05H, CityU 1514/06H) of Hong Kong government. The authors thus acknowledge the generous support of the relevant parties.

syntacticised. Except in some explicitly structured case where there exists an explicit operator or an explicit marking to indicate a division into restrictor and nuclear scope, e.g. *if*-clause and topic-focus structure (cf. von Stechow 1994, Berman 1994 and among others), in simple clauses, syntax is not the sole and crucial factor in determining its tripartite partition, as it is obvious that a positional variability in focus will affect the partition of the tripartite structure. The non-focused part will be selected to be the domain of quantification, with the focus being mapped to the matrix for A-quantifiers, thus, determining the mapping triggered to be focal mapping. Despite this important distinction, they do share one common feature: there is no differentiation between the selection of the item for association with the quantification in question (henceforth, *the selection process*) and the mapping process which determines the mapping from surface structure to semantic tripartite structure. The question now is whether all quantifications share the same pattern, that is having the above-mentioned selection process and the mapping process integrated with each other, particularly those subtypes which fall under A-quantification.

In this paper, adopting a syntax-semantics mapping approach, we study quantification performed by Cantonese verbal particle *-saai* ‘all’ which gives a universal or “all” interpretation to its associated constituent. We will argue for the separation of the selection process from the mapping process, in order to interpret all the *saai*-sentences correctly. *-Saai* as a verbal particle, which by its morpho-syntactic characterization, would be categorized as a subtype of A-quantifiers, “lexical quantifiers”, under Partee’s classification. However, the direct association of *-saai* with verbal arguments and its partial sensitivity to focus make its quantificational property distinct from true A-quantifiers. The quantificational pattern of *-saai* is spelt out as follows: the selection of a constituent for association is determined solely by a grammatical function hierarchy to be proposed in this paper, which is then followed by the mapping process, determined either by the lexical semantics of the quantifier or by focal mapping. Focal mapping comes into play only if the constituent selected by the grammatical function hierarchy is in focus; otherwise, the relevant mapping will be determined by the lexical semantics of *-saai*. The quantificational pattern of *-saai* thus leads us to arrive at an important theoretical claim --- the selection process needs to be separated from the mapping process, hence the necessity of a two-step process approach to quantification in natural language.

The remaining part of this paper is organized as follows: in Section 2, we will first show that Cantonese verbal particle *-saai* ‘all’ is a quantifier. In Section 3, we will briefly introduce the semantics of *-saai*. In Section 4, we will propose a grammatical function hierarchy from which *-saai* selects its item for association, and examine whether focus will affect such a selection. In Section 5, we will demonstrate the mapping of *-saai*, with and without the presence of focus. The theoretical claim resulted from the quantificational pattern demonstrated by *-saai* will be discussed in this section. Finally, Section 6 comes the conclusion.

## 2. Cantonese *-saai* ‘all’ as a Lexical Quantifier

Although only a few suffixes or particles can follow the resultative verb compound to form the construction “V + R + suffix/particle” like *chi-wan-le* ‘eat-finish-Perf’, *da-si-guo* ‘beat-dead-Exp’ in Mandarin Chinese, there are many such suffixes or

particles in Cantonese. Cheung (1972/2007) who is the first one having conducted a comprehensive study on Cantonese grammar includes 19 verbal suffixes in his study (cf. 7 aspectual verbal suffixes in Gao (1980) and 16 aspectual verbal suffixes and complements in Yue-Hashimoto (1993)). Cheung's verbal suffixes are referred to as "verbal particles" in M&Y (1994) who include 6 aspect markers and 29 verbal particles in their study. Most importantly, the rich inventory of Cantonese verbal suffixes or particles interacts among the four linguistic domains, namely quantification, focus, modality and aspect. Since this paper examines quantification, we will simply focus on quantifying verbal particle *-saai*, in order to examine its quantification structure and how it is related to current quantification theories.

Studies on Cantonese quantificational verbal suffixes/particles are sparse, with most of them descriptive in nature (cf. Cheung 1972, Gao 1980, Yuan 1993, Yue-Hashimoto 1993, Matthews & Yip 1994, etc.). Several studies have been conducted on *-saai* (cf. Mo 1993, Au Yeung 1996, Shi 1996, Teng 1996, etc.), which have given a solid foundation for future theoretical studies. Lee (1994) is the first who have adopted a quantificational approach to study *-saai*, and he points out that *-saai* functions as a universal quantifier, as illustrated in the example below.

- (1) (a) Ngo wui sik godi pinggwo.<sup>2</sup>  
 I will eat those apple  
 "I will eat those apples."  
 (b) Ngo wui sik-saai godi pinggwo.  
 I will eat-SAAI those apple  
 "I will eat up all those apples."

The presence of *-saai* in (1b) has given *godi pinggwo* 'those apples' a universal interpretation, which is otherwise absent in (1a) where *-saai* is not included. Hence, (1a) does not require all the apples denoted by the object to be eaten. Hence, based on sentences like (1), Lee considers *-saai* as a universal quantifier which gives a universal or "all" interpretation to its associated element.

In fact, the contrast between (1a) and (1b) leads to another question. Although *-saai* carries a quantificational meaning as suggested by Lee, besides being a quantifier, there still exist several possibilities, making it not necessarily a quantifier. Out of these possibilities, the most prominent one is considering its performing predication over events, which is a potential argument against the quantificational approach. If this were really the case, it would be predicted that the relevant meaning conveyed by *-saai* will be applied to the event in question. Such a prediction can be easily ruled out by examples like (2) below.

- (2) Keoi sik-saai di je.  
 s/he eat-SAAI the food  
 a. "S/he has completed the event of eating."  
 b. "S/he has finished all the food."

---

<sup>2</sup> All Cantonese Romanization in this paper follows the Romanization proposed by the Linguistic Society of Hong Kong in 1993.

Predication over events will give sentence (2) the interpretation in (2a), where *-saai* gives a completion sense to the event in question. Hence, what is required in (2a) is the eating event has completed, and it is not necessary that the food is completely consumed. On the other hand, following Lee, *-saai* can be taken as a universal quantifier, which quantifies over the object NP. What is required in (2b) will then be the total consumption of the food, and the eating event is thus completed. The interpretation of the sentence confirms that only (2b) not (2a) gives the correct interpretation to (2), and hence, along the lines taken by Lee, it is thus reasonable to treat *-saai* as a universal quantifier instead of its performing predication over events. Based on this, in the remaining part of this paper, *-saai* will be glossed as “all”, and *-saai* will be taken as a particle attached to the verb, and based on Partee’s classification of A-quantifiers, a lexical type, hence a lexical quantifier, a treatment which is on a par with Tang (1996).

Considering *-saai* as a lexical quantifier, the following three questions thus need to be answered.

- i. What exactly does *-saai* quantify over? In other words, what are the factors determining the selection of items for association?
- ii. How is the syntax of the sentences involving *-saai* mapped to its semantic representations?
- iii. How many steps does quantification involve?

### 3. The Semantics of Universal Quantifier *-saai* ‘all’

While adopting Lee’s analysis of *-saai* as a universal quantifier, Tang (1996) considers *-saai* as a lexical quantifier, and functions as a marker which makes distributivity obligatory. According to him, in quantification of *-saai* the event is marked as the distributee and the argument associated with *-saai* is selected to be the distributor distributing over the event. As *-saai* marks the event as the distributee having a scope under the distributor, Tang considers *-saai* to be an anti-quantifier, in the sense of Choe (1987). His proposal of *-saai* as an anti-quantifier is mainly to explain the following properties of *-saai*: (i) the divisibility requirement, (ii) the definiteness/specificity requirement, (iii) the telicity requirement; and (iv) the aspectual constraint, with the first two also mentioned in Lee (1994). Since the focus of this paper is to derive the mapping mechanism of *-saai*, we will not go into the details concerning its semantic properties. We will simply base on the *saai*-properties mentioned in Tang, and focus on the two which will affect the selection of *-saai* over its associated item, namely the definiteness/specificity requirement and the divisibility requirement. For a detailed description of properties of *-saai*, readers are referred to Tang (1996).

Following Lee (2004), we consider that as a universal quantifier, there exist two selectional restrictions for *-saai*: (i) based on Tang’s definiteness/specificity requirement, *-saai* requires its quantified constituent to be specific, and hence, it only selects definite NPs and NPs indefinite in form but specific in meaning (cf. (3ab)); and (ii) based on Tang’s divisibility requirement, being a universal quantifier, *-saai* requires its quantified constituent to be divisible (cf. (4abc)) (also cf. de Swart (1991) who is the first to propose a plurality condition on quantification).

(3) a. Keoi sik-saai go loeng wun faan.

- s/he eat-all those two bowl rice  
 “S/he has eaten all those two bowls of rice.”
- b. Luk go jan lei-saai.  
 six CL person come-all  
 “All those six people have come.”
- (4) a. \*Keoi maai-saai nei bun syu.  
 s/he buy-all this CL book
- b. Ngodei maai-saai nei bun syu.  
 we buy-all this CL book  
 “All of us have bought this book.”
- c. Ngo jam-saai bui seoi. (cited from Tang 1996)  
 I drink-all CL water  
 “I have drunk the whole cup of water.”

(3a) and (3b) involve definite NPs and NPs indefinite in form but specific in meaning, respectively, and the interpretation of the sentences show that *-saai* is able to select both, illustrating that *-saai* requires its selected NP to be specific in meaning, be it definite or indefinite in form. On the other hand, *-saai* selects neither the singular subject nor the singular object in (4a), and the grammaticality of the sentence can be improved by replacing the singular subject with a part structure in (4b), illustrating that *-saai* requires its quantified constituent to be divisible. The divisibility requirement of *-saai* is even more obvious in (4c) which involves a mass noun. According to Tang, (4c) shows that mass nouns can also be associated with *-saai*, as the mass noun *bei seoi* ‘the cup of water’ is divided into proper parts, in the sense of Krifka (1992), and the divisibility requirement is thus satisfied.

Regarding the scope of *-saai*, Lee (2004) proposes that the scope of *-saai* is IP, hence having the widest scope possible to be taken by these quantificational verbal particles. We will not go into the details concerning the relevant arguments, and simply adopt the scope interpretation proposal in Lee (2004). Considering the IP scope taken by *-saai*, we will assume that (i) the grammatical functional hierarchy derived from *-saai* represents the default hierarchy when all arguments and adjuncts are possible candidates to be selected by the quantifier, and (2) the same applies to other lexical quantifiers or quantificational verbal particles, as long as it is within their quantificational scope.

#### 4. The Selection of Items for Association by the Grammatical Function Hierarchy

In the following, we will demonstrate that the constituent with which *-saai* associates is selected by a grammatical function hierarchy, namely that *-saai* will select a constituent within its scope according to the hierarchy to be proposed below, under the condition that the selectional restrictions of *-saai* are not violated.

##### 4.1 Quantification over Subjects or Objects

It is argued in Tang (1996) that *-saai* demonstrates a locality effect, which suggests that *-saai* will associate with the direct argument if there is one; otherwise, it will associate with other elements in the argument structure, for instance, the external or spatiotemporal argument. A similar claim is made in Lee (1994, 1995) who thinks that *-saai* will only associate with the subject if the object is non-divisible and

non-referential. Along the same line, we think that the interpretation of *-saai* demonstrates a hierarchical order of objects over subjects, as shown below.

- (5) Keoidei maai-saai di syu.  
 they buy-all the book  
 “They have bought **all** the books.”  
 > “**All** of them have bought the books.”

In (5), when both the subject and the object satisfy the selectional restrictions of *-saai*, that is, with both being [+specific] and [+divisible], *-saai* selects the direct object (DO) over the subject, hence suggesting the following order: [+divisible] & [+specific] DOs > [+divisible] & [+specific] subjects

#### 4.2 *-Saai* Quantification with Verbal Compound Predicates

(6) involves a [-divisible] subject *nei* ‘you’ and a verbal compound predicate *fangaau* ‘sleep’.

- (6) Tausin soeng tong, nei ting dou fan-saai-gaau wo.  
 Just-now up class you listen arrive fall-all-asleep SFP  
 “In the class just finished, you felt so bored and fell asleep **completely**.”

The well-formedness of (6) demonstrates that when there is no appropriate argument or adjunct for *-saai* to associate with in the sentence, *-saai* can quantify over constituents other than arguments, namely the degree triggered by the predicate in question. In the example above, *-saai* quantifies over the degree to which the relevant event denoted by the verbal compound predicate *fangaau* is incurred, giving a meaning that the relevant event is realized to its fullest degree. In fact, the quantification of *-saai* over the degree denoted by the verbal compound predicates can be considered on a par with that of adjectival predicates, which will be discussed later. While the former describes the maximum degree or extent the event can be realized, the latter indicates the highest degree the property can be attained.

The question now is when we have a [+specific] and [+divisible] subject, will *-saai* associate with the subject or the verbal compound predicate?

- (7) Keoidei fan-saai-gaau laa.  
 they fall-all-asleep SFP  
 “**All** of them have fallen asleep.”  
 > “They have fallen asleep **completely**.”

The sentence above suggests a priority of [+specific] and [+divisible] subjects over verbal compound predicates, with *-saai* associating with plural subjects rather than verbal compound predicates. (7) simply requires all individuals denoted by the subject to have fallen asleep, and whether they have fallen asleep completely (or to their fullest degree) or not is not crucial. The reading here thus suggests that verbal compound predicates are less preferred than subjects. Hence, the above reveals an association order of the following: [+divisible] & [+specific] subject > degrees denoted by verbal compound predicates

Incorporating the above results into the hierarchy, we can arrive at the following.

- (8) [+divisible] & [+specific] DOs > [+divisible] & [+specific] subjects > degrees denoted by verbal compound predicates

#### 4.3 A Priority of DOs over IOs/Postverbal PPs/Preverbal PPs

-*Saai* demonstrates a hierarchical order of direct objects (DOs) over postverbal prepositional phrases (postverbal PPs).

- (9) Ngo fong-saai ngaamngaam maai godi syu hai go gei zoeng dang dou.  
 I place-all just buy those books on those few CL chair location  
 “I have placed **all** the books I just bought on those chairs.”  
 > “I have placed the books I just bought on **all** of those chairs.”

From the interpretation of the above sentence, we can see that quantifiers like *-saai* will select the DO instead of the postverbal PP, since (9) only requires all the books to be placed in a particular location as indicated by the postverbal PP, namely on those chairs, but it is not necessary the case that each of the chairs denoted by the NP within the postverbal PP must have the book(s) in question on it. This demonstrates a hierarchical order of DOs over postverbal PPs. Now consider the examples of indirect objects (IOs) and DOs.

- (10) a. Ngo sung-saai jicin di VCD bei keoidei.  
 I give-all old those VCD to them  
 “I have given **all** my old VCDs to them.”  
 > “I have given my old VCDs to **all** of them.”  
 b. Ngo sung-saai-faa bei keoidei.  
 I give-all-flower to them  
 “I have given flowers to **all** of them.”
- (11) a. Ngo bei-saai ngaamngaam maai godi syu keoidei.  
 I give-all just buy those book them  
 “I have given **all** the books I have just bought to them.”  
 > “I have given the books I have just bought to **all** of them.”  
 b. Ngo bei-saai-zin keoidei.  
 I give-all-money them  
 “I have given money to **all** of them.”

(10) and (11) involve IOs introduced by either a covert or an overt dative marker. When both the DO and the IO are [+specific] and [+divisible], the preferred reading is to associate with the DO, as shown in (10a) and (11a). On the other hand, when we have a bare noun DO and a [+specific] and [+divisible] IO, as exemplified in (10b) and (11b), the readings of the sentences show that *-saai* associates with the [+specific] and [+divisible] IO, due to the non-specificity of the bare noun DO. (10) and (11) reveal that when both IOs and DOs in PDC and IDOC constructions are possible candidates, quantification of *-saai* demonstrates a hierarchical order of DOs over IOs, hence a hierarchical order of direct arguments over indirect ones.

How about cases where we have a bare noun DO and with both IOs and postverbal directional PPs being possible candidates for *-saai*?

- (12) Ngo sung-saai-faa heoi di gungsi dou bei keoidei.  
 I send-all-flowers to the companies location to them  
 a. “I have sent flowers to **all** the companies for them.”  
 b. “I have sent flowers to the companies for **all** of them.”

The interpretations of (12) demonstrate that, when both postverbal PPs and IOs are present in the sentences, the relevant interpretations are ambiguous between (a) and (b). This suggests that it is reasonable to consider postverbal PPs and IOs logically occupying the same position in the hierarchy, leading to the two being possible to take scope over one another.

Based on all the above, we then come up with a hierarchical order of *-saai* as follows: DOs > IOs/postverbal PPs > subjects > degrees denoted by verbal compound predicates.

Regarding the hierarchical order between preverbal prepositional phrases (preverbal PPs) and subjects, the examples below show that the former have a higher priority over the latter.

- (13) a. Ngodei gei go tung keoi faan-saai-min.  
 We few CL with him/her over-all-face  
 “**All** of us are in bad terms with him/her.”  
 b. Ngo tung keoidei gei go faan-saai-min.  
 I with they few CL over-all-face  
 “I am in bad terms with **all** of them.”  
 c. Ngo tung keoi faan-saai-min.  
 I with him/her over-all-face  
 “I am **totally** in bad terms with him/her.”  
 d. Ngodei tung keoidei gei go faan-saai-min.  
 we with they few CL over-all-face  
 “We are in bad terms with **all** of them.”  
 > “**All** of us are in bad terms with them.”

(13a), (13b) and (13c) demonstrate that *-saai* will select either the [+specific] and [+divisible] subject or the preverbal PP with a [+specific] and [+divisible] NP, if there is one, with the degree denoted by the verbal compound predicate being the last option. (13d) demonstrates that when both subject and the NP in the preverbal PP are [+specific] and [+divisible], *-saai* will quantify over the NP in the preverbal PP instead of the subject.

Finally, the interpretation of (14) below demonstrates a hierarchical order of IOs over preverbal PPs.

- (14) Ngodei hai gogei go deifong sung-saai-syu bei keoidei.  
 We at those CL places give-all-books to them  
 “We have given books to **all** of them in those places.”  
 > “We have given books to them in **all** those places.”

Both preverbal PPs and dative arguments are possible candidates of *-saai*, since the bare

noun DO in the sentence is [-specific], thus not a possible candidate for *-saai*. *-Saai* is found to select the dative argument instead of the preverbal PP in the sentence, supporting a hierarchical order of IOs > preverbal PPs.

From the above, we arrive at the conclusion that the association of *-saai* demonstrates the following hierarchical order in eventive sentences.

(15) The Hierarchy for Association of *-saai* in Eventives

DOs > IOs/postverbal PPs > preverbal PPs > subjects > degrees denoted by verbal compound predicates

#### 4.4 *-Saai* with Statives

Previous analyses argue that when *-saai* occurs with adjectival predicates, the predicates are required to denote a change of state (cf. Lee 1994, Teng 1996, Tang 1996, etc). However, this requirement is too strong. Following Pan&Man (1998), we consider that *-saai* can quantify over the degree denoted by adjectival predicates, and hence, it can co-occur with any adjectival predicate as long as it is possible to trigger a degree set for quantification. Consider the occurrence of adjectival predicates and *-saai* below.

- (16) Nei co-saai. (from Pan & Man 1998)  
 you wrong-all  
 “You are **completely** wrong/**all** wrong.”

(16) demonstrates that *-saai* can quantify over the degree denoted by an adjectival predicate, giving a reading that the relevant property has reached its maximum degree. The predicate above does not necessarily indicate a change of state, as the individual may have entered into the relevant state long before.

However, when there is an appropriate argument for *-saai* to quantify over, *-saai* will select such an argument, instead of the degree associated with the predicate.

- (17) Keoidei co-saai.  
 they wrong-all  
 “**All** of them are wrong.”  
 > “They are **completely** wrong/**all** wrong.”

- (18) Ngodei suk-saai godi jan.  
 we familiar-all those person  
 “We are familiar with **all** those people.”  
 > “**All** of us are familiar with those people.”  
 > “We are **completely** familiar with those people.”

(17) shows that *-saai* will associate with the [+divisible] and [+specific] subject, instead of the degree denoted by the adjectival predicate. *-Saai* will only associate with the degree denoted by the adjectival predicate when the subject is not a possible candidate for quantification, showing a hierarchical order of subjects > degree denoted by adjectival predicates. On the other hand, with *suk* ‘familiar’ taken as an adjective in (18), there are three candidates possible to be associated with *-saai*, namely the subject *ngodei* ‘we’, the object *godi jan* ‘those people’ and the degree triggered by the

adjectival predicate *suk*. The preferred reading of (18) is having *-saai* associated with the object, giving the object a universal interpretation. Hence, (18) is interpreted as “We are familiar with all those people”, instead of “All of us are familiar with those people” with *-saai* associated with the subject and “We are completely familiar with those people” with *-saai* associated with the degree triggered by the adjectival predicate.

Based on the above, we can see that when there is an appropriate argument for *-saai* to quantify over, *-saai* will select the argument, instead of the degree associated with the predicate, and like eventives, direct object is still preferred over the subject. Despite the fact that NP-quantification is still the preferred interpretation in the case of *-saai*, the possibility of *-saai* quantifying over the degree triggered by the adjectival predicates does exist, and hence, empirical problems would exist if the claim that *-saai* cannot occur with adjectival predicates without a change of state were true. Moreover, (17) and (18) demonstrate the following hierarchical order: [+specific] and [+divisible] objects > [+specific] and [+divisible] subjects > degrees denoted by adjectival predicates. Such a hierarchical order is along the same line as that of the eventives.

Furthermore, the same hierarchical order between postverbal PPs and subjects can be found in adjectival predicates, as shown below.

- (19) a. Keoi lek-saai hai nei lam-dak-dou ge sei je dou.  
 s/he smart-all at you think-can-arrive POSS bad thing location  
 “S/he is smart at **all** the bad things you can think of.”
- b. Keoidei lek-saai hai nei lam-dak-dou ge sei je dou.  
 they smart-all at you think-can-arrive POSS bad thing location  
 “They have their talent spent on **all** the bad things you can think of.”  
 > “**All** of them have their talent spent on the bad things you can think of.”

While (19a) shows that *-saai* can select the postverbal PP, (19b) clearly shows that *-saai* will select the postverbal PP over the subject. The above thus reveals the following hierarchical order.

- (20) [+specific] and [+divisible] objects > Postverbal PPs > [+specific] and [+divisible] subjects > degree denoted by adjectival predicates

For the case of stative verbs, no matter whether they are individual-level or stage-level, the quantificational pattern is similar to that of eventive predicates, and hence, the details will not be repeated here.

Generalizing from the above discussions on *-saai* with statives and eventives, we can now come up with the following hierarchy.

(21) The Hierarchy for the Association of *-saai* ‘all’

DOs > IOs/postverbal PPs > preverbal PPs > subjects > degrees denoted by verbal compound predicates/stative predicates

(21) represents the hierarchical order of association for the lexical quantifier *-saai*, and the relevant association is subject to the selectional restrictions of *-saai*, namely the divisibility condition and the specificity condition. The hierarchy simply shows that

when all verbal arguments and the degree triggered by the predicate within the IP-scope are possible candidates for *-saai*, the hierarchical order of association will be that of (21), i.e. the candidate at a relatively higher position in the hierarchy will be selected. In other words, when all the candidates in the hierarchy satisfy the selectional restrictions of *-saai* and possible to be selected by it, the one occupying the higher position in the hierarchy will always be the preferred reading without appealing to any contextual accommodation; on the other hand, if those occupying the lower positions in the hierarchy are selected, the lower the position in the hierarchy, the less preferred will be the reading, and more contextual accommodation may be needed then.

#### 4.4 Can Focus Affect the Selection Determined by the Grammatical Function Hierarchy?

In (21) above, we have shown that when there is no focus, the selection of items for association from the grammatical function hierarchy demonstrates that association of *-saai* is determined by grammatical relations. If grammatical relation is an important factor in determining *saai*-quantification, a crucial question now is whether the lexical quantifier *-saai* behave like other A-quantifiers in the way that semantic factors like focus will influence the selection determined by the grammatical function hierarchy.

In the following, we will show that an introduction of focus fails to affect the selection determined by the grammatical function hierarchy. All focused constituents in this paper are marked by the notation of boldfaced [ ]f. Since prosodic focus or phonologically stressed focus is not that easy to be recognized in Cantonese, the presence of the copula *hai* ‘be’, a kind of established focus construction in Cantonese or Chinese (cf. M&Y, Liu & Xu 1998 and among others), will be used wherever necessary, so as to make the discussion more convincing in cases where the interaction of *-saai* with focus is studied.

Concerning the interaction of *-saai* with focus, we will first consider the case of subjects and objects.

(22) Hai [**keoidei**]f lo-faan-saai zigei di je.

Be they take-back-all own plural stuff

a. “They (not others) have taken **all** their own stuff.”

b. Not “**All** of them have taken their own stuff (but not necessarily all).”

According to the grammatical function hierarchy, when both the subjects and the DOs are [+divisible] and [+specific], *-saai* selects the DO over the subject. When focus is placed on the subject, there are two possibilities: *-saai* associate (a) with the [+divisible] & [+specific] DO or (b) with the focused subject. If it is case (a), those denoted by the subject, as a group, have completed the action or finished the quantity denoted by the DO. The relevant sentence will be true as long as the quantity denoted by the DO have all been finished. If it is case (b), the reading will be “all individuals denoted by the subject have performed the event”, and it is not necessarily true that they have completed the action or finished the quantity denoted by the DO. The relevant sentence will be true as long as all individuals denoted by the focused subjects are involved in the action denoted by the predicate.

The interpretation of (22) shows that when the subject is in focus and the DO is

[+specific] and [+divisible], *-saai* still associates with the DO, giving (22) the reading of (22a) instead of (22b). With *-saai* quantifying over the DO, (22a) requires all the quantity denoted by the DO “their own stuff” to be taken by the subject, which gives the desired interpretation to (22). Hence, it seems that the grammatical function hierarchy is still the crucial factor in determining the quantification of *-saai*, and once the DO is selected according to the hierarchy, focus fails to override it.

Notice that unlike the prediction made by the grammatical function hierarchy, when focus is competing with the selection done by the grammatical function hierarchy, it is not possible for *-saai* to select the focus, which will lead to a misinterpretation of the sentence in question. Hence, the symbol “not” is used here to rule out the possibility of the relevant interpretation, instead of the symbol “>” which indicates a tendency.

Now, consider cases where we have focus placed on the postverbal PPs and preverbal PPs.

- (23) Ngo fong-saai ngaamngaam maai godi syu hai [go gei zoeng dang dou]f.  
 I place-all just buy those books on those few CL chair location  
 a. “It is on those chairs where I placed **all** the books we have just bought.”  
 b. Not “I have placed the books we have just bought on **all** those chairs.”
- (24) Keoidei hai hai [go gei gaan syuguk]f maai-saai godi syu.  
 they be at those few CL bookstores buy-all those books  
 a. “It is in those bookstores where they bought **all** those books.”  
 b. Not “They bought those books in **all** those bookstores.”

In (23) and (24), when there is no focus, *-saai* by default will select the [+specific] and [+divisible] DO instead of the preverbal and postverbal locative adjuncts. The discussion so far suggests that semantic focus fails to override the quantification of *-saai* determined by the grammatical function hierarchy, and hence, it is reasonable to predict that *-saai* will select the DO, as determined by the grammatical function hierarchy, instead of the focus. This prediction is in fact borne out in (23) and (24). Neither focus placed on postverbal PP nor on preverbal PP can override the selection determined by the grammatical function hierarchy, with *-saai* still associating with the [+specific] and [+divisible] DO, according to the grammatical function hierarchy, giving the interpretation of “It is on those chairs where I placed all the books we have just bought” and “It is in those bookstores where they bought all those books,” in (23a) and (24a), respectively. (23) does not give the reading as indicated by the association with focus, cf. (23b). It does not require the books to be placed all over those chairs, as it allows the possibility that the speaker has just placed the books on one or two of those chairs. Similarly, (24) only requires them to buy all the books in those bookstores, and whether the buying event occurred in all bookstores or simply one single bookstore is not an issue. This is what is given in (24a), since *-saai* in (24a) quantifies over “those books”, as long as all of them are bought, the sentence would be true, while (24b) requires the buying event to be preformed in all bookstores, which is not consistent with the fact. Both sentences reveal that the selection determined by the grammatical function hierarchy can’t be altered by focus.

Therefore, the above discussion confirms our claim that in the case of *saai*-quantification, the grammatical function hierarchy always comes into play first,

with focus failing to change the selection determined by the grammatical function hierarchy; otherwise it would lead to misinterpretation of the sentence.

## 5. The Syntax-semantics Mapping of *-saai*

In the above sections, we have shown that the selection of the item for association in quantification is determined by the grammatical function hierarchy, and focus fails to change such a selection. The question now is what are the factors which determine the mapping of *-saai*? In what ways does the selection by the grammatical function hierarchy determine the tripartite partition of *-saai*? If focus cannot change the selection by the grammatical function hierarchy, will focal mapping come into play at all?

### 5.1 The Syntax-semantics Mapping of *-saai* when there is No Focus

Assumed that the selected constituent is the DO, *-saai* will have the following two possible quantificational structures:

#### (25) Two Possible Quantificational Structures for Lexical Quantifier *-saai*

Assume that the constituent selected by the grammatical function hierarchy is the direct object (DO).

a.  $\lambda PQx [x \in [DO]] [P(\text{Subj}, x)]$

b.  $\lambda PQx [P(\text{Subj}, x)][x = DO]$

where Q is the lexical quantifier and under such a case, *-saai*, x is a member of the set denoted by the selected DO or other constituents selected, according to the grammatical function hierarchy.

For the sake of simplifying the formulation, (25) simply assumes the selected constituent to be the DO, and similar structures can be extended to other selected constituents. What is crucial here is that (25a) and (25b) differ in whether the selected DO or other selected constituents is mapped to the restrictor or the matrix. (25a) has the selected constituent mapped to the restrictor, in order to set up a domain for the quantifier to quantify over. Everything else within the scope of the quantifier in question will then be mapped to the matrix, such that all members who belong to the set denoted in the restrictor are related to the situation/event denoted by the matrix. On the other hand, (25b) has the selected DO mapped to the matrix, with everything else mapped to the restrictor to set up the domain for quantification. The quantificational structure represented in (25b) is in fact on a par with the focus-background partition, which has the focus mapped to the matrix, and everything else in the sentence to the background. The interpretation of (25b) will be for the members which have the property denoted in the restrictor, they must all be the selected DO.

In order to derive the syntax-semantics mapping of *-saai*, we will first consider the example with the selected item to be the subject.

(26) Go paai hoksaang fan-saai-gaau.

that row student fall-all-asleep

a. SAAIx  $[x \in [\text{that row of students}]] [\text{Fall-asleep}(x)]$

“For all x’s who are students sitting in that row, they have fallen asleep.”

b. %SAAIx [Fall-asleep(x)] [x = that row of students]

Lit.: “For all x’s who have fallen asleep, x is that row of students.”

In (26), according to the grammatical function hierarchy, since we have a verbal compound predicate *fangaau*, the [+divisible] and [+specific] subject will be selected. (26a) is the meaning represented by the possibility in (25a), and the reading is for the selected subject – ‘that row of students’ - all the members of the set denoted by the selected subject are involved in the situation “having fallen asleep”. The selected subject is mapped to the restrictor. In other words, *-saai* quantifies over the set of individuals denoted by the restrictor and each member of the set has the property P denoted by the matrix or is relevant to the event/situation described by the nuclear scope.

Assume the following scenario. 200 students are sitting in a lecture hall and attending a public lecture, and the students have occupied at least 20 rows of seats in the hall. Sitting at row 17, my friend has noticed a very interesting phenomenon. S/he points at a particular row in front of him/her, let’s say row 10, and utters (26). In order to make (26) true, what is required is all the students sitting in row 10 have fallen asleep, and whether other students in the lecture hall have also fallen asleep or not is not our concern. This is what is conveyed in (26a). On the other hand, if (26) is interpreted as (26b), since the subject is mapped to the matrix, what constitutes the restrictor is the set of students in the lecture hall who have fallen asleep, and (26) will be true under the condition that only students sitting at row 10 have fallen asleep. What is more important is it does not allow students sitting at other rows to have fallen asleep, and hence, an exclusive reading is imposed on the nuclear scope “that row of students”. This interpretation is too strong, since the sentence will be true, as long as all the students sitting at row 10 have fallen asleep, and it should allow such a situation having occurred to students sitting in rows other than row 10, too.

Consider another example where we have the selected constituent to be the DO.

(27) Ngo nei go jyut wui se-saai go gei pin man .

I this CL month will write-all those few CL paper

a. SAAIx [x ∈ [those papers]] [Write (I, x) within this month]

“Within this month, for all x’s which are those papers, I will write them.”

b. %SAAIx [Write(I, x) within this month]] [x = those papers]

Lit.: “Within this month, for all x’s which I will write, x is those papers.”

According to the grammatical function hierarchy, *-saai* will associate with the DO which is [+specific] and [+divisible] in (27). (27a) represents the correct meaning of (27), and it states that “for the things denoted by the DO, I will write them all”. Hence, what the sentence concerns is whether the subject will write the set of things denoted by the DO or not. It allows the case that the subject will write other things besides those papers. However, the interpretation in (27b) does not allow the case that the subject will write other things besides those papers within this month, since the representation in (27b) will give (27) the meaning that “for all the things which the subject will write during this month, they all have to be those papers”. Hence, only (27a) not (27b) gives the correct mapping for *-saai*.

Hence, both examples of the selected subject and the DO support the claim that selected constituents are mapped to the restrictor in the case of *-saai*. Finally, consider an example where we have *-saai* associated with the degree predicate triggered by the adjectival predicate.

(28) Nei co-saai.

you wrong-all

“You are completely wrong/all wrong.”

a. SAAIq [q ∈ Degree(Be-wrong)] [Be-wrong(you) at q]

“For all the degrees q of being wrong, you are wrong at degree q.”

b. %SAAIq [Be-wrong(you) at q] [q = Degree(Be-wrong(you))]

Lit.: “For all q’s which are the degrees of your being wrong, q is the degree of your being wrong.”

According to the grammatical function hierarchy, since the subject in (28) is [-divisible], *-saai* will select the degree denoted by the adjectival predicate as its last resort. Notice that what *-saai* quantifies over is the degree denoted by the adjectival predicate, since if *-saai* quantifies over the predicate directly, we will have the incorrect interpretation of “For all the properties the subject has, they are those denoted by the adjectival predicate”. That is, an exhaustive or “only” meaning will be given to the relevant properties. Under (28a), the degree denoted by the predicate is mapped to the restrictor, with everything else in the sentence mapped to the matrix. Hence, the interpretation of (28a) is “The individual realizes the property denoted in the matrix which is being wrong to a maximum degree”. However, if the degree predicate is mapped to the matrix, and with everything else in the sentence to the restrictor, as in (28b), the interpretation is simply semantically awkward.

Summarizing from the examples above, we propose the following syntax-semantics mapping for *-saai*.

(29) A Mapping Hypothesis for the Universal Lexical Quantifier *-saai* ‘all’

For the universal lexical quantifier *-saai*, the item selected from the grammatical function hierarchy will be mapped to the restrictor, in order to set up a domain for quantification such that the event/situation denoted by the remaining parts of the sentence is related to all the members in the set denoted by the selected constituent. Hence, the representation is simplified as follows:

SAAIx (x ∈ [[the selected constituent]]) (IP (including x))

OP                      RESTRICTOR                      MATRIX

where x is a member of the set denoted by the constituent selected according to the grammatical function hierarchy.

The mapping mechanism of *-saai* shows that whether the lexical quantifier demonstrates a quantificational structure (25a) or (25b) is determined by the lexical semantics of the quantifier in question. For *-saai*, as a universal quantifier, the selected constituent serves as setting the domain for quantification, hence mapped to the restrictor.

## 5.2 Can Focus Affect the Mapping of *-saai* if the Selected Constituent is in Focus?

However, the story does not end here, as one question still remains to be answered: can focus affect the mapping of *-saai* if the constituent determined by the grammatical function hierarchy is in focus? In other words, whether focus-background partition will be triggered or the relevant mapping is still determined by the lexical semantics of the quantifier in question. Consider the sentence below with the selected DO in focus.

- (30) Keoidei tai-saai hai [go gei bun syu]f laa.  
they read-all be those few CL book SFP
- a. %SAAIx [ $x \in$  [those few books]] [Read(they, x)] (mapping determined by the lexical semantics of *-saai*)  
Lit.: “For those few books, they have read them all.”
- b. SAAIf [They have read f] [f = those few books] (focus-background partition)  
“For the stuff they have read, they are all those few books (and nothing else).”

According to the grammatical function hierarchy, *-saai* interprets with the [+divisible] and [+specific] DOs. If focus does not affect the mapping, then the DO will be mapped to the restrictor, as shown in (30a), and the interpretation becomes “for those few books, they have read them all.” Does such an interpretation give the correct reading to (30)? The answer is no, as the correct reading for (30) should be (30b), which is “for the stuff they have read, they have to be those few books”, resulting in the exclusive reading on “those few books”. (30a) and (30b) correspond to two different restrictor sets, leading to two different readings: (30a) does not give any exclusive reading on the selected DO “those few books”, as long as the subject has read all of those few books, (30a) will be true; on the other hand, in (30b), since the selected DO is mapped to the focus part (matrix), an exclusive reading will be imposed on the selected DO due to the reason that the background (the restrictor set) has been made into the set of books which they have read. Comparing (30a) with (30b), we can see that having focus on the selected DO gives (30) an additional meaning of exclusiveness on the DO, and hence, (30b) not (30a) is the desired reading of (30). Therefore, (30) demonstrates that the tripartite structure mapping of *-saai* is determined by focal mapping when the constituent selected by the grammatical function hierarchy is in focus. Under such a case, the selected DO which is in focus is mapped to the matrix (the focus part), with the remaining of the sentence mapped to the restrictor (the background part), giving a meaning of “for all x’s which are involved in the event/situation described in the restrictor, it is the DO”. Such a mapping is the opposite to the non-focused case when the DO is not in focus, since the quantified DO will be mapped to the restrictor, with the remaining part of the sentence to the matrix, hence, lacking an additional meaning of exclusiveness on the selected DO. Hence, the crucial factor which contributes to the difference between the focused and non-focused cases is the different mechanisms that determine the mapping: the former case involves the focal mapping and the latter the particular mapping triggered by *-saai*.

A similar feature is found in the case where we have a focused IO and a verbal compound predicate.

- (31) Ngo sung-saai-syu bei [keoidei]f.

- I give-all-book to them
- a. %SAAIx [x ∈ [them]] [Give-books-to(I, x)] (mapping determined by the lexical semantics of *-saai*)  
Lit.: “For them, I have given books to them all.”
  - b. SAAI<sub>f</sub> [I give books to f] [f = them] (focus-background partition)  
“I have given books to all of them (and no one else).”

The grammatical function hierarchy selects the IO to be the associated constituent in (31). Assuming that all selected constituents which are in focus should trigger the same partition, one would predict that focus-background partition will be triggered under (31), since the selected IO is in focus. This prediction is borne out. Consider (31a) first. The representation in (31a) is the mapping determined by the lexical semantics of *-saai*, since the selected IO is mapped to the restrictor. Hence, the reading given by (31a) is “for them, I have given books to them all”, and there is no exclusive meaning on the selected IO “them”, since as long as all individuals denoted in the restrictor have received books from the speaker, (31a) would be true. (31a) allows individuals other than the IO to receive books from the speaker, which is in fact not the desired reading of (31). Making the selected IO in focus in fact has induced an additional reading of exclusiveness on the selected IO, and hence, (31) should be interpreted as “All of them (and only them) have received books from the speaker”. Only the focus-background partition in (31b) would give such an interpretation. Therefore, on a par with (30), when the selected IO is in focus, focus association will occur, with focus-background partition triggered. *-Saai* associates with the focused IO, which is then mapped to the matrix (the focus part), giving an additional exclusive meaning.

The same feature is found in cases where we have focus placed on the subject.

- (32) Hai [go gei go hoksaang]f lo-saai-tips.  
be those few CL student get-all-tips
- a. %SAAIx [x ∈ [those students]] [Get-tips(x)] (mapping determined by the lexical semantics of *-saai*)  
Lit.: “For those students, all of them have got tips.”
  - b. SAAI<sub>f</sub> [f have got tips] [f = those students] (focus-background partition)  
“All of those students (and no one else) have got tips.”

(32) involves no [+specific] DOs. The grammatical function hierarchy has determined *-saai* to associate with the [+specific] and [+divisible] subject. As the selected constituent is in focus, we would predict that like (30) and (31), it is focal mapping that is triggered under these cases. Such a prediction is again borne out. The contrast between (32a) and (32b) lies in whether an additional meaning of exclusiveness exists on the selected subject or not if it is in focus. The desired reading of (32) is “All those students and only they have got tips (from someone)”, which is what is conveyed by the representation in (32b). Therefore, focus-background partition in (32b) again gives the correct interpretation to (32) when the constituent selected by the grammatical function hierarchy, the focused subject in this case, is in focus. On the other hand, (32a) represents the mapping triggered by the lexical semantics of *-saai* and it gives an interpretation that as long as those students have got tips (from someone), whether there

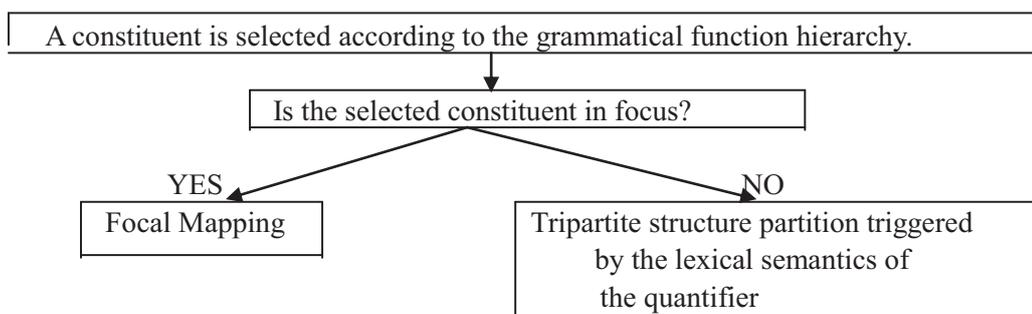

are other students or no students at all who got tips as well will not affect the truth value of (32), which is not consistent with the fact.

The above shows that in the case of *-saai*, when the constituent selected according to the grammatical function hierarchy is in focus, rather than using the mapping triggered by the lexical semantics of *-saai*, focal mapping will come into play instead. From the examples above, we can conclude that focus-background partition will be triggered if the selected constituent is in focus, and the focused selected constituent will then be mapped to the matrix (focus part). Since the lexical semantics of *-saai* suggests the selected constituent mapped to the restrictor, focus-background partition triggered by the selected constituent in focus gives a kind of mapping which is the opposite to the mapping triggered by the lexical semantics of *-saai*, and an exclusive reading on the focused selected constituent, which is absent when there is no focus, is found in the *saai*-sentence.

### 6. Theoretical Consequence: A two-step mechanism for quantification

From the discussion so far, we can see that in the case of the lexical quantifier *-saai*, focus fails to change the selection conducted by the grammatical function hierarchy: DOs > IOs/postverbal PPs > preverbal PPs > subjects > verbal compound predicates/stative predicates. *-Saai* can only associate with the focus when the constituent selected, according to the grammatical function hierarchy, is in focus, showing that the grammatical function hierarchy always comes into play first before focus association. When focus association occurs, what is triggered will be a focus-background partition, instead of the mapping triggered by *-saai*. The mapping regarding *-saai* can thus be summarized as follows:

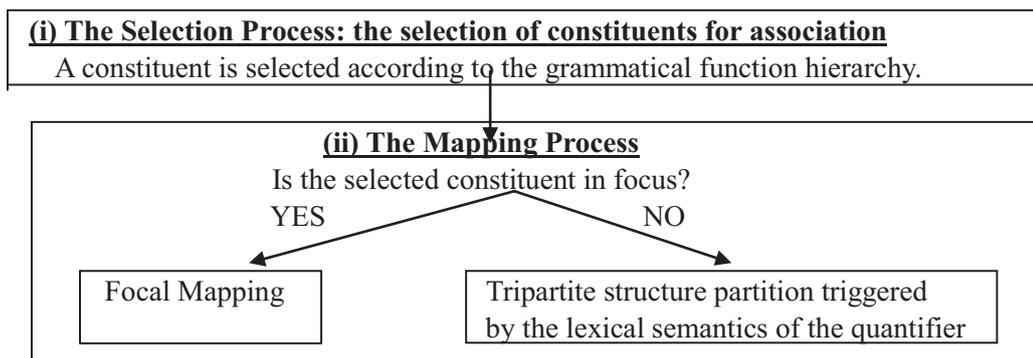

#### (33) Syntax-semantics Mapping of Lexical Quantifier *-saai* ‘all’

(33) clearly demonstrates that focus fails to change the constituent selected by the grammatical function hierarchy. This suggests that the selection process by the grammatical function hierarchy and the mapping process, no matter whether it is conducted by focal mapping or by the mapping determined by the lexical semantics of *-saai*, must be separated from each other. In other words, the quantificational pattern of *-saai* shown in (33) suggests that quantification involves two processes which are the selection of items for association (*the selection process*) and the mapping process, and the two must be separated. Since in the case of *saai*-quantification, focus fails to override the selection conducted by the grammatical function hierarchy, the selection of constituents for association according to the grammatical function hierarchy must be the

first step in quantification, and it is after the selection that the mapping process comes into play. Moreover, (33) also shows that the focal mapping will be triggered only if the selected constituent is in focus; otherwise, the mapping will be determined by the lexical semantics of the quantifier. Separating the selection process from the mapping process, we can have (33) reformulated as (34) below to reflect the two-step mechanism:

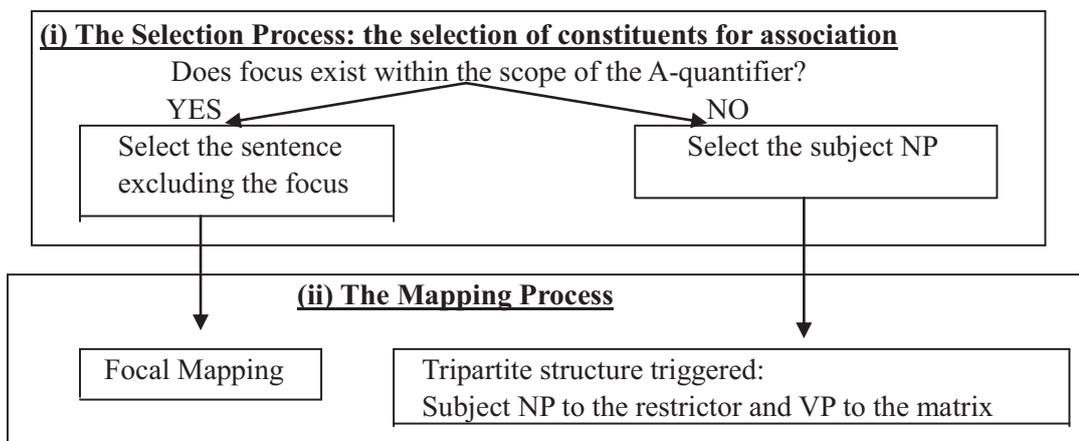

(34) A Two-step Mechanism in Lexical Quantifier –*saai* ‘all’

(34) differs significantly from (33) in that it demonstrates clearly that *saai*-quantification is divided into two steps, with the mapping process following the selection process.

Now the question is if the two-step mechanism applies to *saai*-quantification, we should be able to apply the same mechanism to D-quantifiers and other A-quantifiers. The difference lies only in that in the case of A-quantification, the selection of items is not determined by the grammatical function hierarchy, but by focus, and once focus is identified, the mapping process will be focal mapping. On the other hand, if no focus can be identified, the mapping will then be triggered by the lexical semantics of the A-quantifier in question. This is represented in (35) below.

(35) A Two-step Mechanism in Adverbial Quantification

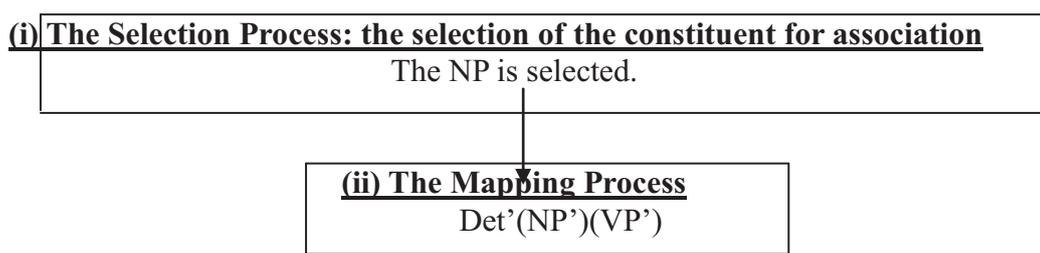

Comparing (35) with (34), we can see that the identification of focus has taken up the

role of the grammatical function hierarchy in *saai*-quantification, with the same two steps, which are the selection process and the mapping process, also existing in A-quantification.

Extending the same mechanism to D-quantification, we can see that unlike the case of *saai*-quantification and A-quantification, the selection of D-quantification will be determined by syntax, with the mapping then be triggered automatically. This is represented in (36).

(36) A Two-step Mechanism in Determiner Quantification

Comparing (36) with (34) and (35), we can see that a pure syntactic selection, that is the selection of NP, has taken up the role of focus in A-quantification and the grammatical function hierarchy in *saai*-quantification, with the same two steps, which are the selection process and the mapping process, also existing in D-quantification.

Having established the two-step mechanism for all three kinds of quantification, one final question is what are the differences among them regarding the role of focus in the two relevant processes? This can be captured by Table 1 below.

**Table 1: D-quantification, A-quantification and *Saai*-quantification under the two-step mechanism for quantification**

	<b>Selection process affected by focus</b>	<b>Mapping process affected by focus</b>
D-quantification	–	–
A-quantification	+	+
<b><i>Saai</i>-quantification</b>	–	+

The two plus values and the two minus values shown in D-quantification and A-quantification, respectively, suggest that the two processes are inseparable and merged, while the minus and plus values demonstrated by *saai*-quantification further reinstate that the two processes in question should be separated.

In the case of D-quantification, the NP is selected and mapped to the restrictor as the domain of quantification, with the VP to the matrix. Hence, selection is determined by syntax and focus cannot affect the selection or the mapping. Therefore, Table 1 demonstrates that D-quantification takes minus values in both the selection process and the mapping process, demonstrating that the two processes are not clearly separated and can be considered as being merged together. In the case of A-quantification, when there is no focus in the sentence, the NP subject is selected and mapped to the restrictor and VP to the matrix. When there is a focus in the sentence, selection will be determined by focus and the mapping will also be determined by focus, with focal mapping triggered.

Hence, focus can affect both the selection and mapping processes in A-quantification. Therefore, Table 1 shows that A-quantification takes plus values in both processes, again demonstrating that the two processes are not clearly separated and can be considered as being merged into one. This explains why in previous analyses, the selection process and the mapping process are simply integrated into one, without the need of separating them.

However, in the case of *saai*-quantification, selection is conducted by the grammatical function hierarchy, and focus cannot affect the selection, though it can affect the mapping. Mapping is determined by the lexical semantics of the quantifier or focus. When the selected item is in focus, focal mapping will be triggered. When the selected item is not in focus, the mapping will be determined by the lexical semantics of the quantifier. In other words, the two values, with one being minus and the other being plus shown in Table 1, support that the selection process and the mapping process cannot simply be considered as one, and must be separated from each other.

## 7. Conclusions

In this paper, on the basis of quantification performed by Cantonese verbal particle *-saai*, we have argued that quantification involves two processes which are the selection of items for association and the mapping process, and these processes must be separated. Such a claim has gained strong support in the case of quantification performed by *-saai*, as *-saai* selects its constituent for association, according to the grammatical function hierarchy proposed in this paper, and focal mapping will come into play only if the selected constituent is in focus; otherwise, the mapping will be determined by the lexical semantics of the quantifier. In other words, focus fails to change the constituent selected by the grammatical function hierarchy, showing that the selection process and the mapping process are indeed two separate processes. These two processes also exist in D- and A-quantifications claimed previously. In the case of A-quantification, the selection process is performed via focus instead of the grammatical function hierarchy, with focal mapping then triggered. In the case of D-quantification, the selection process is conducted by syntax, with the relevant syntactic partition then triggered.

## Abstract

We contend that word-initial tensification occurring amid Korean loanword adaptation is triggered to explicitly convey speakers' intimacy to the referents. We would say that it is a kind of phonological empathy. To reach out to the sound patterning, it is essential to meet two prior conditions: First, a certain threshold level of frequency with concerned words should be crossed; second, the semantic features geared to the empathic effects are compatible with the inherent connotative properties of the concerned words. With respect to laryngeal feature specification, we claim that every fortis consonant involved with the concerned data is specified in feature [spread glottis] while they are null in the case of lenis consonants. This idea sheds light on the question why aspiration of the fortis consonants in the source languages is allowable, while they strongly resist tensification.

**Keywords:** empathy, laryngeal feature, frequency, aspiration, tensification

## 1. Introduction

For the most part, discussion on the Korean tensification has concerned the operations arising in ideophones (Martin 1962, J.S. Lee 1992) and those at the medial positions of ordinary native words, e.g., Post-Obstruent Tensification (Kim-Renaud 1974, J. R. Oh 1987). Instead, this study will focus on the word-initial tensification happening at the word-initial position of loanwords.

Our position is somewhat unique in that we are going to achieve hybrid goals for the laryngeal drifts taking place at the specific position of those words hosted from English. First of all, we will try to seek a functional rationale for the sound patterning. In other words, we are going to disclose the functional factors which are going to play a role to trigger the consonant alternations. In this sense, we are interested in the frequency effect of concerned lexical items, semantic association of a word, paralinguistic or extra

aspects employed for the sake of efficient conveyance of speakers' intimacy towards what they are referring to. Second of all, we are concerned with modeling the modification of laryngeal properties by providing a proper phonological analysis in a formal way.

This work unfolds as follows: Section 2 tries to present the fundamentals to Korean word-initial tensification: data survey, introduction of the percept "empathy" originated by Kuno and Kaburaki (1977). Additionally, the exclusive allowance of tensification rather than aspiration, and the intermittent nature of tensification in loanword sound patterning will be discussed. In section 3, we try to provide a hybrid model for Korean word-initial tensification: we are going to give a formal analysis employing the laryngeal feature specification framework of Iverson and Salmons (1995) as well as a functional explanation in terms of phonological empathy and frequent effects of lexical items. As an addendum, section 4 discusses why word-initial tensification has ever slipped from our attention in Korean phonological analyses and orthographical conventions. Section 5 summarizes our discussion and draws implications of our suggestions to Korean lexical stratification.

## 2. Preliminaries

### 2.1. Data

Let us look at the emergence of tense consonants at the left edge of the following lexical items loaned from English:

(1)	[pənə]	~	[p'ana]	'burner'
	[kolp <sup>h</sup> i]	~	[k'olp <sup>h</sup> i]	'golf'
	[təbil]	~	[t'abil]	'double'
	[šyo]	~	[š'yo]	'show'

To obtain the empirical ground of the data, a questionnaire survey to Korean speakers was conducted. The subjects consists of 31 (10 male and 21 female), mostly in their early and mid twenties and come from central part of Korea. The test items consist of 51 loanwords from English, which initiate with plain obstruents (lenis consonants in the source language). They were paid and had a practice session before getting started into

the test session. Some tips for the test were given to the subjects: Considering that tensification is facilitated in the casual speech, a suggestion is given to them to figure out a “quite comfortably natural situation like conversing with a close friend” and to imagine to say themselves the words in a frame sentence “ige mueongahamyeon\_\_\_\_\_iya (This is \_\_\_\_\_, I would say). They are provided three choices for each entry: plain, tense and both. The final suggestion was to ignore the Korean spelling in the test sheets as much as possible. The test took 15 minutes or so. The test results are: Among 1,581 (51x31) tokens, we obtained 1,088 tokens for plain consonants (68.8%), 308 tokens for exclusively tense consonants (19.5%), and 218 tokens for marking both (13.8%). The combination of tense-only and plain-tense-both accounts for 33.2%. In this paper, aside from the statistical significance of the percentage of tensification, the phonological manifestation of tensification applied to loanwords will be considered

## 2.2. *Parallelism with Syntactic Empathy*

Kuno and Kaburaki’s (1977) seminal work on the role of syntactic empathy has enlightened us regarding speaker’s attitude toward discourse. Empathy is ‘the speaker’s identification, with varying degrees (ranging from degree 0 to 1), with a person who participates in the event that he describes in a sentence’ (p. 627). For example, the content of a sentence can be delivered in diversified forms:

- (2) a. John hit Mary.  
b. John hit his wife.  
c. Mary’s husband hit her.  
d. Mary was hit by John

In (2a) the speaker is neutral toward the event, and in (2b) he identifies himself with John more than Mary, while in (2c) merely the opposite, and in (2d) Mary is all the more identified with the speaker. Passivization is used to highlight the referent rather than the subject. This is the nutshell of syntactic empathy introduced by Kuno and Kaburaki (*ibid*). What we would like to claim here is that Korean word-initial tensification takes place to make explicit empathy of the speaker in a phonological sense. In other words, speakers imagine some objects as sharing their feelings like a movie or play actors tend to show their empathy with the characters they are cast to play

a role of. For the purpose, it is likely that they make use of not merely sentential structure, but also phonological patterning. Our claim is that depending upon empathetic strategies at hand, the content of a word or sentence gives different impressions to listeners. Let us take an example. Forms [pɛk] and [p'ɛk] 'back' are used in totally different contexts. The former is used in an ordinary context, and means 'rear, again' e.g. *back number, come back*. On the other hand, the form [p'ɛk] has pejorative or derogatory meaning 'illegal background, power.' We have tensification to Sino-Koreans as well, e.g., in a minimal pair [kwa] ~ [k'wa] 'department,' the latter form implies 'our department to the exclusion of others,' while the former is neutral. To break down the connotation conveyed by neutral and empathetic meaning, the following polarity table can be drawn in a quite sketchy manner:<sup>1</sup>

Neutral	Empathetic
-SUBJECTIVE	+SUBJECTIVE
-ENDEARING	+ENDEARING
-DEROGATORY	+DEROGATORY
-EXCITING	+EXCITING
-PRIVATE	+PRIVATE

<Table 1> Phonological Empathy: A Showcase

We assume that every word, nominal in particular, is equipped with connotative meaning of their own and the values of each semantic features are at variance: +, -, and ±. What we are going to claim is that the conflict between the connotative meaning of a lexeme with empathetic meaning results in blocking of employment of empathetic instantiation. This topic will be discussed in the following sections at length.

### 2.3. *Why just Tensification?*

As to the tensification at the left-edge of Korean ideophones, Martin (1962) proposes that the involved laryngeal features serve the semantic function to connote the degree of intensity on top of the denotative meaning of a word. In this sense, he employs ternary degree of intensity: [PLAIN] for plain series, [INTENSE] for tense series, and [PARAINTENSE] for aspirated series. The independent nature of feature-size morpheme is not startling at all and well-documented by Zoll (1996). Meanwhile,

<sup>1</sup> It is of no doubt that semantic primitives constituting empathy do not confine to the enumerated six features in <Table 1>, and thus the list can be extended *ad infinitum*.

criticizing the ternary scale of intensity in Korean sound symbolism, J. S. Lee (1992) tries to rectify the intensity relation between tense and aspirated series and introduces a revised model: each laryngeal feature has distinct semantic connotation to the effect that the single-feature morpheme {spread glottis} is decomposed into series of semantic primitives [DENSE, COMPACT, SOLID, TOUCH, HEAVY, SLOW...] and {constricted glottis} into [AIRY, CRISPY, SPARSE, LIGHT, SWIFT...]. Her idea is tantamount to say that phonological features [spread glottis] and [constricted glottis] exhibit independent semantic properties of their own right, denying hierarchical relationship between them. As we will see in the later on, this idea has some welcome consequences to our analysis.

Above all, her analysis is likely to shed light on some serious difficulties encountered in Martin's model. In other words, if laryngeal features are really adopted in Korean to manifest ternary degree of intensity in Korean onomatopoeic or mimetic words, it is hard to explain the gaps commonly encountered, e.g., *panc'ak-p'anc'ak-<sup>\*</sup>p<sup>h</sup>anc'ak*, *calluk-cs'alluk-<sup>\*</sup>c<sup>h</sup>alluck*. The hierarchical model predicts every tensed form has an aspirated counterpart. Conversely, our stance to regard tense and aspirated forms as a means to convey different connotations looks like quite promising to account for the asymmetry between tensification and aspiration derived from ideophonic alternations.

Let us turn our attention to the loanword situation. When it comes to asymmetry between tensification and aspiration, as illustrated in (3), it is not hard to notice that the lack of aspirated forms in loanwords is far more serious than in the case of ideophonic case:

### (3) Discrepancy between Tense and Aspirated Equivalents in Loanwords

[cəmp <sup>h</sup> i]	~	[c'əmp <sup>h</sup> i]	<sup>*</sup> [c <sup>h</sup> əmp <sup>h</sup> i]	'jump'
[ponəsi]	~	[p'onəsi]	<sup>*</sup> [p <sup>h</sup> onəs'i]	'bonus'
[pɛk]	~	[p'ɛk]	<sup>*</sup> [p <sup>h</sup> ɛk]	'bag'
[pɛk]	~	[p'ɛk]	<sup>*</sup> [p <sup>h</sup> ɛk]	'back'
[cɛdzɔ]	~	[c'ɛdzɔ]	<sup>*</sup> [c <sup>h</sup> ɛdzɔ]	'jazz'
[taun]	~	[t'aun]	<sup>*</sup> [t <sup>h</sup> aun]	'down'
[cip]	~	c[c'ip]	<sup>*</sup> [ts <sup>h</sup> ip]	'jeep'
[taibiŋ]	~	[t'aibiŋ]	<sup>*</sup> [t <sup>h</sup> aibiŋ]	'diving'
[pat'eri]	~	[p'at'eri]	<sup>*</sup> [p <sup>h</sup> at'eri]	'battery'
[pəs'i]	~	[p'əs'i]	<sup>*</sup> [p <sup>h</sup> əs'ɨ]	'bus'
[pɛt]	~	[p'ɛt]	<sup>*</sup> [p <sup>h</sup> ɛt]	'bat'

The pervasive lack of aspiration in loanwords gives an outstanding line of evidence to our idea that tensification has a fundamentally distinct *raison d'être* from that of aspiration.

#### 2.4. *Tensification as On-and-Off Process*

In above sections, we observed that tensification is a favorite to convey speakers' attitude towards what they are referring to. As suggested in section 2.2, another important issue to be incorporated in the discussion of Korean loanword phonology is that the concerned word-initial tensification is not applicable to relevant items across the board. As we compare the data in (1) and (3) with those in (4) below, it is easy to notice the differences:

#### (4) Forbidden Tensification

[pəbul]	~	*[pəbul]	'bubble'
[peik <sup>h</sup> on]	~	*[p'eik <sup>h</sup> on]	'bacon'
[tinə]	~	*[t'inə]	'dinner'
[teit <sup>h</sup> a]	~	*[t'eit <sup>h</sup> a]	'data'
[kei]	~	*[k'ei]	'gay'
[kɛgi]	~	*[kɛgi]	'gag'

We are going to discuss what is intervening factors to intercept the potential process of tensification in section 3.3.

### 3. Discussion

#### 3.1. *Laryngeal Feature Specifications*

With respect to laryngeal feature representation involved with Korean word-initial tensification, let us take a look at the presumption taken by Iverson and Salmons (1995), Iverson and A.R. Lee (2006). Militating against traditional views on Germanic languages including English, the feature model above claims that unmarked laryngeal feature in English is [voice] rather than [voiceless]. In the meantime, Korean obstruents

have ternary system and plain consonants are null and aspirated and tense consonants are specified with features [s.g.] and [c.g.], respectively

Here let us make sure our position on the controversial issue of the input identification in loanword adaptation. Essentially, we support the contention that the underlying feature structure of the source language is transferred as input, as LaCharité and Paradis (2005) claim. Another thing is that considering that English obstruents are not easy to jam into the straitjacket of voicing and voiceless distinction. Thus, instead of voiced and voiceless distinction, the distinction of fortis and lenis is adopted in our analysis. One more thing is that we assume that all the fortis obstruents of English are specified in feature [s.g.] underlyingly, while lenis obstruents are null in terms of laryngeal features, as shown in (5):<sup>2</sup>

(5) Representation of English Laryngeal Features

<p>a. Fortis</p> <p style="text-align: center;">p</p> <p style="text-align: center;"> </p> <p style="text-align: center;">[s.g]</p>	<p>b. Lenis</p> <p style="text-align: center;">b</p> <p style="text-align: center;">[ ]</p>
---	---

3.2. Option for Feature Filling

Now, we are well prepared to give an account for the tensification occurring amid Korean loanword adaptation. As depicted in (5), laryngeal features involved with the lenis obstruents in English are empty while the concerned lexical items are transferring to Korean lexicon. Under the conceptualization, we can readily answer the prime question on Korean word-initial tensification: Why does the process apply to merely plain consonants? The answer is that the empty laryngeal nodes involved with lenis consonants come to be filled by feature [constricted glottis], which is believed to be employed in our analysis that as a single featured morpheme, it plays a role to convey the speaker’s attitude towards the referring objects at stake. On the contrary, in the case of fortis obstruents, relevant laryngeal features are already specified and for this reason, if we want to realize feature [c. g.], it needs a process of feature replacement rather than feature filling. However, it is obvious that the feature replacement process is more marked than a simple process of feature filling. The feature replacement is a composite

---

<sup>2</sup> For the notion of fortis and lenis, we rely upon the phonetic tradition ever since Lisker and Abramson (1964): fortis sounds are produced with a greater force in articulation, whereas the opposite situation happens to lenis consonants.

of feature removal plus feature filling. As a means of phonological empathy, latter type of tensification is seldom opted for, as illustrated below of the example ‘back’:

(6) Laryngeal Layer	[c.g.]				
	⋮				
Supralaryngeal Layer	p	ε	k		‘back’

To deliver empathetic meaning to the English loanword ‘back’, signifying ‘illegal background,’ the empty space on the laryngeal tier is to be taken by the mono-featural morpheme [c. g.]. By contrast, in the case of ‘pack’, the word-initial fortis obstruent is already taken by feature [spread glottis] and additional laryngeal feature linking is disallowed:

(7) Laryngeal Layer	[s.g.]				
Supralaryngeal Layer	p	ε	k		‘pack’

An important strength of our analysis is that the present model is successful to explain why tensification of fortis stops is usually disallowed in ordinary speech.<sup>3</sup> In Korean loanword phonology, it is usual for fortis input to realize as aspirated consonants rather than other options, as we can see in (8):

(8)	[op <sup>h</sup> in]	*[op’in]	‘open’
	[sit <sup>h</sup> iraik <sup>h</sup> ]	*[si <sup>h</sup> t’iraik <sup>h</sup> ]	‘strike’
	[sip <sup>h</sup> un]	*[sip’un]	‘spoon’
	[sik <sup>h</sup> i]	*[sik’i]	‘ski’

To obtain a plausible answer to the question why Korean loanword adaptation prefer aspiration to tensification of fortis obstruents of the source language, the adoption of the

---

<sup>3</sup> To my knowledge, forms like [t<sup>h</sup>ɛŋk<sup>h</sup>i] ~ [t’ɛŋk’i] ‘tank,’ [p<sup>h</sup>aip<sup>h</sup>i]~[p’aip’i] ‘pipe,’ [p<sup>h</sup>ents<sup>h</sup>] ~ [p’ants’] ‘pants,’ [p<sup>h</sup>irint<sup>h</sup>i] ~ [p’irint’i] ‘print’ challenge our current generalization. It is highly suspected that the exceptional occurrences are owing to the Japanese influence as a mediating language. Also recently it is not unusual to find tensified versions like [p’iano] ‘piano,’ [p’et] ‘pet.’ found in the current Internet dictions. Here I ignore the consciously warped forms of linguistic forms burgeoning lately in Internet blogs and other kinds of sites.

input representation on laryngeal features is sufficient without further ado: the laryngeal feature slot is preempted with feature [s.g.] and it cost more to resort to feature replacement. Ultimately, feature [s.g.] instantiates as aspiration at the surface.

In this regard, the analysis relying on orthographic information, proposed by M. R. Oh (1996) is misguided. As she suggests, if the realization of Korean loanwords from English fortis consonants is really due to the influence of orthography, that is, to substitute Korean aspirated for English fortis regardless positions, it is hard to answer the following question: Why not tense consonants rather than aspirated counterparts? It is not fair to ascribe the aspiration dominance effect to the orthographic influence. It is equally possible to evoke the tensification of the concerned consonants as much as aspiration. Under the idea, there is no reason to give a priority to aspiration, unlike our analysis.

### 3.3. Feature Incompatibility

As pointed out in section 2.4, there is a subset relation between words compatible with empathy and a loanword as a whole: e.g., [taiamond]/\*[t'aiamond] 'diamond', [paid]/paid 'bind', [paiə]/\*[p'aiə] 'buyer', [kaid]/\*[k'aid] 'guide', etc. For the explanation, we contend that the empathetic demand is merely applicable to words whose semantic connotation is not in conflict with semantic primitives required to instantiate the empathic meaning to the words at stake. Let us illustrate the case, 'guide.', which disallows word-initial tensification:

(9) guide

*connotation*

±SUBJECTIVE
-DEROGATORY
±ENDEARING
±EXCITING
±PRIVATE

*empathetic features*

+ SUBJECTIVE
+DEROGATORY
+ENDEARING
+EXCITING
+PRIVATE

We propose that the partial incompatibility between inherent and empathetic meaning is enough to prevent superimposing empathetic features. In the case (9), the multiple-

crashes among features lead Korean speakers are reluctant to permit tense forms during loanword adaptation. Conversely, in the case of ‘back’, signifying ‘illegal background’, inter-feature crash never occurs and for this reason, tensification is allowed.

(10) back (‘illegal background’)

<i>connotation</i>	<i>empathetic features</i>
<div style="border-left: 1px solid black; border-right: 1px solid black; padding: 10px; display: inline-block;">           +SUBJECTIVE            +DEROGATORY            +ENDEARING            +EXCITING            +PRIVATE         </div>	<div style="border-left: 1px solid black; border-right: 1px solid black; padding: 10px; display: inline-block;">           +SUBJECTIVE            +DEROGATORY            +ENDEARING            +EXCITING            +PRIVATE         </div>

### 3.4. Frequency Effect

Connectionist position would be the most *bona fide* example of modeling the frequency variable in phonology: Under the intricate network of neural nodes, each node has a numerical activation value and those associated with high frequent items have low thresholds of activation values. (McCarthy 2001: 59-61). More concretely, according to Bybee (2001), the role of frequency is integral to predict lenition like schwa deletion, e.g., *summary* (frequent: deleted) vs. *summery* (infrequent: retained); coronal stop deletion in the words with double past tense maker, e.g., *told* (frequent: deleted) vs. *meant* (infrequent: retained).

To prove the connection between the frequency or intimacy of loanwords and the likelihood of tensification, I conducted a pilot investigation employing a small group of arbitrary chosen loanwords having the English sources. The randomly chosen minimal pairs contrasting in light of word-initial tense features were explored at the website <http://kr.search.yahoo.com> and I gained the ratio between that of the readily tensified words over rarely tensified counterparts. During the Internet examination, the forms with homonymous with native Korean like *down* (다운), *ball* (볼), *gang* (갱) were expelled from our consideration from the outset.

No	Rarely Tensified (A)	Frequency	Readily Tensified (B)	Frequency	B/A (%)
1	gold	3,470,000	game	50,700,000	1461%
2	disk	4,690,000	diving	632,000	13%
3	gag	5,530,000	gas	5,210,000	94%
4	dinner	184,000	dance	7,030,000	3821%
5	bubble	2,450,000	band	3,070,000	125%
6	gay	878,000	gang	257,000	29%
7	bowling	439,000	boxing	1,220,000	278%
8	drive	2,590,000	dam	1,010,000	39%
9	bacon	412,000	bonus	2,380,000	578%
10	guide	9,170,000	gown	940,800	10%
11	Gypsy	171,000	jazz	2,200,000	1287%
12	gesture	275,000	jump	2,030,000	738%
13	zipper	385,000	jam	1,780,000	462%
mean					687%

<Table 2> Ratio of the Frequency of Tensified over the Lenis

The frequency mean value calculated from the ratio of the tense forms over plain forms amounts to 687%. Certainly it is necessary to take into account the haphazardness of variables intervening in examining the internet data during the calculation: e.g., individual tastes of site constructors, frequency of the terminology typical to specific fields, and so forth. Nonetheless, the percentage over 600% is still meaningful to us. The overwhelming percentage of tense forms in terms of frequency over plain-only forms is unlikely to be nullified by the property of precariousness of the uncontrolled data inherent to the data posted on the internet sites. This means that a certain amount of thresholds of frequency must be passed over to trigger tensification of the concerned words.

#### 4. On the Orthographic Conventions on Laryngeal Features

Orthographically, it is extremely rare to find empathetic forms of loanwords in written documents like dictionaries, textbooks, newspaper. The first reason can be conjectured that words involving tense consonants are statistically less in number than plain or

aspirated words. Notice that almost 70% of Korean word stock consists of Sino-Korean words, in which morphemes started with tensed obstruents take just tiny portion, attested in the morphemes like s'i (氏), s'aŋ (雙), k'ik (喫). So it would be surmised that Korean lexicographers have consciously or subconsciously avoided tensed forms as regular forms. The situation is the same in the loanword adaptation from English: sibilants are regularly spelled as plain consonants, even though they clearly perceived them as tensed ones in *solo, sofa, side, sea, soda, sauna, cycle, psychology, siren*, and so forth. We have never perceived the plain sibilants in the loanwords listed above, at least in informal and ordinary speech. Nonetheless, it is extremely rare to witness the tense consonants in the filed documents.

The second reason to skip tense forms in spelling as delivery of empathetic attitude of speakers is that empathetic meaning is a superimposed meaning on top of regular meaning of a word. The situation is similar to that of prosodic features like stress, pitch accent, tone. To my knowledge, it has been customary to omit the predictable prosodic features in the spelling convention of a language. For instance, in English, word stress, which could be arguably predictable, is never orthographically represented, and Spanish indicates merely unpredictable stress on the word by word basis in the lexicography.

The current Korean spelling convention employs an interesting criterion to designate tense feature on the spelling. The overt symbols to designate tense consonants merely show up when we need to tell apart two native lexical items constituting minimal pairs in terms of laryngeal features. The consonants that matter for minimal pairs are emboldened:

(11)	<b>t</b> aŋkida	'to pull'	ilkun	'to be plowed'
	<b>t'</b> aŋkida	'to be cramped'	il <b>k'</b> un	'worker'
	kaca	'let's go'	nalca	'let's fly'
	kac'a	'bogus'	nalc'a	'date'

Likewise, for the identification of loanwords from the existing native lexical items, tense forms are exceptionally reflected in the minimal pairs:

(12) a.	sauna	'sauna'	b.	s'ain	'autograph, signature'
---------	-------	---------	----	-------	------------------------

s'auna 'to fight (interrogative)      sain 'cause of death'

In (12a), considering that the existing native word *s'auna* initiated with a tense consonant and it is also represented in spelling, tense feature needs to be dropped in spelling to loan word 'sauna.' By contrast, in (12b), there is no available existing word, regardless of native or Sino-Korean, containing tense feature with the same segmental structure, so for the sake of distinction among word stock, the loanword has an orthographical tense feature.

### 5. Summary and Implications to Korean lexicon

So far we have tried to account for why and how word-initial tensification available in English loanwords to Korean takes place. The upshot is that the consonant mutation is motivated to empathize speaker's personal attitude towards the objects that they are referring to. Considering that Korean lacks phonologically valid word stress or tonal variation, Korean calls for other devices equivalent to the prosodic qualities. To identify the factors involved with the triggering the laryngeal feature drift, we have called for the frequency of the concerned lexical items. The allowance of lexical frequency in the determination of the shape of phonological words stands for the interplay of the lexicon and grammar. In other words, two components are not clearly separated as independent modules but they are interconnected to decide a word shape in the loanword adaptation. .

Lastly, let us examine the implications obtained from our analysis to the structure of Korean lexical strata. First of all, the separation of tense and aspirated forms of Korean ideophones in a functional sense proves to be effective to account for the asymmetric distribution concerning Korean tense and aspirated obstruents. The functional independency of two laryngeal features is further supported by another asymmetry between them: It is extremely rare to find aspirated counterparts of tense forms imported from English as a source language.<sup>4</sup> By contrast, the aspirated forms are not so sparse in Korean onomatopoeic or mimetic words, as exemplified below:

(13)	<i>plain</i>	<i>tense</i>	<i>aspirated</i>	
	piŋ	p'iŋ	p <sup>h</sup> iŋ	'turning round'
	kamkam	k'amk'am	k <sup>h</sup> amk <sup>h</sup> am	'dark'
	tantan	t'ant'an	t <sup>h</sup> ant <sup>h</sup> an	'hard'

<sup>4</sup> Aside from the single exception [kit<sup>h</sup>a] ~ [k<sup>h</sup>it<sup>h</sup>a] 'guitar,' the aspirated equivalents of lenis obstruents in loanwords are unattested.

Thus, the parallelism between ideophonic words and loanwords should be given up at this point. They are separate in their degree of allowance of aspirated forms corresponding to plain forms. The separation of native and Sino-Korean words is supported by the distant gap between them in light of the rate of word-initial tensification. On the other hand, both native and Sino-Korean words hardly lose their laryngeal features at the non-initial position, unlike in ideophones or loanwords, as noted by P. H. Lee (2005: 61). From the viewpoint of susceptibility to loss, let us arrange the pros and cons obtained from the proposed four subsectors of Korean lexicon:

(14)	Loss of aspiration	Examples	
Native	NAY	[pat <sup>h</sup> aŋ]	‘base’
Sino-Korean	NAY	[kits <sup>h</sup> o]	‘base’
Ideophones	AYE	[t <sup>h</sup> a-ta-ŋ]	‘bang-bang’
Loanwords	AYE	[pediro]	‘Peter’ (Biblical)

Ideophones and loanwords are identical in their generous allowance of laryngeal feature alteration in exquisite contrast to native and Sino-Korean. In this sense, our partitioning Korean lexicon is supported from the viewpoint of processes involving laryngeal features. To recapitulate, from the standpoint of laryngeal features, the substrata of Korean lexicon prove to have discernable asymmetry among them, as tabulated below:

	Aspiration		Tensification	
	loss	gain	loss	gain
Native words	no	no	no	yes
Sino-Korean	no	no	no	no
loanwords	yes	no	indeterminate <sup>5</sup>	yes
ideophones	yes	yes	yes	yes

<Table 3> Likelihood of Laryngeal drifts in Korean Lexicon

<sup>5</sup> Considering that we are concerned with borrowing from English, and it is hard to find the input possessing tense consonants, we leave the issue indeterminate.

Sino-Korean lexical items turn out to be the most resistant to the laryngeal alterations, while the ideophones are the most lenient to the changes. Loanwords from English belong to the second most generous group to laryngeal feature alternations. Native Korean words just allow newly generated tense features to the exclusion of other options.

# Prolegomena to an Agent-Oriented Theory of Context

Roland Hausser

Universität Erlangen-Nürnberg  
Abteilung Computerlinguistik (CLUE)  
rrh@linguistik.uni-erlangen.de

**Abstract** Among the rule-based<sup>1</sup> approaches in linguistics, the most basic distinction is that between the sign-oriented and the agent-oriented analyses.<sup>2</sup> This distinction leads also to vastly different notions of context. While sign-oriented approaches such as the schools of Nativism define context as some background information which is attached to the grammatical analysis of language expressions (signs), the agent-oriented approach of Database Semantics (DBS) treats the context as an autonomous component within the cognitive agent.

This component consist of a memory and interfaces, as well as an algorithm mediating between the two. It (i) predates the language component in phylogeny (evolution) and ontogeny (child development) and (ii) provides the context of use relative to which the different natural languages are interpreted.

For the goal of Database Semantics, i.e., a computational model of natural language communication, the context component must be defined as the declarative specification for a suitable software. This requires solutions to highly technical issues, which have been presented elsewhere. Here, the context component is approached in a conceptual manner, leaving such issues as the definition of the data structure, the algorithm, memory-based pattern recognition, etc., aside.

The word “context” occurs not only frequently in everyday language, but also has many different technical interpretations. It has been used to refer to the previous sentences in a text, or to the domain of a text, such as medicine, law, architecture, etc. It has been used to refer to world knowledge (Grice 1975), or to knowledge shared between the speaker and the hearer (Leech 1983). In Artificial Intelligence, context has been treated in the form of schemata representing typical situations (Schank and Abelson 1977). In HPSG context is added as an attribute to lexical entries. The values of this attribute are called constraints, and express such knowledge as “the use of the name *John* is legitimate only if the intended referent is named *John*” or “the complement of the verb *regret* is presupposed to be true” (cf. Pollard and Sag 1994, Green 1997).

From the view point of Database Semantics, these notions of context are partial at best. What is required for an agent-oriented approach instead is a component serving

---

<sup>1</sup> In addition to (i) the rule-based method there are the methods of (ii) statistics and of (iii) metadata-markup. These may be combined with a rule-based method.

<sup>2</sup> Related is the distinction between *language as product* and *language as action* of Clark (1996). However, while Clark counts Speech Act Theory (Austin 1962, Grice 1965, Searle 1969) among the language as action theories, Speech Act Theory is sign-oriented insofar as it is based on enriching the analyzed sign with performative clauses, such as *I declare*, *I promise*, etc. For a more detailed review of Ordinary Language Philosophy see FoCL’99, p. 84 f.

as the “context of use” for the interpretation and production of natural language by a cognitive agent with a body acting in the real world (e.g., a talking robot). Furthermore, this component must be suitable to integrate all the partial notions of context, such as the previous text, the domain, the shared knowledge, etc.

## 1 Context as a Cognitive Agent without Language

Faced with such a daunting task, we propose to simplify matters by taking evolution (phylogeny) and child development (ontogeny) as our guide. In other words, let us begin with a cognitive agent without language. Consider for example a squirrel: It has two eyes, two ears, a nose, etc., for recognition, and hands, hind-legs, a mouth, etc., for action. It can bury a nut, when needed retrieve it even after a long time, and eat it.

In the terminology of Database Semantics, the squirrel has a very good context component, but no language component.<sup>3</sup> If we could use the cognition of an artificial squirrel as our context, we would adapt the ears to hearing language, add synthesizers for speaking, provide ample computing power, and design a theory to use it for natural language communication. This theory is Database Semantics, presented in NLC’06.

That we begin our model of natural language communication with the context level may be motivated as follows:

### 1.1 SUPPORT FOR BUILDING THE CONTEXT COMPONENT FIRST

1. Constructs from the context-level may be reused at the language level. This holds for (i) the concepts, as types and as token, (ii) the external interfaces for input and output, (iii) the data structure, (iv) the algorithm, and (v) the inferences.
2. An agent without a context component could not report to us what it perceives (contextual recognition), and could not do what we tell it to do (contextual action).
3. The context is universal – in the sense of being independent of a particular language, yet all the different natural languages may be interpreted relative to the same kind of context component.
4. In phylogeny (evolution) and ontogeny (child development) the context component comes first.

To strengthen the empirical foundations of our model let us proceed from what can be seen and touched to what must be inferred. In other words, let us begin with the body of the cognitive agent and its external interfaces.

That natural cognitive agents have bodies<sup>4</sup> with interfaces for transporting cognitive content from the external world into the agent (recognition) and out of the agent into the external world (action) can be shown comparatively easily. The properties of the interfaces may be established externally by observing the interaction of other agents with their environment and with each other, and internally by observing the functioning

---

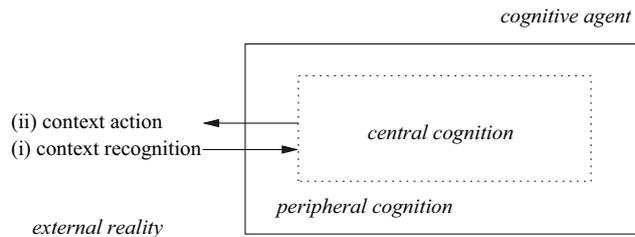

<sup>3</sup> Though this may be debated. See Hauser (1996).

<sup>4</sup> The role of the body has recently been reemphasized by Emergentism, cf. MacWhinney (1999).

of one's own interfaces through introspection. In addition, there is the analysis of the external interface organs involved, provided by the natural sciences such as physiology and anatomy, as well as the modeling of these organs in robotics.

The external interfaces of the context component correspond to those of a cognitive agent without language, and may be shown schematically as follows:

## 1.2 EXTERNAL INTERFACES OF A COGNITIVE AGENT WITHOUT LANGUAGE

For present purposes we deal with the interfaces at a very high level of abstraction, such that the distinction between recognition and action in general is sufficient.

The differentiation of the external interfaces into modalities such as vision, audio, variants of locomotion, manipulation, etc., is relevant here only insofar as peripheral cognition during recognition translates the heterogeneous modality-dependent data of the different interfaces into the homogenous coding of central cognition. During action, peripheral cognition translates the homogeneously coded commands of central cognition into the heterogeneous modality-dependent kinds of external action procedures.<sup>5</sup>

Starting the reconstruction of cognition with the agents' external interfaces determines the ontological foundations of Database Semantics in a way which makes it incompatible with the traditional sign-oriented theories. The reason is that the sign-oriented theories abstract the cognitive agent away, defining semantics as a direct relation between "language and the world." This may have advantages, yet without an agent there cannot be external interfaces, and a cognitive theory without external interfaces is unsuitable for modeling natural language communication in its most basic form.<sup>6</sup>

## 2 Concept Types and Concept Tokens

Having established the interfaces of the context component, we turn to the reconstruction of recognition and action. Our model of a cognitive agent should be able to recog-

<sup>5</sup> We know of two kinds of homogeneous coding: neurological in natural agents and electronic in computers. Functionally, the task of central cognition is the analysis and storage of modality-independent (homogenous) content, inferencing on the content, and turning the result of these inferences into action schemata.

<sup>6</sup> There remains the possibility of extending the sign-oriented theories without external interfaces into ones which have them. This is not a promising option, however, as shown by the analogy with software development: A piece of running software can practically never be extended to an interface which was forgotten in the initial design – except for ad hoc emergency measures cleverly adapting some accidental feature of the program. For a clean solution, the program has to be rewritten from scratch.

nize new objects of a known type, like a brand new pair of shoes. Thereby it should be forgiving in marginal cases, like clogs, but give a clear “no” when it comes to wheelchairs or shovels. This kind of classification is based on concepts which can distinguish between necessary and accidental<sup>7</sup> properties of an object.

The considerable literature on concepts presents the schema (Piaget 1926; Stein and Trabasso 1982), the template (Neisser 1964), the feature (Hubel and Wiesel 1962; Gibson 1969), the prototype (Bransford and Franks 1971; Rosch 1975), and the geon (Biederman 1987) approach. For simplicity, let us join the debate at a slightly higher level of abstraction by beginning with a distinction which should be common to all of these approaches, namely the distinction between concept *types* and concept *tokens*.<sup>8</sup>

For present purposes, we define concepts as feature structures, i.e., as sets of features, each defined as an attribute-value pair. The necessary properties of a type are represented by the attributes and certain constant values. These are shared with the tokens. The accidental properties are represented in the type by certain variable values, which are instantiated in different tokens as different constants. Thus, to a given type there corresponds an infinite number of tokens which differ from their type in that the type’s variables have been replaced by specific values (constants).

To simplify the explanation of the most basic notions, we use here a preliminary holistic representation, which will have to be replaced by the declarative specification of incremental, time-linear procedures for recognizing concepts based on geons, and geons based on features (described in L&I’05).<sup>9</sup> Consider the following example using the preliminary holistic representation, borrowed from CoL’89 and FoCL’99:

## 2.1 TYPE AND TOKEN OF THE CONCEPT *square*

<i>type</i>	<i>token</i>
$\left[ \begin{array}{l} \text{edge 1: } \alpha \\ \text{angle 1/2: } 90^\circ \\ \text{edge 2: } \alpha \\ \text{angle 2/3: } 90^\circ \\ \text{edge 3: } \alpha \\ \text{angle 3/4: } 90^\circ \\ \text{edge 4: } \alpha \\ \text{angle 4/1: } 90^\circ \end{array} \right]$	$\left[ \begin{array}{l} \text{edge 1: } 2 \text{ cm} \\ \text{angle 1/2: } 90^\circ \\ \text{edge 2: } 2 \text{ cm} \\ \text{angle 2/3: } 90^\circ \\ \text{edge 3: } 2 \text{ cm} \\ \text{angle 3/4: } 90^\circ \\ \text{edge 4: } 2 \text{ cm} \\ \text{angle 4/1: } 90^\circ \end{array} \right]$

<sup>7</sup> The term accidental is used here in the philosophical tradition of Aristotle, who distinguishes between the necessary and the accidental (or incidental – kata sumbebêkos).

<sup>8</sup> The notions of type and token were introduced by Peirce (CP, Vol.4, p. 537).

<sup>9</sup> The incremental time-linear recognition procedure described in L&I’05 is based on the data structure of DBS. The procedure begins with detecting some arbitrary feature of the object to be recognized, such as a line or an edge. Then all the previously encountered connections of this feature to other features are retrieved from memory and actively checked, beginning with the most frequent ones. If a match for such a combination is found in the external object, all previously encountered connections of this combination to other features are retrieved from memory and actively checked, etc. It is shown that this method converges very quickly at the level of features, resulting in the recognition of geons (cf. Biederman 1987, Kirkpatrick 2001). At the level of geons, the same incremental method can be used, resulting in the recognition of concepts.

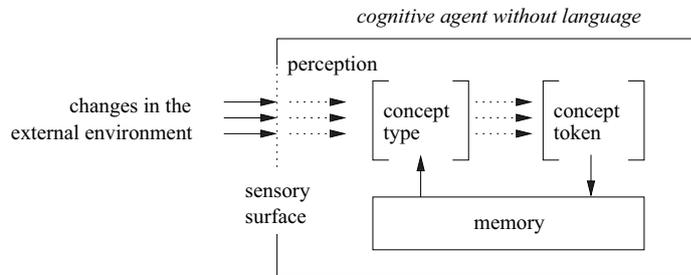

The necessary properties, shared by the type and its token, are represented by four attributes for edges and four attributes for angles. Furthermore, all angle attributes have the same value, namely the constant “90 degrees” in the type and the token. The edge attributes also have the same value, though it is different for the type and the token.

The accidental property of a square is the edge *length*, represented by the variable  $\alpha$  in the type. In the token, all occurrences of this variable have been instantiated by a constant, here 2 cm. Because of its variable, the type of the concept *square* is compatible with infinitely many corresponding tokens, each with another edge length.

### 3 Context Recognition

The type–token relation of concepts is central to the external interfaces at the context level. In contextual recognition, concept type and concept token function together as follows:

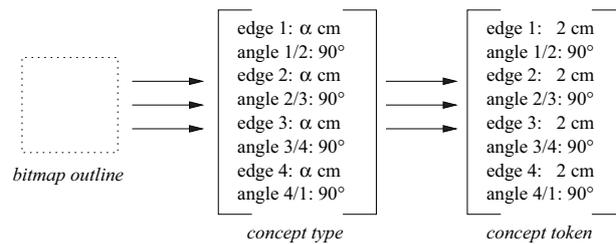

#### 3.1 CONCEPT TYPE AND CONCEPT TOKEN IN CONTEXTUAL RECOGNITION

The sensory surface produces incoming parameter values, for example, in the form of a bitmap, which are matched by a concept type provided by the database. Thereby, the variables of the type are instantiated by constants. The resulting concept token may be stored in memory.

The matching process shown in 3.1 is illustrated below in more detail with the recognition of a square:

#### 3.2 CONCEPT TYPE AND CONCEPT TOKEN IN RECOGNIZING A SQUARE

The type can be matched with the outline of all kinds of different squares, whereby its variables are instantiated accordingly.

Our preliminary holistic method of representing the concept **square** may be applied to other polygons, using the same recognition procedure based on matching concept types with bitmap outlines. The approach may also be extended to other kind of data, such as the recognition of colors, defining concept types as certain intervals in the electromagnetic spectrum and the tokens as particular constant values in such an interval (cf. CoL'89, pp. 296 ff.). The method is even suitable to implement the recognition of relations like "A is contained in B."

Today, there already exist pattern recognition programs which are quite good at recognizing geometric objects. They differ from our approach in that they are based almost completely on statistics. However, even if the terms of type and token may not be found in their theoretical descriptions, the type–token distinction is nevertheless implicit in any pattern recognition process. Furthermore, the rule-based, incremental procedures of pattern recognition presented in L&I'05 are well-suited to be combined with statistical methods.

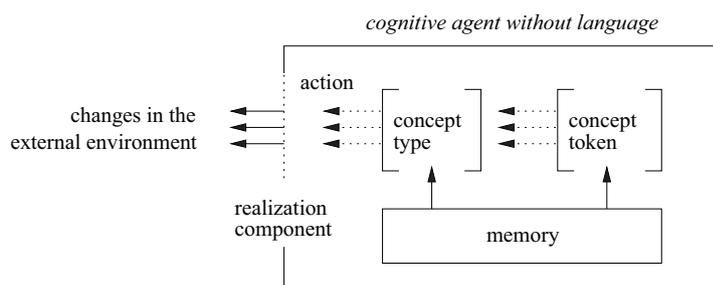

As shown by the work of Steels (1999), suitable algorithms can evolve new types automatically from similar data by abstracting from what they take to be accidental. For Database Semantics, the automatic evolution of types has to result in concepts which correspond to those of a language community. This may be achieved by presenting the artificial agent with properly selected data in combination with human guidance.

## 4 Context Action

Having examined incoming data in terms of perception and recognition, let us turn to the outgoing data, which are analyzed in terms of intention and action. Intention is the process of developing an action cognitively, while action is the mechanism of realizing an intention by changing the environment.

Like recognition, action is based on concept types and concept tokens, but in the inverse order: While recognition is based on the sequence *periphery–type–token*, action is based on the sequence *token–type–periphery*, as shown in the following schema:

### 4.1 CONCEPT TYPES AND CONCEPT TOKENS IN ACTION

The input to an action is an intention. Intentions (in the sense of wanting to act in a certain way) must be specific with respect to time and space as well as to the properties of the objects involved. Therefore, intentions are defined as concept tokens.

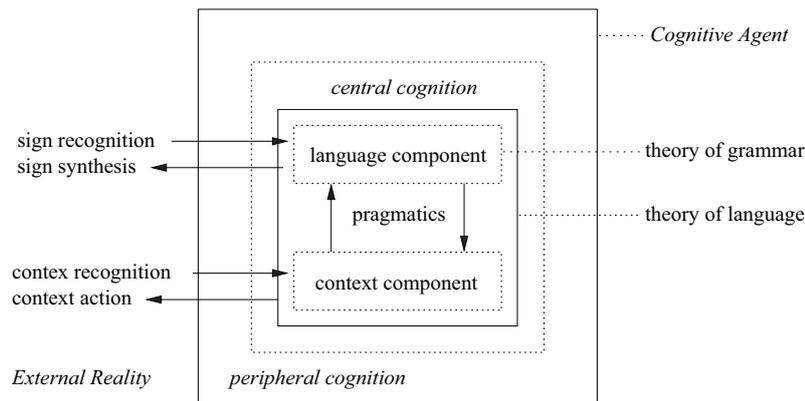

Actions, as the corresponding concept types, are defined as general realization procedures, for example, drinking from a cup. They are provided by the database for a given intention. The action procedure (type) is matched with the intention (token), whereby the variables of the action type are instantiated by the constants of the intention (specialization). The specialized action is realized by peripheral cognition as changes in the environment. Tasks for which no standard action is available, like the creative opening of a difficult lock in an unfamiliar door, are realized by trying different combinations of smaller standard actions.

## 5 Upscaling to Agents with Language

From the viewpoint of evolution, the step from agents without language to agents with language may be visualized as a doubling of the context component as described so far. Thereby the newly gained component is reutilized for the purposes of language in two fundamental ways.<sup>10</sup>

First, the existing interfaces for (i) context recognition and (ii) context action are reused by the new language component for (iii) sign recognition and (iv) sign synthesis, respectively.

### 5.1 STRUCTURING CENTRAL COGNITION IN AGENTS WITH LANGUAGE

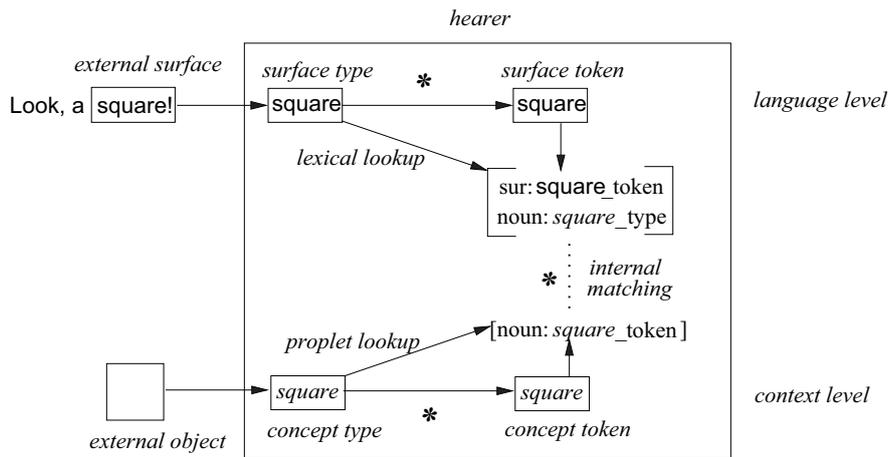

For example, just as the recognition of the *object* of a square at the context level is based on parameter values in a certain modality (here vision) which are matched by a concept type and instantiated as a concept token, the recognition of the *surface* of the word **square** is based on parameter values in a certain modality (e.g., hearing) which are matched by a surface type and instantiated as a token, and similarly for surface synthesis in language production. In short, the surface types and tokens used at the language level are a special kind of the concept types and tokens used at the context level.

<sup>10</sup> This is in line with the Emergentist view (MacWhinney 1999) of evolution reusing older forms for newer functions.

Second, the concept types used for recognition and action at the context level are reused as the basic language meanings. Thus the cycle of communication is based on three type-token relations: (i) between concept types and raw input at the context level, resulting in concept tokens (cf. 3.1), (ii) between surface types and raw input at the language level, resulting in surface tokens (cf. 4.1), and (iii) between concept types serving as word meanings at the language level and concept tokens serving as referents at the context level:<sup>11</sup>

## 5.2 THREE TYPE-TOKEN RELATIONS IN THE CYCLE OF COMMUNICATION

The three instances of a type-token relation are indicated by \*.

At the language level, recognition of the external surface **square** is based on matching it with a surface type and instantiating it as a token. The type triggers the lexical lookup of an appropriate proplet.<sup>12</sup> The surface token replaces<sup>13</sup> the original type value of the *sur* attribute (indicated as [sur: **square\_token**]). The lexical value of the core attribute *noun* is the concept type *square* (indicated as [noun: *square\_type*]).

At the context level, recognition of the external object is based on a concept type, which is instantiated as a concept token. The type triggers lookup of a corresponding context proplet. The token replaces the original type value<sup>14</sup> of the core attribute of

<sup>11</sup> As shown in FoCL'99, Sect. 23.5, there are altogether 10 different variants of 5.2, depending on different combinations of recognition and action at the language and the context level. In 5.2, the hearer mode is shown in a constellation of immediate reference (SLIM 8, cf. FoCL'99, 23.5.8).

<sup>12</sup> A proplet is a non-recursive feature structure representing the basic elements of a proposition.

<sup>13</sup> This is because the hearer remembers the pronunciation of a word. Also, we would like to maintain symmetry with the context level. The current JSLIM implementation simplifies the issue by turning language proplets into context proplets right after lexical lookup by deleting the surface values.

<sup>14</sup> In the current implementation, concepts are represented by placeholders. This is because without contextual interfaces (as in 6.1), concepts defined as effective procedures are not yet avail-

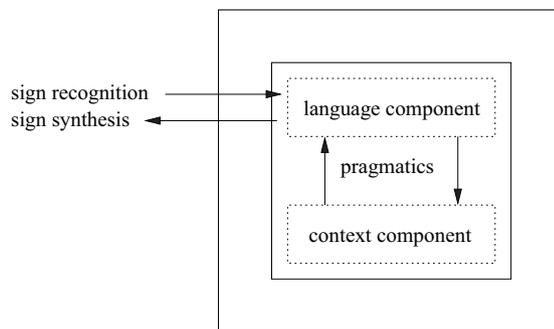

the context proplet (indicated as [noun: *square\_token*]). As a result, the feature [noun: *square\_type*] at the language level can be matched with the feature [noun: *square\_token*] at the context level.<sup>15</sup>

## 6 Immediate Reference and Mediated Reference

The relation between language expressions and the intended objects in the world is called reference.<sup>16</sup> From an ontogenetical and phylogenetical point of view, the most basic form of reference is *immediate reference*. It consists in referring with language to objects in the immediate task environment of the communicating agents, for example, to the book in front of them. Thereby, the agents' external interfaces are involved at the language as well as the context level (as in 5.1 and 5.2).

In addition, there is also the referring with language to referents which are not in the immediate task environment, but that exist solely in the databases of the communicating agents, for example, the historical figure of Aristotle. In this *mediated reference*, only the external interfaces of the language level, but not of the context level, are involved.<sup>17</sup>

### 6.1 USE OF EXTERNAL INTERFACES IN MEDIATED REFERENCE

able. In placeholders, the distinction between concept types and concept tokens is in name only.

<sup>15</sup> Apart from the vertical internal matching of types with tokens, there is also the possibility of matching types with types. This case arises in the interpretation of absolute, rather than episodic, propositions (cf. NLC'06, Sect. 5.2). For example, in the proposition *A square has four corners*, the context proplet *square* would contain the concept type rather than a token as its core value. This is no problem for matching with a corresponding language proplet, however, because matching a type with a type is structurally straightforward.

<sup>16</sup> In agent-oriented Database Semantics, reference is reconstructed computationally as a purely cognitive relation, based on the three type-token relation. This is in contradistinction to truth-conditional semantics, in which reference is defined as a direct relation between language expressions and objects of the world. Thereby, the world is defined by the logician as a set-theoretic model, and the relation between the language and the model is defined in terms of a metalanguage. In order to utilize metalanguage definitions computationally, they must be reconstructed procedurally. Most existing metalanguage-based systems, for example, modal logic, are unsuitable for a procedural reconstruction. See FoCL'99, Sect. 19.4.

<sup>17</sup> For further discussion of immediate and mediated reference see FoCL'99, Sect. 4.3.

Even though immediate reference is phylogenetically and ontogenetically primary, it is a special case of mediated reference from a theoretical point of view. This is because the cognitive procedures of mediated reference are used also by immediate reference. In other words, the functional difference between immediate and mediated reference consists in that immediate reference requires the additional external interfaces of the context level.

Cognitive agents without contextual interfaces but with language (and thus limited to mediated reference) are interesting for the following reasons. First, the contextual recognition and action capabilities of today's robots are still far removed from those of a squirrel, for example. Recognition and action at the language level, in contrast, can always be managed without principled loss of function by using the keyboard and the screen of today's standard computers. Thus, if we want to model natural language communication with today's technologies, i.e., without suitable robots, we must make due with cognitive agents which lack contextual interfaces and are therefore incapable of immediate reference.

Second, there are many tasks for which agents without contextual interfaces but with language are sufficient. In research, this applies to the modeling of cognitive operations which are based on stored data alone. In practice, it applies to such applications as the natural language interaction with databases and the Internet, involving the reading in of new content and the answering of queries.

In the long run, however, an absence of external interfaces at the context level (with the associated capabilities of recognition and action) has the following disadvantages:

## 6.2 DISADVANTAGES OF NOT HAVING CONTEXTUAL INTERFACES

### 1. *The conceptual core of language meanings remains undefined.*

Most basic concepts originate in agents without language as recognition and action procedures of their contextual interfaces, and are reused as the core of language meanings in agents with language.<sup>18</sup> Therefore, agents with language but without contextual interfaces use meanings which are void of a conceptual core – though the relations between the concepts, represented by placeholder words, may still be defined, both absolutely (for example, in the *is-a* or *is-part-of* hierarchies) and episodically.

### 2. *The coherence or incoherence of content cannot be judged autonomously.*

The coherence of stored content originates in the coherence of the external world.<sup>19</sup> Therefore, only agents with contextual interfaces are able to relate content “imported” by means of language to the data of their own experience. An agent without contextual interfaces, in contrast, has nothing but imported data – which is why the responsibility for their coherence lies solely with the users who store the data in the agent.

Due to the absence of suitable robots, the software development of Database Semantics is currently limited to standard computers. As soon the technologies needed for contextual interfaces become available, however, the theoretical framework of Database

<sup>18</sup> Cf. FoCL'99, Sect. 22.1.

<sup>19</sup> Ibid, Sect. 24.1.

Semantics will be ready for the extension. The reason for this is – roughly speaking – that immediate reference is a special case of mediated reference.

Thus, all the components developed for the version without contextual interfaces will be suitable to serve in the extended system as well. This holds, for example, for the components of the lexicon, the automatic word-form recognition and production, the syntactic–semantic and semantic–syntactic parsers, and the pragmatic inferences in the speaker and the hearer mode.

## 7 Conclusion

This paper takes a holistic approach to the analysis of natural language communication by designing a computational model of a cognitive agent. Replicating the development in phylogeny (evolution) and ontogeny (child development), the model begins with cognitive agents without language, i.e., agents which have only a context component. After reconstructing recognition and action based on the type-token relation, the language component is added as a specialized version of the original context component.

Thereby, (i) context recognition and action are reused for language recognition and synthesis and (ii) the concept types originally used for recognition and action at the context level are reused as language meanings. In this way the basic interaction between the language and the context component may likewise be based on the type-token relation. Formally, this relation is defined in terms of feature structures with variables and constants as values. It has a straightforward computational implementation and allows the agent to recognize and refer to items of a known kind, but never encountered before.

# The system of graphemes in modern Korean

Sangtae Kim

University of Cheongju  
Cheongju, Chungbuk, Republic of Korea  
kst2002@cju.ac.kr

## Abstract

The graphemics treats the written language as a linguistic system in its own right. The purpose of this treatise is to systematize the graphemes in modern Korean. This treatise is largely into two parts; one is a definition of grapheme and classification of graphemes, the other is a systematization of graphemes, focusing on Korean orthography. Consequently, the grapheme was to be defined as the smallest identifiable unit of the writing system of a given language which differentiates a meaning. And then, the writer classified graphemes into primary and secondary grapheme. As of these graphemes, the writer found that the graphemes in modern Korean were included phonemic grapheme in primary grapheme, and zero and punctuation graphemes in secondary grapheme.

**Keywords:** graphemics, grapheme, primary grapheme, secondary grapheme

## 1. Introduction

For a long time, the spoken language has been considered as a primary, and the written language a secondary. A spoken language is a human natural language in which the words are uttered through the mouth. Most human languages are generally spoken language. From the linguistic development, the spoken language is prior to the written language. The written language has been evolved or invented when we need the necessity of recording information and communicating from a long distance.

There are many letters in the world. But, the research works on these letters have been mainly studied in terms of spoken language. Until now, we have not differentiated between spoken and written language. For this reason, the written language has long been regarded as a replacement of spoken language and a secondary system of representation. Therefore, the consequences in the preceding works have been very confused with transcription and writing system. But, in recent works, we are able to see the written language is no longer described as a secondary system of spoken language.

For example, Vachek(1989) said that the spoken and written language have separately norms and have different utterances. He treated the relation between two languages, the written norm marked and the spoken norm unmarked.

We call the written language (also writing system) a graphemics. The graphemics treats written language as a linguistic system apart from phonemics which treats spoken language. Graphemics is mainly concerned with the properties which have its own domain and a structural description.

The purpose of this treatise<sup>1</sup> is to investigate the system of graphemes in modern Korean, focusing on Korean orthography<sup>2</sup>. To accomplish this purpose, this treatise is largely divided into two parts. Firstly, the writer is to define the grapheme which is the smallest unit in graphemics, and classify the graphemes. Secondly, based on graphemics, as comparing the linguistic level between the spoken and written language, the writer is to investigate into the system of graphemes of Korean orthography.

## **2. The system of graphemes in Korean orthography**

The graphemics has its own domain, apart from phonemics, the study of sound. But this graphemics has an analogy to phonemics. Graphemics is very often compared to phonemics. Phonemics is divided into segmental and suprasegmental phonemes.

Likewise phonemics, graphemics was constructed with letters and some features(Gleason, H. 1960:32). Every meaning in written language is expressed by visual means, either figural (shapes) or spatial(Mountford, J.D. 1990:704). That is to say, graphemics is not only made up of letters, which form the word, but also all visual means, such as symbol, number, punctuation marks, space and etc. More than anything else, the space is very important in interpreting the sentence in Korean. Therefore, the writer is to define graphemics as a writing system consisting of spelling system as well as non-spelling system expressed by visual means, besides the letters.

Graphemics has its own linguistic level by visual means. Just as phoneme is the smallest formal unit of phonemics, as grapheme is the smallest formal unit of graphemics. The phonemics is based on a system of phonic oppositions capable of differentiating meanings in the given community. As is well known, the system is called phonemic system and its units are known as phonemes. Analogously, graphemics must

---

<sup>1</sup> In this treatise, Korean expressions are written in the Yale system of romanization except the proper noun

<sup>2</sup> Currently, the Korean orthography was established in 1988. The orthography is made up of 57 regulations and appendix for explaining the usage of punctuation marks.

be based on a system of graphic oppositions capable of differentiating meanings in the given community. The units of this system may be called grapheme. In this treatise, the writer is to define grapheme as “A grapheme is the smallest identifiable unit of the writing system of a given language which differentiates a meaning.”

And, the kinds of graphemes are as follows;

spelling grapheme : alphabet in forming the word

prosodic grapheme : the dot indicating the toneme in middle Korean

zero grapheme : space causing to separate the word in Korean

punctuation grapheme : punctuation marks causing a contrast in meaning

symbolic grapheme : the symbols which represent various meaning

numeric grapheme : number

The writer is to classify these graphemes above, whether graphemes are forming the word or not. Firstly, the writer is to call the graphemes of forming the word a primary grapheme, and the graphemes expressed by visual means a secondary grapheme.<sup>3</sup>

In this chapter, the writer is to investigate into the system of graphemes in Korean orthography, as explaining the difference between spoken and written language.

### *2.1. Primary grapheme*

The primary grapheme is the spelling graphemes forming the word. The spelling system is the central system in graphemics(Mountford, J. D., 1990:704). Spelling graphemes are classified into two main types, logographic and phonetic, on the basis of the ways they represent language. Logographic graphemes represent primarily the meaning of a word or morpheme. The writer is to call these graphemes a morphemic grapheme.

The phonetic graphemes are classified into two things; syllabic and phonemic graphemes. For example, the former is Japanese, the latter is Korean, and English. In a syllabic grapheme, one sign represents one syllable, and in a phonemic grapheme, an alphabet represents one phoneme.

The graphemes in Korean orthography includes in phonemic graphemes

---

<sup>3</sup> These terms are analogized with phonemics. In phonemics, the segmental phoneme is called a primary phoneme, whereas the suprasegmental phoneme, such as pitch, stress and juncture is called a secondary phoneme.

There is a regulation of letters(camo, 字母) in the 4<sup>th</sup> regulation of Korean orthography. The cardinal letters are 24 letters; ㄱ *k*, ㄴ *n*, ㄷ *t*, ㄹ *l*, ㅁ *m*, ㅂ *p*, ㅅ *s*, ㅇ *ng*, ㅈ *c*, ㅊ *ch*, ㅋ *kh*, ㅌ *th*, ㅍ *ph*, ㅎ *h*, ㅏ *a*, ㅑ *ya*, ㅓ *e*, ㅕ *ye*, ㅗ *o*, ㅛ *yo*, ㅜ *wu*, ㅠ *yu*, ㅡ *u*, ㅣ *i*. And then, the other letters are combined with cardinal letters; ㄱㄱ *kk*, ㄷㄷ *tt*, ㅂㅂ *pp*, ㅅㅅ *ss*, ㅈㅈ *cc*, ㅏㅏ *ay*, ㅑㅑ *yay*, ㅓㅓ *ey*, ㅕㅕ *yey*, ㅏㅑ *wa*, ㅑㅓ *way*, ㅓㅕ *oy*, ㅓㅌ *we*, ㅌㅓ *wey*, ㅌㅣ *wi*, ㅓㅣ *uy*. These letters are compound letters. These letters is written to form a character.

The characteristic of Korean writing system is that except for a few grammatical morphemes in archaic texts, no letter may stand alone to represent elements of the Korean language. When *Hunminjeongeum* was created, the letters were combined into blocks which were called as a syllable. But we have been considered the same term with syllable and character. The writer suggested a new term *cacel*<sup>4</sup>(character, 字節) from the standpoint of written language as opposed to syllable of spoken language.(Kim, Sangtae 2008) That is to say, just as *umcel*(syllable) is a combination of phonemes, as *cacel*(character) is a combination of graphemes. Therefore, *umcel*(syllable) means the combination of onset, nucleus and coda, whereas *cacel*(character) means the combination of initial, medial and final.<sup>5</sup>

Let us consider the examples of explaining the difference between syllable and character in modern Korean.

For example, the grapheme <ㅇ> has two phonetic values. When ‘ㅇ’ is positioned in the initial of character, the phonetic value is zero, but when it is positioned in the final of character, the phonetic value is [ŋ]. For example, we consider 일어나다 *ilenata* [ilənata]. We are quickly able to know the number of syllable and think of the phoneme /ㅇ/ as the onset and the phoneme /ㄹ/ as the coda in the first syllable based on writing system. However, the phonetic value of <ㅇ> is actually zero in the first syllable, and the phonetic value of <ㄹ> in the final position of character is not the coda in the first syllable but onset in the second syllable. For this phenomenon, we should consider the principle of onset-first principle. Therefore, the /ㄹ/ of 일어나다 *ilenata* is not coda in the first syllable but the onset in the second syllable. Similarly, consider the 할머니 *halmeni* [halaməni] and 할아버지 *halapeci* [halabəci]. The unit of syllable in 할머니 *halmeni* corresponds to the unit of character. But, the /ㄹ/, // is not coda of the

<sup>4</sup> In most cases there is no difficulty in understanding, since the meaning is usually evident from context, but a terminological distinction would have given their exposition a clarity commensurated with their theory.(Gari K Ledyard 1998 : 194-195)

<sup>5</sup> I inferred this term, *cacel* from the excerpt *chocwucongsenghapisengca* (初中終聲合而成字) in the chapter of *Hunminjeongeum Congpepjang*. This means that the letters of initial, medial, and final are combined into *Ca*(character, 字).

first syllable but onset of the second syllable in 할아버지 *halapeci*. The phonetic value is closely connected with the position in the character. All the sounds are not positioned in the syllable. Of all the 19 consonants in modern Korean, the only [ŋ] is not located in the onset. Other consonants are located in the onset and actualized as a phonetic value of their own. And 27 letters are able to write in the final position of character. But the sounds of the coda are confined to 7 sounds; ㄱ[k], ㄴ[n], ㄷ[t], ㄹ[l], ㅁ[m], ㅂ[p], ㅇ[ŋ]. At this time, we find the fact that the spoken and written language is not always parallel.

The 19 consonants used in the Korean Standardization are as follows;

ㄱ[k] ㅋ[k'] ㄴ[n] ㄷ[t] ㄸ[t'] ㄹ[l] ㅁ[m] ㅂ[p] ㅃ[p'] ㅅ[s] ㅆ[s'] ㅇ[ŋ]  
 ㅈ[c] ㅉ[c'] ㅊ[ch] ㅋ[kh] ㅌ[th] ㅍ[ph] ㅎ[h]

The 21 vowels used in the Korean Standardization are as follows;

ㅏ[a] ㅑ[e] ㅓ[ja] ㅕ[je] ㅗ[ə] ㅛ[e] ㅜ[jə] ㅠ[je] ㅡ[o] ㅘ[wa] ㅙ[we]  
 ㅚ[we] ㅜ[jo] ㅛ[u] ㅜ[wə] ㅠ[we] ㅟ[wi] ㅠ[ju] ㅡ[i] ㅟ[ji] ㅣ[i]

And, let us consider the letters which were combined into character in Korean orthography. The letters used in Korean orthography are as follows;

the letters of the initial : ㄱ *k*, ㅋ *kk*, ㄴ *n*, ㄷ *t*, ㄸ *tt*, ㄹ *l*, ㅁ *m*, ㅂ *p*,  
 ㅃ *pp*, ㅅ *s*, ㅆ *ss*, ㅇ *ng*, ㅈ *c*, ㅉ *cc*, ㅊ *ch*, ㅋ *kh*, ㅌ *th*,  
 ㅍ *ph*, ㅎ *h*

the letters of the medial : ㅏ *a*, ㅑ *ay*, ㅓ *ya*, ㅕ *yay*, ㅗ *e*, ㅛ *ey*, ㅜ *ye*,  
 ㅠ *yey*, ㅡ *o*, ㅘ *wa*, ㅙ *way*, ㅚ *oy*, ㅜ *yo*, ㅛ *wu*, ㅜ *we*,  
 ㅠ *wey*, ㅟ *wi*, ㅠ *yu*, ㅡ *u*, ㅟ *uy*, ㅣ *i*

the letters of the final : ㄱ *k*, ㅋ *kk*, ㄴ *ks*, ㄴ *n*, ㄷ *nc*, ㄹ *nh*, ㄷ *t*, ㄹ *l*,  
 ㄷ *lk*, ㄹ *lm*, ㅂ *lp*, ㄷ *ls*, ㄹ *lth*, ㅍ *lph*, ㄹ *lh*, ㅁ *m*, ㅂ *p*,  
 ㅃ *ps*, ㅅ *s*, ㅆ *ss*, ㅇ *ng*, ㅈ *c*, ㅊ *ch*, ㅋ *kh*, ㅌ *th*, ㅍ *ph*, ㅎ *h*

These letters are combined to form a character. Therefore, these letters are called a grapheme. Of all the letters, the 19 consonantal letters are used in the initial of the character, 21 vowel letters are used in the medial of the character, 27 letters are used in the final of the character.

In the above letters, the letters which are written in both the initial and final at the same time are 16 letters; ㄱ, ㄴ, ㄷ, ㄹ, ㅁ, ㅂ, ㅅ, ㅇ, ㅈ, ㅊ, ㅋ, ㆁ, ㆆ, ㆏, ㆑, ㆒, ㆓. The letters which are only written in the initial are 3 letters; ㄸ, ㅃ, ㅆ. And, the letters which are only written in the final are 11 letters; ㄱ, ㄴ, ㄷ, ㄹ, ㅁ, ㅂ, ㅅ, ㅈ, ㅊ, ㅋ, ㆁ.

Now, we establish the system of graphemes in modern Korean orthography. The graphemes in Korean orthography are classified into two kinds. One is a simple grapheme, the other is a compound grapheme. The criteria are whether the letters are divided into two letters or not. That is to say, the criteria of classification are not phonetic but a system of letter. And then the simple and compound graphemes are classified into consonant and vowel letters. For example, although the letter ‘ㅋ kh’ is phonetically complex sounds [kh], the letter is included in a simple grapheme. Likewise, the consonant letters, ㆁ, ㆆ are phonetically aspirated derivatives of ㄷ, ㅂ, respectively, formed by combining the unaspirated letters with an extra stroke. This extra stroke does not solely function as a grapheme. And, the double letters are, ㄸ, ㄸ, ㅃ, ㅃ and ㅆ, ㅆ do not represent geminate consonants, but rather a “tense” phonation.

And, the vowel letters, ㅏ, ㅑ, ㅓ, and ㅕ are derived by means of short stroke to signify iotation (a preceding i sound before ㅏ, ㅑ, ㅓ, ㅕ). These four vowel letters are phonetically diphthong vowels, but graphically are going to include simple grapheme, because the iotating stroke taken out of these letters does not represent [y]. In fact, there is no separate grapheme for [y].

Also, in modern Korean, the vowel sounds, ‘ㅗ, ㅛ, ㅜ, ㅠ’ are included in simple vowels. But these sounds were originally diphthongs, but have evolved into simple vowels. But in this treatise, the writer is going to include these letters in compound vowel letters graphically.<sup>6</sup>

Therefore, the letters which are written in the medial are classified into two classes. One is simple vowel letters; ㅏ, ㅑ, ㅓ, ㅕ, ㅗ, ㅛ, ㅜ, ㅠ. The other is compound vowel letters; ㅝ, ㅞ, ㅟ, ㅠ, ㅡ, ㅢ, ㅣ, ㅤ, ㅥ, ㅦ, ㅧ.

The results are as follows;

### Simple grapheme

- Consonant letters : ㄱ, ㄴ, ㄷ, ㄹ, ㅁ, ㅂ, ㅅ, ㅇ, ㅈ, ㅊ, ㅋ, ㆁ, ㆆ, ㆏, ㆑, ㆒, ㆓
- Vowel letters : ㅏ, ㅑ, ㅓ, ㅕ, ㅗ, ㅛ, ㅜ, ㅠ

---

<sup>6</sup> Cf. In Korean orthoepy,  
 simple vowel : ㅏ [a] ㅑ [ɛ] ㅓ [ɔ] ㅕ [e] ㅗ [o] ㅛ [we] ㅜ [u] ㅠ [wi] ㅡ [∅] ㅣ [i]  
 diphthong vowel : ㅝ [ja] ㅞ [jɔ] ㅟ [jo] ㅠ [ju] ㅡ [je] ㅢ [je] ㅣ [wa] ㅤ [we] ㅥ [wɔ] ㅦ [we] ㅧ [∅j]

The results of compound grapheme are as follows;

#### Consonant letters

digraph double letters : ㄲ, ㄸ, ㅃ, ㅆ, ㅉ

double clusters : ㄱㅅ, ㄴㅌ, ㄴㅇ, ㄹㅇ, ㄹㅁ, ㄹㅂ, ㄹㅅ, ㄹㅆ, ㄹㅇ, ㅁㅂ

#### Vowel letters

digraph double clusters : ㅏ, ㅑ,

iotated letters : ㅓ, ㅕ, ㅗ, ㅛ, ㅜ, ㅠ, ㅡ, ㅟ

trigraph letters : ㅛ, ㅜ

## 2.2. Secondary grapheme

The secondary graphemes are not concerned with forming the word. These are classified into two kinds. One is a figural grapheme, the other is a spatial grapheme. The figural graphemes function as letters do. These graphemes include punctuation, symbolic, numeric and prosodic graphemes. The prosodic grapheme is marked by a dot in middle Korean. This grapheme indicates the toneme. But these marks have disappeared in most dialects of Korean. And the spatial grapheme is called zero grapheme in this treatise.

In this part, the writer is to investigate into the secondary grapheme used in Korean orthography.

### 2.2.1. zero grapheme

The 2<sup>th</sup> regulation in Korean orthography is that the space should be inserted between the words. This means that it is impossible to insert a space and another word within a word. In running texts, space is placed before each free word. Thus, all suffixes are attached to the respective stems, and all particles to the heads. Therefore, a word is defined as the minimal free form and consists of one or more morphemes, which is to say ‘나라 *nala*, 사랑 *salang*, 손톱 *sonthop*’, and also cannot be separated. The space is very important in understanding the sentence.

Let's take examples such as ‘작은아버지 *cakunapeci*’ and ‘작은 아버지 *cakun#apeci*’. As the former means a younger brother of father's, another word cannot be inserted into the former. Whereas, we can insert another word between ‘작은 *cakun*’ and ‘아버지 *apeci*’. This is made up of two words, hence forming a phrase. The meaning of this phrase is changed by the word of inserting between two words. In Korean orthography, the spacing marks the boundary of word.

Another example, the sentence, “아버지가 방에 들어 가신다 *apecika pangey tule kasinta*” means *Father enters the room*. But “아버지 가방에 들어가신다 *apeci kapangey tule kasinta*” means *Father enters the bag*. The meaning of two sentences is differentiated by space. The writer is to call space a zero grapheme.

The space in written language corresponds with pause in spoken language. So, the space does not always agree with a pause. The writer proposed the phonological word in terms of phonology(Kim, Sangtae 2006b). The morphological word is separated from other words by way of a space, whereas the phonological word is separated from other words by way of a pause. Phonological word is marked by the potential pause which can be realized. And the morphological word can be strongly divided because the abundance of phonological separation, in this case the morphological word is two phonological words. For example, And the forms such as ‘한 *han*, 맨 *mayn*’, have two functions as a determiner and a derivational affix. When two forms were used as a determiner, the space should be inserted between two words; for example, ‘맨 꼭대기 *mayn#kkotayki* (on the highest)’, ‘한 개 *han#kay*(a piece)’. But when these forms were used as a derivational affix, especially prefix, these prefixes were forced to attach to roots; for example ‘한핏줄 *han-phicwul*(one blood)’, ‘맨몸 *mayn-mom*(a naked body)’. When these forms are used as a prefix, the pause is inserted into two characters. Therefore, we could know two phonological words, though the forms are visually a morphological word. Also when two morphological words can be pronounced without a pause, this phrase could be one phonological word. For example, the phrase ‘할 수 있다 *hal#swu#issta*(can do)’ is morphologically three words, but phonologically one word because there is no pause between the forms.

Therefore, the zero grapheme is very important in understanding the texts in written language as opposed to a pause in spoken language.

### 2.2.2. Punctuation grapheme

The punctuation marks are very important in communicating with letters as opposed to suprasegmental phonemes in spoken language. That is to say, the spoken language has an emphasis on the suprasegmental features such as intonation, stress, pitch and accent, whereas the written language has an emphasis on punctuation marks(Chang, Sowon 1986:198-199). These punctuation marks carry the message which is necessary to communicate. Also, the spoken language is varied in its meaning according to length, pitch, stress, and etc(Sin, Jiyoung 2004:5).

Therefore, the writer is to include the punctuation marks into a grapheme. And this grapheme is to call a punctuation grapheme.

The usage of punctuation marks is regulated in the appendix of Korean orthography established in 1988. The punctuation is a method of interrupting periodically in reading a text and providing punctuation marks in writing a text. The punctuation marks in Korean orthography made up of a period, question, exclamation, comma, middle point, colon, quotation, parenthesis, slash, dash, emphasis and veiling marks<sup>7</sup>.

### 3. Conclusion

The writer was to investigate into the system of graphemes in modern Korean, focusing on Korean orthography. Until now, we have very confused with spoken and written language. For this reason, the written language has been considered as a secondary system of spoken language and has not been acknowledged as its own linguistic system. And the terms are very confused with phoneme and grapheme.

In conclusion, this treatise tries to establish the system of grapheme as concentrating on the difference between spoken and written language in modern Korean. The starting point of this treatise was that the spoken and written language has its own domain and system separately.

The summary discussed in this treatise is as follows.

First, the writer defined the graphemics, the study of writing, as a writing system consisting of spelling system as well as non-spelling system expressed by visual means, besides the letters. And the writer defined the grapheme, the smallest unit in graphemics, as a smallest identifiable unit of the writing system of a given language which differentiates a meaning, and then classified into two things; primary and secondary grapheme in analogous with phonemics.

Second, based on graphemics, this treatise is to systematize the graphemes in Korean orthography. Firstly, the writer is to systematize the graphemes which form a word. This grapheme is concretely into phonemic grapheme. Especially, the writer is to establish the system of grapheme in comparing the character with the syllable which is combined with phonemes in spoken language. Secondary, the secondary graphemes used in Korean orthography are zero and punctuation graphemes. The zero grapheme is a space in written language and is opposed to a pause in spoken language. Just as a space functions of separating the morphological word, as a pause functions of

---

<sup>7</sup> The emphasis mark is a ‘, °’. These marks put a stress on the letter to indicate a important part. And the veiling mark is a ××, ○○. These marks are intentionally to disclose the point.

separating a phonological word. The morphological word does not always coincide with a phonological word. Therefore, we could know that the zero grapheme is very important in understanding texts. Another secondary grapheme is punctuation grapheme. This grapheme is opposed to suprasegmental phonemes. That is to say, the punctuation marks are a means for communicating message in written language, whereas the suprasegmental phonemes are very important in conveying a message. At this point, we also realized the importance of punctuation marks.

To sum up, the writer thinks that it is very important to recognize the difference spoken and written language. And when graphemics and phonemics develop together with at the same time, this is very helpful in teaching language to the students and foreigners. Also, this study is expected to contribute to transform speech-to-grapheme in Korean Natural Language Processing in Computer.

# L'inchoativité en japonais dans le cadre du TAM

Satoshi Someya

Université Paris VIII-CNRS LACITO

20 rue des Perchamps 75016

someya.satoshi@gmail.com

## Résumé

Le présent article a pour objectif d'examiner l'inchoativité en japonais, notamment les valeurs du verbe <なる naru> (devenir) dans le cadre de la typologie linguistique du Temps Aspect Mode (TAM) et de mettre en lumière la construction d'inchoativité, en observant l'association aux marqueurs marginaux dans la phrase et en comparant <なる naru> avec les deux marqueurs d'inchoativité comme <始める hajimeru> (commencer) et <ところ tokoro> (endroit).

**Mots clés : inchoativité, aspect, naru (devenir), japonais, typologie, achèvement**

## 1 なる naru

La forme <なる naru> est utilisée en japonais comme suivant.

non-passé	なる na-ru
passé	なった nat-ta
connecteur	なって nat-te

(1) 彼は大統領になった。

Kare-wa daitooryoo-ni nat-ta

Il-nom président-à devenir-passé

Il est devenu président.

En japonais, il y a une construction des verbes composés grâce à la grammaticalisation de certains verbes. Ce type de construction se caractérise par deuxième verbe final (V2) avec marqueur définitif et premier verbe connectif (V1) ou premier nom connectif (N1). Dans les exemples suivants, le deuxième verbe final n'a plus son sens littéral. En plus, il devient l'auxiliaire, qui marque l'aspect temporel.

食べるようになる taberu-yoo-ni-naru

V1	nom	particule	V2
食べる	よう	に	なる
taberu	yoo	ni	naru-non-passé
(manger)	(état)	(à)	(devenir)

(2) 毎日、肉を食べるようになった。(ibid.)

mainichi niku-o taberu-yoo-ni-nat-ta  
tous les jours viande-acc manger-état-ni-NARU-passé  
J'ai commencé à manger de la viande tous les jours. (je constate)

Lorsque <なる naru> est utilisé en tant que l'inchoativité, <なる naru> joue un rôle comme « j'ai constaté que » « j'ai vu que » discuté par Tournadre (2004 : 53). C'est une différence entre <なる naru> et <始める hajimeru> (commencer) dans la situation suivante. Dans les verbes composés, <なる naru> est difficilement compatible avec l'adverbe <juste maintenant>, tandis que <始める hajimeru> est bien associé.

(3) a この子は本を読むようになった。

(capacité acquise) (graduel, de plus en plus) (on peut continuer et répéter)

kono-ko-wa hon-o yomu-yoo-ni-nat-ta  
Cet enfant-nom livre-acc lire-état-à-NARU-passé  
Cet enfant a commencé à lire le livre. (le locuteur constate)  
/-----R/----- T。 →

b この子は\*ちょうど今本を読むようになった。

Kono-ko-wa \*choodo-ima hon-o yomu-yoo-ni-nat-ta  
cet-enfant-nom juste-maintenant livre-acc lire-état-à-NARU-passé  
Cet enfant a commencé à lire le livre. (juste maintenant)

c この子はちょうど今本を読み始めた。

kono-ko-wa choodo-ima hon-o yomi-hajime-ta  
cet-enfant-nom juste-maintenant livre-acc lire-commencer-passé  
Cet enfant a commencé à lire le livre. (voici)  
/-----R T。 / →

## 2 Marque-Pucheu (1999)

Marque-Pucheu (1999: 240-241) présente deux catégories d'inchoativité. La première « l'inchoativité instantanée », indique une transition vers un état ou vers une action, la seconde « l'inchoativité graduelle » indique le début d'une transformation. L'adverbe « longuement » (J.-C. Ascombe 1990) nous permet de séparer ces deux catégories de verbes.

- (4) a Le papier est en feu. (l'inchoativité instantanée : état)  
b Le papier prend feu/Max endosse son pardessus.  
(l'inchoativité instantanée : action)  
c Le papier noircit.  
(Le papier (commence à être + devient) de plus en plus noir)  
(l'inchoativité graduelle)  
d Le papier noircit longuement.  
e \*Le papier prend longuement feu/\*Max endosse longuement son pardessus.

## 3 Bourdin (1999)

Bourdin (1999: 208-209) propose la notion de la « récence » en analysant typologiquement beaucoup de langues (japonais inclus). Cependant, Bourdin n'analyse pas la « récence » en tant que l'inchoativité.

- (5) これから勉強するところだ。  
kore kara benkyoo suru tokoro da  
maintenant abl études faire lieu/moment copule : PRES  
Maintenant je suis sur le point de me mettre à étudier.  
T<sub>o</sub> → -----R/-----

## 4 Cohen (1989) et Tournadre (2004)

Concernant « l'accompli », Cohen (1989 : 62) ajoute la précision suivante :

« la délimitation de la relation prédicative met en œuvre dans de nombreuses langues

des éléments divers qui focalisent l'attention sur l'achèvement (du procès) certes, mais sur son début. »

Tournadre (2004 : 32) remanie cette définition, donnant l'exemple ainsi que le schéma illustrant « l'accompli » « l'inchoatif ».

(6) Claude a marché à l'âge de deux ans. (Claude a commencé à marcher)

/-----R/----- T<sub>o</sub> → Passé accompli

Dans cette situation, on peut continuer et répéter le procès de marcher comme « capacité » acquise. Je définis cette notion comme « inchoativité de capacité acquise ».

## 5 Redéfinition d'inchoativité

Je redéfinit la notion « inchoativité » comme suivant : une action et un état vers le commencement (pré-processuelle), ou une action et un état déjà commencé, soit en cours, soit raté.

Nous pouvons diviser cette notion en trois catégories. La première « inchoativité de faillite (tentative) » indique le seuil final d'une action ou d'un état, qui tend vers l'achèvement, mais échoue juste avant. La deuxième, « inchoativité juste avant l'achèvement », indique le seuil final d'une action ou d'un état en cours, et qui est sur le point de s'achever, sans l'être encore. Le troisième « inchoativité pré-processuelle » indique qu'une action ou un état est sur le point de commencer, sans que cela soit encore le cas.

(7) a J'ai failli être tué. (être sauvé, échapper à la mort) (faillite)

/----- seuil final ----- échoué R/----- T<sub>o</sub> →

b Le chien est sur le point de mourir.

(le chien commence à mourir, mais pas encore)

(juste avant l'achèvement)

/----- seuil final T<sub>o</sub> → ----- R/

c Maintenant je suis sur le point de me mettre à étudier.

(pré-processuelle) (pas encore commencé)

T<sub>o</sub> → -----R/-----

## 6 Les marqueurs <こと koto> <よう yoo> <そう soo>

Il existe en japonais trois marqueurs : <こと koto> (projet ou résultat), <よう yoo> (changement de manière vers un état de faisabilité), et <そう soo> (conjecture fondée sur l'observation d'une réalité extérieure ou une impression). Ces trois marqueurs sont bien associés à <なる naru>.

(8) a 彼女は若い弁護士と結婚することになった。

(c'est pas l'inchoativité) (prévu)

Kanojo-wa wakai bengoshi-to kekkonsuru-koto-ni-nat-ta

Elle-nom jeune avocat-avec se marier-projet-ni-devenir-passé

Elle va se marier avec un jeune avocat.

/-----R projet /----- T。 → -----R marier /

b この子は2歳で歩けるようになった。(capacité acquise)

Kono-ko-wa ni-sai-de aru-keru-yoo-ni-nat-ta

Cet-enfant-nom deux-ans-à marcher-capable-YOO-à-devenir-passé

Cet enfant a marché à l'âge de deux ans. (capable de marcher)

/-----R/----- T。 →

c 犬が死にそうになっている。(juste avant l'achèvement)

inu-ga sini-soo-ni-nat-te-iru

chien-nom mourir-SOO-ni-devenir-connecteur TE-prog

Le chien est sur le point de mourir.

/----- seuil final T。 → ----- R/

'soo-ni-naru' n'est pas utilisé en tant que verbe de volition résultatif, lorsque le sujet est première personne. En revanche, avec 'tokoro' (endroit), cela marche bien en japonais.

(8) d \*僕は出かけそうになっている。

\*boku-wa dekake-soo-ni-nat-te-iru

je-suj sortir-SOO-ni-devenir-connecteur TE-prog

Je suis sur le point de sortir.

(8) e 僕は出かけるところだ。

boku-wa dekakeru-tokoro-da

je-suj sortir-endroit-copule

Je suis sur le point de sortir.

## 7 L'association de *なる* *naru* aux différents types de procès

Cette section analyse l'association de *<なる naru>* (devenir) au procès d'achèvement en observant les différences parmi les trois marqueurs dans la phrase et en comparant *<なる naru>* avec un autre marqueur d'inchoativité *<始める hajimeru>* (commencer). Un classement des types de procès est proposé par Vendler (1967 : 106) et revu et corrigé par Recanati C. et Recanati F. (1999 : 167). Tournadre (2004 : 23) y ajoute la distinction entre achèvement et procès ponctuel.

### 7.1 L'association de *<なる naru>* au verbe « se marier »

*<なる naru>* associé à *<結婚する kekkonsuru>* (se marier) signifie le projet du sujet. Dans ce cas, *<なる naru>* est utilisé dans un contexte prévu.

Le procès de *<se marier>* est difficilement compatible avec le marqueur *<よう yoo>*. Le marqueur composé *<ようになる yoo-ni-naru>* est essentiellement bien associé au procès d'état ou d'habituel. Normalement, on ne peut pas continuer et répéter le procès d'achèvement *<se marier>* sauf le divorce.

(9) \*彼女は若い弁護士と結婚するようになった。

Kanojo-wa wakai bengoshi-to \*kekkonsuru-yoo-ni-nat-ta

Elle-nom jeune avocat-avec se marier-YOO-à-devenir-passé

\*Elle commence à se marier avec un jeune avocat.

Cependant, *<ようになる yoo-ni-naru>* est associé à *<結婚する kekkonsuru>*, lorsque le sujet s'est marié avec plusieurs avocats.

(10) 彼女は次々と若い弁護士と結婚するようになった。(itératif)

Kanojo-wa tugitugito wakai bengoshi-to kekkonsuru-yoo-ni-nat-ta

Elle-nom l'une après l'autre jeune avocat-avec se marier-YOO-à-devenir-passé

Elle commence à se marier avec plusieurs jeunes avocats l'un après l'autre

/-----R/.../-----R/.../-----R/... T。 →

avocat avocat avocat

*<始める hajimeru>* n'est pas associé à *<結婚する kekkonsuru>*, lorsque le sujet est singulier. En revanche, deux sont compatibles lorsque le sujet est pluriel dans la

situation « itératif ».

(11) a 彼女は若い弁護士と\*結婚し始めた。

Kanojo-wa wakai bengoshi-to \*kekkonshi-hajime-ta  
Elle-nom jeune avocat-avec se marier-commencer-passé  
\*Elle a commencé à se marier avec un jeune avocat.

b 彼女たちは次々と結婚し始めている。

Kanojo-tachi-wa tugitugito kekkonshi-hajime-te-iru  
Elle-pluriel-nom l'une après l'autre se marier-commencer-te-continuatif  
Elles commencent à se marier l'une après l'autre. (itératif)

/-----R/.../-----R/.../-----R/... T。 →  
                  elle                    elle                    elle

## 7.2 L'association de <なるnaru> au verbe « mourir »

<なるnaru> associé à <死ぬshinu> (mourir) est utilisé dans un contexte imprévu.

(12) a 彼は死にそうになった。(faillite)

kare-wa shini-soo-ni-nat-ta  
il-nom mourir-SOO-ni-NARU-passé  
Il a failli mourir. (être sauvé, échapper à la mort)  
/----- seuil final ----- échoué R/----- T。 →

b 彼は死にそうになっている。(juste avant l'achèvement)

kare-wa shini-soo-ni-nat-te-iru  
il-nom mourir-SOO-ni-NARU-conjec-continuatif  
Il me semble que/J'ai bien l'impression qu'il va bientôt mourir.  
/----- seuil final ----- T。 → pas encore R/

Cependant, <なるnaru> associé à <死ぬshinu> (mourir) est utilisé dans un contexte « prévu » comme suivant.

(13) 患者は病気でもうすぐ死ぬことになっている。(juste avant l'achèvement)

Kanja-wa byooki-de moosugu shinu-koto-ni-nat-te-iru  
Patient-nom maladie-caus bientôt mourir-projet-à-devenir-conjec-continuatif  
Ce patient va bientôt mourir à cause de maladie. (prévu)  
/----- seuil final T。 ----- → pas encore R/

<mourir> n'est pas compatible avec le marqueur <よう yoo>. Le marqueur composé <ようになる yoo-ni-naru> est essentiellement bien associé au procès d'état ou habituel. On ne peut absolument pas continuer et répéter le procès d'achèvement « mourir ».

(14) 彼は事故で\*死ぬようになった。

Kare-wa jiko-de \*shinu-yoo-ni-nat-ta

Il-nom accident-caus mourir-médiatif-ni-devenir-passé

Il commence à mourir dans un accident.

En revanche, deux sont compatibles lorsque le sujet est pluriel dans la situation « itératif » comme suit.

(15) 多くの人々が事故で死ぬようになった。

Ookuno-hito-ga jiko-de shinu-yoo-ni-nat-ta

Beaucoup-gens-nom accident-caus mourir-médiatif-à-devenir-passé

Beaucoup-gens commencent à mourir dans des accidents.

/-----R/.../-----R/.../-----R/... T。 →

Également en cas de <始める hajimeru> (commencer), deux sont compatibles lorsque le sujet est pluriel, tandis que le sujet singulier n'est pas compatible.

(16) a 患者は病気で\*死に始めた。

kanja-wa byooki-de \*shini-hajime-ta

patient-nom maladie-caus mourir-commencer-passé

\*Le patient a commencé à mourir à cause de maladie.

b 患者たちは次々と病気で死に始めている。

Kanja-tachi-wa tugitugito byooki-de shini-hajime-te-iru

Patient-pluriel-nom l'un après l'autre maladie-caus mourir-commencer-te-iru

Les patients commencent à mourir l'un après l'autre à cause de maladie.

/-----R/.../-----R/.../-----R/... T。 →

## Résumé

Le présent article se propose de mettre en évidence les propriétés syntactico-sémantiques des noms de propriété en coréen comme *yonggi*(courage), *chameulseong*(patience), *seongkyeok* (caractère), *muge*(poids), etc. et de montrer la nécessité de répartir ces noms en deux groupes : noms de propriétés « identifiantes » et noms de propriétés « attributives ». Les premiers, qui sont du type *seongkyeok*(caractère) et *muge*(poids), permettent de cerner le type de propriétés dont on veut parler, alors que les seconds, représentés par les noms du type *yonggi*(courage) et *chameulseong*(patience), « parlent » eux-mêmes des propriétés. Pour justifier cette idée, nous mettons en lumière la différence des comportements syntaxiques de ces deux types de noms : les noms de propriétés « identifiantes » peuvent apparaître en position de N1 dans la construction *N0-ga N1-ga (N2-ida + Adj)* alors que ce n'est pas le cas pour les noms de propriétés « attributives » ; ceux-ci n'apparaissent en effet qu'en position de N2. Par ailleurs, nous montrons diverses sous-classes de ces deux types de noms et, ce faisant, nous révélons également la corrélation syntactico-sémantique de ces deux types de noms : si, dans la construction *N0-ga N1-ga (N2-ida + Adj)*, N1 relève de la classe <Pr. identifiantes de X>, N2 et Adj. appartiennent à la classe < Pr. attributives de X >.

**Mots-clés :** noms de propriété, propriétés « identifiantes », propriétés « attributives », noms prédicatifs.

## 1. Introduction

La présente étude se propose de mettre en évidence les propriétés syntactico-sémantiques des noms de propriété en coréen comme *yonggi*(courage), *chameulseong* (patience), *seongkyeok*(caractère), etc. et de montrer la nécessité de répartir ces noms en deux groupes : les noms de propriétés « identifiantes » et ceux de propriétés

« attributives ».

Avec le développement de l'industrie langagière, le souci de décrire les phénomènes linguistiques n'a cessé d'augmenter. Ce qui a conduit les linguistes, quelle que soit la théorie qu'ils adoptent, à tenter de faire la description linguistique la plus systématique et la plus formelle possible. Les travaux menés dans le cadre du lexique-grammaire ou des classes d'objets s'inscrivent dans ce courant de recherche. Les travaux sur le lexique-grammaire, partant de l'idée que l'unité minimale de sens n'est pas un mot isolé mais une phrase simple – celle-ci étant définie comme un prédicat muni de ses propres arguments – consiste à construire le lexique d'une langue en décrivant de façon exhaustive les propriétés syntaxiques – distributionnelles et transformationnelles – d'un prédicat au niveau de la phrase simple.<sup>1</sup>

Quant aux travaux concernant les classes d'objets qui s'inscrivent dans la même perspective, ils consistent à compléter le lexique en renforçant l'aspect sémantique, autrement dit en fournissant au lexique autant d'informations sémantiques que syntaxiques. Ainsi les travaux sur les classes d'objets proposent-ils de décrire les mots, que ce soit des prédicats ou bien de simples arguments, en les classifiant selon leurs propriétés sémantiques et syntaxiques. C'est-à-dire que, du point de vue des classes d'objets, construire le lexique d'une langue revient à construire les classes sémantiques des mots à partir de leurs propriétés syntaxiques : leurs classes d'objets.<sup>2</sup>

C'est dans cette perspective que notre étude se situe et qu'elle se concentre sur la construction des classes d'objets en coréen. Pour construire les classes des prédicats, en particulier celles des prédicats nominaux, il nous faut différencier, au sein des classes des noms d'états, les classes des noms de propriétés de celles des noms d'autres types ; ce faisant, nous sommes également amenés à distinguer ces noms de propriété en deux groupes, et cela pour mettre en évidence la corrélation existant entre les classes des prédicats nominaux et celles des prédicats de types verbaux et adjectivaux. C'est cette démarche qui sera présentée dans ce qui suit.

Pour cela, nous allons tout d'abord présenter la motivation de cette étude et définir les noms de « propriétés » en nous fondant sur leurs propriétés syntactico-

---

<sup>2</sup> Voir entre autres Le Pesant, D. & Mathieu-Colas, M. (1998) ; Gross, G. (1992, 1994, 1996).

sémantiques. Ensuite, nous allons montrer qu'il y a deux types de noms de propriétés qui se distinguent par des comportements syntaxiques différents : noms de propriétés « identifiantes » et noms de propriétés « attributives ». Pour finir, nous présenterons différentes sous-classes appartenant à ces deux types de noms ainsi que l'intérêt de leur établissement.

## **2. Classes d'objets en coréen**

### *2.1. Construction des classes d'objets en coréen*

Depuis 2001, nous travaillons sur l'établissement des classes d'objets des noms coréens en vue de représenter de façon formelle et systématique les informations sémantiques dans le Dic *Sejong*. Le Dic *Sejong* est le dictionnaire électronique du coréen qui a été construit en 10 ans (1998~2007) et qui contient 600 000 entrées : 150 000 entrées dans le Dic « détaillé » et 450 000 entrées dans le Dic « élémentaire ».<sup>3</sup>

Les classes des noms servent dans le Dic *Sejong* à discriminer et représenter les différents sens (ou emplois) des entrées nominales et à coder les restrictions sur la sélection des arguments pour les entrées d'emploi prédicatif : les entrées verbales, adjectivales et nominales d'une part et, d'autre part, les entrées syntagmatiques comme les collocations, les expressions figées et différents types de syntagmes nominaux.

Actuellement, une étude est en cours pour établir les classes d'objets des adjectifs et des verbes, une étude qui consiste à comparer les classes des noms avec les différents types de procès représentés par les adjectifs et les verbes et à élaborer les classes des adjectifs et des verbes en complétant et réorganisant les classes des noms qui existent.

### *2.2. Problèmes soulevés lors de la construction des classes d'objets en coréen*

En menant les travaux desquels nous venons de parler, nous avons constaté deux choses. La première est qu'il y a une corrélation entre les classes des noms prédicatifs et

---

<sup>3</sup> Voir pour plus de détails Hong, C.-S. & Lee, S. H.(2003) ; Lee, S. H. & Hong, C.-S.(2008).

celles des verbes et des adjectifs : les classes de <valeurs des propriétés> et d'<états> établies pour les substantifs sont en grande partie également valides pour les adjectifs prédicatifs, tandis que les classes d'<actions> sont de leur côté valides pour les verbes prédicatifs. La seconde constatation est qu'une grande partie des classes d'<objets (noms) abstraits> révèlent des caractéristiques difficiles à traiter.<sup>4</sup> Ces classes n'ont pas de classes correspondantes représentées par les adjectifs et elles contiennent des noms qui sont étroitement liés aux types de procès « propriétés ».

A partir de ces constatations, nous avons été amenés à nous poser deux questions : quelles sont les « propriétés » et comment traiter les noms de ce type qui ont été répartis sous l'hyperclasse d'<objets (noms) abstraits> ? Pour ce qui est de la première question, elle revient à se demander lesquels des noms présentés en (1) sont vraiment des noms de propriétés :

- (1) a. *saek* (couleur) vs *parang* (bleu)  
b. *banghyang* (direction) vs *dong* (est)  
c. *seongyeok* (caractère) vs *chameulseong* (patience)

Pour ce qui est de la seconde question, elle revient à demander s'il ne faudrait pas intégrer ces classes aux hyperclasses de prédicats qui représentent différents types de procès ; et si oui, comment les répartir en fonction des classes <valeurs des propriétés>.

### 3. Noms de propriétés

#### 3.1. Propriétés vs Etats

A l'heure actuelle, il est bien connu qu'il existe des noms fonctionnant comme

---

<sup>4</sup> L'hyperclasse d'<objets(noms) abstraits> renvoie à une hyperclasse regroupant différents noms abstraits dont la prédictivité n'a pas été suffisamment attestée et qui sont par exemple : *gili*(longueur), *geori*(distance), *gyumo*(dimension), *muge*(poids), *yang*(quantité), *jeongdo*(degré), *banghyang*(direction), *saek*(couleur), *seongkyeok*(caractère), *bangbeop*(méthode), *gyeongchi*(paysage), *sangwhang* (situation). Les noms de ce type sont couramment utilisés pour étiqueter des classes alors qu'ils se différencient - par leurs comportements syntaxiques - des noms appartenant aux classes en question :

- *saek*(couleur) vs *parang*(bleu), *ppalgang*(rouge), etc.  
- *banghyang* (direction) vs *dong*(est), *nam(sud)*, etc.

des prédicats et que ces noms peuvent représenter différents types de procès en composant la phrase à l'aide des verbes supports. Les types de procès ainsi représentés se distinguent en gros en trois catégories : les états, les actions et les événements.

- (2) a. *Paul a de la patience.*  
b. *Paul a fait une étude sur la vie des immigrants.*  
c. *Il y a eu un grave accident sur l'autoroute A6.*

Ainsi, ces distinctions servent de point de repère lorsque l'on classe les noms prédicatifs en vue de la description de leurs propriétés syntaxiques et sémantiques. A titre d'exemple, Anscombe (1995 :45), voulant décrire les noms de sentiment et d'attitude, distingue avant tout les états en deux types : les états « permanents et constitutifs » et les états « accidentels et transitoires ».

D'après lui, les premiers renvoient à un type de procès non processifs comme à des qualités attribuées à des personnes ou à des choses ou des jugements portés sur elles qui sont représentés par des noms tels que *blondeur, mineur, gentillesse, intelligence, méchanceté*, etc. En revanche, les seconds dénotent un type de procès processifs comme des états ayant une certaine durée qui sont représentés par des noms tels que *maladie, ivresse, absence, silence*, etc. C'est ainsi que seuls les seconds sont susceptibles de se combiner avec les expressions de temps et de se soumettre à une interprétation événementielle :

- (3) a. *\*Pendant la blondeur de ses cheveux, Léa avait un succès fou auprès des hommes.*  
b. *\*A peine deux minutes après la gentillesse, il a changé brusquement d'attitude.*

- (4) a. *Pendant sa maladie, Léa ne voyait aucun de ses amis.*  
b. *A peine après deux minutes de silence, les enfants ont recommencé à faire du bruit dans la classe.*

En tenant compte de ces caractéristiques, Anscombe nomme respectivement ces

deux types d'états : propriétés intrinsèques et propriétés extrinsèques.

Nous admettons, nous aussi, l'existence des deux types d'états (ou de propriétés) différents. Mais nous qualifions, quant à nous, les propriétés intrinsèques seules de *propriétés* et appelons *états* les propriétés extrinsèques. Cela pour éviter une éventuelle confusion terminologique mais aussi pour suggérer qu'il vaudrait mieux donner le nom d'*états* que celui de *propriétés* aux états transitoires qui sont processifs.

### 3.2. Définition des noms de propriétés

Nous définissons donc les noms de propriétés en coréen comme ce qui suit : sur le plan sémantique, il s'agit de noms prédicatifs dénotant un type de procès qui s'analyse comme représentant des états « permanents et constitutifs » tels que des qualités attribuées à des personnes ou à des choses ou des jugements portés sur elles ; sur le plan syntaxique, ces noms se caractérisent par leur apparition en position de  $N_1$  dans la construction à support *issda* (= : *il y a* ou *avoir*) :  $N_0-i/ga + N_1-i /ga issda$ .

Il faut dire ici qu'il existe, en coréen, deux types de prédications représentant les propriétés : prédication adjectivale et prédication nominale. Pour ce qui est de la prédication adjectivale, elle est assumée par la seule construction du type *N0-ga+Adj.*, où l'adjectif se conjugue comme un verbe :

- (5) a. *Minu-ga chakha-da.* [= : Minu est gentil]  
Minu-Nom (être gentil)-Pré-Déc  
b. *Mina-ga yeppeu-da.* [= : Mina est jolie]  
Mina-Nom (être jolie)-Pré-Déc  
c. *Insu-ga yonggamha-da.* [= : Insu est courageux]  
Insu-Nom (être courageux)-Pré-Déc

En revanche, la prédication nominale est assumée par deux constructions à support : construction à support *issda* (= : *il y a* ou *avoir*) *N0-ga+N1-ga+issda* et construction à support *ida* (= : être) *N0-ga+N1-ida*. En voici quelques exemples :

- (6) a. *Minu-ga chameulseong-i iss-da.*

Minu-Nom patience-Nom il y a-Pré-Déc

[=: Minu a de la patience < Minu est patient.]

b. *Mina-ga jaeneung-i iss-da.*

Mina-Nom talent-Nom il y a-Pré-Déc

[=: Mina a du talent.]

c. *Insu-ga yonggi-ga iss-da.*

Insu-Nom courage-Nom il y a-Pré-Déc

[=: Insu a du courage.]

(7) a. *Minu-neun geopjaingi-ida.*

Minu-Nom peureux(n.)-être-Pré-Déc

[=: Minu est un peureux.]

b. *Mina-neun miin-ida.*

Mina-Nom (belle personne)-être-Pré-Déc

[=: Mina est une belle femme.]

c. *Gyeonggi-ga yudongjeok-ida.*

Situation économique-Nom fluctuation-être-Pré-Déc

[=: La situation économique est fluctuante.]

Cela étant, les noms *yonggi*(courage) et *chameulseong*(patience) qui dénotent des qualités attribuées à des personnes apparaissent tous deux en position de N<sub>1</sub> dans la construction à support *issda* (= *il y a* ou *avoir*) :

(8) a. *Minu-ga chameulseong-i iss-da.*

Minu-Nom patience-Nom il y a-Pré-Déc

[=: Minu a de la patience.]

b. *Insu-ga yonggi-ga iss-da.*

Insu-Nom courage-Nom il y a-Pré-Déc

[=: Insu a du courage.]

En revanche, les noms *joreum*(sommeil) et *piro*(fatigue) qui dénotent des états physiques passagers apparaissent difficilement dans cette construction :

- (9) a. \**Minu-ga joreum-i iss-da.*  
 Minu-Nom sommeil-Nom il y a-Pré-Déc  
 [=: Minu a sommeil.]
- b. \**Insu-ga piro(fatigue)-ga iss-da.*  
 Insu-Nom fatigue-Nom il y a-Pré-Déc  
 [=: Insu a de la fatigue.]

Ces noms apparaissent plutôt dans la construction à support *oda* (=venir) :

- (10) a. *Minu-ga joreum-i wat-da.*  
 Minu-Nom sommeil-Nom venir-Pass-Déc  
 [=: Minu a sommeil.]
- b. *Insu-ga piro(fatigue)-ga wat-da.*  
 Insu-Nom fatigue-Nom venir-Pass-Déc  
 [=: Insu a de la fatigue.]

Les propriétés syntaxiques et sémantiques des noms de propriétés que nous venons de voir permettent ainsi de les distinguer des noms d'états qui ont en effet des caractéristiques différentes.

#### 4. Noms de propriétés « identifiantes » vs Noms de propriétés « attributives »

##### 4.1. Noms de propriétés du type *seongkyeok*(caractère)

Une fois définis les noms de propriétés, il reste encore à les distinguer en deux groupes. En fait, il existe des noms comme *seongkyeok*(caractère), *muge*(poids), etc. qui peuvent eux aussi s'analyser comme relevant des noms de propriétés.

- (11) a. *Insu-ga seongkyeok-i iss-da.*  
 Insu-Nom caractère -Nom il y a-Pré-Déc

[=: Insu a du caractère.]

b. *I gabang-i muge-ga iss-da.*  
CE sac-Nom poids-Nom il y a-Pré-Déc

[=: Ce sac pèse lourd.]

Comme nous le voyons dans les exemples en (11), les noms *seongkyeok* (caractère) et *muge*(poids) apparaissent sans difficulté dans la construction à support *issda* et représentent, tout comme les noms *yonggi*(courage) et *chameulseong*(patience), des qualités ou des jugements à une différence d'intensité près.

En effet, dans les exemples en (11a) et (11b), le support *issda* fonctionne plus comme un support aspectuel intensif que comme un support de base. Autrement dit, avec le support *issda*, les phrases composées avec les noms *seongkyeok*(caractère) et *muge*(poids) représentent l'intensité de la « propriété » que ces noms dénotent. C'est ainsi que le support *issda* en (11a) et (11b) peut être remplacé dans chaque cas par des adjectifs d'intensité : *se-da*(=: être fort) en (11a) et *mugeop-da*(=: être lourd) en (11b).

(12) a. *Insu-ga seongkyeok-i (iss + se)-da.*

Insu-Nom caractère-Nom (il y a + être fort)-Pré-Déc

[=: Insu a du caractère.]

b. *I gabang-i muge-ga (iss + mugeop)-da.*

CE sac-Nom poids-Nom (il y a + être lourd)-Pré-Déc

[=: Ce sac pèse lourd.]

Mais cela n'empêche pas d'analyser ces deux phrases comme représentant bien des propriétés. Le problème qui se pose alors est de savoir comment traiter les noms du type (11) qui sont respectivement analysés comme des noms classifieurs ou des noms de mesure (ou de grandeur) ?<sup>5</sup> ; et aussi de savoir si les deux noms *seongkyeok*(caractère) et *chameulseong*(patience) représentent la propriété de la même façon.

Pour répondre à ces questions, nous proposons de distinguer les propriétés « identifiantes » des propriétés « attributives ». Les premières sont représentées par les

---

<sup>5</sup> cf. Giry-Schneider, J. (1996) et Le Pesant, D. (1996) respectivement.

noms du type *seongkyeok*(caractère) et *muge*(poids) qui permettent de cerner le type de propriétés dont on veut parler, alors que les secondes sont représentées par les noms du type *yonggi*(courage) et *chameulseong*(patience) qui « parlent » d’eux-mêmes des propriétés. En effet, cette idée peut être justifiée par les comportements syntaxiques différents de ces deux types de noms.

#### 4.2. Différence des comportements syntaxiques

Les comportements des noms de propriétés « identifiantes » et « attributives » se différencient entre autres selon les trois points suivants :

- la fonction sémantique du support *issda*(il y a) qui se combine avec ces noms
- la possibilité d’apparaître dans la question en *otteohani*(être comment)
- l’existence des prédicats nominaux ou adjectivaux en corrélation sémantique.

D’abord, avec les noms de propriétés « identifiantes », le support *issda* peut être remplacé par des adjectifs d’intensité comme cela a été montré en (12) alors que ce n’est pas possible avec les noms de propriétés « attributives ». En effet, lorsque le support *issda*(il y a) apparaissant, par exemple, avec les noms *yonggi*(courage) et *chameulseong*(patience) en (8a)-(8b) est remplacé par des adjectifs d’intensité appropriés respectifs le sens des phrases n’est plus le même :

(13) a. *Minu-ga chameulseong-i (iss ≠ manh)-da.*

Minu-Nom patience-Nom (il y a≠il y a beaucoup de)-Pré-Déc

[=: Minu a (de la ≠ beaucoup de) patience < Minu est patient.]

b. *Insu-ga yonggi-ga (iss ≠ manh)-da.*

Insu-Nom courage-Nom (il y a≠il y a beaucoup de)-Pré-Déc

[=: Insu a (du ≠ beaucoup de) courage.]

Ensuite, les noms de propriétés « identifiantes » comme *muge*(poids) doivent être précisés dans la question en *otteohani*(être comment) pour que l’on obtienne la réponse concernant les propriétés qu’ils dénotent :

(14) *I gabang-eun (?? E + muge-ga) eotteoha-ni ?*  
 CE sac-Top poids-Nom (être comment)-Pré-Int ?  
 [=: Quel est (??E + le poids de) ce sac ?]

⇒ *Geu gabang-eun muge-ga (iss + mugeop)-da.*  
 CE sac -Top poids-Nom (il y a +être lourd)-Pré-Déc  
 [=: Ce sac pèse lourd.]

Sinon, on risque d'avoir différentes réponses inattendues mais pas impossibles :

(15) *I gabang-eun eotteoha-ni ?*  
 CE sac-Top (être comment)-Pré-Int ?  
 [=: Comment est ce sac ?]

⇒ *Geu gabang-eun (yeppeu + keu + bissa + ...)-da.*  
 CE sac-Top être (joli+grand+cher+...)-Pré-Déc  
 [=: Ce sac est (joli+grand+cher+...).]

Mais il n'en est pas de même pour les noms de propriétés « attributives ». Ces derniers sont difficilement précisés dans la question en *eotteohani*(être comment) :

(16) *Insu-ga (E + ?? yonggi-ga) eotteoha-ni ?*  
 Insu-Nom courage-Nom (être comment)-Pré-Int ?  
 [=: Comment est (E + ?? le courage de) Insu ?]

⇒ *Insu-ga yonggi-ga (iss + manh)-da.*  
 Insu-Nom courage-Nom (il y a+il y a beaucoup de)-Pré-Déc  
 [=: Insu a (du + beaucoup de) courage.]

Par ailleurs, les noms de propriétés « identifiantes » peuvent se combiner avec

différentes expressions spécifiques à la propriété qu'ils dénotent (ou cernent). Ainsi, le nom *muge*(poids) dispose de noms d'unités spécifiques à la propriété qu'il dénote tels que *geuraem* (gramme), *kilograem* (kilogramme), *ton* (tonne), etc., et il se combine avec eux pour préciser la propriété qu'il dénote :

- (17) *I gabang-i muge-ga 30 kilograem-ida.*  
 CE sac-Nom poids-Nom 30 kilogrammes-être-Pré-Déc  
 [=: Ce sac pèse 30 kilogrammes.]

Il en est même pour les noms *moyang*(forme) et *saek*(couleur) qui s'analysent eux aussi comme des noms de propriétés « identifiantes » :

- (18) a. *I sangja-neun moyang-i (semo+nemo+weonhyeong +...)-ida.*  
 CE boîte-Nom forme-Nom (triangle+carré+rond+...)-être-Pré-Déc<sup>6</sup>  
 [=: Cette boîte a une forme (triangulaire+carrée+ronde+...).]  
 b. *I chima-neun saek-i (parang+norang+ppalgang +...)-ida.*  
 CE jupe-Nom couleur-Nom (bleu+jaune+rouge+...)-être-Pré-Déc<sup>7</sup>  
 [=: Cette jupe est d'une couleur (bleue+jaune+rouge+.....).]

En plus, les noms de propriétés « identifiantes » disposent de différents adjectifs précisant diverses valeurs de la propriété qu'ils dénotent :

- (19) a. *I gabang-i muge-ga (mugeop+gabyeop)-da.*  
 CE sac-Nom poids-Nom être (lourd+léger)-Pré-Déc  
 [=: Ce sac pèse (lourd+léger).]  
 b. *I sangja-neun moyang-i (dunggeul+giljjukha)-da.*  
 CE boîte-Nom forme-Nom être (rond+long)-Pré-Déc  
 [=: La forme de cette boîte est (ronde+longue).]  
 c. *I chima-neun saek-i (parat+norat+ppalgat)-da.*  
 CE jupe-Nom couleur-Nom (bleu+jaune+rouge)-être-Pré-Déc<sup>8</sup>

<sup>6</sup> Les mots *carré* et *rond* sont utilisés ici dans leur emploi nominal.

<sup>7</sup> Les mots *bleu*, *jaune* et *rouge* sont utilisés ici dans leur emploi nominal.

[=: La couleur de cette jupe est (bleue+jaune+rouge).]

Les noms de propriétés « identifiantes » se caractérisent ainsi par l'existence des prédicats nominaux ou adjectivaux en corrélation sémantique avec eux. Mais le cas n'est pas identique avec les noms de propriétés « attributives ». Ces derniers ne disposent pas de prédicats nominaux ni de prédicats adjectivaux en corrélation sémantique de ce type étant donné qu'ils ont eux-mêmes la fonction d'attribuer diverses valeurs aux propriétés simplement cernées ou évoquées par les noms de propriétés « identifiantes ».

Ainsi, les noms de propriétés « identifiantes » se différencient des noms de propriétés « attributives » par leurs comportements syntaxiques. Ce qui revient à justifier notre idée de distinguer les deux classes de noms de propriétés.

#### 4. 3. Corrélation syntactico-sémantique des deux classes des noms de propriétés

Une fois faite la distinction des deux classes des noms de propriétés, nous sommes en mesure d'établir de nombreuses sous-classes dans lesquelles seront répartis différents noms qui ont été mal classifiés jusqu'à présent. Voici quelques exemples de sous-classes de noms de propriétés « identifiantes » :

**Table 1.** Exemples de sous-classes des noms de propriétés « identifiantes »

- <gili>-*ga gilda/jjalpda* =: <longueur>-Nom être long/court  
ex. : *gili*(longueur), *gijang*(longueur), *jireum*(diamètre), *bangyeong*(demi-diamètre), *jeonjang*(longueur totale), *garo*(largeur), *sero*(longueur), etc.
- <nopi>-*ga nopda/natda* =: <hauteur>-Nom être haut/bas  
ex. : *nopi*(hauteur), *pago*(hauteur des vagues), *godo* (degré de hauteur), etc.
- <geori>-*ga meolda/gakkapda* =: <distance>-Nom être loin/proche  
ex. : *geori* (distance), *gangyeok* (intervalle), *gyeokcha* (écartement), etc.
- <neolbi>-*ga neolpda/jopda* =: <largeur>-Nom être spacieux/étroit, resserré

<sup>8</sup> Les mots *bleu*, *jaune* et *rouge* sont utilisés ici dans leur emploi adjectival.

ex. : *neolbi*(largeur), *myeonjeok*(étendue), *pyomyeonjeok*(superficie), etc.

- <keugi>-*ga keuda/jakda* =: <grandeur>-Nom être grand/petit  
ex. : *keugi*(grandeur), *gyumo*(envergure), *chawon*(dimension), *bupi*(volume), etc.
- <yang>-*i manta/jeokda* =: <quantité>-Nom il y a beaucoup de/peu de  
ex. : *yang*(quantité), *jeokseolyang*(quantité de neige), *undongyang*(quantité de mouvement), etc.
- <him>-*i seda/yakhada* =: <force, énergie>-Nom être fort/faible  
ex. : *him* (force), *suryeok* (énergie hydraulique), *apryeok* (pression), *jeonap* (pression électrique), *akryeok* (poigne), etc.

Comme on le voit dans la table 1, les sous-classes des noms de « propriétés identifiantes » sont diverses et elles se distinguent notamment par leurs adjectifs appropriés respectifs : par exemple la sous-classe <*nopi*(hauteur)> se caractérise par ses adjectifs appropriés comme *nopda/natda* (=: être haut/bas) tandis que la sous-classe <*geori*(distance)> se caractérise par des adjectifs appropriés tels que *meolda/gakkapda*(=: être loin/proche).

Il faut noter ici que les adjectifs appropriés à chacune de ces sous-classes relèvent des classes des prédicats dénotant les propriétés « attributives » qui sont en corrélation avec ces sous-classes de propriétés « identifiantes ». A titre d'exemple, les adjectifs *nopda/natda* caractérisant la classe de propriétés « identifiantes » <*nopi*(hauteur)> constituent la classe de propriétés « attributives » <*nopi*(hauteur)>. Nous pouvons allonger la liste de ce type de corrélation. En voici un autre exemple :

**Table 2.** Les deux classes de *moyang*(forme)

- < Pr. identifiantes de *moyang* (forme) > :
  - Noms : *moyang*(forme), *hyeongtae*(forme), *oehyeong*(apparence), *moseup*(figure), *oogwan*(physionomie), *poungmo*(air), etc.
- < Pr. attributives de *moyang* (forme) >
  - Noms : *wonhyeong*(forme ronde), *seonhyeong*(forme linéaire),

*semo*(triangle), *nemo*(carré), *jangbanghyeong*(rectangle), etc.

- Adj : *dunggeulda*(être rond), *giljjukhada*(être long), etc.

C'est ainsi que nous pouvons mettre en évidence la corrélation syntactico-sémantique entre les classes de propriétés « identifiantes » et « attributives ». Cette corrélation peut être représentée comme dans la table 3.

**Table 3.** La corrélation syntactico-sémantique des deux classes de propriétés

- Soit la construction *N0-ga N1-ga (N2-ida + Adj)*
- Si  $N1 = \langle \text{Pr. identifiantes de } moyang \text{ (forme)} \rangle$   
 $\Rightarrow N2, \text{ Adj.} = \langle \text{Pr. attributives de } moyang \text{ (forme)} \rangle$

En tenant compte de cette corrélation et des caractéristiques des deux classes de propriétés, nous sommes en mesure d'analyser les noms de propriétés « identifiantes » comme des prédicats du second degré qui sélectionnent un argument sujet et un prédicat apportant des précisions sur la propriété cernée. Quant aux noms de propriétés « attributives », ils s'analysent, tout comme les adjectifs prédicatifs, comme des prédicats du premier degré qui apportent eux-mêmes de nouvelles informations au sujet de la phrase.

## 5. Conclusion

Nous avons ainsi mis en évidence les propriétés syntaxiques et sémantiques des noms de propriétés et montré la nécessité de les distinguer en deux groupes : noms de propriétés « identifiantes » et noms de propriétés « attributives ». Ce faisant, nous avons également mis en lumière la corrélation syntactico-sémantique des deux classes de propriétés.

Nous avons vu en effet que les propriétés « identifiantes » servent à cerner le type

de propriétés dont on veut parler tandis que les propriétés « attributives » ont comme fonction de « parler » elles-mêmes des propriétés ; cette différence sémantique a été révélée par les comportements syntaxiques distincts des noms qui dénotent ces deux types de propriétés. Nous avons vu en effet que les noms de propriétés « identifiantes » comme par exemple *seongkyeok*(caractère) et *muge*(poids) peuvent apparaître en position de N1 dans la construction *N0-ga N1-ga (N2-ida + Adj)* alors que ce n'est pas le cas pour les noms de propriétés « attributives » tels que *yonggi*(courage) et *chameulseong* (patience) ; ceux-ci n'apparaissent qu'en position de N2. Ce qui en revient à justifier notre idée qu'il fallait distinguer ces deux types de noms.

La distinction des deux classes des noms de propriétés a permis ainsi de mettre en évidence la corrélation entre les classes de « propriétés identifiantes » et celles de « propriétés attributives ». Ce qui laisse deviner que cette distinction permettra également de faire les choses suivantes : traiter de façon adéquate des noms comme *seongkyeok* (caractère), *ireum*(nom), *sanghwang*(situation) qui devraient également être répartis dans les classes de <propriétés identifiantes> ; mettre en bon ordre les classes qui ont été organisées de la manière inadéquate, autrement dit répartir sous l'hyperclasse de <propriétés> les différents prédicats du second degré qui ont été faussement regroupés sous l'hyperclasse non prédicative d'<objets abstraits> ; et enfin élaborer de façon cohérente et systématique les classes des adjectifs et des verbes.

# How do we capture the Persian core vocabulary of Iranian primary school students?

Shahin Nematzadeh

Alzahra University  
[snematzad@yahoo.com](mailto:snematzad@yahoo.com)

## ABSTRACT

This paper is a brief report of a national project which was launched by the Organization of Educational Research and Programming (OERP) as the official body in Iran for curricular programming and developing course materials. Considering the fact that curricula developer must know the extent of vocabulary in order to accelerate the learning process the project titled "Identification of Iranian Primary School Students Core Vocabulary" was launched. In this project through a massive field study, accurate first hand data have been collected from 20,000 students and 1,885 teachers in all provinces of the country. Three tests were developed and 40 test managers and 350 test conductors were trained in order to collect data. Then after 4 years a big vocabulary corpus was established and the most frequent words were introduced in the framework of semantic fields.

**Key words:** core vocabulary, primary school students, Persian, Iran

Research had shown that due attention has not been given to mutual linguistic understanding between educators and those who receive it (Javadi, 1998; Sharifi, 1997; Tayyebi, 1999, Dadsetan, 1999). With a glance at the Persian course books in Iran we can see that their linguistic content is far from the needs and capabilities of students. Many words and phrases used in these books have nothing to do with the daily life of students or what they use to express their feelings and thoughts. In all these books we face a phrase bombardment, most of them used once. One can ask himself when student cannot fully differentiate green and blue at age 8 what is the logic behind using the term turquoise? Or this question can be posed that what is the percentage of adults or even university graduates that know what kind of flower a Susan (name of a Persian rare flower) is?

This becomes a critical issue in multicultural/multilingual societies with centralized education system, where textbooks are prepared in center and distributed throughout country, like the situation we have in Iran. This situation ignores linguistic differences of a great number of students and makes serious problems for bilingual students. Therefore it is necessary for curricula developers to know the extent of children's vocabulary.

Vocabulary is one of the matters of concern in the children language. Systematic basic /core vocabulary studies have 80 years of background in the world, but in Iran less than 30 years. These 30 years of studies have several weak points. To mention a few, it had not enjoyed a logical continuation, it lacked a critical eye on basic vocabulary estimating projects in other countries, and the last but not the least, it has not been taken seriously. As a result children book writers and curricula developers have applied intuition, humor and experience in using their own mental basic vocabulary.

Considering the fact that any programming should be based on valid data and core vocabulary is an essential data for curricula programmers and developers, OERP (Organization for Educational Research and Programming) launched a national project for identification of "Iranian Primary School Students Core Vocabulary". In this project appropriate methods for estimating basic vocabulary were identified. Then through a massive field study, real, first hand data has been collected from 175 schools. These schools were sampled using systematic stratified cluster PPS method. This sample included 46 girl schools, 64 mixed schools and 65 boy schools and 20,000 students 1,885 teachers in 875 classrooms, in 28 provinces. By descriptive research and interviewing children, teachers, literature experts, psychologists, and linguists this basic vocabulary is listed. These principles are applied to the research outcomes:

- Core vocabulary can not be determined but estimated
- There is no upper limit for it
- And this list should be updated from time to time

## Programme strategy

We designed and implemented a field research to capture the core vocabulary of Iranian students in primary schools (grade 1-5).

For this purpose we developed the following research tools.

## **Checklists**

Four checklists were developed in the course of this project:

### **Concrete nouns checklist**

1641 concrete nouns were extracted from “ the Persian Dictionary of School Children” and classified on the basis of semantic criteria. In this way 45 semantic domains/fields for the concrete nouns were determined.

### **Verbs checklist**

2700 verbs were extracted from “ the Persian Dictionary of School Children” and classified on the basis of semantic criteria. In this way 22 semantic domains for the verbs were determined.

This classification form 15 verbs files proposed by “WorldNet” and such lexical semantic criteria as sense relations and especially hyponymy among verbs. Each class represents one underlying lexical concept, which is often realized as a hyponym word for that class.

### **Adjectives checklist**

Categorizing the adjectives from a lexical point of view has not a long and rich tradition. Concerning the objectives of the above project the Persian adjectives were extracted from the above mentioned Dictionary and classified on the basis of the semantic factors. In this way more than 100 adjectival categories were determined.

### **Vocabulary trace checklist**

A chart containing 5 boxes was developed to make vocabularies traceable. The first box shows the grade level that the vocabulary belongs to. The second box shows whether it is a vocabulary used by students or printed in the textbooks. The third box shows types of vocabulary. The fourth box shows parts of speech. The fifth box shows semantic fields. Each semantic field will have a table containing words.

### **Content analysis**

A vocabulary card was developed for collecting the needed information items such as lexical entry, part of speech, semantic field, type of vocabulary, etc. Using these cards content of the primary school (grades 1-5) textbooks of Iran, UK, Germany, France, and United Arab Emirates were analyzed to extract the size and type of core primary vocabulary. Also from 108 children literature books published in Iran, a list of most frequently used words was extracted.

### **Questionnaires**

Three vocabulary tests were developed with consultation of famous children literature writers, educationists, linguists, psychologists, teachers, children books’ designers and picture designers, computer graphists, etc. and they were modified by site observation of how children behave. Each test booklet contains school and student information including grade, sex, urban, rural, semi-urban

*Teacher questionnaire.* It contained 1950 nouns, 2331 verbs, 612 adjectives which were obtained through the previous stages applying the data gathered by checklists and content analysis.

*Student questionnaire.* there are two student questionnaires. Productive test and perceptive test.

*Productive test.* A list of core situations were compiled with the help of educationists and handed to Hushang Moradi Kermani; internationally praised Iranian children literature writer. He wrote short stories for each situation, according to them up to four pictures were drawn. Students were asked to list all the words that a picture represents in one minute and in other instance to write a story for the pictures in three minutes.

*Perceptive test.* It contained 800 illustrations of nouns, adjectives and verbs. After test conductor pronounced the word, students were asked to put number in or color the box at the top right corner of related picture.

### **Observation**

In order to know how children behave with regard to the instructions in the questionnaires a researcher went to several schools in Tehran to observe their attitude to direction words (up / down).

### **Interview**

Since first grade students cannot read and write at that time of the year their voices were recorded individually using tape recorders given to the test conductors.

Other groups that had been interviewed were experts and high-ranking authorities. Their opinions were collected using open interview in several sessions.

### **Pilot study**

In order to afford culturally, socially, linguistically (dialects) and economically unbiased tests, pilot studies were conducted.

### **Implementation**

Each province has a program executor (province manager) whose role was to find the necessary number of qualified test conductors. Each school had two test conductors; one for productive and one for perceptive test. Since 175 schools were tested, 350 conductors were employed. MoE (Ministry of Education) had given us one week to carry out this test; therefore two conductors were necessary to complete the tests in due time. (The schools were closed during this time).

It was critical to find local conductors to assure full comprehension of students' responses. 40 test managers were trained by the project director in Tehran (capital of Iran). These 40 managers trained and monitored the 350 test conductors. The test nationally took long 45 days and up to 10 days at each school.

*Budget:* 1,500,000,000 Rials (about 17000 \$)

### **Human resource management**

Staff employed

20 full time researchers (12 in phase one , 8 in phase 2), 40 test managers, 29 province managers , 350 test conductors, 12 research staff, 4 teacher consultants, 10 part time staff, 1 accountant.

### **Special characteristics**

- Collecting information from experts and students
- Collecting unbiased data
- Collecting traceable data
- Collecting and Preserving linguistic differences of the sample
- Collecting and Preserving ethnic culture of the sample

- Applying systematic stratified cluster PPS sampling model for the first time in MoE.
- Making a model for nationwide successful projects – sampling
- Making a model for nationwide successful projects – management
- Providing a collection of classified pictures with educational orientation - Teachers are asking for the test booklets to use them in teaching writing

### **Achievements (in brief)**

Quantitative assessment of the results of the undertaking such as:

Training 40 test manager, 350 test conductor; developing 3 questionnaires and 4 checklists; distributing 20,000 student perceptive and productive questionnaires and collecting 19,974 productive and 17,864 perceptive ones, also 1,885 teacher questionnaire; collecting more than 10 million records in teacher questionnaire, 16 million record in perceptive questionnaire, 12 million record in productive questionnaire, 266 million basic information records, 76 million record basic data for vocabularies, transferring four thousand hours voice of students (grade 1) recorded on tapes .

Now according to the corpus we know that the most frequent productive words of first grade students are: machine, school, tree, fish, shoes, spoon, game, ball, house, boy, child, and train. And the first frequent jobs in grade 5 students are: teacher, doctor, worker, postman, engineer, driver and painter.

### **Problems encountered**

- Money shortages made us to confine our sample to 175 schools
- Dialect differences. Although we tried to employ ethnic test conductors, still in some parts of Kurdistan the dialect of Kurdish that students spoke were different with the Kurdish that of the test conductor.
- Some of the province managers to get to the school site first used airplane, then car, and for some distances walking along the road.
- Since no graphist specialized in making pictures for the tests was available, we trained some of the Printing and Publication staff for this purpose.

# Theories of parts of speech in the major early French and English grammars (I): Renovations of the traditional theories for vernacular languages

SHIN Osik

Department of French Language, Chungnam National University  
220, Gungdong Yusunggu DAEJON, South Korea  
shinosik@cnu.ac.kr

## Abstract

From antiquity to the classical period, grammarians raised questions about the enumeration of the parts of speech and the assignment of some specific words to these parts of speech, and their specific assignments were, at times, very different. The disagreements between grammarians on these questions were often due, on the one hand, to the nature of the analysed language, and on the other hand, to the criteria of analyses. For the classification of words, they applied sometimes their meanings and morphological characteristics, and sometimes their roles in a sentence or relationships to the thought. The present article has the purpose to clarify the influence between some early French and English grammars until the middle of the 18<sup>th</sup> century, and what was the change of the grammatical description during this period.<sup>1</sup>

**Keywords:** Parts of speech, French grammar, English grammar, History of grammar.

## 1. Adaptations of the traditional classification

Traditional classification is based on the logical and morphological criteria and gives 8 parts of speech divided into two groups as follows: words with inflection (noun, pronoun, verb and participle) and words without inflection

---

<sup>1</sup> This first part (from the 16<sup>th</sup> century to the Port-Royal's grammar) treats the renovations of the traditional theories for vernacular languages. The attempts of a proper theory for vernacular languages in Wilkins' *Essay* (1668), Buffier's *Grammaire françoise* (1709), Girard's *Principes* (1747) and Harri's *Hermes* (1751), which was orally presented in CIL 2008 (Seoul), will be treated in another occasion because of the space limit. The first part is a renewal of the article, which was presented in the 2004 International Conference on English Linguistics: In Commemoration of Otto Jespersen's Scholarship (June 18-19, 2004) of the English Linguistics Society of Korea.

(adverb, conjunction, preposition and interjection). This classification, with some modifications, is applied in the first French and English grammars.

### Greek Classification

	categoremata		syncategoremata
Aristoteles	onoma	rhema	syndesmos
Dionysius Thrax	onoma epirrema	rhema metoxe	prothesis syndesmos antonymia arthron

### Latin Classification

Varro , Priscian	Flexiles nomen pronomen verbum participium	Inflexiles adverbium coniunctio praepositio interiectio
------------------	--	---

### English Grammar and French Grammar

Lily 1567	Declined Noune Pronoune Verbe Participle	Undeclined Adverb Conjunction Preposition Interjection
Chiflet 1659	<i>Déclinable</i> <i>nom</i> <i>pronon</i> <i>verbe</i> <i>participe</i> <i>article</i>	<i>Indéclinable</i> <i>adverbe</i> <i>conjonction</i> <i>préposition</i> <i>interjection</i>

In French grammars, the article presents difficulties because this category of Greek origin and replaced by the interjection in Latin grammars, needs again to be mentioned. Palsgrave (1530) and Estienne (1557) admit 9 parts of speech regarding the article. Meigret (1550) admits 8 parts of speech but lays out an independent chapter for the article. Maupas (1607) and Oudin (1632) continuously treat the 9 parts of speech without overtly stating the allowed number of parts of speech. Chiflet (1659) admits 9 parts of speech divided into two morphological groups.

The article raises fewer problems in the first English grammars because it is not regarded as an independent part of speech until much later. For Lily (1567), Greaves (1594), Hume (1612), Wharton (1654), Newton (1669) and Saxon (1737), the article is only assigned to the noun. Miège (1688) admits 8 parts of speech and treats the article as a "short word" (particle). Greenwood (1711) accepts it as an "adjectival expletive," and Duncan (1731) defines it as "kind of adjectival pronoun." Jonson (1640) seems to be the first English grammarian who accepts the article as the 9th part of speech and especially since Wilkins introduces the article into his *Essay* (1668), this category is more frequently noted. Maittaire (1712) replaces the interjection by the

article in his 8 parts of speech and Jones (1724) accepts it among his 9 parts of speech.

<i>French Grammar</i>	<i>English Grammar</i>			
<i>article</i>	<i>article</i>			
1530 Palsgrave 1550 Meigret 1557 Estienne 1607 Maupas 1632 Oudin 1659 Chiflet . . .	1640 Jonson 1668 Wilkins . .			
	<i>part of noun</i>	<i>short word</i>	<i>adjectival expletive</i>	<i>adjectival pronoun</i>
	1567 Lily 1594 Greaves 1612 Hume 1654 Wharton 1669 Newton 1712 Maittaire 1737 Saxon	1688 Miège	1711 Greenwood	1731 Duncan

## 2. The first attempt of a new classification

### 2.1. Ramus' Gramere

Rejecting the Latin traditional distinction between variables and invariables,<sup>2</sup> Pierre de la Ramée proposes as a basic distinction the opposition between words with number and without number<sup>3</sup>:

“Elę’ (efpeę) fon’ deus, l’unę avec nombre, l’autre fan’ nombre” (1562: 40).

<sup>2</sup> Lily was the first to transmit the Medieval Latin tradition to English grammarians. Many English grammarians followed Lily’s work. The adjectives are here considered as noun, and articles as nominal signs. For the Greek and Latin traditions, see Poldauf (1948: 151-152), Vorlat (1975: 42-48).

<sup>3</sup> According to Padley, Ramée takes “Aristotle’s semantically based dichotomy of *categoremata* and *syncategoremata* turns it... into a formally based one” (1983: 34). Pricien first used the term *syncategoremata* for the semantically dependent class (cf. Ibid, note 116).

Thus, he reacts against the Latin grammatical traditions of the 16<sup>th</sup> century. Noun and verb have number, whereas adverb and conjunction are without. Noun has gender, and verb has person and tense. An adverb is a word which joins to another word, and by conjunction, the composed parts of speech are joined:

“Lę mot aian’ nōbre e’ nom ou verbę. Nom et un mot dę nombr’ avec jenrę (ibid 41).

Lę verbę et un mot dę nombrę perfonel avec tam (ibid 49).

Lę mot fan’ nombrę, e’ est fęlui ci n’a aucune diferensę dę nombrę, par lacleę il puisę etrę varie, comę l’Averb’ e la Conjonxion. L’Averb’ et un mo’ fan’ nombrę ci et ajoint a un autrę (ibid 72).

Conjonxion et un mot fan’ nombrę par lęcel le’ partię dę l’orezon cōpozeę son’ conjointęs” (ibid 74).

He discerns, as subsets of the words with number, words with finite number, in which morphological changes denote number, and words with infinite number, where this is not the case.<sup>4</sup>

“Le mot de nōbre est finit ou infinit. Finit quād il signifie son nombre par certaine terminaifon: cōme les cerfs courent. L’infinit au cōtraire, cōme Courir, Aimer” (1572: 58).

This distinction between finite number class and infinite number class is an advantage for the English grammarians who apply Ramée’s classification to a language so poor in flexional endings as English. Number, as criterion of word class, was applied in the English grammars during a half century, from the end of 16<sup>th</sup> century to the middle of 17<sup>th</sup> century. Some grammarians mix Ramée’s principle with elements from the Greek and the Latin school, and others make a personal adaptation.<sup>5</sup> But Ramée’s

---

<sup>4</sup> Ramée applied it for the division of verb, finite verb (*aime*) vs. infinite verb (*aimer*). See also Ramée (1562: 50).

<sup>5</sup> Writing their English grammar in Latin, two grammarians apply Ramée’s principle. Paul Greave (*Grammatica Anglicana*, Cantabrigiae, Johannis Legatt, 1594) offers an incomplete copy of the Rameian classification. He treats first the words with number (noun and verb), then the adverb and the conjunction one after the other, without grouping the latter together as words without number: “CAP. 3. *De Substantivo*. Vox numeri est nomen aut verbum” (1594: 175). “CAP. 7. *De Adverbio*. Adverbium est quod aliis vocibus adiicitur (...) CAP. 8. *De Coniunctione*. Copulativa: ut *And, also, neither, nor*” (ibid 184). He defined the adverb with Ramée’s words, but the conjunction has no definition. The article is treated as a kind of adjective, which constitutes an independent chapter (CAP. 4). Alexandro Gil (*Logonomia Anglica*, Londini, Iohannes Beale, 1621) divides words in 3 parts: “Partes orationis sunt tres. Nomen, Verbum, Quorum est numerus, Singularis, Pluralis. Consignificatiua dictio, ubi sunt Articulus, Aduerbia, Proepositiones” (1621: 49). Noun and verb are defined on a formal basis, as variable words with number, but the term

influence was restricted to one particular moment when the grammarians needed another criterion than Latin. No grammarian after the middle of 17<sup>th</sup> century adheres to the Rameian division. The classification of some invariable words (adjectives) among words with number, and of others (adverbs) among the words without number was for the English grammarians arbitrary from the beginning.

## 2.2. *English Grammars in the Rameian Tradition*

In the English grammar of Alexander Hume (1612), the dichotomy personal-impersonal replaces Ramée's contrast between words with and those without number.<sup>6</sup>

“OF THE PERSON. Cap. 1. 1. Al wordes *quhilk* we use to expresse our mynde are personal and impersonal. 2. A personal word is *quhilk* admittes diversitie of person” (1612: 27).

“OF THE DETERMINATION OF THE PERSON. Cap. 3. 1. A personal word is a noun or a verb. A noun is a word of one person with gender and case” (ibid: 28).

“OF THE VERB'S PERSON AND NUMBER. Cap. 7. 1. (...) The verb is of al persones declined with mood and tyme (ibid: 30)

“OF THE ADVERB. Cap. 11. 1. A word impersonal is *quhilk* in al formes of speach keeps one face, and this is adverb or conjunction” (ibid: 32).

In other words, a personal word is an inflected word and an impersonal word is invariable. Personal words are nouns and verbs; impersonal words are adverbs and conjunctions. Thus, he mixes the Latin definition with Rameian division. The articles *a*, *an* and *the* are the words of determination of person and, as such, they do not constitute a separate word class:

“OF THE DETERMINATION OF THE PERSON. Cap. 3. (...) 3. The determined person is noted with the, and it is determined either be an other substantive; as, the king of Britan ; or be an adjective ; as, the best king in Europ ; or be a relative ; as, God preserve the king quhom he hath geven us. 4. The undetermined noun is noated with an before a voual ; as, an ald man sould

---

*consignificativa dictio* reminds one of Greek classification. This heterogeneous classification based on two criteria, form and signification, reveals Greek and Rameian influences. In fact, Ramée did not separate the article from the noun, and the preposition and the interjection were classified as subsets of adverb. For Greave and Gill, see Vorlat (1975: 57-58).

<sup>6</sup> According to Vorlat, the Rameian influence for Hume is obvious. Hume admits reading Ramée's work but far from copying it, he reflects on it and defends his own viewpoint (cf. 1975: 61).

be wyse ; and with a before a consonant ; as, a father sould command his son” <sup>7</sup>(ibid: 28).

### Ramée -1562

<b>mots avec nombre</b> (words with number)		<b>mots sans nombre</b> (words without number)	
<b>avec genre</b> (with gender)	<b>avec temps</b> (with tense)		
<b>nom</b> substantif adjectif article pronom participe	<b>verbe</b>	<b>adverbe</b> interjection préposition	<b>conjonction</b>

### Hume -1612

<b>Personal Words</b>		<b>Impersonal Words</b>	
<b>Gender &amp; Case</b>	<b>Mood &amp; Time</b>		
<b>Noun</b> (article as note of noun)	<b>Verb</b>	<b>Adverb</b>	<b>Conjunction</b>

Butler (1633) distinguishes 2 groups of word classes: words with number and case and *words without number and case*. *The noun and the verb constitute the former and the preposition and the adverb, the latter:*

“A Woord is eider wit number and caſe, as Noun and Verb ; or witout, as Prepoſition and Adverb” (32).

In Butler’s grammar, case means the different terminations of the same word. In other words, Nominal cases are the nominative and the genitive and verbal cases are tense morphemes:

“Caſe is the different termination of the ſame word, in the ſame Number and Perſon; as *man mans*<sup>8</sup>, *loov looved*” (32).

<sup>7</sup> Hume did not consider the articles as an independent word class, but his description of determination is very modern. It is based on a syntactical criterion. The grammarians of Port-Royal will, a half century later, show a theory of determination. For the theory of article of Port-Royal grammar, see Swiggers (1985) and Shin (1994).

<sup>8</sup> *Mans* means here *man’s*. Butler explains in the footnote that “*men* is no caſe of *man*” (1633: 32, note ★).

So, the form *loved* is the oblique case of *love*<sup>9</sup>. Common to verb and noun is that they have endings other than those of number and person. That is what Butler called *case* and is his original point of view. A difference of time distinguishes two categories of the words with number and case:

“A Noun is a woord of Number and Caf<sup>e</sup>, witout differenc<sup>e</sup> of tim<sup>e</sup>” (33). A Verb is a word of number and caf<sup>e</sup> wit differenc<sup>e</sup> of tim<sup>e</sup>” (42).

Butler was inspired by Ramée but he introduces two additional concepts, case and difference of time. For the words without number, Butler discerns prepositions and adverbs while Ramée discerns adverbs and conjunctions. Butler considers the article as a nominal sign :

“A Noun abfolut<sup>e</sup> is de nam<sup>e</sup> of a ting : \ie der<sup>e</sup>for<sup>e</sup> may hav<sup>e</sup> de article A or De befor<sup>e</sup> it. And it is eider Substantiv<sup>e</sup>, or Adjectiv<sup>e</sup>. A Substantiv<sup>e</sup> is dat, \ie, witout an Adjectiv<sup>e</sup>, may hav<sup>e</sup> de Articles befor<sup>e</sup> it : as a man, de man” (33).

Ben Jonson (1640) gives two contradictory classifications of the word classes. He is inspired by the Lilyan model and introduces a Latin classification:

“In our English speech, we number the same parts with the Latins.

*Noune, Adverbe.*

*Pronoune. Conjunction.*

*Verbe. Praeposition.*

*Participle. Interjection.”* (50).

But he adds the Rameian dichotomy to this traditional Latin classification:

“A word is of *number*, or *without Number*. Of *number* that word is termed to be, which signifieth a number *singular*, or *plural*” (48). “Moreover, a word of number is a *noun*, or a *Verb*” (49). “A *word* without number is that which without his principal signification noteth not any number. Whereof there be two kinds, an *adverb*, and a *conjunction*” (67).

Ben Jonson treats the article first as the ninth part of speech, and after as pronoun.

---

<sup>9</sup> The oblique forms of *fall*, *confess* is *fallen*, *confessed*. For the verbal case, see Butler (1633: 42).

But he introduces the distinction of the finite and infinite articles which is very pertinent in that time:<sup>10</sup>

“CHAP. IX. OF THE PARTS OF SPEECH. ... Only we add a ninth, which is the *article* : and that is two-fold ;

*Finite, i. e.* relating to both numbers ; as *the*.

*Infinite*, relating only to the *singular* ; as *a*” (50).

“ CHAP. XV. OF PRONOUNS. (...) Two articles, in gender and number infinite, which the Latins lack : *a, the*” (57).

## 3. The new logical classifications

### 3.1. Port-Royal's *Grammaire générale et raisonnée* (1660)

The theory of the word class in the Port-Royal grammar has a logical basis. Language is said to express, by means of words, the ideas, chronologically prior to the word. Once humans have well-formed ideas in their minds, they recur to words.

---

<sup>10</sup> This distinction of finite and infinite articles is earlier than Port-Royal grammar which introduces the modern concept and distinction of article in French grammar.

Therefore, an insight into the human mind must underlie a classification of those words:

“(Ainsi) l'on peut définir les mots, des sons distincts & articulés dont les hommes ont fait des signes pour signifier leurs pensées. C'est pourquoy on ne peut bien comprendre les diverses sortes de significations, qui sont enfermées dans les mots, qu'on n'ait bien compris auparavant ce qui se passe dans nos pensées, puis que les mots n'ont été inventés que pour les faire connaître” (Arnauld et Claude Lancelot 1660: 27).

According to the *Grammaire générale et raisonnée*, there are three operations of the mind, Perception, Judgment and Reasoning. Perception is the simple apprehension of anything or quality of a thing. Judgment affirms that the thing we perceive is so, or not so as having the ideas of the *earth* and *roundness*, I affirm that the earth is round. The third operation of the mind, reasoning is an extension of the second, a concatenation of judgments. It will therefore be sufficient to consider the first two operations:

“Tous les Philosophes enseignent qu'il y a trois opérations de notre esprit : CONCEVOIR, JUGER, RAISONNER. CONCEVOIR, n'est autre chose qu'un simple regard de notre esprit sur les choses, soit d'une manière purement intellectuelle; comme quand je conçois l'être, la durée, la pensée, Dieu : soit avec des images corporelles, comme quand je m'imagine un carré, un rond, un chien, un cheval. JUGER, c'est affirmer qu'une chose que nous concevons, est telle, ou n'est pas telle. Comme lors qu'ayant conçu ce que c'est que la *terre*, & ce que c'est que *rondeur*, j'affirme de la *terre* qu'elle *est ronde*. RAISONNER, est se servir de deux jugemens pour en faire un troisième (...) D'où l'on voit que la troisième opération de l'esprit, n'est qu'une extension de la seconde” (ibid: 27-28).

The judgment made of things, as when said, *the earth is round*,<sup>11</sup> is called a proposition. This proposition naturally includes two terms, one called the subject, which is the thing, of which the affirmation is made, as *the earth*, and the other is called the attribute, which is the thing, that is affirmed of the subject, as *round*. And then, *is*, which is the connection between these two terms:

---

<sup>11</sup> Finally, every verb can be analyzed as *be+participle*. This is one of the common points between Port-Royal's general grammar and Wilkins's universal grammar (cf, Arnauld et Lancelot 1660: 91 and Wilkins 1668: 303). In fact, this kind of analysis (*amat=est amans*) was a medieval practice (cf. Padley 1983: 307). For the theories of the French verb in that period, see Swiggers (1984: 29-32), and Shin (2000).

“Le jugement que nous faisons des choses, comme quand je dis; *la terre est ronde*, s'appelle PROPOSITION; & ainsi toute proposition renferme nécessairement deux termes : l'un appelé *sujet*, qui est ce dont on affirme, comme *terre* ; & l'autre appelé *attribut*, qui est ce qu'on affirme, comme *ronde*; & de plus la liaison entre ces deux termes, *est*” (ibid 28-29).

The two terms belong to the first operation of the mind because that is what we conceive, and are the objects of our thought. The connection belongs to the second operation, which may be called the action of the mind, and the manner in which we think. Thus, the most general distinction of words must be of those, which signify the objects and manners of our thought:

“Or il est aisé de voir que les deux termes appartiennent proprement à la première opération de l'esprit, parce que c'est ce que nous concevons, & ce qui est l'objet de notre pensée : & que la liaison appartient à la seconde, qu'on peut dire être proprement l'action de notre esprit, & la manière dont nous pensons. Et ainsi la plus grande distinction de ce qui se passe dans notre esprit, est de dire qu'on y peut considérer l'objet de notre pensée ; & la forme ou la manière de notre pensée, dont la principale est le jugement. (...) Il s'en suit de là que les hommes ayant eu besoin de signes pour marquer tout ce qui se passe dans leur esprit, il faut aussi la plus générale distinction des mots, soit que les uns signifient les objets des pensées, & les autres la forme & la manière de nos pensées, quoiqu'ils ne la signifient pas seule, mais avec l'objet” (p. 30).

Words expressing the objects of thoughts are noun, pronoun, participle, preposition, adverb and article. Words expressing the manner of thoughts are verb, conjunction and interjection:

“Les mots de la première sorte sont ceux que l'on a appelé *noms, articles, pronoms, participes, prépositions, & adverbess*. Ceux de la seconde, sont *les verbes, les conjonctions, et les interjections*” (ibid: 30).

Thought in <b>Logic</b> (Ideas)		Speech in <b>Grammar</b> (Words)

	<i>Raisonner</i> (Reasoning)		
			<i>GRAMMAIRE</i>

### 3.2. *The Port-Royal grammar and Brightland*

Some of the English grammarians follow Port-Royal's method even though they do not adapt their word classes.<sup>12</sup> John Brightland (1711) translates the Port-Royal grammar and takes it over without critical sense. *A grammar of the English Tongue* is composed by a juxtaposition of two texts, a text of the translation and the comments of the author. But he transformed the original text at the end of speech parts theory, and introduced his own theory:

“The Words of the first Class, are those which we call *Names, Personal Names*; QUALITIES deriv'd from *Words of Affirmation, or Verbs* (call'd in the *Latin Participle*), *Foreplac'd Words*, (or *Prepositions*), and *added Words*, (or *Adverbs*). Those of the second, are *Words of Affirmation*, (or *Verbs*), *Joining Words*, (or *Conjunctions*) and *Interjections*, as the old *Grammarians* call'd them Absurdly, distinguishing them into a peculiar Part of Speech, which

<sup>12</sup> Priestley's definitions of the verb and the adverb are, for example, dependent upon the Port-Royal definition. For the definitions of verb and adverb, see Donzé (1967: 27-34) and Swiggers (1994: 47-48, notes 34, 39).

are plainly only *added Words of Passion*”<sup>13</sup> (1711: 79, [71]).

Brightland does not mention the article as a separate part of speech and treats the interjection rather as an adverb than as an independent word class. And thus, he establishes his original four word classes, names, qualities, affirmations and manners:

“Words are naturally to that End, to be divided into four Original classes or Orders, i. e. *Things*, or rather the *Names of Things*; the *Qualities* of these Things, the *Circumstances*, *Action*, *Passions*, and *Beings* of Things; with their *Relations*, *Regards*, and *Connections* to, and with each other in Sentences. According to this, there are four Parts of Speech, or four Heads, to which every Word in all Languages may be reduc’d” (ibid: 76-77, [68]-[69]).

Participles and articles are included among the qualities, pronouns among the names. For the first time in the history of English grammar, the adjectives are separated from the substantives and constitute an independent word class. During the next century, the English and French grammarians follow this distinction of Brightland, and the adjective definitely acquires its grammatical status.<sup>14</sup>

---

<sup>13</sup> Compare this citation to the text of p.30 of Port-Royal’s grammar.

<sup>14</sup> Priestly (1769) is, for example, proud of his innovation about the adjectives: “All the innovation I have made hath been to throw out the *Participle*, and substitute the *Adjective*, as more evidently a distinct part of speech” (1769: 20). According to Poldauf (1948: 155), Richard Johnson (*Grammatical Commentaries*, 1706, quoted by Poldauf) is the first grammarian who suggested the separation of two categories, but we know that Brightland is earlier than Johnson on this topic. We remember also that the adjectives constitute an independent chapter in *Grammatica Anglicana* de Greaves (see this article, note 5). In France, Girard (1747) carried out this separation in practice. For Girard, see Swiggers (1982).

Brightland	<i>Port-Royal</i>
<b>The Words of the first Class</b> Names (noun) Personal Names (pronoun) Qualities ( <b>adjective, article</b> , participle) Fore-plac'd Words (preposition) Added Words (adverb, <b>interjection</b> )	<i>Les mots de la première sorte</i> <i>article</i> <i>nom</i> <i>pronom</i> <i>participe</i> <i>préposition</i> <i>adverbe</i>
<b>The Words of the second Class</b> Words of Affirmation (verb) Joining Words (conjunction)	<i>Les mots de la seconde sorte</i> <i>verbe</i> <i>conjonction</i> <i>interjection</i>

William Loughton (1734), in his question-answer form grammar, copies Brightland's four parts of speech but changes the name of the fourth part into *particles* instead of *manners of words*:

“Q. What Things are properly the Subject of our Speech or Discourse ?

A. Whatever is the Object of our Senses, Reflection, or Understanding, may be the Subject of our Discourse, and this may be either a Thing or Substance, or the Manner or Quality of a Thing, or the Action of a Thing, or the Manner or Quality of that Action.

Q. Have we Words adapted to, and expressive of, these Things ?

A. Yes, and these are of four Sorts, which are sufficient to express all our Ideas or Notions of Things, and are therefore call'd the four Parts of Speech ; as 1. Names which express Things or Substance ; 2. Qualities which express the Manners, Properties, or Affections of Things ; 3. Affirmations expressing the Actions, Passions, or Being of Things. 4. Particles showing the Manner or Quality of Actions, Passions or Being, &c” (1734: 47).

He recognized the article as a quality of things and distinguished definite and indefinite articles:

“Q. What Part of Speech are *a* and *the* ?

A. Qualities being joined to Names, as other Qualities are, but they are usually called Articles.

(...)

Q. What is the Difference between *a* and *the* ?

A. *A* is called the indefinite Article, because it leaves the Sense of the Word to which it is prefix'd undetermined to what particular you mean (...) *The* is called a Demonstrative or definite Article, because it points out and determines the Sense of the Word, it is put before, to some particular” (ibid: 67-68).

Brightland's four parts of speech are taken by Samuel Saxon (1737) with other labels. The class of adnoun which was the Brightland's class of qualities consists of adjective, participle and pronoun. The pronoun was taken as a noun in Brightland's grammar:

“The Words or Parts of Speech are Four, viz. *Noun, Adnoun, Verb, and Particle*. Under the *Adnoun* are comprehended *Pronoun* and *Participle*, commonly called two distinct Parts of Speech. Under the *Particle* (by reason of its different Use and Signification) is comprehended *Adverb, Conjunction, Preposition* and *Interjection*, said to be four distinct Parts of Speech too” (1737: 34-35).

But Saxon links his four word classes to the traditional idea of declinable-indeclinable:

“Note, The *Noun, Adnoun, Verb* are termed declinable Parts of Speech ; but the *Particle* is an Indeclinable Part (i.e. it varies not it's Ending)” (1737: 34-35).

The article is a nominal sign for Saxon while it was treated as a quality in Brightland's grammars:

“*Of a Noun, &c. the first Part of Speech.* (...) The Particles usually placed before the Noun, are *a, an, or the* ; and distinguish it from an Adnoun” (ibid 35).

## Brightland (B)-1711, Loughton-1737, Saxon-1737

Brightland (B)		Loughton		Saxon (A)

<b>Saxon (B)</b>					
			Declined Noun Adnoun Verb	Undeclined Particle	

### 4. Conclusion

Some of the English grammarians at the beginning of the vernacular grammar tried to apply the French grammatical theories of parts of speech for English language but they did not obtain a more satisfying result than the English grammarians who followed Greek or Latin traditions. However, the grammatical analysis was becoming more and more discerning with their attempts.

The Port-Royal grammarians clearly distinguished the adjectives from the substantives, but these two parts of speech remained within the same category, noun. Brightland who introduced the Port-Royal grammar into England, definitely separated these two categories for the first time in the history of English and French grammars. Several English grammarians immediately followed Brightland's division, but more than half a century was necessary for the French grammarians to accept the separation of the adjectival category from the substantives. The French adjectives, which reflect nominal inflexions, might have prevented the French grammarians from reaching an agreement to the separation of the two categories.

The independence of the adjectives has shaken the entire division of parts of

speech because the grammarians tried to retain the same number of speech parts as before. The participle, which generally had stayed as a separate part of speech or had been treated as a noun in England and in France, was becoming a topic whether or not it should be considered as a part of the verb category but only from the middle of the 18<sup>th</sup> century.

The article was recognized as an independent part of speech in the beginning of the 17<sup>th</sup> century in France by grammarians such as Maupas and Chiflet and acquired the modern definition and subdivision of this category in the Port-Royal's Grammar. But the majority of the English grammarians described the article as a nominal sign or particle, and some of them defined the article as an adjective. The English grammars generally deemed the article a separate word class in the middle of the 18<sup>th</sup> century. The English articles which, compare to the French ones, have reduced forms and usages, did not attract enough attention of the grammarians of that time. Here too, their concern with the 8 parts of speech would have exercised an influence. Curiously, neither the French grammarians nor the English grammarians paid attention to the original and pertinent analysis of one of the first grammarians of vernacular language, Palsgrave who, writing a first French grammar in 1530, not only recognized the article as an independent part of speech but also denied the existence of case in the article. Would this English gentleman not have been considered as an authentic grammarian of French language in England? And, in France, would he have been a grammarian who hurt the pride of French grammarians by his first French grammar?

# Effects of Morphological Transfer in prepositions of Spatial Reference on Korean Learners of English

Shinae Kang

Seoul National University  
Dept. of English Education, College of Education, Gwanak-gu, Seoul

## Abstract

This study aims to find out whether there exists a morphological transfer in using English preposition of the spatial expressions by Korean Learners of English at a different level and what kinds of process is under surface of the transfer. Since it was widely accepted that prepositions and other linguistic entity that plays what prepositions are severely difficult for second language learners to attain, there have been a lot of studies on exploring the nature of learning difficulty in prepositions. Among various uses of prepositions, the study focused on the spatial reference with three different levels of Korean learners. Two different types of verbs that require either location or direction preposition were used to see the possible transfer effect. The learners were given several pictures and six descriptions for each picture using different preposition, and were asked to judge grammaticality of each sentence. The result of the experiment showed that in directional preposition, learners showed a strong tendency to choose a preposition that corresponds to the literal translation of the Korean. In location preposition, *on*, frequently translated to Korean correspondence *-e*, are much easily understood by Korean learners that *in*. Moreover, Korean learners showed similar patterns in using prepositions with the different verb types. That is, literal translations, or semantic features of preposition play more important role in learners' choice on preposition of spatial reference

## 1. Introduction

Prepositions are generally known to be the most difficult part for foreign learners to attain. (Celce-Murcia and Larsen-Freeman, 1999; Lindstromberg, 1996) One of the reasons suggested is the interference from the learner's first Language(L1). The issue of language transfer has been researched upon from many aspects in the fields of second language acquisition (SLA). However, transfer effects in prepositions have remained relatively unnoticed. This is partly because prepositions are included in a domain that is usually believed to be free of transfer.

Prepositions or any other linguistic unit that is compatible to the English prepositions play a many different roles in a sentence and assume a critical part in morphology that varies cross linguistically. For instance, Korean has abound, agglutinative (postpositional) morphology whereas English has a free, prepositional morphology. Since bound morphology is regarded as a domain where transfer effects do not occur, it has be has rarely been researched whether there exist transfer effects among languages that have difference morphological system.

The issue of transfer on prepositions between Korean and English was being researched by Kim& Kim (1999). They proved that Koreans have difficulty in acquiring prepositional system due to the absence of the corresponding system in their L1. They conducted a cloze-test with which should be filled with one of the five kinds prepositions *at*, *on*, *in*, *for*, and *with*. Korean learners at the beginner level tend to accept the sentence with no preposition (Null preposition) in an obligatory context, and such

phenomenon decreases with participants' increased proficiency. They did not specially divide the functions of prepositions.

Jarvis & Odlin (2000) also have investigated on transferability of bound morphology. They especially focused on one of the main functions of prepositions, a spatial reference. They have classified the English morphemes of spatial reference system into three categories: source, location (place) and direction (goal). The English prepositional system was compared with corresponding L1 spatial reference system with participants of Swedish learners and Finnish learners of English. The study found out that L1 influence is at play in the morphological system. It showed that the semantic transfer in learner's spatial reference and simplification in the area of SLA occurs.

Another study of Eng et al. (2004) also has asserted that learners' L1 seems to have an effect on acquisition of preposition system of English with Chinese learners of English. The study specifically investigated the acquisition of prepositions of locational and directional reference with participants at different levels. It showed that the English preposition of location seemed more problematic than preposition of direction for L1 Chinese Speakers on account of cross-linguistic influence. Furthermore, it proved that age and proficiency levels have an effect on the acquisition of English prepositions.

Along with researches above that considered the nature of prepositions themselves, Inagaki (2000, 2001) has focused on interpretations of verbs and prepositional phrases (PP) following them. It was unique in a sense that taking types of verbs into consideration. The study asserted that in English, manner-of-motions verbs with location PPs can be interpreted in either location or directional meaning in English. However, such interpretation is not possible in Japanese due to the difference in argument structure. It is this difference between Japanese and English in motion verbs that allows different ways in interpretations. Hence, while native speakers of English interpret certain sentences to be directional and location, Japanese fails to interpret the sentence in both way, but likely to involve the sentence with location meaning only. The study suggests a possibility of different process regarding the acquisition of prepositions according to the verb type and yet another possibility of L1 effects. Kim (2005) has replicated Inagaki's experiment with the Korean learners and proven that Korean learners as well tend to interpret the manner-of-motions verbs with location PPs in location meaning only, also possibly attributable to the L1. These studies imply that different types of verb would affect the use of prepositions in spatial reference in Korean.

Given that Korean is somewhat close to the language system of Finnish, it might be noteworthy to see if language transfer in morphology does take place between English and Korean as well. In addition, with different kinds of verbs being observed, it is possible to find out what kind of and how the process of language transfer is occurring whether it's semantic similarity or the argument structure. Moreover, the use of English preposition of spatial reference is observed with the participants of different level, so as to identify the possible differences to what degree L1 effect is applied.

To sum up, this study aims to find out whether there exists a morphological transfer in using English preposition of the spatial expressions by Korean Learners of English at a different level and what kinds of process is under surface of the transfer. As will be seen, the patterns of spatial reference preferred by the Korean learners are quite different from the native speakers of English and such results reflect the influence of their L1, Korean. Before the procedure is introduced, some of the theoretical

background is discussed for the better understanding. First, it includes the concept of morphological transfer, and secondly a comparison of morpho-syntax of spatial reference between Korean and English. Finally, the different types of motion verbs and PPs and their interpretations are explained briefly. Then, the research method used in the study is described with the information of participants and data collection. Finally, the result of the experiment is presented with possible explanation suggesting a possibility of semantic transfer to English spatial reference system.

## **2. Theoretical Background**

### *2.1. Morphological Transfer*

"Transfer" is defined as a learner making an interlingual identification and applying one's knowledge of one language to another. Morphological transfer means a cross-linguistic influence involving any free or bound morpheme. (Jarvis&Odlin, 2000) Bound morpheme itself can be classified into two types of morphology; that is, derivational morphology and inflectional morphology. It has been asserted by many researchers that "overt inflectional morphology generally does not transfer from NL to L2"(Eubank, 1993/1994). However, according to Jarvis&Odlin, the transfer can take place in bound morphology as well in two ways. It is possible that the transfer could occur both on semantic and phonological structures, or it can occur purely on semantic basis. Although the effect of transfer in the domain of bound morphology has been laid unnoticed, there are certain possible effects that have become manifest due to cross linguistic differences. For example, word order errors in English produced by Finnish learners might have arisen due to the difference in morphology system between two languages, in that Finnish have highly flexible word order with a highly developed bound morphology. Therefore, the transferability of bound morphology can be investigated by observing the use of prepositions of spatial reference of two languages.

### *2.2. Typological Comparison*

English and Korean are different in several aspects by typological comparison. One of the main characteristic of Korean that is different from English is that Koreans have rich suffix systems (postpositional systems) that express its nominal case, whereas English does not overtly realize its Case. Rather Cases are given structurally in English. English instead have richer systems in grammatical article and prepositional systems.

English prepositional systems function as to represent spatial, temporal, and other grammatical and semantic relations (Jarvis&Odlin, 2000). Koreans, on the other hand, only have two or more postpositions that are used to realize its nominal case system. That is, most of the spatial and temporal relations that are expressed in English with prepositions are expressed in Finnish through the nominal case system, and all others are expressed with postpositions.(Jarvis&Odlin, p.542) Spatial reference expressed with prepositions include three functions; location, direction, and source.

However, since prepositions referring to source are quite distinct from the location and direction prepositions, and because of aim of the study is to investigate the

use of preposition usage in directional and locational sentence, prepositions of source have been excluded in the observation of the paper.

Korean Locative cases			English basic spatial prepositions	
	goal	goal/location	goal	goal/location
Internal	<i>~an-i-ro</i>	<i>~an-e(seo)</i>	into	in
External	<i>~ui-ro</i>	<i>~ui-e(seo)</i>	onto	on
Neutral	<i>~ro</i>	<i>~e(seo)</i>	to	at

Table 1. Typological Comparison on spatial reference between Korean and English

In Korean, there are two main corresponding postposition which assume what prepositions do in English is *~e* and *~ro*. *~e* fundamentally assume location reference, and *~ro* takes a directional reference.

*~e*, however, is used in many different functions as well such as [location] [place of action] [goal] [place of arrival] [adjacency] [source]. Thus *-e* is used both locationally and directionally. When used as [location], *-e* can alternate with *-eseo*, while it can be substituted by *-ro* when used as [goal] or [place of arrival]. Since [goal] and [place of arrival] both refer to direction, *-e* refers to both location and direction.

On the other hand, when *-ro* is used as directional reference, it is also replacable with *-e*. Thus, *-e* and *-ro* is conflated as directional reference. Thus, *-e* is used to describe both the [location] and the [landing site], or [goal] in Korean as shown following.

(1) na-u bang-un echug-e itta.  
My room second floor-at/on/in placed.

(2) ilyoil- mada kyohoi-e kanta  
Sunday-every Church-to go.

*~e* in the context of the sentence in (2) can be substituted to *-ro* in Korean, and has a contrastive meaning.

(2)' ilyoil-mada kyohoi-ro kanta.  
Sunday-every Church-to go.

The factor that decides which postposition is used depends on the semantic factors of verbs, the NPs before them, and a given context.

### 3. Research Questions

- (1) Do learners show gradual development in using both direction and location prepositions?
- (2) In what way the learners' L1 have an effect on the use of prepositions of spatial reference?

- (2-1) Do learners show a semantic and phonological transfer or semantic transfer only?  
 (2-2) Which preposition do learners have more trouble in judging grammaticality?

## 4. Research Method

### 4.1. Participants

The participants were forty nine university students who were selected from different majors. They were classified by their TEPS score. A group of students that has less than 500 was classified to the beginner group, and a group of students who got between 501 and 700 was classified into an intermediate group. Finally, the rest of the participants, who had received more than 700 were classified to advanced group. The indicator basically reflects the minimum guideline suggested by College English Center, which is used to help students to take the English class according to their level. All of them at the time of experiment were attending one of the three English classes which are recommended as an obligatory by College English Committee.

	Beginners	Intermediate	Advanced
TEPS	below 500	501~700	above 701
Number	15	14	20

Table 2. Number of Participants by their level

None of the beginner and intermediate group students have had stayed in English-Speaking country and 4 students from advanced group had an experience of receiving formal education in English-speaking countries no more than three years. Additionally, four native speakers of English participated in the research as a control group. They did the same questionnaire with the instruction in English.

### 4.2. Material

A grammaticality judgment task, with pictures and descriptions which contain 6 types of preposition and 3 types of verbs, was used. In each picture there was a "figure"(an object that moves) and the "ground"(an object with respect to which the figure moves) (Talmy, 1985). Both the figure and the ground was labeled to ensure that participants were familiar with the vocabulary and the scene. There was also an arrow in each picture, which participants were told was being used to indicate the direction and endpoint of the motion depicted in the picture. (See Appendix) Prepositions and Verbs included in the questionnaire are as following:

#### 4.2.1. prepositions

The target items in the questionnaire had a picture and 7 sentences, among them six contained one English preposition from 6 prepositions in Table 1, and one more sentence without a preposition(null preposition). Thus, a picture had 7 sentences below

it. The 7 sentences were randomly distributed to minimize any possible ordering effects.

#### 4.2.2. *verbs*

The number of verbs used in questionnaire is four, one of them being a distractor. Among the three verbs, two of the verbs were adapted from the study of Jarvis&Odlin(2000) and one from Inagaki(2001).

In study of Jarvis&Odlin(2000), participants were asked to write down a description of a silent movie and analysis was done with the three verbs each corresponding to location, direction, and source respectively. The result has shown that all of the native speakers involved the verb *sit* with the location preposition, and *take* with direction preposition. Since this study aims to find out the comprehensibility or acceptability as well as their actual production, the grammaticality judgment test containing two types of verbs were adopted rather than actual writing task.

In addition, the study of Inagaki suggested that the certain ambiguous verbs , combined with the conflation of goal/location prepositions, make certain English sentences have either location or direction meaning. The study used a picture matching task. It first provided a sentence that is ambiguous by itself, and provided a picture as a multiple-choice. In this study, as the aim is to observe the L1 transfer in use of spatial reference, the method is other way around; the picture is shown first and then the grammaticality judgment scale for learners to choose is given. By doing so, more detailed elaboration on learners' preference can be shown more clearly. Thus, the three verbs being researched on are as following.

1. location - sit
2. goal(direction) - take
3. goal/location - jump
4. distracter - enter

#### 4.2.3. *Data collection*

Participants were asked to judge to what degree each sentence sounded natural or grammatical as a description of the situation depicted in the picture. Judgments were given on a five-point scale ranging from -2(completely unnatural) through 0(not sure) to +2(completely natural). In addition, participants were asked to write a short description of the picture in Korean so as to observe any possible transfer effect from L1. The experiment was done within 10 minutes for all participants.

#### 4.2.4. *Data Analysis*

Firstly, the mean value of prepositions used with each verb was calculated and compared by the learner groups. Then picture description in Korean was analyzed. The morphemes used in spatial reference was sorted and counted.

## 5. Result

### 5.1. *Location verbs*

5.1.1. *sit*

5.1.1.1. *results* First of all, the mean value of prepositions used with *sit* and *grass* was calculated. The value for each preposition is clustered by learners' proficiency level.

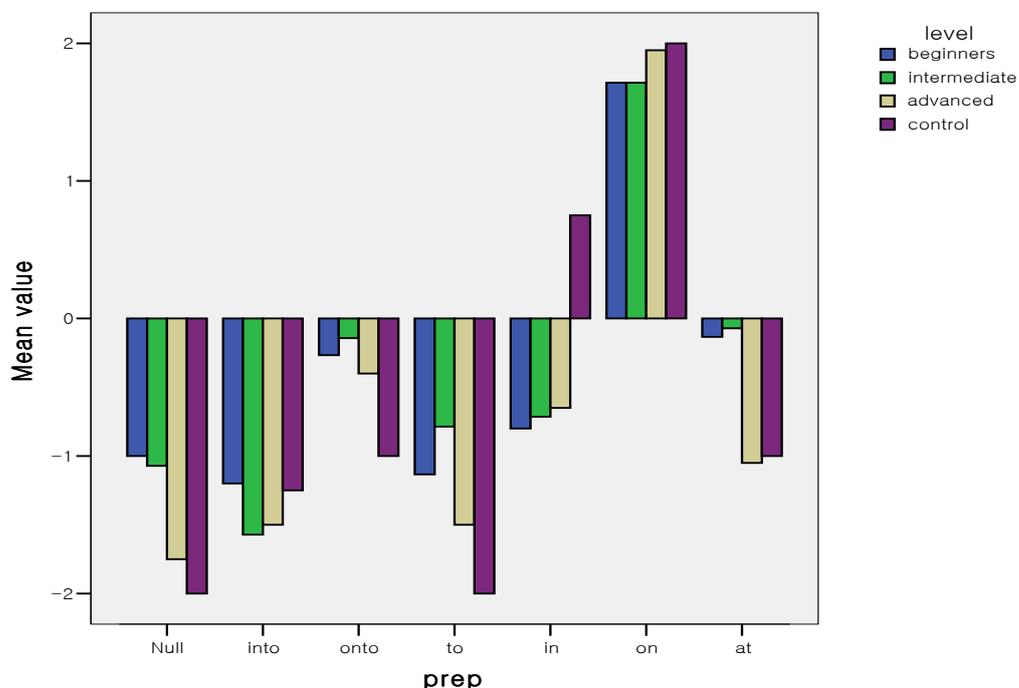

Figure 1. The mean value of prepositions used with *sit*

As for goal/location prepositions, *on* is most preferred by both learner and control groups. *in* is judged as natural by control group, but not by all three learner groups. Finally, *at* is judged as unnatural by control and advanced learner group, but the other was unsure. For goal prepositions, it was quite significant that *to* and *onto* was regarded unnatural for control group, but was more natural for learner groups, and they showed gradual development for with proficiency level except for intermediate group. Note that use of *at* is quite different between groups and it is confirmed by One way ANOVA result. (  $F=5.406, p=.003, <.05$ )

Then Korean morphemes were counted. Table 3 shows the count and percentage of Korean postposition morphemes used by each group. It is shown that Korean postposition used in the description test was mostly ui-e and e. e is especially preferred by intermediate group.

	beginners		intermediate		advanced	
	Count	%	Count	%	Count	%
ui-e	9	60.0%	5	35.7%	11	55.0%
e	5	33.3%	8	57.1%	9	45.0%
etc	1	6.7%	1	7.1%		

Table 3. Frequencies for Korean morphemes for *sit*

5.1.1.2 Analysis Location prepositions in English, *at*, *on*, and *in*, is altogether can be translated to *e* in Korean. Direction preposition *-to* also can be translated into *~e*, since *~e* can refer to either location or direction. Thus, relatively high acceptance of *to* and *onto* by learner groups can be explained in terms of overgeneralization of *at*.

5.1.1. jump [location]

5.1.1.1. results The result shows similar pattern as in *sit*. Figure 2 represents the mean value of prepositions used with jump as a location reference. For goal/location prepositions, it is clear that *on* is regarded as most natural by both the learner groups and the control group. While *at* is completely unnatural for control group, learner groups judged is to be slightly natural, and the naturalness decreases with increased proficiency. *in* is judged to be slightly unnatural for all four groups, with intermediate group being prominent among 4 groups.

In goal prepositions, *to* is judged to be completely unnatural by control group. On the other hand, learner groups' judgment of the sentence shows gradual increase in unnaturalness. That is, more advanced learners are, the more likely they will judge the jump to be unnatural. *into* is regarded to be completely unnatural for control group and more unnatural by learner groups, too. Advanced groups, however, is significantly different from the two other learner groups in that they judged the sentence to be less unnatural. In addition, *onto* is by all four groups regarded as rather unsure to judge naturalness. Use of *into* is significantly different between groups. The Kruskal-wallis test was conducted instead of ANOVA because the results failed to satisfy prerequisite qualifications to conduct ANOVA (into : Chi-Sq.=8.371, p=.015) In addition, though found to be statistically insignificant, *at* is also interesting to note. (Chi-Sq.=5.052, p=.062)

Next, the kind and number of Korean morphemes was looked into. Table 4 shows actual count and percentage for each Korean Morpheme used by learner group.

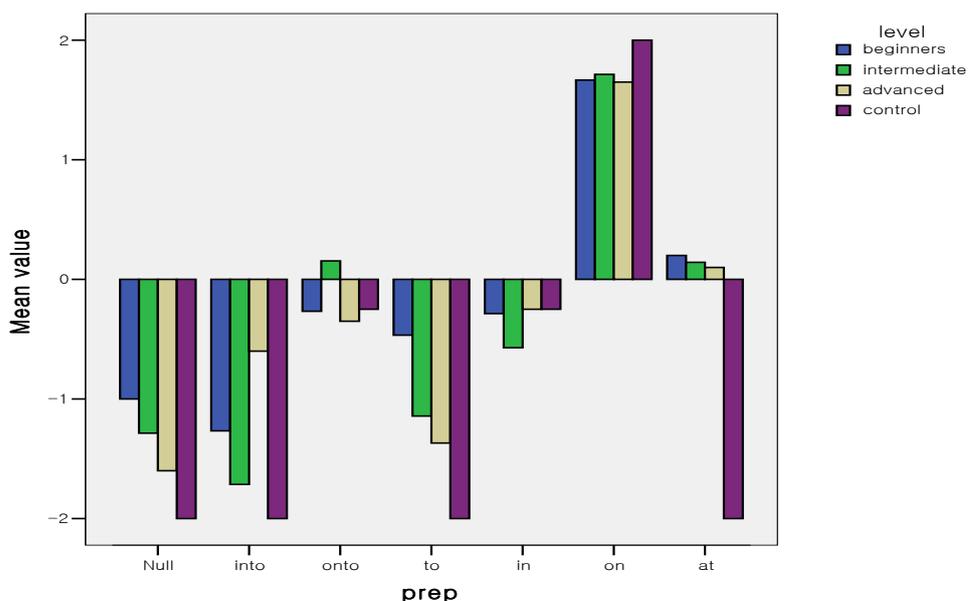

Figure 2. The mean value of prepositions used with jump (location)

	beginners		intermediate		advanced	
	Count	%	Count	%	Count	%
ui-eseo	12	85.7%	8	57.1%	14	70.0%
eseo	1	7.1%	6	42.9%	6	30.0%
etc	1	7.1%				

Table 4. use of korean morphemes with jump(location)

Note that *eseo* is prevalent in the description test. As mentioned, *e* used as [location of action] can be replaced with *eseo*.

5.1.1.2. Analysis Since, *eseo* can be translated to all three locative prepositions in English; *at*, *on*, and *in*. learners are left with much wider choices when referring to locational reference. However, Learner groups tend to prefer only one preposition, *on*, for referring to one spatial reference.

Learner groups have difficulty in deciding grammaticality of other locative prepositions. Among three directional prepositions, onto which share *on* phonologically and semantically, is regarded as least unnatural.

## 5.2. Directional Verbs

### 5.2.1. take

5.2.1.1. results The mean value of prepositions used with *take* and *car* is clustered by learners' proficiency level, illustrated in figure 3.

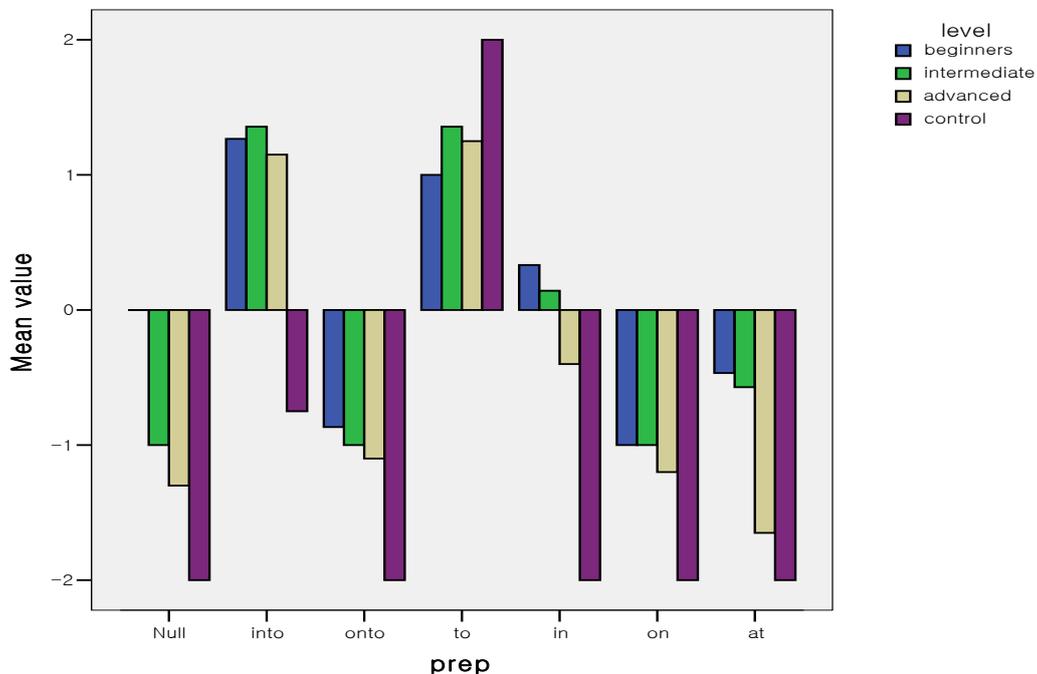

Figure 3. The mean value of prepositions used with take(directional)

	beginners		intermediate		advanced	
	Count	%	Count	%	Count	%
ro	9	60.0%	3	21.4%	10	50.0%
e	3	20.0%	8	57.1%	6	30.0%
an-i-ro	1	6.7%			2	10.0%
etc	2	13.3%	3	21.4%	2	10.0%

Table 5. Use of Korean Morphemes of take (directional)

All three location prepositions are judged to be completely unnatural by the control group. Learner groups' judgment tend to accept these prepositions; *at*, *on*, and *in*, by the order of difficulty. For goal prepositions, the result shows that *to* used with take is accepted as most natural by all four groups. However, while *onto* is judged as completely unnatural by the control group, and learner group show gradual similar aspect in grammaticality judging with increased proficiency. Likewise, *into* is judged to be unnatural by the control group; on the other hand, all learner group replied it to be quite natural. Use of preposition *at* is again significantly different between groups..(Ch-Sq=12.631, p=.003)

The result of Korean description test is shown in table 5. *-ro* and *an-i-ro* takes up the most of the Korean morpheme used to describe the scene. What is significant is that unlike location verbs which only one kind of preposition was used, *e* is quite frequently used in the description.

5.2.1.2. *Analysis* Learner of all levels have no problem in making *to* as the directional spatial reference. Learners tend to judge *into* to be natural, and this tendency is consistent with the low rate of unnaturalness of *at* by learner groups. It is likely that learner groups show difficulty in judging the ungrammaticality of sentences with location prepositions.

### 5.2.2. *jump [direction]*

5.2.2.1. *results* Goal/location prepositions were observed first. It has been already shown that because of semantic features of *jump*, it can be connected with goal/location preposition and refer direction. Such case is represented with low mean score of unnaturalness of *on* by control group while other two goal/location prepositions are judged to be completely unnatural. *at* and *in* shows similar patterns; learners show gradual decrease in score in judgment. For goal prepositions, it clearly shows that *onto* is preferred most by the control group while all learners group prefer *to* more. *into* is judged to be unclear by all groups except advanced learner group . Use of *on*, *into*, and *at* are found to be significantly different between groups.(into:Chi-Sq=8.926, p=.012; on:Chi-Sq=7.875, p=.02; at:Chi-Sq=5.871, p=.05)

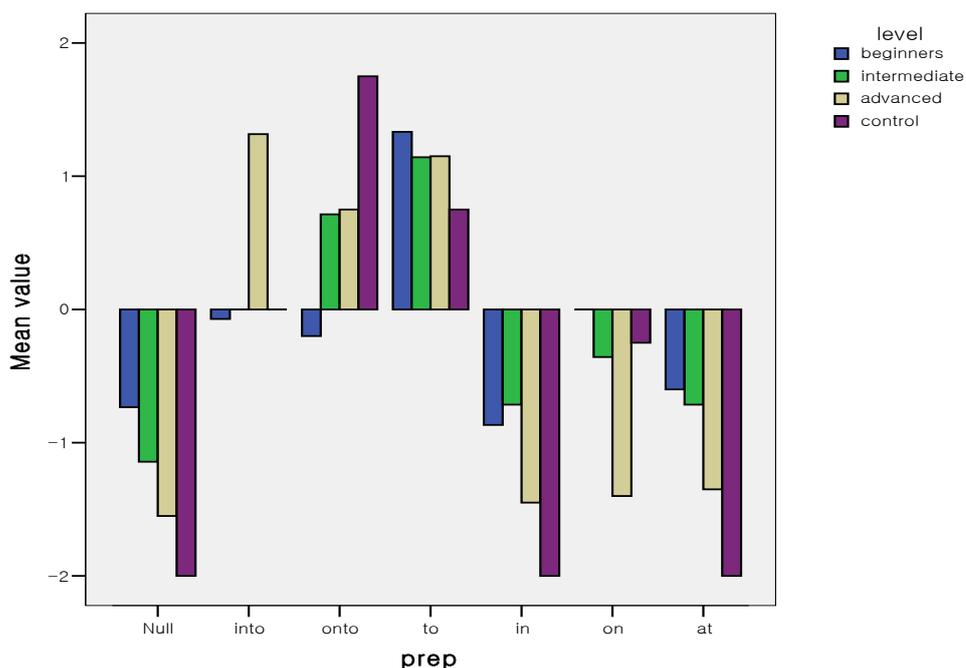

Figure 4. The mean value of prepositions used with jump(directional)

	beginners		intermediate		advanced	
	Count	%	Count	%	Count	%
ui-ro	5	33.3%	6	42.9%	3	15.0%
ro	9	60.0%	5	35.7%	14	70.0%
e	1	6.7%	2	14.3%	2	10.0%
etc			1	7.1%	1	5.0%

Table 6. use of korean morphemes with jump(directional)

Similar with *take*, *-ro* was most frequently used, but the number of alternations is noticeably low.

## 6. Discussion

- (1) In all levels of learner groups, the phenomena of Null preposition decreases with increased proficiency, bolstering the result of Kim&Kim(1998). Given that advanced groups show the similar aspects in using spatial reference to the control group, it can be assumed that the advanced group has reached a certain level in the acquisition development of prepositions of spatial reference. Then, by comparing the mean value of advanced group and the control group could possibly suggest the degree of attainment Korean learners can attain. In the respect, the difference between the advanced group and the control group is the greatest with the *take(directional)*, and similar in *jump(locational)* and *jump(directional)*, and finally

sit(locational). This result can suggest that Korean learners of English have more difficulty in using spatial reference with directional verbs than with locational verbs.

- (2) In location verbs, learners have trouble with judging location prepositions partly due to semantic transfer.
  - (2a) Because of the similarity in translation, *to* is regarded as less unnatural than other directional prepositions.
  - (2b) *at* and *to*, the neutral prepositions, show similar patterns.
- (3) In location verbs, learners make intralingual generalization besides of L1 transfer.
  - (3a) Learners tend to choose only one preposition for one scene.
  - (3b) Learners conflate the two categories of prepositions. *onto* is more preferred in both location verbs with which *on* is usually used; on the other hand, *into* is regarded as unnatural *in* proportion to *in* by learner groups. That is, if learners once judge one preposition to be grammatical, the prepositions morphologically similar to the one chosen is also regarded natural to the degree the chosen preposition is considered grammatical. Since learners make generalization in scope of English, intralingual application is at play.
- (4) In directional verbs, learners have more trouble in discriminating *to* and *into*. In other words, Korean learners, In referring to the directional verb *take* and *jump*(directional), Korean learners of English show a strong tendency to use consistent preposition with the similar semantic meaning. The two directional verbs in fact show different preference on prepositions, however they show a consistent pattern on their preference. *take* is preferred and accepted as natural with prepositions *into*, *to*, *in*. verb *jump*(directional) is preferred with *onto*, *to*, *on*. *to* is also considered natural by native speakers but the other two prepositions are not. Their translation test confirms that their misuse of spatial reference is closely associated with their understanding. This possibly means that Korean learners primarily consider semantic meaning before the grammatical function in using spatial reference.
- (5) Between verbs that can be interpreted in either location and direction and those that can be interpreted in both ways, learners seem to have no difference in using spatial reference. This also supports that learners use their semantic knowledge of prepositions prior to the grammatical functions.

## 7. Conclusion

Taking the research questions into account again, the following conclusion can be made.

- (1) The use of preposition in spatial reference shows a gradual development regardless of its type; location and direction.

(2) L1 semantic transfer is at play. Korean learners show similar aspect with the different verb types, which means literal translations, or semantic features of preposition play more important role in learners' choice of preposition. In direction verbs, learners show a strong tendency to choose a preposition that corresponds to the literal translation of the Korean. In location preposition, *at* is preferred in location reference that can be translated into *~e* in Korean. In addition, *in* is more difficult for learners than *on* or *at*. That is because *on* is more easily translated to *-e* in Korean and more frequently used in English while the use of *in* is restricted to specific context.

These conclusions need to be revisited with more semantic analysis of Korean. Also why and how the learner groups differ, especially what happen in development between beginner group and intermediate group is a part that needs a further research.

sheena@korea.ac.kr

## Abstract

This study is a sociolinguistic investigation on the use and perception of the quotative ‘be like’ by local Koreans, with analyses from various perspectives. The paper is a combination of the following; a) an examination on the ongoing diffusion of the globally spread English quotative ‘be like’, taking one step further to hardly researched regions where English is not spoken as L1 (in this particular study, South Korea), and b) perception of the quotative ‘be like’ by Koreans especially indicated by their awareness in terms of differentiating the quotative ‘be like’ from focuser ‘like’. 37 informants were voice-recorded as they were engaged in casual conversation. Every instance of quotative including ‘be like’, together with other kinds of ‘like’ as well, was incorporated in the data set and analyzed. Retrospective interview was followed afterwards in order to examine the perceptual information. The results ascertain ‘be like’ having been incorporated into the English quotative system in Korea, even though the distribution of quotative indicates that traditional quotative ‘say’ represents the highest proportion. Comparing ‘be like’ to focuser ‘like’, utterances of the latter distinctively exceed the former in number. An attempt to account for this ramification is made regarding Koreans’ perception of ‘be like’. The majority of informants, though not all, does not differentiate the quotative ‘be like’ from the focuser ‘like’. While both the function and style of focuser ‘like’ are discerned by them, those of ‘be like’ are not. In terms of how the style of ‘be like’ is recognized and how it has transmitted, the concept of linguistic spatiality is discussed in relation to the issue of world Englishes.

**Key Words:** *be like*, quotative, focuser *like*, language diffusion, linguistic spatiality, world Englishes.

## 1 Introduction

Quotatives<sup>2</sup>, or ‘dialogue introducers’ (Johnstone 1987) in English encompass a wide variety of verbs which are used to report previous discourse whether it was indirect or direct speech, or inner monologue. Traditionally, ‘say’, ‘think’, ‘go’, ‘call’, and etc. have been regarded as lexical items used when quoting previous utterances or thoughts. Some of the examples are given in the following sentences.

---

<sup>1</sup> A shorter and pre-revised version of this paper was presented at the Cil18 conference in Seoul, Korea (21st – 26th July 2008). I would like to express my gratitude to my advisor, Professor Hikyoung Lee, for her fruitful comments and feedback on this research. I also wish to thank Nari Lee for her help in collecting data and insightful suggestions, to all of my informants for bearing thirty minutes of recording and for being continuously patient with the following interview.

<sup>2</sup> Compared to other equivalent terms suggested in the literature such as *verbs of saying*, *dialogue introducer*, *constructed dialogue introducer*, the term *quotative* is the most encompassing in that it is ‘semantically transparent and neutral’ as pointed out by Blyth et al. (1990), Ferrara and Bell (1995) and many others.

- a. 'Donald,' Bech said, 'we would never eat any candy without telling you'. (Urdike 1965: 111, excerpted from Meyerhoff 2006)
- b. He was getting upset. So I thought, 'uh oh, this is not going well'.
- c. I said, 'hi, can I help you?' and she goes, 'oh, I was just getting some lemons'. (Buchstaller 2001b)

More recently, however, the newcomer 'be like' has been highly paid attention in the English speaking regions among sociolinguists because of its noticeable characteristics; another case of grammaticalization and its remarkable versatility and dynamic diffusion in terms of its usage. Unlike other existing quotatives, 'be like' is able to perform almost all the possible discourse functions from dramatic reports of previous utterances(d), dynamic actions or gestures(e) to inner monologue(f) (Blyth et al. 1990).

- d. I'm like, 'Can I please speak with Antonio?' And his mom's like, 'Oh no sorry! He's not home.' (Tagliamonte & D'Arcy 2004, excerpted from Meyerhoff 2006)
- e. And I was just like, '[making a face].' (Blyth et al. 1990)
- f. She was acting so strange again. We were like, 'oh no, what's she gonna do now?'

For the last two decades since it was first documented in scholarly literature (Butters 1982), 'be like' has been delved into from many different angles of research. Studies on 'be like' so far investigated a number of issues ranging from historical origin mainly in relation with its pragmatic shift with the concomitant process of grammaticalization (Romaine & Lange 1991; Buchstaller 2001a/2001b), constraints on the use of 'be like' such as tense, grammatical person, or content of the quote (Blyth et al. 1990; Tagliamonte & D'Arcy 2004; Barbieri 2005) to sociolinguistic distributions and frequencies (Blyth et al. 1990; Ferrara & Bell 1995; Tagliamonte & Hudson 1999; Dailey-O'Cain 2000; Macaulay 2001; Baird 2001; Winter 2002; Cukor-Avila 2002; Levey 2003; Tagliamonte & D'Arcy 2004; Barbieri 2005; Buchstaller 2006a; Tagliamonte & D'Arcy 2007) and attitudinal studies (Dailey-O'Cain 2000; Buchstaller 2006a/2006b). Some of these studies also explored the relationship between the quotative 'be like' and focuser 'like', a term suggested by Underhill(1988), indicating the use of particle 'like' with a function of introducing new information.

- a. Well, it's not like wonderful, but it's okay.
- b. Do we have to read like the chapters covered on the midterm for the final?  
(both excerpted from Underhill 1988)

As one might have noticed, proportion of the literature is concentrated on documenting the sociolinguistic distribution and frequency of 'be like'. This is due to the keen interest among sociolinguists in that this newcomer has been dynamically diffused in many varieties of English with or without spatial discontinuity. For example, Cukor-Avila observed the prevalent use of 'be like' within African American Vernacular English (AAVE) (2002). Outside of America, Tagliamonte and Hudson ascertained global diffusion of 'be like' across the British and Canadian corpora (1999) and Macaulay (2001) also documented the usage of 'be like' by adolescents in Glasgow. The spread did not stop there and further paved its way into Australian English (Winter 2002), New Zealand English (Baird 2001), and even into some countries where English is not used as L1, such as Singapore (Singler & Woods 2002 as cited in Buchstaller 2008) and Germany. For instance, Müller (2005) conducted a comparative study on the overall use of 'like' both as a discourse marker and a quotative between American native speakers and German EFL speakers with reference to age, gender, and linguistic factors. This study proves the diffusion of 'be like' into the countries which belong to the 'expanding circle', the outermost circle among the three concentric circles

schematization (namely, inner circle, outer circle, and expanding circle) in terms of the global situation of English, i.e., countries where English is used as a foreign language (Kachru & Nelson 1996).

The evidence of nonnative speakers' use of 'be like', though not altogether missing, is exiguous. Before the cases of Germany and Singapore mentioned above, it was first noted in Ferrara and Bell (1995) as they analyzed the corpus collected in Texas from 1992 in terms of ethnicity of 'be like' users. Nonnative speakers were categorized as 'Foreign students' among other ethnicities of Anglo, Black, and Hispanic. The result indicated that only 2 foreign students out of 200 people from diverse ethnic background used 'be like' in their narrative. Granted that the sparse use of 'be like' by nonnative speakers was at least documented, it was still very briefly covered with no significance. Thus, the following inquiries are yet to be definitively answered due to the lack of substantial empirical data: How far this global linguistic item 'be like' has traveled? Do speakers<sup>3</sup> of English as a foreign language use this non-standard innovation in speech? If so, in what percentage 'be like' is incorporated in their narrative? How is 'be like' perceived by them?

The present study is an attempt to provide some answers for the inquiries above. In general terms, the study sets out to probe the ongoing dispersion of the globally spread English quotative 'be like' in the EFL setting of Korea, and tries to explore the perception of 'be like' by Koreans. Elaborated research questions are as follows.

- 1) Has 'be like' been incorporated into the quotative system of Korean speakers of English? If it has, in what degree of frequency is it observed in their narrative?
- 2) Are there any localized features of 'be like', or other types of English quotative, manifested in their narrative?
- 3) Do they perceive 'be like' as a quotative, separately from the focuser 'like'?
- 4) Do they recognize the style of 'be like' or any kinds of 'like'?
- 5) How was 'be like' transmitted if it is observed?

Detailed explanation regarding the research method will be presented in the following section.

## **2 The Data and Method**

### **2.1 A preliminary study**

Investigating English language item in the region where English is rarely used is an extremely convoluted matter. The case becomes even more challenging to look into when the particular linguistic item under scrutiny belongs to the inventory of most casual speech, which is not overtly instructed in the EFL or ESL classroom setting. In order to ascertain the potential informants whose English competence exceeds the four walls of classroom, questionnaire sheets<sup>4</sup> which asked informants to paraphrase five sentences containing quotative 'be like' and focuser 'like' were distributed to 27 Korean learners of English stratified by proficiency, namely, beginner, low-intermediate, high-intermediate, and advanced. This grounding study showed that beginners and low-intermediates are generally confused about the word 'like' unless its referential meaning is used as the basic verb

---

<sup>3</sup> This term will be used interchangeably with the term 'learner'.

<sup>4</sup> The questionnaire sheet for the preliminary study is provided at the end (Appendix 1).

meaning, ‘to be fond of’. Based on this preliminary finding, subsequent research selectively took the high-intermediate and advanced as informants, excluding beginners and low-intermediates. The rationale for this exclusion is twofold; firstly the probability increases substantially in terms of eliciting ‘be like’ or focuser ‘like’ from the informants who are high-intermediate and advanced, and secondly according to ACTFL(American Council on the Teaching of Foreign Languages) proficiency guidelines for speaking, the evidence of ‘simple narration and/or description’ emerges for the first time when speakers of foreign languages come to reach the high-intermediate level (ACTFL 1986). Therefore, in order to elicit narratives displaying various quotatives with solid probability of occurrences of ‘be like’, informants for the present study are selectively chosen according to their proficiency level. The informants who had been engaged in the preliminary study were not further included in the subsequent research.

## 2.2 Procedure

In the winter of 2007, 40 informants<sup>5</sup> were voice-recorded as each of them informally conversed with the interviewer (the author) for approximately half an hour in English. Out of 40 informants, three were excluded from the data since their speaking proficiency turned out to be below high-intermediate, not capable of eliciting narratives with proper use of quotatives. After 30 minutes of recording session was over, a follow-up interview was utilized in order to investigate overall perception of the quotative ‘be like’ by the informants, including their recognition of its style, the route from which ‘be like’ was transmitted to each informant if ever used, and their awareness in terms of differentiating the quotative ‘be like’ from focuser ‘like’. The off-record session was administered in Korean for thorough analysis about perceptual information of ‘be like’. All the informants were university students between 20 and 32 years of age and quite evenly distributed in terms of gender (16 males and 21 females). The data mainly consists of narratives of personal experience of each informant regarding family, friends, and their school life. The total of 37 recordings were analyzed with reference to the frequency of occurrence of ‘be like’ in comparison with other quotatives, and to the correlation between the occurrences of ‘be like’ and the focuser ‘like’. Informants’ overall perception of ‘be like’ was concomitantly analyzed based on the follow-up interview.

## 2.3 Analysis

All tokens of reported speech including direct, indirect, or inner thought were taken into consideration with regard to their introducers, i.e., quotatives. Most of the previous literature on ‘be like’ included five other major quotatives – say, go, think, zero, and others – when investigating the distribution and percentage of quotatives. The present study also adapted this inventory of six quotatives, plus another newcomer quotative ‘all’(Rickford et al. 2007 among others). In terms of non-quotative occurrences of ‘like’, the data revealed two other usages of ‘like’; one as a focuser and the other as a hedge. In a sentence, ‘like’ can be used as a focuser whereby the ‘new information’ of the sentence is conveyed (Underhill 1988), or as a hedge which expresses hesitancy or unsureness of the speaker (Johnstone 2002). All three different ‘like’ were counted and categorized.

---

<sup>5</sup> The mean score of TOEIC(Test of English for International Communication) is 911.9, indicating that all the informants are securely placed above the level of high-intermediate.

### 3 Results and Discussions

#### 3.1 Partitioning of the quotatives

Table 1 shows the overall distribution of the quotatives used by Korean speakers of English. The total number of quotatives is 732 and the table below displays anomalous distribution of competing variants of quotative, compared to the result of other literature such as Tagliamonte and Hudson(1999), Tagliamonte and D’Arcy(2004), or Macaulay(2001).

**Table 1.** Descriptive statistics for the distribution of quotatives used by Korean speakers of English (Ratio statistics for each quotative/total n of quotatives drawn from 37 informants)

	M	SD	N
<b>say</b>	.406	.164	305
<b>be like</b>	.081	.152	68
<b>think</b>	.046	.070	32
<b>zero</b>	.244	.145	170
<b>others*</b>	.224	.130	157
<b>go</b>	.000	.000	0
<b>all</b>	.000	.000	0
<b>Total</b>	1.000	-	732

\* This category contained *tell, ask, advise, shout, call, be, be just, answer, and talk.*

As indicated in table 1, only ‘say’, ‘zero’, and ‘others’ significantly contribute to the total sum. There are 68 occurrences of ‘be like’, representing less than 0.1 percentage at most. Also, the standard deviation appears to be high (.152), suggesting the number of times ‘be like’ is used varies drastically; out of 37 informants, 25 of them did not use it at all while two speakers used it more than ten times. Another noteworthy result is that of ‘go’ and ‘all’. Among 37 informants, literally none of them uttered either ‘go’ or ‘all’. ‘Say’, however, almost takes up 40 percent of all the quotatives. Some of the samples are provided below.

- (1a) I’ve been worried about job applying these days and she said, “Don’t worry. You are qualified enough.”
- (1b) What they said was, (pause) “No, you can’t.”
- (1c) “Ten years is long enough for a couple to get divorced”, she said that.

Most occurrences of ‘say’ were similar to (1a), featuring the most ‘unmarked’ form of dialogue introducer (Tannen 1986, as cited in Romaine & Lange 1991), or less clear-cut as in (1b) and (1c) though all categorized into the quotative ‘say’. In accounting for the choice of quotatives, Romaine and Lange (1991) mentioned that it represents a significant communicative option, affecting styles and genres of a particular discourse. In the same vein, Givón (1980) characterized ‘say’ as a quotative ‘with no commitment’<sup>6</sup>(as cited in Romaine and Lange 1991). In keeping with these ideas, ‘say’ indeed has proved to be the most frequent form of quotative in many other studies as well (Blyth et al. 1990; Baird 2001; Tagliamonte & Hudson 1999 and many others). In addition to this, it may be surmised that the highest concentration on ‘say’ in the current data has something to do with interlanguage feature of L2 speakers in general. For example, one of the important interlanguage characteristics is the reduced system, both in form and function, resulting in one-to-many correspondence. Assumingly, this asymmetric relation between ‘say’ and various intentions to report previous

<sup>6</sup> Clark and Gerrig mentioned that the choice of quotative when demonstrating previous speech is influenced by ‘increased subjectivity’ (1990).

utterances may attribute to the highest percentage of ‘say’ among the inventory.

The second-highest quotative is ‘zero’ quotative, totaling 170 tokens, followed by almost the same number of quotative categorized as ‘others’, totaling 157 tokens. The allotment of ‘zero’ or ‘others’ represents an exceptionally high ratio, particularly with reference to other studies. For instance, in Tagliamonte and Hudson (1999), there are only a small number of others (*decide, tell, yell, ask, scream, shout, call, laugh, venture, feel, be just, and to be*); 4% in the British corpus and 5% in the Canadian corpus of all the quotatives. Among the category of ‘others’, the result also shows an uneven proportion, highly focalized on certain quotatives such as ‘tell’ and ‘ask’. More specifically, ‘tell’ and ‘ask’ consist of over two-thirds of all quotatives used in the ‘others’ category. Some of the samples are as follows.

(2a) He told me that, (pause) “Hey, I broke up with my girlfriend.”

(2b) Yesterday my mom asked me that, (changing intonation) “Do you know where that church is?”

(2c) My mom is really strict and uptight but my dad is the opposite. He is, “Don’t worry and relax.”

Here, the deviation from the standard use of English is manifested. Grammatically, ‘that’ in (2a) and (2b) requires a subordinate clause with subject and tense agreement, so that the sentence could be completed (e.g. He told me that he broke up with his girlfriend). Yet, the quoted dialogue introduced after certain cues such as the pause or changed intonation is clearly a direct quotation, which again brings up the issue of interlanguage, or speaker’s lack of proficiency. Also, a smattering number of ‘be’ or ‘be just’ as in (2c) were observed.

The effect of interlanguage may have caused another high concentration on ‘zero’ quotative as well. The following examples show that the speakers are operating ‘avoidance strategy’, one of the interlanguage features.

(3a) Every time we fight, he always touches emotional sides. (zero) “Don’t you have to accomplish something by now?”

(3b) Then I have no choice but lying to my friend. (zero) “Of course you look good today! I like your dress.”

(3c) I particularly emphasized it. (zero) “Please make sure the route before going out tomorrow.”

(3d) 20 minutes ago, I called my friend and (zero) “where are you?”

(3a-d) suggests that the informants chose to report previous utterances without further complicating the sentence, thereby avoiding the risk of potential ungrammatical utterances. Even though they did not utilize any overt quotative, the discourse flows smoothly facilitated by changed intonation and non-verbal expressions accompanied by the quotations.

As briefly mentioned earlier, the fact that literally none of the informants uttered either ‘go’ or ‘all’ is quite remarkable. The quotative ‘go’ has been existent since the 1980s (Butters 1980). Subsequent observations of ‘go’ as a quotative have continuously followed from many geographically separated regions including Canada, England, Scotland, Australia, and so forth (Blyth et al. 1990; Ferrara & Bell 1995; Winter 2002 among others). ‘All’, relatively new quotative, also appeared around the 1980s apparently originating in California. According to the current data, it might be safe to conclude that ‘all’, as well as ‘go’, did not enter the EFL setting of Korea for now.

The mean ratio of ‘be like’ to the total number of quotative, as shown in Table 1, indicates the low frequency of occurrence (N=68 out of 732). However, it has to be pointed out here that some direct quotations introduced by ‘say’ displayed a notable pattern. This is

illustrated in the following examples.

- (4a) She said, “You went too far and wreck the whole situation.”, or something like that.  
(4b) One of my friends hated that movie. (laugh) She said, “<sup>#</sup>I want to break the theater screen<sup>7</sup>”, or something.

These samples are categorized into the sector of ‘say’ for obvious reason, and yet this calls for further analysis. In (4a) and (4b), two different intents clash within an utterance. That is, ‘say’ and ‘or something like that’ contradict with each other since ‘say’ is a choice of quotative when a narrator wishes to report the verbatim of previous utterance whereas the tailed ‘or something (like that)’ has an intention of weakening former rendition. Because ‘or something like that’ at the end completely negates the effect of ‘say’, quotative expressions in (4a) and (4b) are eventually equivalent to the effect of ‘be like’ per se. Nevertheless, many informants insisted on using ‘say’ which reports an ‘accurate rendition’ of what may have been ‘explicitly lexicalized’ at the time of the event (Romaine & Lange, 1991, p.238), and tried to compensate this heavy verbatim rendition by adding a lighter element ‘something like that’ before or after the quote. Furthermore, the frequency of ‘accurate rendition’ in speech cannot be possibly higher than that of modulated speech in actuality. Unless all the lexeme of a particular utterance is carved into one’s brain for some sentimental reason, it is usually the case that previous utterances are stored in our memory with preserving only the overall meaning and the nuance of it, not the verbatim<sup>8</sup>.

Arguing that the use of ‘say’ with ‘or something (like that)’ at the end of the utterance might be considered a localized form of ‘be like’ is not very cogent. There are multilayered factors affecting the use of ‘be like’, or any other quotatives for that matter, by Korean speakers of English, in all probability mainly due to their imperfect English proficiency. Rather, the outstripping use of ‘say’ as a quotative and that of ‘other’ verbs of saying such as ‘tell’ or ‘ask’ can be seen as particularly localized feature of quotative usage in Korea. Even if the occurrences of ‘be like’ are not statistically telling compared to other variants and there are whatsoever no specifically localized feature of ‘be like’ observed, the study at least corroborated the diffusion of ‘be like’ traveling far enough to Korea. In the next section, the use of ‘be like’ by Korean speakers of English will be discussed in relation with the focuser ‘like’ and hedge ‘like’.

### 3.2 Magnifying the occurrences of ‘like’

With the evidence of diffusion of ‘be like’ in mind, further elaboration of ‘be like’ was followed. Concomitantly, data of non-quotative ‘like’ was examined in order to understand the status of ‘be like’ more fully, and in a more holistic perspective. Analyses in the present section are based on the number of occurrences of each ‘like’, and the number and percentage of informants who used it according to the types of ‘like’.

---

<sup>7</sup> The superscripted symbol ‘#’ indicates a less-conventional English expression uttered by nonnative speakers of English. Native speakers of English might find the sentence awkwardly put, although the meaning may be understood.

<sup>8</sup> According to empirical research such as Issacs 1989, Hjelmquist & Gidlund 1985, Lehrer 1989, and Stafford & Dali 1984, people cannot remember an utterance word for word, even after a few seconds, with no painstaking endeavor to memorize it (as cited in Clark & Gerrig 1990).

Table 2. Descriptive statistics in terms of different uses of ‘like’

Types of ‘like’ and the number of each token from the data	The number of informants who used it	% of informants who used it
<b>‘be like’</b> (N=68)	12	.324
<b>focuser ‘like’</b> (N=193)	21	.567
<b>‘like’ as a hedge</b> (N=65)	20	.540

Table 2 shows the number and percentage of informants in terms of different uses of 'like'. Out of 37 informants, 12 of them used 'be like' when reporting previous dialogue and 21 of them forming over 50 percent uttered 'like' as a focuser. Similar number of informants (N=20) inserted 'like' during utterances as a hedge. In total, out of 37 informants, 25 of them (taking up to 67%) used the token 'like' at least once whether as a quotative, a focuser, or as a hedge.

As mentioned in the previous sections of the paper, the non-quotative particle ‘like’ can function either as a focuser, the introducer of new information in an utterance, or as a hedge, the effect of which is seemingly to ‘leave the statement slightly open’ (Underhill 1988, p.241). Refer to the following example in (5a).

- (5a) After I’d go to like college ... then get into a like computer program.  
(Underhill 1988)

In terms of actual counting of utterances, 'be like' has 68 cases and hedge 'like' has 65, almost the same as 'be like'. However, there are 193 cases of focuser 'like' in number, which is nearly three times as many as the cases of 'be like', or that of hedge ‘like’. What, then, would be the logical and cogent explanation for the oversubscribed usage of focuser ‘like’ by L2ers?

Unraveling the reason for this disparate use of ‘be like’ and ‘like’ seems to be a complicated matter. Perhaps the difference between the quotative ‘be like’ and focuser ‘like’, along with the definition given above by Underhill(1988), might be better understood by considering the process of grammaticalization. The use of ‘like’ as a quotative appeared later in time compared to the focuser ‘like’. This newly gained function of ‘like’ accompanied by stative verb ‘be’ as a quotative is seen as a prototypical example of grammaticalization, a process by which grammatical morphemes develop out of formerly lexical items (Romaine & Lange 1991; Ferrara & Bell 1995; Tagliamonte & Hudson 1999). The result of the present study indicates that ‘like’ as a focuser, and thereby a lexical item, is widely spread in use among those whose English proficiency suffice communicative goal, whereas quotative ‘like’, a grammaticalized item with a new grammatical function, is yet to be settled in.

Further examination on whether this is attributed to the weaker degree of grammaticalization on ‘be like’<sup>9</sup> or not had better be delimited in order to prevent the discussion at hand from running off the track. For now, it should be briefly pointed out that more traditional meaning of ‘like’ as a conjunction or a preposition, expressing ‘approximative’ seems to contribute to the increasing use of focuser ‘like’ in Korea. Examples (6a) and (6b) illustrate typical usage of ‘like’ as a purely syntactic particle, functioning as a conjunction(6b) or a preposition(6a).

- (6a) He looks like his father.  
(6b) Winston tastes good like a cigarette should. (Romaine & Lange 1991)

<sup>9</sup> For example, another typical example of grammaticalization is that of ‘be going to / be gonna’. The grammaticalized use of ‘go’ here had been stably conventionalized over time, even losing some of the original meaning of ‘go’; specifically motion and directionality (Hopper & Traugott 2003).

As Romaine and Lange argued, the ‘natural outgrowths of existing uses and functions of ‘like’ even in an EFL setting is ascribed to this ‘approximative’ meaning of ‘like’ (1991, p. 245).

The remaining question at this point, then, is to examine how the set of ‘like’ is perceived in terms of the function, style, and usage by Korean speakers of English. This perceptual information on different kinds of ‘like’ provides another rationale for the disparate use of ‘be like’ and ‘like’.

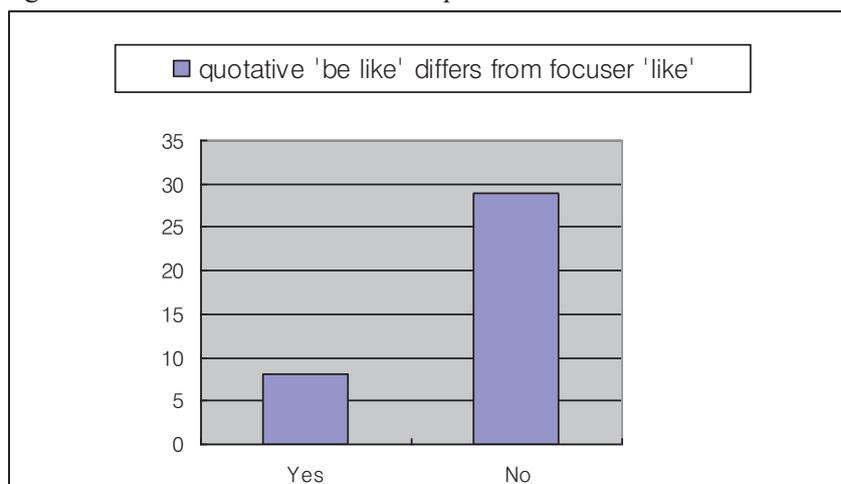

### 3.3 Perception of ‘be like’

#### 3.3.1 Differentiation between the quotative ‘be like’ and focuser ‘like’

In order to investigate the perceptual information of ‘be like’ by the informants, ‘think-aloud’ protocol was utilized in the follow-up interview by overtly casting questions on whether they were aware of the phenomena of ‘like’. The interview was conducted in Korean with each informant immediately after 30 minutes of recording session was over. Before asking about the difference between ‘be like’ and focuser ‘like’, the interviewer (author herself) demonstrated both uses of ‘like’ in a casual manner with a scripted dialogue<sup>10</sup> containing both ‘be like’ and focuser ‘like’.

Figure 1 illustrates the difference awareness over quotative ‘be like’ and focuser ‘like’ among 37 informants.

Figure 1. Difference awareness over quotative ‘be like’ and focuser ‘like’

8 informants out of 37 answered they do differentiate ‘be like’ from focuser ‘like’, while the remainder of 29 informants said they do not know the difference. All 8 of them who answered ‘yes’ to the question also used quotative ‘be like’ themselves. One common response from these 8 is their direct mentioning of the word ‘quote’ while explaining the difference between ‘be like’ and focuser ‘like’ to the interviewer. Also, grammaticality was another factor in determining both uses of ‘like’. For example, 2 informants out of 8 who answered ‘yes, they are different’ said that whereas ‘be like’ is grammatically indispensable, focuser ‘like’ is not.

However, the majority of the informants answered that there are no differences, comprehending the quotative ‘be like’ as a traditional meaning of ‘like’ as in ‘That cake is

<sup>10</sup> Refer to the appendix 2 for the script.

like Sam's birthday cake' (excerpted from Meyerhoff 2006), that is, an approximation of an event or a thing. Even 4 among 12 who used 'be like' during the recording in their discourse did not distinguish 'be like' against focuser 'like'. To the informants who did not differentiate the two 'like', more direct question was cast; with demonstration, the interviewer asked if they knew 'be like' could substitute 'say' or 'think', quoting previous remarks. Again, all the 29 informants are not aware of its quotative function. Considering the argument that it has to be noticed and processed for input to be incorporated into spontaneous speech of L2ers (Gass 1988 as cited in Ellis 1994), it might well be the case that those who do not perceive 'be like' as a quotative are not yet ready to integrate 'be like' into their storage. This line of thought provides an explanation for the small occurrences of 'be like' in the data. Because the informants do not distinctively recognize 'be like' as a quotative, the frequency of 'be like' appears low, which is not at all surprising.

### 3.3.2 Influence of perception on 'like' utterances

Out of 37 informants, 21 of them used 'like' as a focuser and the number of occurrences of it reached almost 200 (N=193). In the follow-up interview, the informants who used 'like' were particularly reminded of their own use of 'like' as a focuser by the interviewer and subsequently asked if they were aware of its usage. Unlike the unawareness of 'be like' as a quotative, they were aware of the feature of focuser 'like' to some extent; they perceived 'like' as an approximative with an emphasizing effect.

The overlap between quotative 'be like' and focuser 'like' has been succinctly pointed out by Buchstaller(2001b). The point she makes is that the quotative 'be like' is a subset of focuser 'like'. Based on Underhill(1988) and Blyth et al.(1990), she asserts that 'if 'like' co-occurs with quoted material, it focuses on the most significant information in a sentence', hence the quotation can be interpreted as 'a variant of that focus' (Buchstaller 2001b, p. 3). This, in turn, implies a partial awareness of 'like' by Korean speakers of English; since they do not perceive the quotative 'be like' whereas they do recognize the function of focuser 'like', more specialized subset of 'like' as a quotative is not as clearly delivered and activated as the encompassing set of 'like' as a focuser. Thus, perception as an influential factor for actual utterance of 'be like' or 'like' is ascertained. The follow-up interview revealed the overall perception of the quotative 'be like' and focuser 'like', which respectively accounts for the sparse use of 'be like' and spread use of 'like' as a focuser among Korean speakers of English.

Among 37 informants participated, 20 of them used 'like' as a hedge, or a filler. While this takes up over 50 percent of all the informants (.540), the number of occurrences ceases to go over 65. This means that on average term each of the informants uttered hedge 'like' only twice in their whole thirty-minute narrative. For nonnative speakers of English, hedge 'like' is the easiest to acquire due to its status as a discourse marker, functioning like other fillers such as 'well, now, you know, I mean, etc.'. This is because the designated location for fillers is not syntactically fixed. Yet, the number indicates a small number of occurrences of hedge 'like'. A possible conjecture for this could be established during the interview, when several informants mentioned that 'like' as a hedge seems to be an indicator of one's unclearness or unsureness and that they consciously tried to avoid using 'like' as a filler even though their speech might come to a halt.

### 3.3.3 The channel of 'be like' transmission into an EFL setting

Two questions were given to the informants in order to examine their recognition of the style regarding 'be like', and the source of their exposure to it. Specifically, the questions were 'do you think 'be like' is formal or informal?' and 'if you have heard or learned the use of 'be

like' before, how and where?' To the first question, their answers were strikingly unanimous; all 37 informants were not at all reluctant asserting that 'be like' is informal. To the sub-question of why, two of them shrewdly pointed out the formal setting of English education in Korea, saying they have never been taught the use of 'be like' formally (or in school). Some other informants mentioned that they have been trained not to use 'be like', or any kinds of 'like' in an academic setting. This is a feasible answer considering they are all university students with some extent of knowledge in academic writing or academic presentation.

Second question of 'how and where' yielded only two types of answers; interpersonal contact and media. Some informants were formerly exposed to colloquial English when they stayed in English-speaking countries<sup>11</sup>, and became the carriers of the innovation 'be like'. For those with no such experience, and yet being aware of the usage of 'be like', the only channel for them to have acquired colloquial English is media; movies and television show programs. Media as a channel of intercontinental transmission of 'be like' was noted by some researchers as well (Macaulay 2001 among others). In particular, movies and television programs are often utilized as authentic teaching material in Korean EFL setting. If media is the only source of authentic English, and in turn, Korean speakers of English acquired the innovation 'be like' from the media, both in its usage and also its style as ascertained in the previous paragraph, then the role of media in terms of the global diffusion of 'be like' in progress can be rightly claimed. In other words, since they know the proper context in which 'be like' can occur, the influence of media on the diffusion of linguistic innovations, or on SLA, at least, proves to be more significant than it has been acknowledged before.

As globalization has been accelerated for decades around the world, Euclidean concept of space is regarded as less deterministic than ever in terms of the spread of linguistic resources (Buchstaller 2008). This is especially the case when the linguistic item is mainly sustained by younger people, whose 'mediated' forms of contact including e-mail, blogs, web messengers, etc. might well be just as active, or even more so, than face-to-face communication. Then, the forum of language contact is by no means Euclidean or physical any longer. A growing body of sociolinguistic research, therefore, pursues the investigation on the globalization of sociolinguistic phenomena with emphasis on the reconceptualization of linguistic spatiality. The importance of linguistic spatiality is even more evidently acknowledged in the field of world Englishes and SLA as noted above. Along with the purely linguistic factor of L2, demarcating the boundary of a subsequent language learner in that they can hardly reach the level of native speaker proficiency, supra-linguistic factors also affect the way they speak. For example, if a new language is acquired through a particular channel, say, media (TV, movies, etc.), not only the language itself but a particularly attached style of that language becomes a non-negligible feature in the eyes of L2ers. Since a learner cannot distinguish the idiosyncrasies of the target language with the general aspect when first exposed to any types of language learning material, they tend to incorporate the input they receive with the existing L2 knowledge. Both the Americanization of English in Korea in a broad sense, and the spread of 'be like' or focuser 'like' in a narrower sense, are attributed to the channel of English transmission, in all probability mainly via the media especially

---

<sup>11</sup> All the informants were controlled in terms of the staying abroad experience; learners of English who have stayed more than two years were excluded from the study. Among 37 informants, only three of them lived in English speaking countries up to two years and the remainder lived less than a year.

regarding casual and informal English.

#### 4 Conclusion

So far the study examined the use and perception of quotative 'be like' in an EFL setting of Korea. It holds its significance in that the present study is one of the sparse attempts to document the ongoing diffusion of 'be like' in an 'expanding circle' in terms of the world of English, where English is learned as a foreign language (Kachru 1985). The number of occurrences of 'be like' is albeit small compared to the traditional quotative 'say' which represented the highest proportion among all the quotatives, the number of informants who used it in their narrative reaches over one third of all the informants participated in the recording (12 among 37). This suggests that even though the frequency of 'be like' is low, the evidence of the diffusion of 'be like' is indeed manifested. Comparing 'be like' to focuser 'like', the latter distinctively exceeds the former in number. This is because the traditional meaning of 'like', expressing 'approximative', is closer to the use of focuser 'like' and subsequently affecting the increase in the use of 'like' as a focuser. In terms of perceptual information of 'be like', the majority of Korean speakers of English, though not all, could not differentiate the quotative 'be like' from the focuser 'like'. Regarding how the innovation has transmitted, the role of media was discussed in particular. Large amount of the media source mainly originates from America, resulting in Americanization of English in Korea. While the evidence of indigenous adaptation of the global English quotative 'be like' is revealed in many studies (Macaulay 2001; Winter 2002; Meyerhoff & Niedzielski 2003; Buchstaller 2008), it is still true that the 'English levelling' has taken place along with the global disperse of 'be like'. Further investigation on the use of quotative 'be like' by a variety of people from diverse linguistic and cultural background would shed light on the issue at hand, ideally when examined both in macro and micro perspective.

### **Appendix 1. Questionnaire sheet**

Paraphrase the following sentences. (Try to switch the words as much as you can)

1. My mom was so angry. She was like, 'you are grounded for a month!'

→

2. It skinned us. It was like 'whoosh!'

→

3. He was getting upset. I was like 'uh oh, this is not going well'

→

4. Well, it's not like wonderful, but it's okay.

→

5. Do we have to read like the chapters covered on the midterm for the final?

→

### **Appendix 2. Script with 'be like' and 'like'**

A: I stayed at Lucy's last night.

B: You did? That's cool.

A: Yeah... but this morning my mom was so upset about it. She was like, 'you are grounded for a month!'

B: (laughing) Oh no! well, that's bad. Though the same thing happened to me before. Once I was sneaking into my house at about 5 a.m., and there was like my mom standing right in front of me as I turned the doorknob!

A: (laughing) She got you.

B: Yeah! So I was like 'Uh oh, this is not going well'

A: So what did you tell her?

B: Nothing. I just had to let her nag for hours... I was like, 'I'm sorry mom' (both laughing)

# FINDING LINGUISTIC PUBLICATIONS ON AND OFF THE WEB -requirements for an ideal search tool-\*

Sijmen Tol

Linguistic Bibliography, Leiden

[tol@inl.nl](mailto:tol@inl.nl)

## Abstract

The present paper discusses prospects and desired developments of the three major online bibliographies in the field of linguistics: *Linguistic Bibliography (LB)*, *Linguistics and language behavior abstracts (LLBA)* and *MLA International Bibliography (MLAIB)*. First of all it is argued that the best way to retrieve linguistic publications is the use of specialized bibliographical tools, because general search engines do not find everything available and the results they give are not precise enough; in addition, a great number of relevant linguistic publications are only retrievable in bibliographies as they are not represented on the internet otherwise. However, a comparison of the three bibliographies shows that none of them can claim full coverage of the field, each having a different focus. On the technical side, the online version of *LB* offers less sophisticated facilities than the other two, which hampers its usability. To enhance both the coverage and the usability of the three bibliographies, a number of improvements is suggested: for *LB* a rapid technical upgrading is needed; web harvesting combined with a form of automated indexing could guarantee a better coverage; possibilities for cooperation between the three and with other, more specialized bibliographies should be explored; and existing tools for adding entries, tagging and discussion could be applied to linguistic bibliographies, giving the users the opportunity to build user communities.

## 1. Introduction

In this paper I wish to discuss the continued need for and possible developments of special bibliographical tools for linguists. I will do this from the point of view of an involved user, compiler and editor of the *Linguistic Bibliography*, which has been published since 1949 under the aegis of CIPL, the *Comité international permanent de linguistes*. In my discussion I will refer to three important bibliographies in the field: *Linguistics and language behavior abstracts (LLBA)*, the *MLA International bibliography (MLAIB)*, both compiled and published in the USA, and, of course, the *Linguistic Bibliography (LB)* based in The Netherlands.

In the next section I will discuss why linguistic bibliographies are still needed at all. In section three I compare the present situation of the bibliographies discussed and give some suggestions for technical improvements. Section four describes some possible new developments and in section five I summarize the improvements suggested.

## 2. Why use a bibliography?

At present, the first question regarding bibliographies in general seems to be: do we still need them? Why turn to a bibliography when the World Wide Web offers us access to the full text of

---

\* Thanks are due to Hella Olbertz, co-editor of the *Linguistic Bibliography*, for her indispensable critical comments on earlier versions of this paper, and to John Tait and Heather Bleaney for correcting my English.

the publications we need? James Kelly, in his preface to a volume of essays devoted mainly to the future of the *MLAIB*, gave the following answer (Kelly 2003: 2):

“While computer hardware and software have been of unarguable benefit in easing and streamlining the work of data collection, they have in no way obviated the need for the judgment, discernment, education, and experience of the bibliographer in covering materials to be indexed”

and regarding the users of the kind of on-line services I just mentioned, he remarks: “... they may then fall into the trap of assuming that the limited number of full-text linkages represents the universe of scholarship...” (ibidem). Let me illustrate this last point with a few examples.

I searched the internet using two general search engines (*Google Scholar* and *MetaCrawler*), a search engine specialized in scholarly websites (*Scirus*), and a database of scientific journals (*Web of Science*). In their own words, *Google Scholar* “provides a simple way to broadly search for scholarly literature”, *MetaCrawler* combines results from “the Internet’s top search engines, including Google, Yahoo! Search, MSN Search, Ask Jeeves, About, MIVA, LookSmart and more”, while *Scirus* is a search engine which “...searches over 450 million science-specific Web pages”, and *Web of Science* gives access to “...information gathered from thousands of scholarly journals...” With each of these I tried to find documents dealing with phonological aspects of Basque consonants. In *Google Scholar* I restricted my search to the subject area “Social sciences, arts, and humanities” and excluded “Basque” as an author name, in order to make the search as specific as possible. With these restrictions, searching for the combination of the terms “consonant\* + phonolog\* + Basque” resulted in 24 hits. Of course, each of them contained all the terms given, but at closer scrutiny only one hit turned out to be relevant for my question; and this seemingly relevant hit did not lead to any document at all because the link was dead. Among the other hits were ones only distantly related, such as a dissertation on Northern Sotho, where the Basque language turned out to be mentioned in the context of syntax. Compared to *Google Scholar*, the search engine *MetaCrawler* offers considerably less sophisticated limitation options: in particular, it is not possible to define a search area or to exclude a search term when functioning as a personal name. Although, in consequence, my search was broader, it resulted in only 15 hits, none of which was really relevant to my question. My third and fourth experiments were even more disappointing: searching the subject area “language and linguistics” in *Scirus* for the combination of my three terms in the context of “complete document” gave 2 identical hits, dealing with Egyptian Arabic and not with Basque. The last one, *Web of Science*, gave no hits at all, even when I deliberately broadened the search by leaving out the phonology part of it.

These searches were performed on June 17, 2008 and, although an identical search may now produce other results, this case illustrates that not even the use of multiple search engines guarantees the retrieval of any relevant publication from the internet. Results such as these could lead one to think that publications on this subject do not exist, at least not on the internet. This, however, is far from true. Using a bibliographical database dedicated to linguistics, one will easily find what one is looking for. On the same June 17, 2008, the same search terms yielded 16 hits in *MLAIB*; 12 hits in *Linguistic Bibliography Online*, and 1 in *LLBA*. As might be expected, the results were partly overlapping so that these searches together gave 22 different titles. This remarkably better result is due to the fact that in these bibliographical databases descriptors are

added which will not necessarily be found in the title or even in the text of the publication, for example because they were published in languages other than English, such as Spanish, French or Basque. And indeed, none of the general search engines came up with titles in Spanish or French, whereas both *LB Online* and *MLAIB* did.

Yet, there are other developments which seem to make the need for bibliographies questionable. In the first place, the *Open Archives Initiative* (OAI) makes more and more data and documents easily accessible. More than 1,000 universities and other academic institutions give access to research material and publications through OAI. An important tool to search these archives is *OAIster*. Furthermore we have the digital archive *JSTOR*, which archives scholarly journals and other sources in digitized form, and the *Project MUSE*, a cooperation between libraries and publishers (predominantly not-for-profit publishers). Journals in *JSTOR* are stored from their first issue onward, up to a date as recent as agreed upon with the publisher. Usually it keeps pace 3-5 volumes behind current publication. The *Project MUSE* gives fulltext access to nearly 400 scholarly journals, in this case including the latest issues. Table 1 gives the number of journals from the field of languages and linguistics stored in *JSTOR* and *Project MUSE* in June 2008, compared with the number of journals listed in *LB* and *LLBA* in the same month. For *MLAIB* such a number could not easily be computed, due to the broader subject field of this bibliography.

Source	Journals
JSTOR (disciplines “language and literature” + “linguistics”)	23
Project MUSE (subject “language and linguistics”)	9
LB Online	2,661
LLBA	1,536

Table 1: number of journals covered by journal archives and bibliographies

Table 2 compares the number of records related to linguistics which *OAIster* found in open archives in June 2008, with the number of linguistic records retrievable in *LB*, *LLBA* and *MLAIB* at the same time.

Source	Records
Open archives	12,011
LB Online (1993-...)	237,419
LLBA (1973-...)	406,405
MLAIB (1925-...)	±473,000

Table 2: number of linguistic records in open archives and bibliographies

As these tables show, the number of journals in *JSTOR* and *Project MUSE* and the number of linguistic records in open archives constitute only a fraction of the number of publications available. It is clear, therefore, that this kind of archive is far from replacing linguistic bibliographies. And that is not what they pretend, either: witness the close cooperation between *JSTOR* and the *MLA* bibliography (Chen, 2008).

There is at least one more reason for the continued use of specialized bibliographies. Although we tend to think that everything relevant is retrievable online, it is by no means unusual for a scholarly journal still to appear in print only. To give just a few examples, this is true for *Agan*

*yeth: Cornish language studies* from Wales, *Akkadica: périodique bimestriel de la Fondation Assyriologique Georges Dossin* from Belgium, *English linguistics* from Japan, *Mongolovednye issledovanija* from Russia, *Working papers in the theory of grammar* from Hungary, and there are many more. In addition, there is a considerable number of journals which do maintain a website, but use this only to publish a table of contents without any further details. The site of the *MIT Working papers in linguistics*, for example, shows Tables of contents in pdf-format, without any information concerning subject matter, apart from the article titles themselves – no keywords or abstracts are given.

The facts mentioned above, in my view, provide a convincing argument for the statement that, at least in the humanities, scholars cannot do without bibliographies to retrieve all the relevant publications they need for their research.

### **3. How to improve linguistic bibliographies**

Returning again to the three bibliographies under consideration, *LB*, *LLBA*, and *MLAIB*, I will now consider what exactly they offer to the user and what improvements, if any, would be desirable for the short term.

The three bibliographies have much in common. Each of them covers the field of languages and linguistics but each with different limitations. Each of them appears both in print and in one or more digital formats – this paper will be concerned mainly with the online versions. The basic search facilities are more or less the same for all: every relevant field of bibliographic description may be searched, separately or in combination by means of Boolean operators. One desirable improvement for *LLBA* and especially for *MLAIB* would be to add some explanatory text to the many different descriptors. At present, the *MLAIB* user who wishes to search the database with the Search tools option is confronted with a long list of browsable indexes, not all of which have self-explanatory names, at least not in the version of *MLAIB* which is provided by CSA's Illumina. In this case, trial and error is the only way to find out the difference between descriptors such as 'language', 'subject language' and 'specific language'. Short pop-up texts explaining the scope of each index would be very helpful.

At other levels there are three main differences between the three bibliographies: viz. coverage, commercial vs non-commercial distribution, and technical facilities. First, although the coverage of the bibliographies is overlapping to a great extent, it is not identical: the focus of the *MLA* bibliography is on literature and history, and it covers the field of linguistics less extensively than the other two bibliographies. There is also a difference in bibliographical type: whereas *LB* and *MLAIB* are enumerative bibliographies, *LLBA* is an abstracting service, evaluating a list of journals which is much more selective than the one found in *LB* (there is no separate list of linguistic journals indexed in *MLAIB*). A very global comparison of the extent of bibliographic coverage may be gained from table 3, which gives the total number of linguistic records for each bibliography and the average annual increase since the year 2000.

Bibliography	records in print only	records online	increase per year
LB 1939-1992	±550,000		
LB 1993-...		237,419	±18,000
MLAIB 1925-... Linguistics		±473,000	±13,000
LLBA 1973-...		406,405	±14,000

Table 3: Number of records in three linguistic bibliographies, June 2008

Furthermore, both USA-based bibliographies show a clear focus on the Anglo-American world, paying less attention to publications in languages other than English. *LB*, on the other hand, used to claim full coverage of all linguistic publications, but changed its policy in 2006. Nowadays, the emphasis is on non-Indo-European languages and lesser known Indo-European languages. As regards the place of publication, it now focuses particularly on linguistic works published outside Western Europe and North-America. The differences in focus are clearly reflected in search results as exemplified in table 4.

Records on the English language 1993-present		
LB	15,081	6.4%
LLBA	13,866	6.6%
MLAIB	26,069	13.6%
Records on Mongolian languages 1993-present		
LB	1,300	0.55%
LLBA	54	0.02%
MLAIB	14	0.007%
Records on the Welsh language 1993-present		
LB	702	0.29%
LLBA	218	0.1%
MLAIB	243	0.13%
Records on the Macedonian language 1993-present		
LB	2,194 (in Macedonian: 1,737)	0.93%
LLBA	116 (in Macedonian: 15)	0.05%
MLAIB	203 (in Macedonian: 73)	0.1%

Table 4. Number of records on specific languages compared

For the sake of comparability, in this table I have limited my searches to post-1992 publications, the period covered by *LB Online*. In the third column the absolute figures are represented as a percentage of the total number of records for the given period. Rather than the absolute figures, it is the percentages that make the difference here. The *MLA* bibliography, especially, shows a clear focus on publications dealing with the English language, their share in *MLAIB* being twice as large as in the other two bibliographies. On the other hand, when we look at a non-Indo-European language such as Mongolian, the picture is totally different. For a “smaller” Indo-European language such as Welsh, the difference is not that great, but still remarkable. The differences are the more telling, when we also take into consideration the number of publications in a language other than English, exemplified here by Macedonian. At the same time these figures make it clear that none of the three can claim full coverage of the field of linguistics.

One way to make up for the incompleteness signalled above would be by offering to the user the possibility to carry out a federated search of the three databases simultaneously, a point to which I will return later. But even then there is little chance that together they will offer a really complete coverage, even if only because of a sheer lack of staff. A quite natural suggestion would seem to be to combine forces and financial resources and create one all-encompassing bibliographical database of linguistics. However, this does not seem to be a feasible solution, given the completely different organizational settings and scope of the bibliographies involved. In my view, a more promising solution would be, that each concentrate on their own strong points and extend their coverage by applying existing tools for automated harvesting of online resources. UKOLN (*UK Office for Library and Information Network*) is one organization developing this kind of tool. Apart from gaining a better coverage with less effort, there is another advantage connected with automated harvesting of metadata: the harvesting need not be restricted to the core bibliographical metadata (author, title, source). Further data such as abstracts and author's keywords, anything available in the free domain, could be harvested at the same time. This would broaden the set of searchable data in the bibliographical database and enhance the retrievability of the publications.

Another way to guarantee universal coverage to a higher degree than is possible now would be to establish cooperation with national or regional bibliographies of linguistics, as exist for example in Bulgaria, Finland and The Netherlands, and bibliographies on specific linguistic topics. This would be of importance especially for *LB*, as it focuses on non-Anglo-American regions and languages. Furthermore, the possibilities should be explored of facilitating federated searching of *LB* and as many specialized bibliographies as the user wishes, even of bibliographies not present in or subscribed to by the user's library. One way to achieve this could be to combine *LB* with mirror sites of this kind of specialized bibliography. Thus, optimal use could be made of local expertise for the benefit of the linguistic community at large.

A central, but also the most time-consuming part of the bibliographer's work is describing content by means of classification and/or keywords. This may be facilitated by applying tools for automated full-text indexing as developed by enterprises as Wordmap in the US, Collexis in The Netherlands and many others. It should be born in mind, however, that any automated system needs to be controlled, corrected and supplemented by the human expert to stay in tune with new developments and to prevent unforeseen mistakes.

The other two differences between the bibliographies under review are of a more technical nature. Both *LLBA* and *MLAIB* are commercially offered services, at prices affordable for libraries and other institutions only. *LB* is, at least until the end of 2008, a free service available to any interested person, independently of a library network. This partly explains the third difference: both *LLBA* and *MLAIB* fully facilitate a library's linking services, both to full text resources and to library catalogues. *LB* still lacks this function, just as *LB* cannot yet offer an alerting service as offered by *LLBA* and *MLAIB*. Many libraries make use of tools to facilitate federated searching over multiple databases, such as Metalib, provided that the databases support this function. The reason that these functions, which are rather standard, do not yet exist in *LB* lies in the hitherto non-commercial character of this bibliography as a result of which there have been no opportunities to find financial resources for further development after *LB Online* was first constructed around 1995. However, *LB*'s new publisher, Brill, announced plans to launch the

*Linguistic Bibliography Online* in a new form with enhanced functionalities and interface, bringing it completely up-to-date. This new version, expected to become available by mid-2009, will not be accessible free of charge any more, but licences will be sold to libraries and institutions much under the same conditions as now are valid for *LLBA* and *MLAIB*. All features now missing in the free *LB* will then become available: coverage of electronic publications, direct linking to libraries and online sources based on OpenURL and DOI, export facilities, alerting services and facilities for federated searching. On the other hand, a service offered by *LB* but lacking with *LLBA* and *MLAIB* is the possibility of submitting missing items directly to the editors. The new *LB* will, of course, preserve this function and I think *LLBA* and *MLAIB* should consider adding this facility, too.

#### 4. New developments

Developing linguistic bibliographies should not end, however, with adding up-to-date facilities. New ways and possibilities have to be explored in order to render optimal services to the user. One substantial innovation would be the application of ‘Web 2.0’ facilities to bibliographical databases. For users of social websites such as YouTube for pictures and videos or LibraryThing for book collections “tagging” has become a familiar concept. In the same vein I think it should be possible to add personal keywords to bibliographical records in the databases under review. At present, bibliographers decide which keywords apply to a given entry but necessarily their decisions are restricted by the limitations of the thesaurus used and by their personal view. When I put a picture of my garden on a public web-album, I do that perhaps because I am proud of my grapes and therefore give it the keywords “Grapes in Holland”. A professional grape-grower could add “Ill-treated Boskoop Glory”. Someone else, however, may not be interested in these grapes at all, but find the picture remarkable because it shows a specific kind of fence. So he or she adds the keyword “Dutch fence”, which I never would have thought of. Similarly, a linguistic article written by a syntactician may be characterized adequately by keywords like “conjunction” and “subordination” but it may be interesting for a psycholinguist for other reasons, too. When psycholinguists add keywords which are specific for their field of research, the publication will become more easily retrievable for their colleagues. Of course, the editors of a linguistic bibliography cannot be held responsible for these externally added keywords, so it should be made explicit not only that these keywords were added by a user, but also from which point of view they were added. But as soon as we arrive at that point, we could even go further and apply wiki-tools to create facilities for the discussion of these external additions, e.g. in the form of user communities.

In section 3 I have mentioned several times the subject of federated searching. Although a very convenient method in principle, there still are problems to be solved. One that should be solved by bibliographers themselves is that of the diverging use of keywords. To give only one example I am familiar with: the language indexes of *MLAIB* and *LLBA* have both “Flemish language” and “Dutch language” as descriptors, while *LB* correctly only has “Dutch”, for both variants of my mother tongue, cross-referring from “Flemish” to “Dutch”. In other words, to make federated searching as effective as possible, some kind of concordance should be established between different keyword indexes. This would become highly important, if my proposal to include several regional bibliographies in a federated search were realized, because certainly not all of

them apply English keywords. Perhaps the international organization behind both the CIL congresses and the *Linguistic Bibliography*, CIPL, could be the appropriate initiator of this kind of international cooperation between the bibliographers of linguistics.

## **5. Conclusion**

In sum, I see a number of short term and longer term desiderata for the development of linguistic bibliographies. For the short term, the upgrading of *LB* is the first thing to be realized. *MLAIB* and *LLBA* may easily improve their usability by adding short explanatory texts to the different kinds of descriptors and by creating the contact facilities already existing in *LB*. For the longer term five important innovations should be explored: enhanced coverage through web harvesting; automated full-text indexing; cooperation with specialized and national/regional linguistic bibliographies; facilities for the user to add specific or personal keywords; and cooperation between the large linguistic bibliographies to establish a keyword concordance. And, of course, we should never stop discussing new improvements.

# What Determines the Prosodic Structure?<sup>1</sup>

**Sim, Chang-Yong**

Department of English Language Education  
Gyeongin National University of Education  
Gyodae-gil 45, Gyesan-dong Gyengyang-gu  
Incheon 407-753  
Korea  
simyong@ginue.ac.kr

## **Abstract**

This paper explores the syntax-phonology interface with respect to prosodic structures. The prosodic structure for wh-interrogatives in Kyungsang Korean exhibits different characteristics from other dialects of Korean. The wh-phrases does not receive the highest pitch in Kyungsang Korean, which is against the traditional assumption that a wh-phrase is a inherently focus element. This fact indicates that it is not the wh-phrase that determines the prosodic structure, but it is the operator that creates the prosodic structure. One of the consequences of this approach is that the operator-variable relation must be available for generating the prosodic structure at some level of PF. Following Seidl's (2001) approach, which there are two levels of representation at PF, the operator-variable relation is interpreted at PF.

**Keywords:** wh-operator, variable, operator-variable relation, prosodic structure.

## **1. Introduction**

It has been observed that in languages like Korean wh-phrases may have either a wh-interrogative interpretation or an existential indefinite interpretation. For instance, the following sentence in (1a) may have two different interpretations, and each interpretation receives different answer respectively.

<sup>1</sup> I am grateful to the audience of the Spring Conference of the Generative Grammar Circle 2007, the audience of the 18th International Congress of Linguists, and three anonymous reviewers for comments and suggestions. Special thanks to Kim, Kitaek and Choi, Yuna at Seoul National University for helping me obtain the crucial and valuable data. All the remaining errors are, of course, of my own.

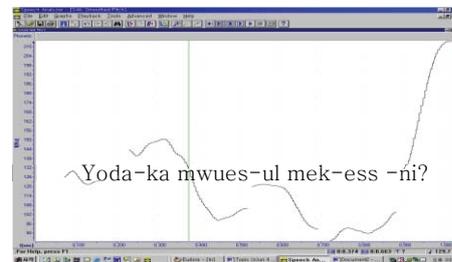

- (1) A: Yoda-ka mwues-ul mek-ess-ni?  
 Yoda-nom what-acc eat-past-Q  
 WH-interrogative: 'What did Yoda eat?'  
 WH-indefinite: 'Did Yoda eat something?'  
 B: Frog.  
 B': Yes.

This ambiguous sentence, however, is unambiguous in actual usage. Each interpretation triggers a distinctive prosodic structure, as illustrated below.<sup>2</sup>

(2) a. What did Yoda eat?

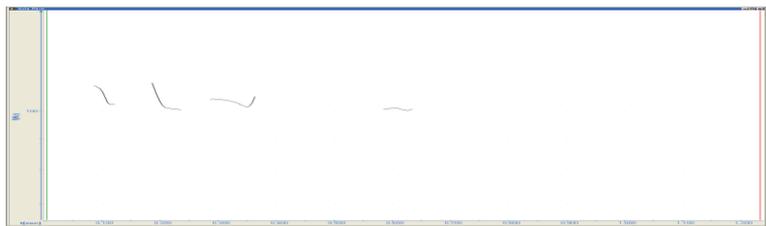

b. Did Yoda eat something?

The two prosodic structures in (2) disambiguate the sentence in (1), otherwise ambiguous. In (2a) the F0 peak of mwues 'what' is realized as the highest pitch, and the F0 peaks of the material after mwues 'what' is lowered. In contrast, the highest pitch falls on the right-most element, the question morpheme -ni, in (2b), and the wh-indefinite mwues receives a normal pitch just like the one in the declarative counterpart of (1), as shown below.

- (3) Yoda-ka pap-ul mek-ess-ta.  
 Yoda-nom meal-acc eat-past-decl  
 'Yoda ate the meal.'

<sup>2</sup> The sound was recorded and analyzed using Speech Analyzer version 2.7.

Based on the fact that the wh-phrase receives the highest pitch in wh-interrogatives, it has been assumed that a wh-phrase is inherently a focus element at PF. Semantically a wh-phrase is understood as new information and focus. This parallelism observed at PF and at LF seems to account for the unique prosodic structure of wh-interrogatives.

However, there is evidence against the traditional assumption that wh-phrases are inherently focus elements. The data from North Kyungsang Korean and South Kyungsang Korean show that wh-phrases do not receive the highest pitch. Rather the highest pitch falls on the penultimate syllable of a sentence, which corresponds to the tense morpheme. This prosodic pattern of Kyungsang Korean casts a doubt on the traditional assumption that a wh-phrase determines the prosodic structure.

This paper is organized as follows. Section 2 summarizes the semantic and phonological characteristics of wh-phrases and wh-indefinites. Section 3 presents the unique prosodic structure observed in Kyungsang Korean, in which the wh-phrase does not undergo focalization process. Section 4 investigates the prosodic structure and its determinant, and reveals that the operator determines the prosody. Section 5 explores the model in which the operator-variable structure is interpretable at PF. Section 6 summarizes the paper.

## 2. The Operator-Variable Structure

This section presents the semantic and phonological facts and assumptions for wh-phrases, and wh-indefinites.

### 2.1. *Wh-phrases*

It has been claimed that all the grammatical properties of the Universal Grammar are derived from the interface of syntax and extra grammatical systems such as logical interpretation (LF) and phonetic production (PF). One of the important instantiations of the requirement that grammatical principles derive from properties of the interface is the principle of Full Interpretation (FI). FI requires that all elements necessary for semantic interpretation must be present at LF and that all elements present at LF must participate in assigning an interpretation.

Given the basic assumptions about the semantics of questions, FI requires that a WH-interrogative must have an operator-variable structure at LF.

(4) The Operator-Variable Structure

OPx [ . . . x . . . ],  
where OP is a question operator binding a variable, x.

Furthermore, it has been argued that the question operator is universally generated as a (null) operator and that the WH form is universally a variable (Cheng 1991, Aoun and Li 1993, Watanabe 1993, Tsai 1994, Chung, D.H. 2000, among others). Languages, however, differ with respect to whether or not the operator and the variable are joined in the lexicon into a single word.

(5) The combination of the WH variable and the operator

Option 1

An OP is base generated in the lexicon as a single unit with the wh-word (the variable).

Option 2

An OP is generated separately from the WH word, with the WH word acting as a variable bound by OP.

Languages like English choose the first option, and the OP and the variable are lexicalized as a single word. Languages like Korean, in contrast, choose the second option, and thus, the question operator is morphologically realized apart from the variable, as illustrated below.

(6) Yoda-ka    **mwues**-ul    mek-ess-**ni**?  
Yoda-nom    what-acc    eat-past-Q  
                  thing(x)    Wh-operator  
'What did Yoda eat?'

In relation to PF, it has been assumed that a Wh-phrase is an inherently focus element, and thus, receives the highest pitch. This wh-focalization affects the prosodic structure in that the material that comes to the right of a focused constituent is phonologically reduced. This phenomenon is known as down-stepping (Lieberman and Pierrehumbert, 1984), deaccenting (Ishihara 2000), eradication (Deguchi and Kitagawa 2002), or

compression (Hirotani 2003). In order to account for the prosodic structure of WH-questions, Nagahara (1994) proposes the following rules.

(7) a. FOCUS-LEFT-EDGE

Left edge of focus = left intermediate phrase edge

b. FOCUS-TO-END

No intervening intermediate phrase boundary between focused phrase and the end of sentence.

The focus-left-edge constraint requires that a focused constituent be located at the left edge of an intermediate phrase. According to the focus-to-end constraint, there is no intermediate phrase boundary between the focused material and the end of the sentence unless there is another focused material. Therefore, this constraint enforces that the material that comes to the right of a focused constituent be phonologically reduced (Tomioka 2007), as illustrated in (8):

(8) Syntax: [..... [ ] .....]#

H\*L

Phonology: [ ] [ Xfocus ]

☞ This part is phonologically reduced.

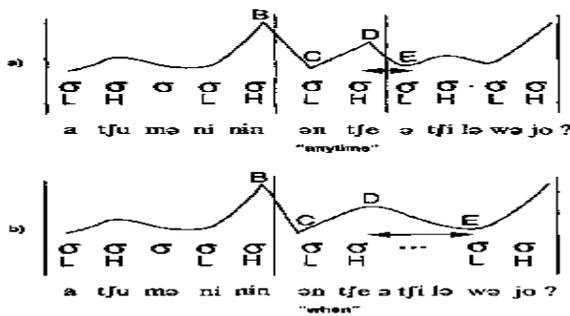

It is also noteworthy that the rules in (7) creates two phonological phrases: one to the left of a wh-phrase, and the other from the wh-phrase and to the right edge. This fact is reported by Jun & Oh (1996). They show that a wh-interrogative forms a single phonological phrase from the wh-phrase to the right edge, while a yes-no counterpart forms two phonological phrases<sup>3</sup>:

(9) a. “Madam, is there any time that you feel dizzy?”

b. “Madam, when do you feel dizzy?”

<sup>3</sup> Jun & Oh (1996) call this phonological phrase as 'Accentual Phrase'.

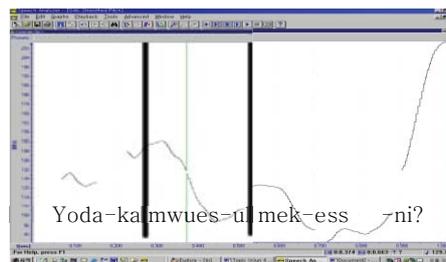

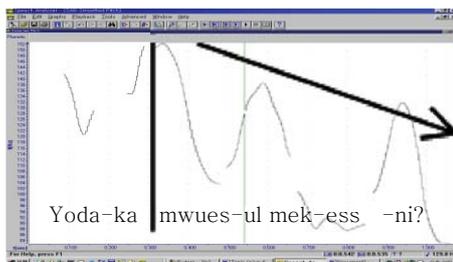

Jun & Oh (1996) p. 48

The vertical line marks the boundary of an phonological phrase. (9a) shows three phonological phrases: the pre-wh-phrase, the wh-word and the verb, while (9b) shows two phonological phrases: the pre-wh-phrase and the wh-phrase. The absence or presence sharp falling tonal transition in (9a) and (9b) indicates a general difference between wh-phrase and wh-indefinite.

The prosodic structures in (2), repeated as (10), show the facts that discussed so far. The wh-interrogative in (10a) has two phonological phrases; the subject part, and the wh-part. The wh-phrase is phonologically prominent and the rest material to the right edge is phonologically reduced. The wh-indefinite, on the other hand, forms three phonological phrases. Especially, the wh-indefinite forms a single phonological phrase of its own.

(10) a. What did Yoda eat?

b. Did Yoda eat something?

## 2.2. Wh-indefinites

It has been claimed that wh-indefinites are like variables, and thus, they are bound by an operator (Heim 1992, Li 1992, Aoun and Li 1993, Tsai 1994, among others). According to Heim's analysis, wh-indefinites are simply open predicates (e.g., mwues= thing(x)) and the variable can be bound by some operator in the sentence. For instance, Mandarin

Chinese exhibits wh-indefinites require some kind of licenser such as a yes-no question operator<sup>4</sup>.

(11) Bound by a yes-no question operator

Ta xihuan **shenme** ma?

He like what Q

'Does he like anything?' (Li 1992)

Following the proposal made in the literature, I assume that wh-indefinites are variable and can be bound by a yes-no question operator.

(12) Yoda-ka **mwues-ul** mek-ess-ni?

Yoda-nom what-acc eat-past-Q

thing(x) Yes-no operator

'Did Yoda eat anything?'

Phonologically wh-indefinites are just like ordinary DPs, and does not receive the highest pitch, and forms its own phonological phrase (Baek 1997).

### 3. Kyungsang Korean

In Kyungsang Korean questions exhibit two different properties from other dialects of Korean. First, as reported by Choe (1995), and Sohn (2004), two distinctive question morphemes are employed: *-na* for yes/no interrogatives and *-no* for wh-interrogatives.

---

<sup>4</sup> Li (1992) shows that wh-indefinites in Madarin Chinese are like negative polarity items and can also be bound by a negation operator, a modal, a non-factive verb. If there is no other operator to bind the variable, it is bound by insertion of an existential quantifier (existential closure).

The types of licenser of wh-indefinite in Korean are slightly different from those of Chinese. For instance a negation operator cannot bind the variable, because the negative polarity items are morphologically realized. Since the purpose of this paper is not to investigate the licensers of wh-indefinites, I will leave this issue for further study.

(13) a. Wh-Question

Mwe mek-ess-no?  
what eat-past-Q<sub>wh</sub>  
'What did you eat?'  
\*'Did you eat anything?'

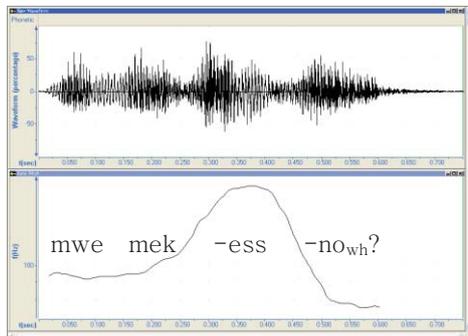

b. Yes-no Question

Mwe mek-ess-na?  
what eat-past-Q<sub>yes-no</sub>  
'What did you eat?'  
'Did you eat anything?'

Second, each question employs a distinctive prosodic structure. Sohn (2004) reports that the prosodic structure of wh-interrogatives in North Kyungsang Korean is not different from those of the rest of Korean. However, the current research reveals that both North Kyungsang Korean and South Kyungsang Korean employ quite unique prosodic structures, as illustrated below<sup>5 6</sup>.

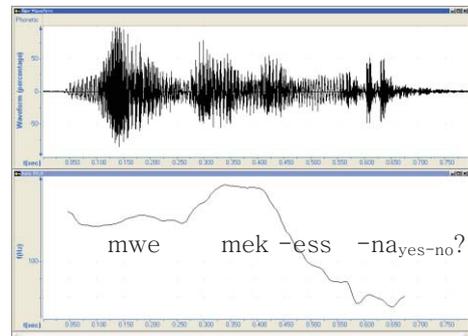

(14) North Kyungsang Korean

a. What did you eat?

mwe mek-ess -no<sub>wh</sub>?  
what eat-past-Q<sub>wh</sub>

b. Did you eat something?

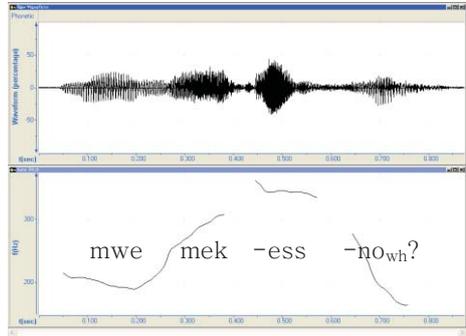

mwe mek ess -na<sub>yes-no</sub>?  
what eat-past-Q<sub>yes-no</sub>

<sup>5</sup> The informant for North Kyungsang Korean is 27-year-old male, who was born and raised in Taegu until 20, and the informant for South Kyungsang Korean is 27-year-old female, who was born and raised in Pusan until 20.

<sup>6</sup> It is well-known that the subject can be *pro* in Korean. When the subject is a second person singular or the subject is a discourse topic, *pro* is used. In order to obtain the most natural data, the current research employs *pro* unless it is required to use an overt subject.

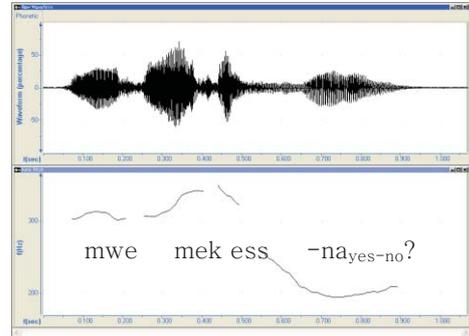

(15) South Kyungsang Korean

a. What did you eat?

mwe mek-ess -no<sub>wh</sub>?  
what eat-past-Q<sub>wh</sub>

b. Did you eat something?

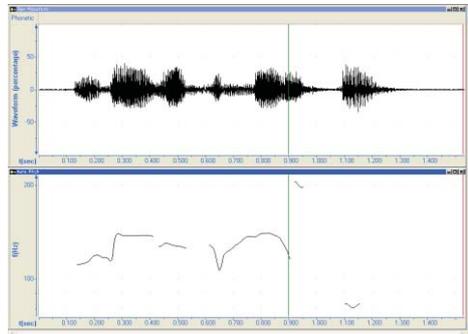

mwe mek-ess -na<sub>yes-no</sub>?  
what eat-past-Q<sub>yes-no</sub>

In (14a) and (15a) the highest pitch does not fall on the *wh*-phrase, but it falls on the past tense morpheme, *-ess*. In contrast, the *wh*-indefinite in (14b) and (15b) bears higher pitch than the *wh*-phrases and the highest pitch falls on the verb stem, *mek* 'eat'. It is also noteworthy that both of the question morphemes are phonologically compressed. Unlike Kyungsang Korean, the rest of Korean employs two homophonous Q-morphemes, *-ni<sub>wh</sub>* and *-ni<sub>yes-no</sub>*, while the prosodic structures reflect the binding relations, a single phonological phrase for *-ni<sub>wh</sub>* and two for *-ni<sub>yes-no</sub>* just like Kyungsang Korean. In addition, because of the lack of morphological distinction, phonological prominence is added to the left edge of the phonological phrase, which triggers deaccenting.

In declaratives, it has been observed that the pitch accent usually fall on the verb stem in Kyungsang dialect due to the lexical tone (Kenstowicz and Sohn 1997, Kim 1997, Sohn 2004). The tonal pattern of declarative sentences in (16) shows that two phonological phrases are formed (one for the subject, and the other for the VP) and the verb stem receives the pitch accent.

(16) North Kyungsang Korean

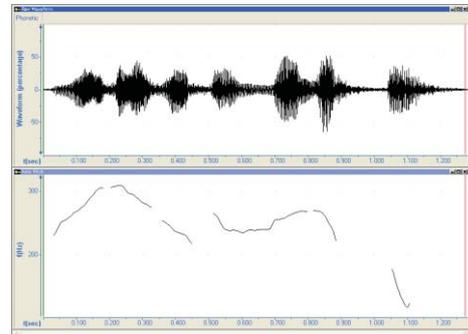

a. Yoda ate the meal.

Yoda-ka pap mek-ess -ta  
 Yoda-nom meal eat-past-decl

South Kyungsang Korean

b. Yoda ate the meal.

Yoda-ka pap mek-ess -ta  
 Yoda-nom meal eat-past-decl

The wh-phrases in both South and North Kyungsang Korean bears the similar F0 peak just like the object in the declaratives, and the tense morpheme bears the highest pitch. The wh-indefinite, in contrast, receives a higher pitch than wh-phrases or the object in declaratives, and the rest of the tonal contour is similar to that of declaratives. The fact that the wh-phrase does not exhibit phonological prominence is quite unexpected under the assumption that wh-phrases are inherently focus. This unexpected prosodic structure raises a question whether the assumption that a wh-phrase is inherently focus is correct.

#### 4. What determines the prosodic structure?

Since variables must be bound by an operator, the Q-morpheme, *-no<sub>wh</sub>*, in (14a) and (15a) binds the variable in the wh-phrase *mwe* 'what' and in (14b) and (15b) the Q-morpheme, *-na<sub>yes/no</sub>*, binds the variable in the wh-indefinite *mwe* 'something'.

Under the assumption that a wh-phrase is inherently focus, the difference must come from the types of variable such as a wh-variable and an indefinite variable. This analysis, however, incorrectly predicts that the wh-phrase would be focalized. Thus, the tonal pattern of wh-interrogatives in Kyungsang Korean shows that wh-phrases are not inherently focus and that wh-phrases are not responsible for determining the prosodic structure.

Then, what determines the prosodic structure of questions that are distinctive from that of declaratives? I argue that it is the operator that binds the variable. The variable in

both wh-phrases and wh-indefinites corresponds to information gaps whose range is restricted by features such as PERSON, THING, TIME, PLACE, etc., and the binder will range over 'open' propositions. If this is the case, there is no reason to believe that there are two distinctive variables in *mwe*. Thus, it is the operator that differentiates the two different operator-variable relations: a wh-operator-variable structure, and a yes-no operator-variable structure.

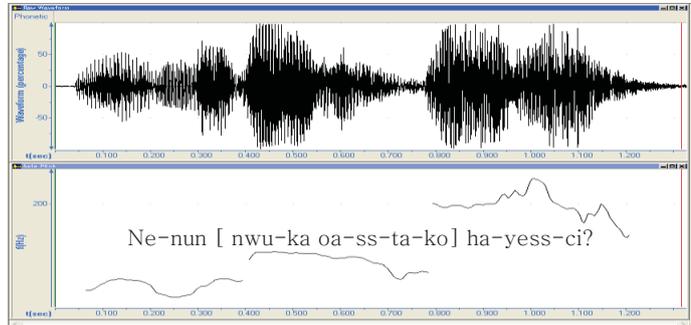

Now it is clear that the type of the operators determines the semantic interpretation and determines the prosodic structure. The wh-binder,  $-no_{wh}$ , binds the variable in *mwe*, and this binding relation is realized in terms of a single phonological phrase from *mwe* to  $-no_{wh}$ . The wh-indefinite binder,  $na_{yes/no}$ , binds the variable in *mwe*, whose binding relationship is represented by two phonological phrases, *mwe*, and the rest to the binder. The numbers of phonological phrases is the result of the phonological interpretation of syntactic structures. An interesting consequence of the current approach is that in order for the phonological component to parse the syntactic structure, especially the binding relations, the relevant features/properties must be available at some level of PF.

## 5. Syntax-Semantics-Phonology Interface

The current analysis makes it clear that not until the binder is found, the prosodic structure cannot be determined and that the operator-variable relation must be interpretable at some level of PF. Otherwise, one has to assume that there is a PF-LF interaction.

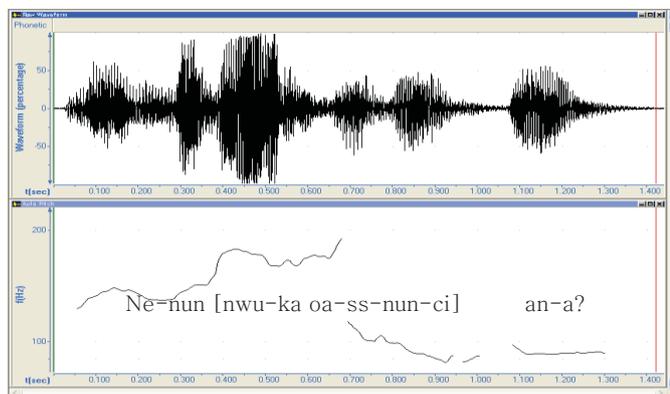

Since the binder is on C, the prosodic structure is determined after spell-out of CP. As shown below, the embedded wh-question forms a single phonological phrase and down-stepping is taken place from the wh-phrase to the binder *-ci*. This pattern is observed across all the dialects of Korean due to the homophonous nature of the binder *-ci*. Just like *-ni*, *-ci* can bind either the variable in a wh-phrase or in a wh-indefinite. Therefore, in order to distinguish the two binding relations, the variable-binder sequence requires a unique prosody.

- (17) Ne-nun [CP nwu-ka oa-ss-nun-ci] an-a?<sup>7</sup>  
 You-top who-nom come-past-NUN-Q<sub>wh</sub> know-Q<sub>yes/no</sub>  
 'Do you know who came?'

The similar phenomenon is observed in the matrix question. As shown in (18), the variable in the wh-phrase is bound by the wh-operator in the matrix clause, *-ci*. Again, due to the homophonous nature of *-ci*, the sentence in (18) exhibits wh-focalization and down-stepping.

- (18) Ne-nun [CP nwu-ka oa-ss-ta-ko] ha-yess-ci?  
 You-top who-nom come-past-decl-Comp do-past-Q<sub>wh</sub>  
 'Who do you know came?'

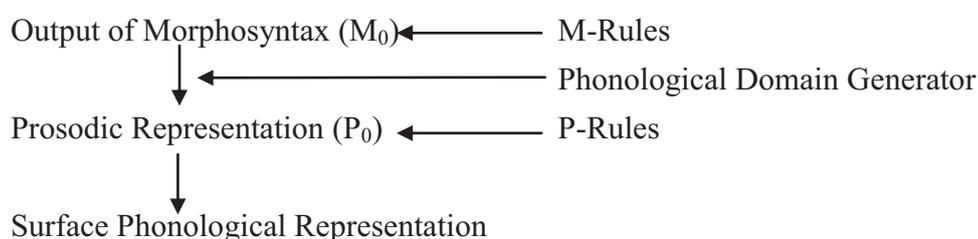

The examples in (17) and (18) show that the prosodic structure is determined after spell-out of CP. However, the operator-variable relation is understood as semantic information, which is not interpretable at PF, and thus must not be present at PF. These contradictory requirements can be mediated if there is a level that operates on the syntactico-semantic information directly.

<sup>7</sup> When the wh-phrase *nwukuw* is combined with the nominative case marker *-ka*, it is contracted as *nwu-ka*.

Seidl(2001) provides such an analysis. She argues that there are two levels of representation of post-syntactic structure: The first Morphosyntactic Representation ( $M_0$ ) is mapped from syntactic structure, and second Prosodic Representation ( $P_0$ ) is mapped from  $M_0$  by the Phonological Domain Generator. She further argues that there are rules that are specified in the grammar to operate at either of these two levels. Rules applying at Morphosyntactic Representation (M-rules) apply on edges of phases,  $\nu P$  and CP, while rules operating at the  $P_0$  (P-rules) can make reference only to theta-domains such as VP,  $\nu P$ , and DP. The architecture of Minimal Indirect Reference mode of Seidl is the following:

(19) Minimal Indirect Reference

While P-rules operate on the level of representation that is not purely syntactic in nature, M-rules operate directly on syntactic information. Under this approach, the contradictory requirement for the operator-variable relation at PF is solved. At  $M_0$  the operator-variable structure is interpreted in order to parse the phonological domain, i.e., the phonological phrases, and then, deletes. Thus, at  $P_0$  the operator-variable structure is not present.

The Phonological Domain Generator parses the morphosyntactic representation of wh-interrogatives, and generates a single phonological phrase from wh-variable to its operator, while it generates two phonological phrases for the wh-indefinite. P-rules apply on the prosodic representations, one of which is that the Q-morpheme triggers a focalization effect. At the absence of ambiguity as in Kyungsang Korean,  $-no_{wh}$  and  $-na_{yes-no}$ , the highest pitch falls on the verbal domain: on the tense morpheme in wh-interrogatives. When a homophonous Q-morpheme is employed, the highest pitch is put on the left edge of the phonological phrase, i.e., on the wh-phrase, and the materials from it are phonologically reduced.

## 6. Concluding Remarks

The current paper investigates the syntax-phonology interface with respect to prosodic structures. Contrary to the traditional assumption that a wh-phrase is an inherently focus element, the wh-phrases do not receive the highest pitch in Kyungsang Korean. Therefore, it cannot be the wh-phrase that determines the prosodic structure. Rather it is the operator that creates the prosodic structure. The pre-requisite for the prosodic structure is that the operator-variable relation must be interpretable at some level of PF. Adopting Seidl's (2001) model in which there are two levels of representation at PF, the operator-variable relation is interpreted at PF, specifically at  $M_0$ .

# A Study on the Intonational Realization of Korean Children

Song Jiyeon, Kang Sunmi, Kim Keeho

Korea University

Anam-dong 5ga, Seongbuk-gu, Seoul, Korea

jiyeoni00@korea.ac.kr, dearsunny@korea.ac.kr, keehokim@korea.ac.kr

## Abstract

This paper examines the results of a study of the ability of preschool children ability to manifest intonations in different sentence types. It demonstrates how South Korean preschool children use intonation to distinguish declaratives, interrogatives, and imperatives, and whether the ability to deal with intonation varies with phonological acquisition. This study also examines whether the speech patterns of children show distinct features from those of adults.

The boundary tone demarcating the edge of the Intonation Phrase (IP) plays a significant role in deciding speech or sentence types. According to the K-ToBI (Jun, 2000), L%, a falling boundary tone, usually appears when stating facts, and in declaratives in reading. H%, a rising boundary tone, is expressed in yes/no questions. Previous studies on children's intonation contours indicated that for young children, rising tones are slightly more difficult to produce than falling tones (Snow, 1998).

Forty-five sentences were constructed in order to measure children's intonation ability and were divided into three categories: declarative, interrogative, and imperative. Although of identical segment structure, each can take on three different meanings or sentence types through variations in intonation. Ten four- to six-year-old preschoolers and ten adults participated in this experiment. All were speakers of the Seoul dialect of Korean.

The results suggest that although preschool children do not acquire all segments, they are able to distinguish different boundary tones for the three sentence types. Declaratives and questions show no significant difference in both preschool children and adults. However, in the case of imperatives, while adults show diverse boundary tones (falling, rising, and even flat), children exclusively prefer a falling tone.

**Keywords:** K-ToBI, Korean Intonation, Child Language, Ambiguous sentences

## 1. Introduction

The present study explores ways in which Korean children distinguish three sentence types -declaratives, questions, and imperatives- through intonation, as compared with native Korean adults. The issues addressed are intonational distinction among three types of standard Korean sentences and differences between Korean children and Korean adults in intonational realization.

### *1.1 Previous Studies*

Many experimental or theoretical linguistic studies of intonational patterns show that humans tend to express their feelings or intentions through intonation. The present study is based on three previous studies, Shin and Cha (2003), Jang, Song, and Lee (1998), and Show (1998). According to Shin and Cha (2003), the tonal pattern of the Seoul dialect of Korean is generally expressed in two to five syllables, most commonly in three or four. As a result, this study utilizes two kinds of materials for the experiment: utterances of three syllables and four syllables. The next study, Jang, Song, and Lee (1998), showed that intonation contour can be used as an important distinguisher in an automatic speech recognition system for Korean, particularly for ambiguous sentences. Based on this research, the sentences designed for this experiment have uniform segmental structures, but can move between three different meanings or sentence types through alteration of intonation. Third, Snow (1998) suggested that it is more difficult for four-year-old children to produce rising tones than falling tones. Therefore, this study is designed to investigate children's intonation preferences.

## **2. Experiment**

### *2.1 Methods*

#### *2.1.1 Subjects*

In this experiment, ten preschool-age children and nine adults participated in the production test. The mean age of the children was 5.4 years, 26 for the adults. All were Seoul dialect speakers who were born and grew up in Seoul, South Korea. The children were students at *Inwang Kindergarten* and *Koz School*, both located in Seoul. The children's parents were Seoul dialect speakers as well. Adults were undergraduate and graduate students at Korea University in Seoul, South Korea.

### 2.1.2 Stimuli

In Korean sentences, two distinct meanings can frequently be drawn from one segmental structure, both orthographically and phonetically. In some cases, a sentence may even contain a triple ambiguity.

Since according to Shin Jiyoung (2003) the tonal pattern of the Seoul dialect of Korean usually appear over two to five syllables, especially in three or four, this study makes use of two types of materials for the experiment. In addition, the materials are made up of two kinds of words. The first group (Set 1) is words that can be separated into smaller words. The second group (Set 2) is composed of words that cannot be separated. The following table lists examples.

**Table 1. Speech materials**

	Types	Suffix	Examples
3 syllables	Set 1	hA [h ε]	<b>goQbu-hA</b> (study) [koŋpuhε ]
	Set 2	E [ə]	<b>maNdIRE</b> (make) [mantilə ]
4 syllables	Set 1	hAyo [hæjo]	<b>goQbu-hAyo</b> [koŋpuhεjo ]
	Set 2	Eyo [əyo]	<b>dudIryEyo</b> [tut iljəjo]

As seen in Table 1, in Set 1 “goQbu-hA” can be separated into “goQbu” and “hA” and “goQbu-hAyo” can be separated into “goQbu” and “hAyo.” On the other hand, in Set 2 “maNdIRE” and “dudIryEyo” cannot be separated.

There are 2280 total tokens (19 subjects \* 120 sentences).

### 2.1.3 Procedure

The subjects produced the sentences in a recording studio. To ensure more natural speech, subjects were shown images on a laptop rather than given a script. Subjects were asked to describe pictures, to make a question, and to order someone to do something. The recordings were made on a SONY TCD-D100, also known as DAT, and were digitalized at a 44100 Hz and 16 bits accuracy. The acoustic measures reported in this study were analyzed by Praat.

### 3. Results and Discussion

#### 3.1 Results

##### 3.1.1 Declaratives

As the first syllables can be H or L by segmental features, alphabet T is assigned them regardless of the first syllables. Declaratives possess a significant discrepancy between children and adults. Figure 1 illustrates these findings.

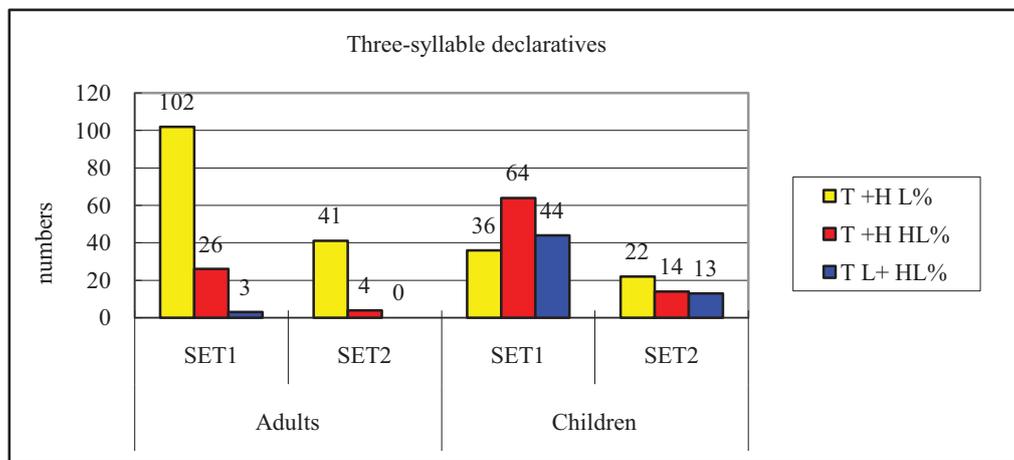

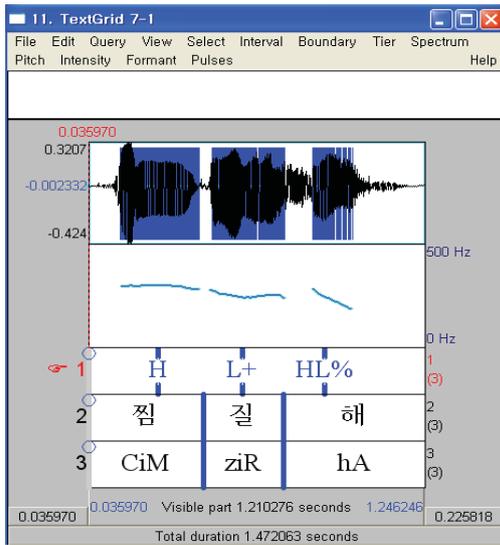

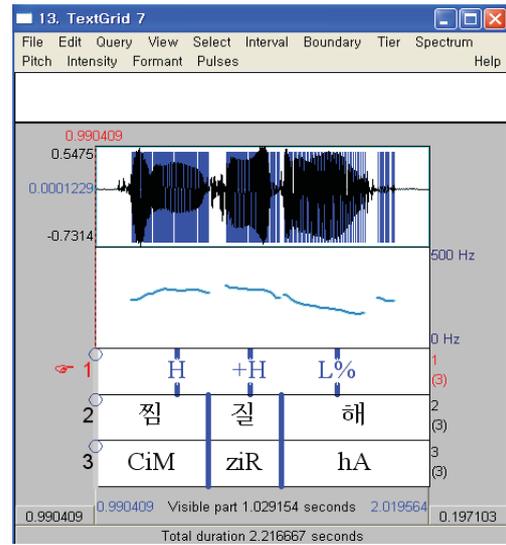

Figure 1. The number of intonational patterns in three-syllable declaratives

In Figure 1, the results of three-syllable declaratives show that adults' speech is generally T+H L%, but children's speech is T+H HL% in Set 1 and T+H L% in Set 2. That is, it seems that the children tend to emphasize the last syllable, "hA [hε]" in Set 1 or "E [ə] or ryE [ljə]" in Set 2.

The major fundamental frequency contours of three-syllable declaratives in both groups are presented in Figures 1.1 and 1.2.

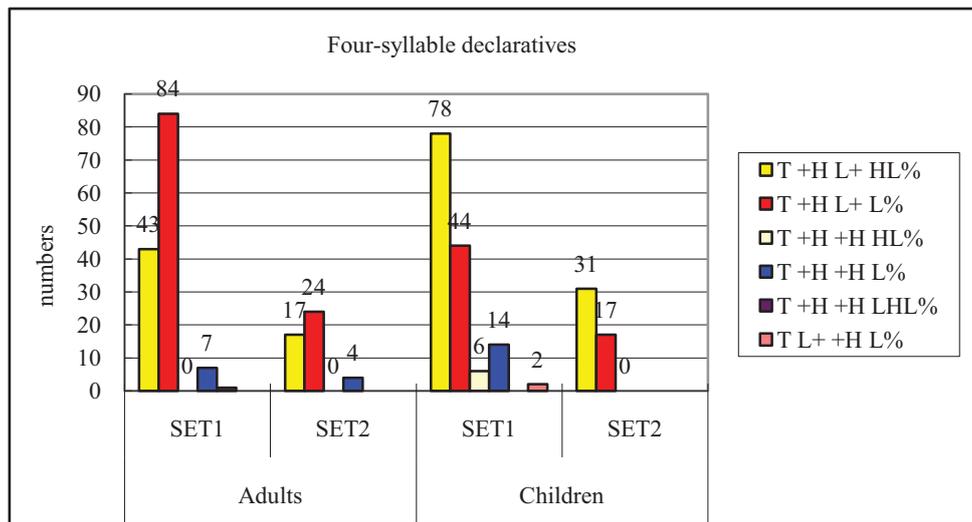

**Figure 1.1 Fundamental frequency contours of three-syllable declaratives of children**

**Figure 1.2 Fundamental frequency contours of three-syllable declaratives of adults**

As shown in Figure 1.1, HL% was found on the last syllable, “hA [hε],” in children’s speech. On the other hand, in adults’ speech, the last syllable is L% as shown in Figure 1.2.

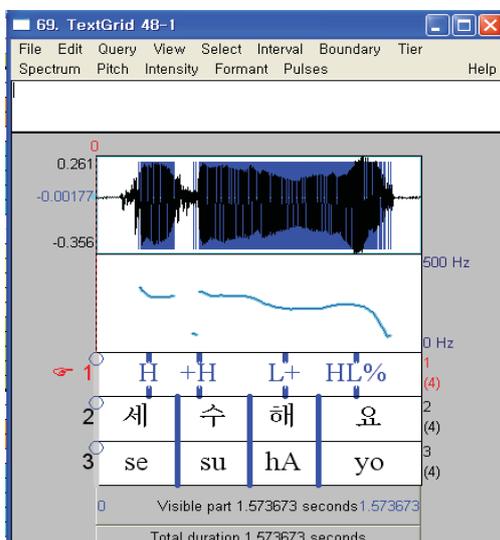

When the utterances are four syllables, their intonational contours are similar to those of three-syllable declaratives. Figure 2 presents these results.

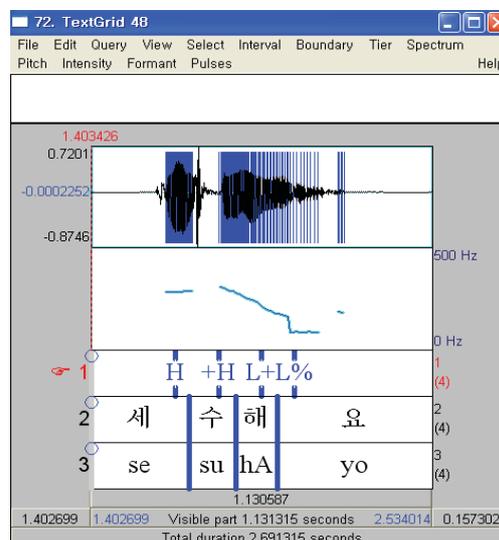

**Figure 2. The number of intonational patterns in four-syllable declaratives**

In Figure 2, most of adults’ speech shows T +H L+ L% but the major pitch contour of children is T +H L+ HL%. The intonational contours of four-syllable

declaratives are shown in Figure 2.1 and 2.2.

**Figure 2.1 Fundamental frequency contours of four-syllable declarative of children**

**Figure 2.2 Fundamental frequency contours of four-syllable declarative of adults**

As seen in Figure 2.1 and 2.2, while children’s last syllable is realized with HL%, L% is realized on the last syllable of adults’ speech.

### 3.1.2 Questions

When forming questions, no significant difference is found between children and adults. The results are presented in Figure 3.

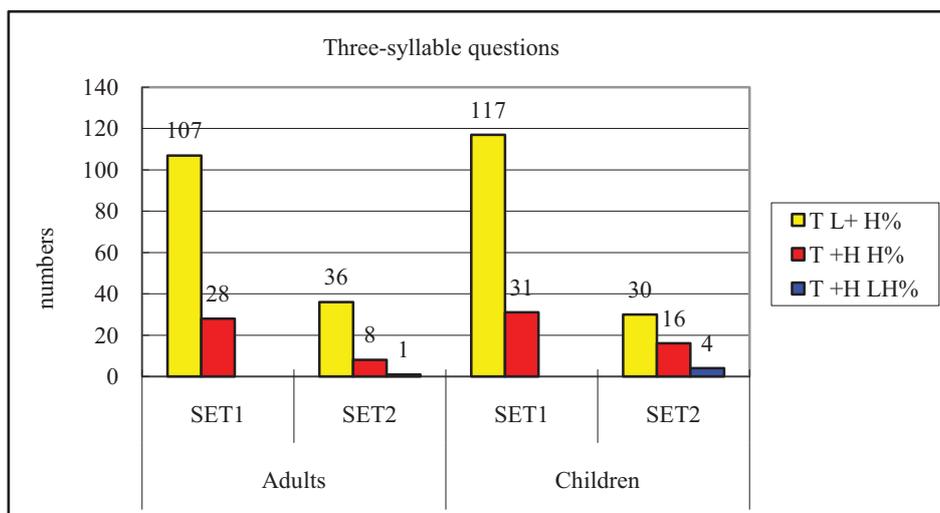

Figure 3. The number of intonational patterns in three-syllable questions

As shown in Figure 3, the major boundary tone is H%. This type of tendency is similar to the result for four-syllable questions presented in Figure 4.

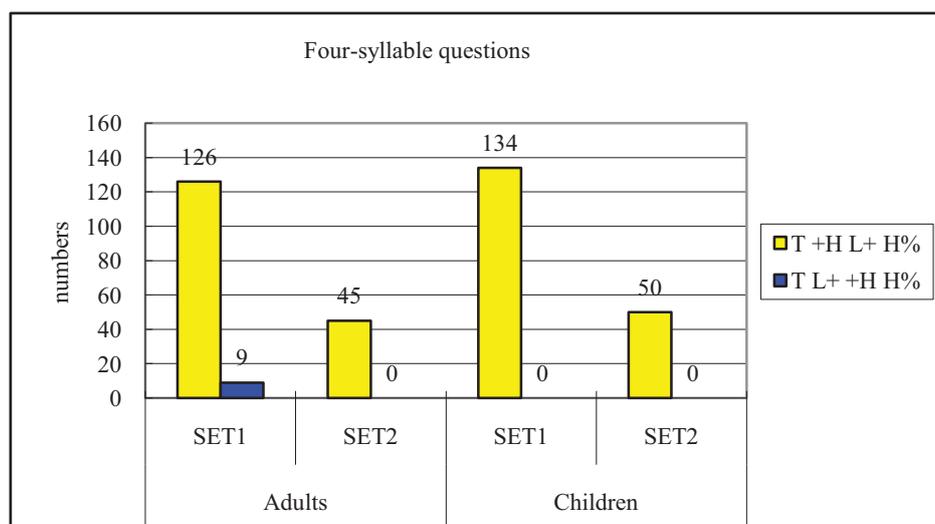

Figure 4. The number of intonational patterns in four-syllable questions

In Figure 4, most subjects among both groups show T+HL+H% for this sentence type. It can be seen that in questions all boundary tones are H% and there is no exceptional boundary tone.

### 3.1.3 Imperatives

In the case of imperatives, a greater variety of tonal patterns appeared than was

present among other sentence types, as shown in Figure 5.

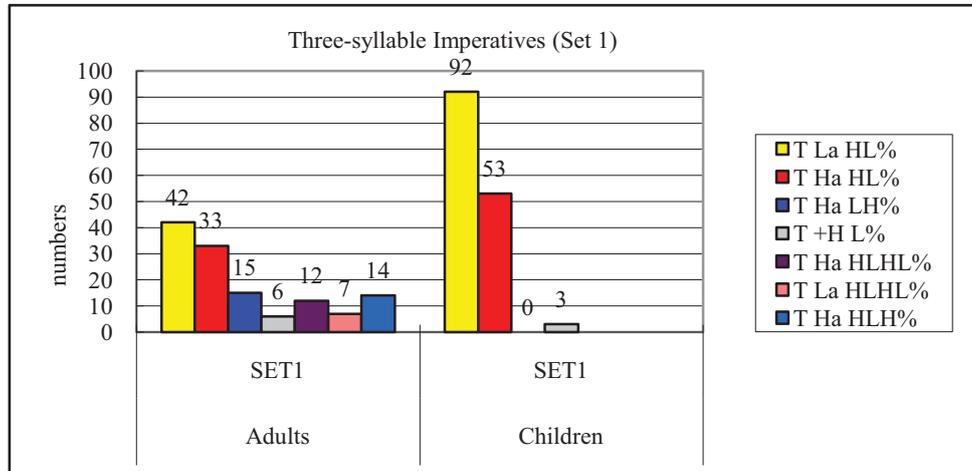

Figure 5. The number of intonational patterns in three-syllable imperatives (Set1)

Figure 5 shows that a variety of intonational patterns are realized by both groups. In addition, the two groups showed a similar tendency to divide the sentences into two APs in three-syllable imperatives. Unlike declaratives that have L% and questions that have H%, both H% and L% appear in imperatives.

The intonational contours are captured in Figure 5.1 and 5.2.

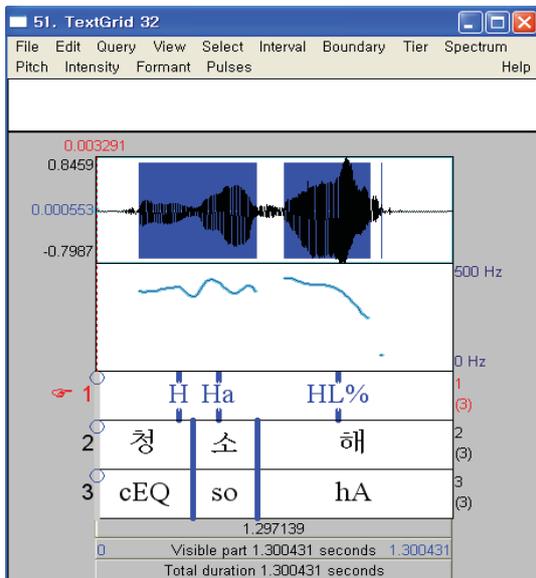

Figure 5.1 Fundamental frequency contours of three-syllable imperative of children

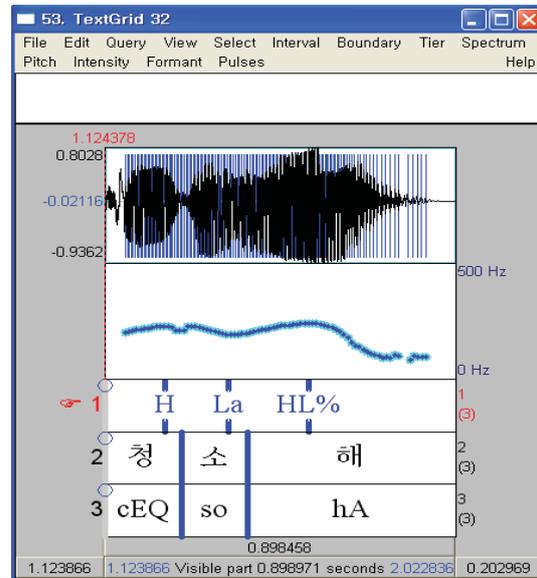

Figure 5.2 Fundamental frequency contours of three-syllable imperative of adults

As seen in Figure 5.1 and 5.2, three-syllable imperatives are split by Ha or La, AP final tones of an IP-medial AP.

In Set 2 of three-syllable imperatives, both groups' utterances have only a single AP. The results are depicted in Figure 6.

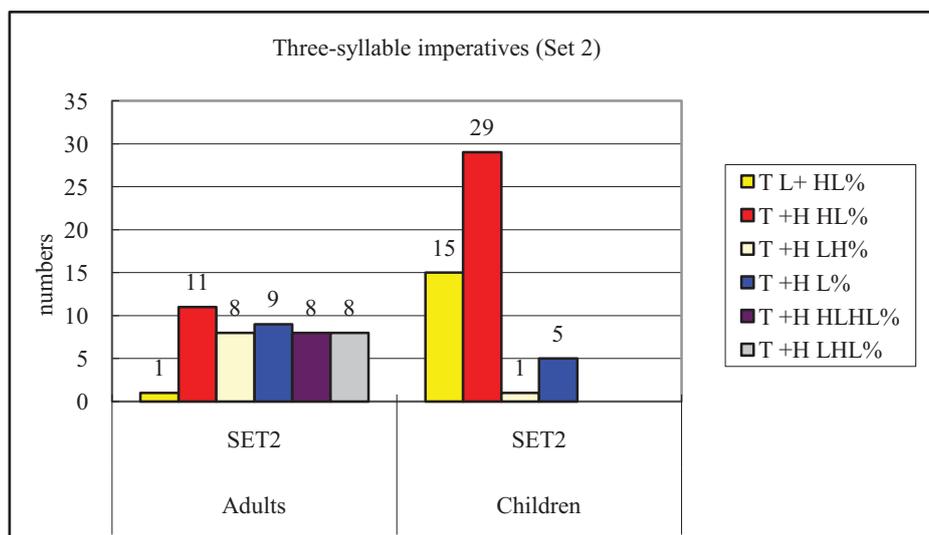

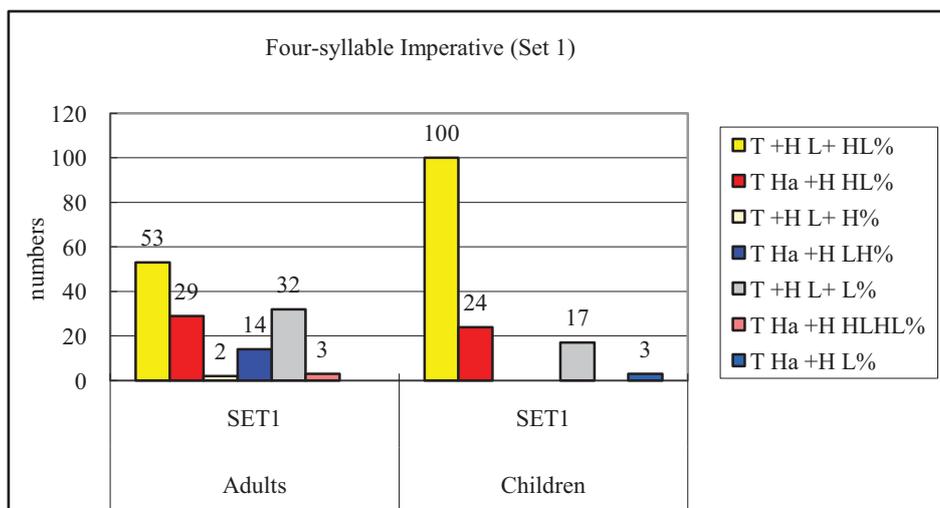

Figure 6. The number of intonational patterns in three-syllable imperatives (Set2)

As seen in Figure 6, adults tend to produce a wider variety of patterns than children. Unlike in Set 1, in Set 2, which cannot be separated into smaller words, three-syllable imperatives are realized as one AP.

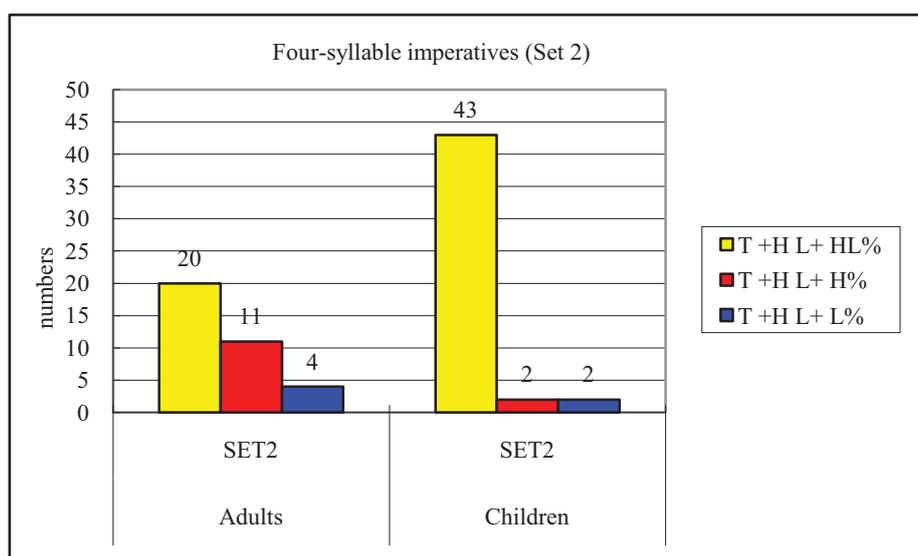

The results for four-syllable imperatives are similar to those for three-syllable imperatives. Figure 7 demonstrates these results.

**Figure 7. The number of intonational patterns in four-syllable imperatives (Set1)**

In the case of four-syllable imperatives in Set 1, which can be separated into smaller words, both groups show some with two APs. As for boundary tones, while children have HL% or L%, adults are not limited to HL% or L%, but also display H% or LH%.

The results of four-syllable imperatives of Set2 can be seen in Figure 8.

**Figure 8. The number of intonational patterns in four-syllable imperatives (Set2)**

As shown in Figure 8, while children's major intonation is T +H L+ HL%, adults' major intonation patterns are T +H L+ HL% and T +H L+ H%. Children generally use L% while adults use both L% and H%.

#### 4. Conclusion and Discussion

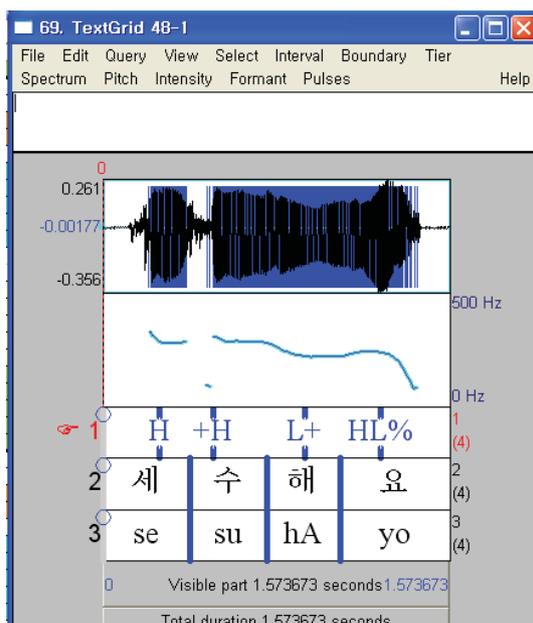

The results of this study offer insight into Korean children’s intonation patterns and the dissimilarities between children and adults, as presented in Table 2.

**Table 2. Major boundary tones**

	Children	Adults
Declaratives	<b>HL%</b>	<b>L%</b>
Questions	H%	H%
Imperatives (Set 1)	Ha or La	Ha or La
Imperatives (Set 2)	<b>HL%</b>	<b>HL%</b>

Table 2 demonstrates that the boundary tone of children’s declaratives, HL%, is similar to adults’ imperatives. In the case of children utterances, there is no significant distinction between declaratives and imperatives. On the other hand, adults’ boundary tones are thoroughly dissimilar: L% in declaratives, HL% in imperatives.

Figure 9.1 and 9.2 illustrate a comparison between children’s declaratives and adults’ imperatives.

**Figure 9.1 Children’s typical declarative**

**Figure 9.2 Adults’ typical imperative**

As shown in Figure 9.1 and 9.2, the tonal pattern of children’s declaratives is almost identical to that of imperatives by adults. While adults usually use HL% in imperatives, children tend to use HL% in declaratives. As for adults, L% is typical boundary tone in declaratives.

With questions, most participants tend to use H% in the majority of sentences. Although angle or slope of intonational contours was not measured exactly, for the most part, children’s H% is lower and results in a gentler slope than that of adults.

In imperatives Set 1, AP phrasing such as preboundary lengthening or pausing occurs in front of “hA [hε]” and “hAyo [hæjo].” This phrasing caused imperatives in Set 1 to possess two APs in a single sentence. Moreover, adults show a wider range of tonal patterns than do children in Set 1 imperatives. In imperatives Set 2, even though the two groups use HL% without phrasing, adults’ tonal patterns are more diverse than those of children.

One additional finding is that Korean imperatives may possess a peculiar pitch contour, depicted in Figure 9.3.

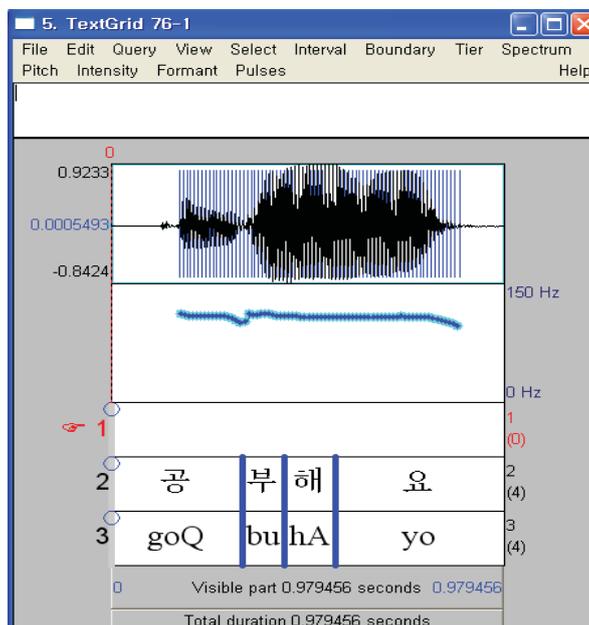

Figure 9.3 Adults’ (T+HL+L%) level tone

Figure 9.3 shows the overall level tone. Without the second syllable, “bu [bu],” there would be no salient part in this sentence. The even pitch extends entirely over the sentence. This type of pattern is classified as T+HL+L% in this study. However, it seems that the pattern is insufficient to label this level tone exactly.

Further study is still required to better identify children's intonational features. In addition, supplementary data from a greater number of subjects in combination with consideration of further prosodic features such as intensity and duration would result in a wider variety of patterns and clear results.

# **An Alternative Analysis of the Retrospective tense marker ‘*te*’ in Korean**

**Sook Lee**

Kookmin University  
861-1, Jeongneung-dong, Seongbuk-gu, Seoul 136-702, Korea  
Slee9941@hotmail.com

## **Abstract**

The retrospective morpheme ‘*te*’ has been considered as a tense-related morpheme; however, these previous analyses have been insufficient in explaining the various characteristics of the retrospective morpheme that are distinct from other general tense morphemes. This paper proposes an alternative analysis from the discourse and pragmatic perspective based on the facts that the appropriateness of the use of the retrospective morpheme is discourse-oriented, and that the retrospective morpheme occurs only in sentences with a defined hearer. This paper reveals that the retrospective morpheme expresses the speaker's psychological distance from the uttered information; this distance serves a function of showing politeness to the hearer by allowing the hearer in the conversation to acquire a sense of camaraderie and/or to protect his face-wants.

**Keywords:** retrospective morpheme, discourse-oriented, defined hearer, speaker’s psychological distance, hearer’s face-wants.

## **1. Introduction**

In Korean, various morphemes with grammar functions can appear following the verb stems. The example in (1) illustrates inflexible morphemes that can follow the verb stem.

- (1) *kkay-ttuli-si-ess-keyss-te-la*.  
break-EMP-HOR-PAST-PRESUMPTION-RETRO-DC  
(In retrospect, he) probably broke (it).

‘*kkay-*’ is a verb stem with a lexical meaning equivalent to ‘break’ in English, and the final ‘*-la*’ serves the function of closing a sentence. ‘*-ttuli-si-ess-keyss-te-*’, appearing

between the verb stem and the verb final, are classified as suffixes that express various grammatical functions. Let us examine the function of the individual suffixes. ‘*-ttuli*’ emphasizes the meaning of the verb with a force while ‘*-si-*’ expresses the speaker’s deference to the reference of subject nominal of the verb stem. ‘*-ess-*’ signifies that the described event took place in the past time, while ‘*-keyss-*’ expresses the speaker’s presumption of the described event.

Meanwhile, ‘*te*’ is traditionally called a retrospective tense suffix with which a speaker reports past events in retrospect. However, ‘*te*’ shows distributional restriction, which does not apply to the other general tense suffixes such as past, present, or future. This paper will point out that the analysis of ‘*te*’ with respect to the tense category cannot account for the distributional properties of ‘*te*’ and will show that the analysis from the functional perspective can properly account for the syntactic and semantic characteristics of ‘*te*’.

The following section will discuss about shortcomings of the analyses of ‘*te*’ as a tense morpheme. And the section 3 will provide the semantic analysis of ‘*te*’ from the discourse perspective. In section 4, the discourse effects of the retrospection will be examined. And the summary will follow in section 5.

## 2. Evidence against the previous analyses

We have empirical evidence showing that ‘*te*’ is distinguished from tense suffixes. First of all, ‘*te*’ is sensitive to the person of the sentential subject.

- (2) a. \**nay-ka cal ttuy-te-la.*  
       I-NM well run-RETRO-DC  
       ‘I retrospect that I ran well.’
- b. *ney-ka cal ttuy-te-la.*  
       you-NM well run-RETRO-DC  
       ‘I retrospect that you ran well.’
- c. *ku-ka cal ttuy-te-la.*  
       He-NM well run-RETRO-DC  
       ‘I retrospect that you ran well.’

The examples in (2) illustrate that ‘*te*’ cannot be used in sentences where the agentive and the speaker are co-referential. This is distinguished from the characteristics of the

general tense suffixes that are usually realized according only to the time of event described in a sentence with disregard to the person of the sentential subject as shown in (3).

- (3) a. Nay-ka cal ttuy-ess-ta/ttuy-keyss-ta/ttuy-n-ta.  
 I- NM well run-PAST-DC/run-FUTURE-DC/run-PRESENT-DC  
 ‘I ran well/ I will run well/ I run well.’
- b. Ney-ka cal ttuy-ess-ta/ttuy-keyss-ta/ttuy-n-ta.  
 you- NM well run-PAST-DC/run-FUTURE-DC/run-PRESENT-DC  
 ‘You ran well/ You will run well/ You run well.’
- c. Ku-ka cal ttuy-ess-ta/ttuy-keyss-ta/ttuy-n-ta.  
 he- NM well run-PAST-DC/run-FUTURE-DC/run-PRESENT-DC  
 ‘He ran well/ He will run well/ He runs well.’

Secondly, tense suffixes are not only required in sentences involving action verbs, but also must be consistent with the temporal adverbs in sentences as shown in (4-5).

- (4) a. Swuni-ka ecey tochakha-ess-ta.  
 S.-NM yesterday arrive-PAST-DC  
 ‘Suni arrived yesterday.’
- b. Swuni-ka nayil tochakha-keyss-ta.  
 S.-NM tomorrow arrive-Future-DC  
 ‘Suni will arrive tomorrow.’
- (5) a. \*Swuni-ka ecey tochakha-keyss-ta.  
 S.-NM yesterday arrive-PAST-DC  
 \*‘Suni will arrive yesterday.’
- b. \*Swuni-ka nayil tochakha-ess-ta.  
 S.-NM tomorrow arrive-Future-DC  
 \*‘Suni arrived tomorrow.’

In (4), past tense suffix ‘-ess-’ co-occurs with yesterday’s time of event while the future tense suffix ‘-keyss-’ co-occurs with tomorrow’s time of event. Meanwhile, (5) shows that the sentence becomes unacceptable when a tense suffix does not co-occur with a temporal adverb in a sentence.

However, as (6-8) shows, the retrospective morpheme can co-occur with time of past, present and future; moreover, this morpheme does not even have to necessarily appear as (a) sentences show in (6-8).

- (6) a. Swuni-ka ecey tochakha-ess-ta.  
 S.-NM yesterday arrive-PAST-DC  
 ‘Suni arrived yesterday.’
- b. Swuni-ka ecey tochakha-ess-te-la.  
 S.-NM yesterday arrive-PAST-DC  
 ‘In retrospect, Suni arrived yesterday.’
- (7) a. Swuni-ka cikum ili-lo o-ko iss-ta.  
 S.-NM now this way come-PROGRESS-DC  
 ‘Suni is coming this way.’
- b. Swuni-ka cikum ili-lo o-ko iss-te-la.  
 S.-NM now this way come-PROGRESS-RETRO-DC  
 ‘In retrospect, Suni is coming this way.’
- (8) a. Swuni-ka nayil tochakha-keyss-ta.  
 S.-NM tomorrow arrive-Future-DC  
 ‘Suni will arrive tomorrow.’
- b. Swuni-ka nayil tochakha-keyss-te-la.  
 S.-NM tomorrow arrive-Future-RETRO-DC  
 ‘In retrospect, Suni will arrive tomorrow.’

The examples in (6-8) prove that realization of the morpheme ‘*te*’ is irrelevant to the time of described event in the sentence. Then, what feature is ‘*te*’ triggered by?

We can assume that ‘*te*’ is triggered not on the sentence level but on the discourse level based on the fact that there is no difference in the acceptance of sentences whether ‘*te*’ appears or not in (6-8).

- (9) **Assumption**: The retrospective morpheme is triggered not on the sentence level but on the discourse level.

A piece of evidences supporting the above assumption can be found in the phenomenon regarding the subject restriction. Let us compare (2a) with the following sentence.

- (10) Kkwum sok-eyse po-nikka nay-ka cal ttuy-te-la.  
 Dream inside-LOC see-when I-NM well run-RETRO-DC  
 ‘In retrospect, I ran well in my dream.’

It has been states that ‘*te*’ is not allowed in first-person subject sentences where the agentive and the speaker are co-referential in (2a). However within the context of being in a dream as in (10), it is more natural for the retrospective morpheme to appear. That is, contextual situations play a crucial role in the distribution of ‘*te*’.

Another piece of evidence supporting the assumption that appearance of ‘*te*’ is discourse oriented comes from the fact that this morpheme is allowed only in dialogues in which the hearer is defined.

- (11) a. Swuni-ka pelse o-ass-ta.  
 S.-NM already come-PAST-DC  
 ‘Suni has already come.’  
 b. Swun-ka pelse o-ass-te-la.  
 S.-NM already come-PAST-RETRO-DC  
 ‘In retrospect, Suni has already come.’
- (12) a. apeci-ka hwa-ka na-si-ess-ta.  
 Father-NM anger-NM occur-HOR-PAST-DC  
 ‘My father got angry.’  
 b. apeci-ka hwa-ka na-si-ess-te-la.  
 Father-NM anger-NM occur-HOR-PAST-RETRO-DC  
 ‘In retrospect, my father got angry.’

The events or the states that the two pairs of sentences describe in (11-12) are identical. However, sentences in the first pair can be used with an uncertain hearer, while sentences in the second pair can be used only when the person listening to the speaker’s utterance is determined. Thus, we can state that the appearance of ‘*te*’ is closely related with the hearer participating in the discourse.

We can find more evidence supporting the discourse oriented characteristics of ‘*te*’ from the fact that the acceptability of ‘*te*’ depends on the hearer participating in the discourse.

- (13) a. wuli atul-i hapkyekha-ess-te-la. (to a friend)  
           my son-NM pass-PAST-RETRO-DC  
           ‘In retrospect, my son has pass the exam.’  
       b. ??wuli atul-i hapkyekha-ess-te-la. (to speaker’s wife)  
           my son-NM pass-PAST-RETRO-DC  
           ‘In retrospect, my son has pass the exam.’

In case that the speaker is relaying to his friend the news of his son’s acceptance, the use of the retrospective morpheme is appropriate. However, this very same sentence sounds awkward when the speaker addresses to his wife. These differences are not explained at the sentence- level.

As shown above, the distribution of ‘*te*’ is not always determined by elements found within the sentence, but instead by contextual situations and the relationship between the speaker and the hearer of dialogues. This supports the assumption that the semantic function of ‘*te*’ does not related to sentential meaning but instead to discourse meaning.

Thus, this paper will attempt to analyze the characteristics of discourse feature triggering ‘*te*’ in a sentence, and the semantic function realized by it.

### 3. Semantic analysis of ‘*te*’ from the functional analysis

Let us first examine the context in which the retrospective morpheme appears.

- (14) a. yay-tul-a,                   sensayngnim o-si-n-ta.  
           Guy-PL-Vocative teacher       come-HOR-PRESENT-DC  
           ‘Guys, the teacher is coming.’  
       b. \*yay-tul-a,               sensayngnim o-si-te-la.  
           Guy-PL-Vocative teacher       come-HOR-RETRO-DC  
           ‘Guys, in retrospect, the teacher is coming.’

The sentences in (14) are in a context where a student is alerting a boisterous classroom that the teacher is on the way. Previous analyses considered retrospective tense to possess the function of reporting an event that the speaker perceives at a different location in the past. That is, retrospective tense could be only realized with the satisfaction of the following three semantic features: ‘speaker’s past perception of the event, ‘locational or temporal interruption’, and ‘function of reporting’. Thus, since the speaker in (14) is reporting in the classroom an event that he saw in the hallway some time ago, the sentence satisfies the above conditions of retrospective tense as set forth by previous analyses. However, we can see that it is not appropriate to use ‘*te*’ in (14b).

In (14), the usage of ‘*te*’ makes the information that the teacher is coming seem irrelevant to the speaker, because the speaker shows her psychological distance from the information by use of ‘*te*’. However, in the given situation, the spoken information would elicit identical emotional response from both the speaker and the hearer.

Thus, we can say that ‘*te*’ retrospection is unacceptable in which the speaker and the hearer shows identical emotional response toward the given information. This can account for the distinction in felicity between the two sentences in (13), which are repeated in (15).

- (15) a. wuli atul-i hapkyekha-ess-te-la.(to a friend)  
 my son-NM pass-PAST-RETRO-DC  
 ‘In retrospect, my son has pass the exam.’  
 b. ??wuli atul-i hapkyekha-ess-te-la.(to speaker’s wife)  
 our son-NM pass-PAST-RETRO-DC  
 ‘In retrospect, our son has pass the exam.’

The news of the speaker’s son’s acceptance elicits identical emotional response from the speaker’s wife as it would from the speaker. However, this is not necessarily the case when the hearer is a friend. Thus the speaker does not speak with a sense of psychological distance to his wife, who shares his emotional response, but keeps this distance with the friend, who is not expected to share his emotional response. The discourse effect to the hearer that follows as a result of this psychological distance shall be discussed in the next section.

In this instance, we can tentatively hypothesize that retrospection is allowed when the hearer and the speaker share non-identical emotional response with regard to the uttered information.

- (16) **Hypothesis1 (tentative)**: The retrospection is allowed only when the listener and the speaker have different emotional responses to the uttered information.

However, retrospection is not always allowed just because of non-identical emotional response between the speaker and the hearer. The sentences in (17) are utterances that a speaker addresses to a friend.

- (17) a. \*wuli cip-ey        pul    na-ass-te-la.  
           My house-LOC    fire    occur-PAST-RETRO-DC  
           ‘In retrospect, my house caught on fire.’  
 b. \*wuli iwus        cip-ey        pul na-ass-te-la.  
           My neighbor    house-LOC    fire occur-PAST-RETRO-DC  
           ‘In retrospect, my neighbor’s house caught on fire.’

Both of the two sentences in (17) describe events that happened closer to the speaker than the hearers. Thus, the sentences elicit more emotional response from the speaker and we can consider there to be non-identical emotional response between the speaker and the hearer. However, while the speaker can talk about the fire in his neighbor’s house as if the event does not concern the speaker, he cannot do the same for a fire at his own house. That is, speaking as if the event has no concern to the speaker signifies a psychological distance, which is awkward when it is present while speaking about an event within one’s control.

Let us consider that retrospective morpheme is natural when a sentence such as (17a) is given within the context in (18).

- (18) Chwulcang-eyse tolao-e    po-ni        nay-ka eps-nun        sai-ey  
       Business trip    come back-see-when    I-NM    absent-MD    moment-LOC  
       wuli cip-ey        pul na-ass-te-la.  
       my house-LOC    fire occur-PAST-RETRO-DC  
       ‘In retrospect, I found that my house had caught on fire when I came back  
       from my business trip.’

The fire in (18) took place while the speaker was absent, thus implying that the speaker had no control over the event. As such, it is natural for the speaker to display signs of psychological distance. On the other hand, the awkwardness of the psychological

distance shown in (17a) occurs because the sentence can be interpreted in a way that the speaker did have control over the fire but did not do anything to prevent it.

Thus, we can hypothesize again that retrospective morpheme cannot appear in a context where speaker have control over the event described by the given sentence.

- (19) **Hypothesis 2 (tentative)**: The retrospective morpheme cannot appear in a context where speaker have control over the event described by the given sentence.

The hypothesis that the realization of the retrospective morpheme is relevant to controllable feature of the speaker can account for the phenomenon regarding person restriction.

- (20) a. \*nay-ka cal talli-te-la.  
I-NM well run-RETRO-DC  
'In retrospect, I ran well.'
- b. Kkwum sok-eyse po-nikka nay-ka cal ttuy-te-la.  
Dream inside-LOC see-when I-NM well run-RETRO-DC  
'In retrospect, I ran well in my dream.'

The running in (20a) occurs on the speaker's own volition and is thus an event that is under the speaker's control. However, if the event occurs in one's dream, the phenomenon is no longer under the speaker's control. Therefore, the difference in acceptance shown in (20) is explained by determining whether the event was under the speaker's control.

Let us now compare (20a) and the sentences in (21).

- (21) a. nay-ka maum-i aphu-te-la.  
I-NM heart-NM hurt-RETRO-DC  
'In retrospect, my heart was hurt.'
- b. nay-ka sulphu-te-la.  
I-NM sad-RETRO-DC  
'In retrospect, I was sad.'

Unlike action verbs, stative verbs carry non-volitional feature. That is, although sentences in (21) have subjects of first person, the speaker can express psychological distance about his emotion because the sentences do not show control of the speaker.

Usage of ‘*te*’ is more natural in 2<sup>nd</sup> and 3<sup>rd</sup> person subject sentences than in first person subject sentences. This can be easily explained by control features of the speaker. Sentences in (22) describe events that occurred under volition of 2<sup>nd</sup> and 3<sup>rd</sup> person subjects and thus are not events under control of the speaker. Therefore, it is possible for the speaker to describe the events with a sense of psychological distance.

- (22) a. ney-ka    cal    talli-te-la.  
          You-NM   well   run-RETRO-DC  
          ‘In retrospect, you ran well.’  
      b. ku-ka    cal    talli-te-la.  
          he-NM    well   run-RETRO-DC  
          ‘In retrospect, he ran well.’

However, the following sentences are often cited as examples proving that ‘*te*’ cannot be used when sentences have second or third person subject with psych-verbs.

- (23) a. \*ney-ka        sulphu-te-la.  
          You-NM    sad-RETRO-DC  
          ‘In retrospect, you were sad.’  
      b. \*ku-ka        sulphu-te-la.  
          he-NM        sad-RETRO-DC  
          ‘In retrospect, he was sad.’

The unacceptability of above sentences is not directly caused by the use of ‘*te*’. As can be seen in (24), these sentences are unacceptable even without ‘*te*’.

- (24) a. \*ney-ka        sulphu-ta.  
          You-NM    sad-DC  
          ‘You were sad.’  
      b. \*ku-ka        sulphu-ta.  
          he-NM    sad-DC  
          ‘He was sad.’

The inappropriateness of the above sentences must be explained by the violation of the restriction that psych-verb sentences require the speaker and the sentential subject to be co-referential in Korean. Thus, the person restriction of sentential subject with retrospective morpheme can be accounted for by controllable feature of the speaker. That is, retrospective morpheme expresses the psychological distance of the speaker to the events that are not under his control.

Based on what we have examined so far, we can revise the previous hypotheses as following:

- (25) **Hypothesis(revised)**: The retrospective morpheme expresses the speaker's psychological distance to events not under his control in context where the speaker and the hearer have non-identical emotional response to the uttered information.

Then for what does the speaker express his psychological distance to the describing event? Psychological distance can be interpreted as a tactic of politeness principles as set forth by Lakoff (1973) and Brown and Levinson (1987).

In the following section, let us examine how the speaker's psychological distance from the information produces discourse effects of politeness..

#### **4. Discourse effects of speaker's psychological distance from the information**

##### *4.1. First person subject and 'te'*

First, let us consider the semantic distinction displayed by declarative sentence and retrospective sentence in first person subject sentences in (26).

- (26) a. nay maum-i     sulphu-ess-ta.  
      My heart-NM    sad-PAST-DC  
      'I was sad.'
- b. nay maum-i     sulphu-te-la.  
      My heart-NM    sad-RETRO-DC  
      'In retrospect, I was sad.'

(26a) simply describes the speaker's emotional state but (26b) describes the speaker's emotional state with a sense of distance. In terms of psychological closeness, information on the speaker's emotional state is a close information to the speaker and distant to the hearer. When the speaker to express this with a sense of distance, it has an effect to adjust non-identical distance to be identical distance between the speaker and the hearer. This effect causes a feeling of camaraderie between the speaker and the hearer in relation to the information.

Let us examine again the two sentences in (27).

- (27) a. *nay-ka cinansihem-eyse iltung ha-ess-e.*  
 I-NM last test-LOC first score do-PAST-DC  
 'I got the first score on the last exam.'
- b. *nay-ka cinan sihem-eyse iltung ha-ess-te-la.*  
 I-NM last test-LOC first score do-PAST-RETRO-DC  
 'In retrospect, I got the first score on the last exam.'

Is achieving the top score on a test an event under the speaker's control? The effort in order to achieve the top score is an event under the speaker's control; however, every effort does not always lead to the desired results. As such, it cannot be considered an event under the speaker's control.

If information in (27) is uttered through a declarative sentence, the sentence can be interpreted in a way that the speaker is expressing his volition in this event of achieving the top score. However, in retrospective sentence where the speaker expresses psychological distance, the speaker implies that the event had a result that was not under his control. This attitude invokes a feeling of camaraderie with the speaker in the hearer, who also had no control over the result.

#### 4.2. *Second person subject and 'te'*

Next, let us examine the discourse effect of the speaker's psychological distance in sentences with second person subject.

- (28) a. *ne sang tha-ass-e.*  
 you prize get-PAST-DC  
 'You got a prize.'
- b. *ne sang tha-ass-te-la.*

you prize get-PAST-RETRO-DC  
'In retrospect, you got a prize.'

- (29) a. ne akka cip-ey eps-ess-e.  
you before house-LOC absent-PAST-DC  
'You were not at home before.'  
b. ne akka cip-ey eps-te-la.  
you before house-LOC absent-RETRO-DC  
'In retrospect, you were not at home before.'

The above sentences contain information relevant to the hearer. However, in declarative sentence, in which the speaker assertively relays the hearer's information to the hearer, the speaker implies that he knows more about the information than the hearer. This violates principle of politeness that honors participants of dialogues. According to Brown & Levinson, participants should not threaten the face-wants of the other party, and all participants have a positive face-want of having their information acknowledged. Thus, the speaker can acknowledge that the information about the hearer is closer to the hearer than the speaker by signifying his psychological distance from the information. Thus, the hearer can receive information regarding himself while retaining his face-wants, allowing for a more friendly discourse.

#### 4.3. Third person subject and 'te'

Let us finally examine the discourse effect of the speaker's distance in sentences with third person subject.

- (30) a. Swuni-ka cikum naka-te-la.  
S.-NM now go out-RETRO-DC  
(lit)'In retrospect, Suni is now going out.'  
b. Swuni-ka cikum naka-n-ta.  
S.-NM now go out-PRESENT-DC  
'Suni is now going out.'
- (31) a. Swuni-ka o-ass-te-la.  
S.-NM come-PAST-RETRO-DC  
'In retrospect, Suni has come.'

b. Swuni-ka o-ass-e.  
S.-NM come-PAST-DC  
'Suni has come.'

- (32) a. Nwu-ka chacao-ass-te-la.  
Somebody-NM visit-PAST-RETRO-DC  
'In retrospect, somebody was asking for you.'
- b. Nwu-ka chacao-ass-e.  
Somebody-NM visit-PAST-DC  
'Somebody was asking for you.'

In (30-32), both declarative and retrospective sentences can serve the function of reporting same information. However, in the dialogue with defined hearer, the delivery of information can be understood to expect a certain reaction from the hearer. (b) sentences express the speaker's assertive manner in reference to the given subject, which directly conveys the speaker's expectation of the hearer's reaction.

From the hearer's view points, however, the declarative sentences include elements that threaten the hearer's face-want of being free from compulsion because the delivery of information implies that the speaker expects a direct reaction from the hearer. At the same time, if the speaker can place psychological distance between himself and the information, the hearer does not feel compelled to react and thus interprets the information as a friendly discourse.

## 5. Summary

In sum, the retrospective morpheme has been considered as a tense-related morpheme; however, these previous analyses have been insufficient in explaining the various characteristics of the retrospective morpheme that are distinct from other general tense morphemes. Therefore, this paper proposes an analysis from the discourse and pragmatic perspective based on the facts that the appropriateness of the use of retrospective morpheme is discourse-oriented, and that the retrospective morpheme occurs only in sentences with a defined hearer. This paper reveals that the retrospective morpheme expresses the speaker's psychological distance from the uttered information; this distance serves a function of showing politeness to the hearer by allowing the

hearer in the conversation to acquire a sense of camaraderie and/or to protect his face-wants.

# **Metacommunicative Functions of Address Terms and Fillers in Conversations between Husband and Wife in Korea and Japan —A Contrastive Study—**

**Sumi Yoon**

Kanazawa University  
Morinosato 1-147-#213, Kanazawa, 920-1167 Japan  
smy8005@hotmail.com

## **Abstract**

In conversations, Korean married couples use address terms frequently and variously in order to signal the speaker's intention to the hearer metacommunicatively as contextualization cues (Gumperz 1982, Yoon 2008b). As contextualization cues, Japanese married couples, on the contrary, use fillers in their dialogues as frequently and variously as address terms in Korean conversations (Yoon 2008c). Why are the means used for contextualization cues so different despite their similarities in grammar? It can be supposed that the reason is related closely to the difference in speech styles of the speakers of these two countries. To test this hypothesis, conversations of actual Korean and Japanese married couples under the same situations were analyzed. The hypothesis was verified positively: The frequent and various use of address terms by the Korean couples reflects the speech style of Korean communication because Korean speakers lead and control the conversation actively. Similarly, the use of fillers by the Japanese couples is linked to Japanese style of communication because Japanese speakers expect the hearers to interpret their intention from their little information in the utterances positively.

**Keywords:** contextualization cues, address terms, fillers, Japanese, Korean

## **1. Introduction**

In utterances in a conversation, a speaker can convey his intention to interlocutors metacommunicatively by adding linguistic and/or paralinguistic means like address terms, fillers, intonation, accent, prosody, etc. Gumperz (1982) described such means as contextualization cues. Especially, uses of address terms and fillers as linguistic means for suggesting the speaker's intention are different from one culture to another.

### *1.1. Use of Address terms in Korean and Japanese*

Address terms are linguistic expressions with which the speakers can call their interlocutors directly. Braun (1988) distinguished address terms into two categories: free forms and bound forms. The former is independent on the syntactic structure of a sentence and can appear freely in any places in utterances. On the other hand, the latter is restricted syntactically and conjugates a predicate verb in a sentence. For example, “Sumi” and “you” in the utterance “Sumi, how are you?” are a free form and a bound form, respectively. In the present research we are interested in free forms of the address terms because they can be selected and used freely by the speaker to signal his intention to the hearer metacommunicatively. So, in the present study, the term “address terms” may refer only to free forms.

Yoon (2008a) researched how address terms are used in conversations between Japanese and Korean married couples comparatively and demonstrated that Korean couples use them more frequently and more variously than Japanese couples. Furthermore Yoon (2008b) claimed that the reason is that address terms can function metacommunicatively as contextualization cues in a conversation.

### *1.2. Use of fillers in Korean and Japanese*

The definition of fillers is ambiguous because the term is used in the literature differently by researchers. In the present study fillers may refer to various interjections that can function metacommunicatively. For example, “well” in the utterance “Well, what do you think about that?” can be regarded as one of such fillers.

Park (2005) analyzed natural conversations between Japanese and Korean people and demonstrated that Japanese use fillers more often than Korean. Yoon (2008c) analyzed dialogues between married couples from a Japanese and a Korean drama and showed that Japanese couples use fillers more frequently and more variously than Korean couples. Furthermore Yoon (2008c) conducted an experimental research of dialogues between married couples in Japan and Korea under the same conditions. She demonstrated that fillers in Japanese conversations appear in the same places as address terms in Korean conversations and claimed that the both means can function similarly as contextualization cues.

### *1.3. Purpose*

Japanese and Korean are syntactically similar languages and they also have similar systems of address terms. However, linguistic means used as contextualization cues are fairly different between both languages. In Korean and Japanese, address terms and fillers are used as metacommunicatively, respectively.

Address terms are linguistic means with which the speakers can call their interlocutors directly as mentioned above. Therefore the speaker utters them directly to the interlocutor. On the other hand, fillers express emotional feelings of the speaker and are not always directed to the interlocutor. In other words, address terms are direct means as contextualization cues while fillers are indirect ones.

Why do Korean and Japanese use different metacommunicative means as contextualization cues? In the present study, we suppose that the reason is in different styles of conversations between Japanese and Korean. The purpose of this research is to verify the hypothesis by analyzing experimental dialogues of married couples in Japanese and Korean.

There have been presented several contrastive studies on conversational cooperation between the speaker and the hearer in Japanese and Korean. Yim (2005) compared relations of conversations and backchannels from a point of view of politeness and claimed that ambiguous topic lines in a Japanese conversation are not aggressive to the interlocutor because they are based on negative politeness. In a Korean conversation, however, Korean use aggressive but “transparent” expressions, which are namely based on positive politeness.

Park (2007) analyzed discourse markers like back channels, hesitations, overlapping, etc. in Japanese and Korean. According to the results of Park (2007), Japanese speakers use back channels and hesitations more often and more variously than Korean speakers, which showed that the hearers have more cooperative, but more indirect attitudes to the speaker in Japanese conversations. As for overlapping, they appear in Korean conversations more frequently than in Japanese so that the speaker can take a turn aggressively. Therefore Korean speakers behave actively, which seems to be non-cooperative.

## **2. Materials and Methods**

### *2.1. Materials*

#### *2.1.1. Materials*

Data for this study will be collected from experimental conversations of Japanese and Korean married couples. In the present research, namely, actual married couples shall talk to each other. It would be ideal and objective to tape-record how real married couples talk to each other in a secret manner, which is, however, not allowed ethically.

I selected four scenes of conversations of married couples from *At Home Dad*, a Japanese drama broadcasted by Fuji TV in 2004, and *Bulyang jubu*, a Korean drama broadcasted by SBS in 2004. Both the dramas are similar in plot since the Korean drama is a remake of the Japanese one.

#### *2.1.2. Informants*

The participants of this research are four Japanese and four Korean married couples in their 20's to 30's, living in the capital spheres Tokyo and Seoul respectively, junior college or university educated. The Japanese couples have no knowledge of Korean language and vice versa.

### *2.2. Methods*

The participants shall verbally react to the role play situations set up by the researcher. The sentences used to instruct the participants do not include any language that would suggest the use of fillers or address terms, for example “Make an apology for coming late”, not part of the conversation like “Sorry for coming late.” The researcher tape records the utterances of the participants and then transcribes them. Note that the participants are not told about the aims of this study and not suggested to use any fillers or address terms in the instructions.

## **3. Results and Discussion**

In this chapter, the results of the comparison of conversations of Japanese and Korean married couples are partly shown (see Appendixes below for the other examples) and

discussed. The following is a list of abbreviations:

- [ ]: Explanation of the situation of a scene
- JW: a Japanese wife
- JH: a Japanese husband
- KW: a Korean wife
- KH: a Korean husband

### 3.1. *Expressing a wish*

<Scene 1>

[A husband and wife are watching the home shopping network. When the wife sees a dishwasher that she wants, she tries to sweet talk her husband into getting it.]

(1) JW1: Kore doo omou?

(What about this one?)

All of the Japanese wives used interrogative sentences to get a dishwasher. Formally they asked their husbands what they think about it. By asking an opinion, however, they communicatively tried to let their husbands understand that they want it.

(2) KW4: Jeogeo jeogeo eoddae? Siggiseceoggi. Jeogeo hana salka? eoddae?

(How about that? The dishwasher. Shall we buy that? Shall we?)

Two of the Korean wives asked their husbands what they think about the dishwasher. Three of them used the word “buy” clearly to convey their wish to get a dishwasher.

The instruction for this utterance is to ask your husband what he thinks about the dishwasher model shown currently on the TV-shop. The informants know the situation of the scene well. Japanese wives want the dishwasher, but only ask the husbands what they think about it without conveying the wish directly to them. In the paralinguistic level, the prosodic pattern of the question uttered by the wives can be different from a usual question.

Korean wives not only ask their husbands what they think about the dishwasher but also explain to them verbally how they need it.

### 3.2. *Apology*

<Scene 2>

[The husband apologizes that he didn't tell his wife that he had been fired.]

- (3) JH1: Hontoni gomen.  
(I'm really sorry.)

All of the four Japanese husbands uttered only an apologizing expression to their wives.

- (4) KH2: Eo mianghada. Miri maleul haeteoya doineunde ireotge doiseo mianhada.  
(I am sorry. I should have told you in advance. I am sorry. I couldn't do that.)

Two of the four Korean husbands uttered only an apologizing expression once, the others apologized twice. One of the husbands used only a routine form for apology, two of the four referred to the reason for apologizing besides a routine formula for apology. One husband uttered an excuse.

The instruction for this utterance is to give a real apology. All the Japanese husbands uttered only an apologizing expression. Korean husbands added the reasons for apologizing. It can be said that Japanese husbands expected their wives to understand their feelings. On the other hand, Korean husbands explained their intentions for apologizing actively to ask their wives to understand their feelings.

### 3.3. *Announcing an intention*

<Scene 3>

[The wife gave up her career in order to take care of her mother-in-law.]

- (5) JW4: Datte okaasanga taiinshitarasa iedesa okaasanno mendoomitahooga iideshoo?  
(Because I think we should take care of your mother after she leaves the hospital, shouldn't we?)

Three of the Japanese wives uttered their opinions in tag-question forms to request an agreement with their husbands. One of them used "omotte" (I think) instead

of a tag-question form. Modality expression “omotte” is used to weaken an opinion. All of the utterances of Japanese wives tried to avoid expressing their opinions clearly.

(6) KW1: Meo daeune gamyoun deolgeotgatgo eomeoni teowonhasimyon ije Uriga mosyoyaji. Jasigirago uribate eobneunde.

(I think I will get another chance in the future. We have to take care of your mother when she gets out of the hospital. She doesn't have any other sons or daughters.)

All Korean wives uttered their opinions clearly. They didn't use any weakening means for their expressing their opinions unlike the Japanese wives.

The instruction for this utterance is to say the need of taking care of her mother-in-law in the house of the couple after her leaving the hospital. In the utterances in Japanese, Japanese wives used rhetorical questions as indirect forms in expressing their opinions. However, all of the Korean wives didn't use any question forms. They conveyed their opinions to their husbands directly with the expression “have to”.

### 3.4. Suggestion

<Scene 4>

[A dishwasher that the wife wanted is too big. So the husband suggested her to buy a smaller one.]

(7) JH1: Ya demo ookisugirunjanaikana. Mochotto chiichainode iinjanaino?

(Well, but it is too big, isn't it? Isn't a little bit smaller one good enough?)

All the Japanese husbands didn't express their evaluation directly by using tag-question form or interrogative sentences. They recommended their wives another model indirectly.

(8) KH3: Geuraedo keuda. Ya dareun model alaboara.

(But that is so big. Hey, find a different one.)

All the Korean husbands uttered their evaluation directly, and suggested their wives to buy another model clearly.

The instruction for this utterance is to ask your wife to select another model. All of the Japanese husbands used interrogative forms to give a proposal, not imperatives, i.e. they formally asked their wives to say their opinions. On the other hand, all of the Korean husbands requested their wives to select another model by using imperatives or invitation forms. Won (2008) compared invitational expressions in Japanese and Korean and showed that Korean use invitation forms for the interlocutor to do something on the basis of the positive politeness strategy. Japanese use request forms or interrogatives from a point of view of negative politeness.

#### **4. Conclusions**

The tasks imposed to the informants were the same: To verbalize what is explained in each scene. But in both languages the differences above were to be observed. The differences are ascribable to the different contribution of the speaker of both languages to the communication. The Korean speakers speak directly and clearly, give more information for persuasion and need not cooperation of the hearers. On the other hand the Japanese speakers speak indirectly and unclearly, give minimum information for persuasion and need active cooperation of the hearers. To sum up, the Korean speaker is mainly responsible for the understanding and leads the communication, while the Japanese speaker will lead the communication negatively and the hearer is expected to interpret the intention of the speaker actively.

The uses of address terms and fillers appear to parallel the styles of communication of Korean and Japanese. The use of address terms in conversation matches to Korean style of communication because Korean speakers lead and control the communication actively. The use of fillers in conversation is appropriate to Japanese style of communication, because a Japanese speaker expect the hearer to interpret the intention of the speaker from his little information in the utterance positively or actively.

In the present study, we compared functions of address terms in Korean and fillers in Japanese, even though address terms and fillers are different linguistic means. Then in the future, we have to discuss about the comparability of address terms and fillers. Furthermore paralinguistic devices functioning as contextualization cues in conversations of married couples are also to be analyzed contrastively in Korean and Japanese.

## Appendixes

### <Scene 1: Expressing a wish>

JW1: Kore doo omou?

(What do you think about this?)

JW2: Umu ano ano syokusenki doo?

(What do you think about that dishwasher?)

JW3: Kore doo omou?

(What do you think about this?)

JW4: Ima kono terebide yatteruno doo omou?

(What do you think about the one that's on TV right now?)

KW1: Jeogeo jeogeo bwabwabwa jeogeo. Jeone naega mal haetdeon geo. Jotchi?

Halindo hadeonde.

(Look at that! That one! That is the one I told you before. Isn't it nice?

And it's on sale now.)

KW2: Oppa jeo siggisecheokgi eoddeonde?

(Honey, how about that dishwasher?)

KW3: Oppa jeo siggisecheokgi sago sipeunde jeogeo eoddae?

(Honey, I'd like to buy that dishwasher but what do you think?)

KW4: Jeogeo jeogeo eoddae? Siggiseceoggi. Jeogeo hana salka? eoddae?

(How about that? The dishwasher. Shall we buy that? Shall we?)

## <Scene 2: Apology>

JH1: Hontooni gomen.

(I am really sorry.)

JH2: Konkaino kotowa hontooni sumanakattato omotteiru.

(I feel really sorry about this.)

JH3: Warukattawa.

(I am sorry.)

JH4: Hontooi gomen.

(I am really sorry.)

KH1: Mianhae yujina. Angeuraedo naega mal haryeogo geuraetneunde.

(I am sorry, Yujin. I was going to talk to you.)

KH2: Eo mianghada. Miri maleul haeteoya doineunde ireotge doiseo mianhada.

(I am sorry. I should have told you in advance, I am sorry I couldn't do that.)

KH3: Mal anhaeseo jeongmal mianhada.

(I am really sorry that I didn't tell you.)

KH4: Seonhyeonga mianhae. Jinjja mianahada.

(Seonyoung, I am sorry. I am really sorry.)

**<Scene 3: Announcing an intention>**

JW1: Okaasanga taiin shitara uchide mendoo minakya ikenaideshyoo?

(Aren't we supposed to take care of your mother at our place when she gets out of the hospital?)

JW2: Un demo hora okaasanga taiin shitara iedene iede mendoo minakyaikenaito omotte. Un ano yameni shitanda.

(I thought we shall take care of your mother when she gets out of the hospital. So I decided to give up.)

JW3: E okaasan taiin shitara iede mendoo minakya ikenaikarasa.

Honkon ikenaideshyou?

(Since we shall take care of your mother when she gets out of the hospital, I can't just go to Hong Kong, can I?)

JW4: Datte okaasanga taiinshhitarasa iedesa okaasanno mendoomitahooga Iideshyoo?

(Because I think we should take care of your mother after she gets out of the hospital, shouldn't we?)

KW1: Meo daeune gamyoun deolgeotgatgo eomeoni teowonhasimyon ije Uriga mosyoyaji. Jasigirago uribate eobneunde.

(I think I will get another chance in the future. We have to take care of your mother when she gets out of the hospital. She doesn't have any other sons or

daughters.)

KW2: Eomeoni toiwonhasimyeon urijibeuro mosyeoyagetda. Geureotge haja.

(When your mother gets out of the hospital, we shall bring her to our place.  
We shall do so.)

KW3: Geunyang eomeoni toiwonhasimyeon uriga dolboa deuryeoya hanika  
jogeumman naega chamji meo.

(Since we should take care of your mother when she gets out of the hospital,  
I'll endure.)

KW4: Eomeoni toiwon hasimeyon urijibe gyeseyoya doijana.

(When your mother gets out of the hospital, she needs to stay at our place.)

**<Scene 4: Suggestion>**

JH1: Ya demo ookisugirunzyanaikana. Moochyotto chiichyaainode iinzyanaino?

(Well, but it is too big, isn't it? Isn't a little bit smaller one good enough?)

JH2: Ya sooittemosa hora uchino daidokoromo semaisisa. Sonnani ookiino iretemo  
damedeshyoo. moochyotto chiichyainonishitara?

(But look. Our kitchen is small. That big one shouldn't be at our place, don't you  
think? Why don't we buy a little smaller one?)

JH3: A demo ookiisine. Huraipan betsuni arawandemo iideshyoo.

Tede araeba iizyanai. moochyotto chiichyaiyatsude iinnzyanaino?

(But it's big. A frying pan doesn't have to be washed in a dishwasher, no?

I think it could be done by hands. Wouldn't it be better to buy a smaller one?)

JH4: Ma sorenisitemo dekaizyanai?

(Well, isn't it still big?)

KH1: Geuraedo jom keungeo gateunika dareungeo alaboa.

(But it looks little big. Look for other ones.)

KH2: Um geunde model maneunika meo igeobake eobneungeon anida.

Dareungeotdo jom alaboayaji.

(Well, there are other types too. This isn't the only one.

We have to look for other ones.)

KH3: Geuraedo keuda. Ya dareun model alaboara.

(But that is still big. Hey, find a different one.)

KH4: Geuraedo jigeum neomu keungeot gateunde gunyang dareun model alaboja.

(It still looks too big. Let's just look for other ones.)

# **Complex Roles of Similarity and Markedness on L2 Phone Acquisition: A Complementary Argument to the SLM and SDRH**

**Sungmi Kwon**

Department of Korean Language and Literature, Ewha Womans University  
11-1 Daehyun-dong, Sodaemun-gu, Seoul  
smkwon@ewha.ac.kr

## **Abstract**

The study attempted an investigation of Speech Learning Model (SLM), which claims that dissimilar phones can be acquired by establishing a new phonetic space, and that it is impossible to acquire authentic pronunciation of similar phones. It also investigated Major and Kim (1999)'s Similarity Differential Rate Hypothesis (SDRH), which maintains that differential rate affects the rate of acquisition, and, finally, provided a complementary argument to the two models. The study utilized the speech data of Kwon (2007b), results of speech production test on 7 Korean simple vowels produced by 16 Korean native speakers and three groups of Japanese learners of Korean (48 in total) who had different levels of learning or experiencing Korean, and of speech perception test on the 7 Korean simple vowels produced by the three Japanese groups, to verify the three hypotheses based on SLM and SDRH. Results suggested that SLM was partially falsified since similarity was closely related to the rate of acquisition, but it was not lineally related to ultimate competence or order of acquisition. On the other hand, SDRH seemed verified for the most part in that the most general principle involving similarity was rate, and markedness played a certain role as a mediating factor on the effect of similarity, although it was hard to find a definite proportional relationship between acquisition and similarity and markedness.

**Keywords:** L2 phone acquisition, similarity, markedness, SLM, SDRH

## **1. Introduction**

The goals of the study are to verify Flege's Speech Learning Model (SLM) by investigating the effect of the phonetic similarity of L1 (Japanese) and L2 (Korean) on L2 phone acquisition, and to verify the Similarity Differential Rate Hypothesis (SDRH) by investigating the significance of rate of acquisition as an effect of the phonetic

similarity and the effects of markedness as a mediator that slows down the rate of L2 phone acquisition.

Various research on L2 phone acquisition has dealt with the factors that make learners succeed or fail in acquiring native-like pronunciation. The factors that facilitate or impede the acquisition can be sorted out for non-linguistic factors such as neurological factors, age, L1 use, experience in L2, motivation, aptitude, and anxiety, as well as for the linguistic factor, which is L1. In this context, diverse hypotheses derived from contrast between L1 and L2 phone systems have been raised as follows: Contrastive Hypothesis Analysis (CAH), which regards interlingual “difference” as an obstacle in learning, Markedness Differential Hypothesis (MDH), which claims the relative degree of markedness affects the order of acquisition, SLM, which assumes new phones are easier to acquire compared to similar phones, and, finally, SDRH, which suggests both the roles of markedness and similarity.

There is something left to be desired in order to prove the notion of SLM, although a large amount of research results support SLM. A majority of the trials that attempted to validate SLM are problematic in assessing the similarity, a primary constituent factor of SLM. A small number of studies have been done for the cases in which the target languages are scarcely exposed to the learners before they began to learn them.<sup>1</sup> The majority investigated the learners whose target language was English, but English is one of those few languages to which learners are frequently exposed even before formal L2 learning begins. Furthermore, empirical research to prove SDRH tends to have been neglected to date. Hereupon the study constructs three hypotheses that accord with SLM and SDRH, and will analyze the validity of the two models by utilizing speech data produced by L2 learners.

## **2. SLM and SDRH: Roles of similarity and markedness**

SLM is a model that explains the interactions between L1 and L2 systems that occur during L2 phone acquisition. According to SLM, phonetic features that constitute phonetic structures exist in common phonological space, and hence L1 and L2 interact.<sup>2</sup>

---

<sup>1</sup> There are a few none-English languages like French (Flege 1987, Levy and Strange 2007) and Spanish (Guion, Flege, and Loftin 2000) investigated, but it should be considered that they might be one of the widely spread languages.

<sup>2</sup> There are two mechanisms in the common phonological space of L1-L2: “Phonetic category assimilation” is thought to operate when a new category fails to be established an L2 speech sound despite audible differences between it and the closest L1 speech sound. By hypothesis, category formation will be blocked if instances of an L2 speech category continue to be identified as instances of an L1

SLM endeavors to make a prediction for success or failure in L2 phone acquisition by the similarity, and a range of studies have ascertained the SLM with the similar results that the more similar the L2 phone is, the more L1 affects the L2 learners' phone acquisition and impedes learning (Flege and Hillenbrand 1984, Flege 1987, Flege 1995, Best, McRoberts, and Gooddell 2001, Aoyama, Flege, Guion, Akahane-Yamada, and Yamada 2004, Baker and Trofimovich 2005).

There, however, are several limitations in the main arguments of SLM and the process of attesting them. First, there is a problem in judging similarity. The majority of the research adopted the International Phonetic Alphabet system for judgment, and they decided the presence of similarity in accordance with whether or not the L2 phones have counterparts in L1 in terms of IPA. Most research related to SLM presupposes that similar phones are L2 phones that have counterparts in L1 in terms of IPA, while new phones are L2 phones that do not have counterparts in L1 in terms of IPA. IPA, however, is a phonetic alphabet system, as its name denotes, and it cannot be a criterion for deciding whether two phones are similar or not, as Kwon (2007b) maintains.

The privative categorizing by IPA can fall into the fallacy of dichotomy (Kwon 2007b). Major and Kim (1999) indicate what constitutes similar or dissimilar is not always clear, and try to treat similarity from a comparative perspective. Flege himself admits the limitation of the judgmental method of similarity, questioning how much must an L2 vowel differ from vowels in the L1 to be regarded as new (Flege 1996:42). From the research on the Dutch learners of English, he made a prediction that Dutch speakers would be able to succeed in acquiring /æ/, since English /æ/ is a new phone to Dutch and easy to build a new category. Flege (1996), however, turned out to make a wrong estimate. He tried to explain the fault, revealing that Dutch speakers had been exposed to /æ/ in some imported words, and /æ/ actually was not a new phone to Dutch. The logical error begot from the fact that empirical research based on speech data was not performed in estimating similarity. Thus, experimental research on acoustic similarity needs to be performed, and, instead of referring to the IPA, the study should consider similarity or dissimilarity as a factor placed in the continuum so that relative describing may be possible.

---

category. The SLM predicts that in such cases, a "merged" category will develop over time that subsumes the phonetic properties of the perceptually linked L1 and L2 speech sounds. "Phonetic category dissimilation" is thought to operate when a new category has been established for an L2 speech sound. It will cause a newly established L2 category and the nearest L1 speech category to shift away from one another in phonetic space. The SLM posits that category dissimilation occurs because bilinguals strive to maintain phonetic contrast between all of the elements in their combined L1+L2 phonetic space in the same way that monolinguals (or human languages, see Lindblom 1998) strive to maintain phonetic contrast among the elements making up their (L1-only) phonetic space (Flege et al. 2003:468-470).

Second, “difficult to acquire” has been vaguely defined as Eckman, Elreyes, and Iverson (2003) and Major and Kim (1999) pointed out, while it is characterized with order of acquisition in MDH and with rate of acquisition in SDRH. SLM-related research has been performed from different perspectives in terms of “difficulty.” Scores of studies (Flege 1987, Bohn and Felge 1996, Munro 1993) considered ultimate competence for that, and investigated whether certain L2 phones would eventually be mastered or not by checking whether the most experienced group was able to learn. However, all the multiple aspects of acquisition, such as rate of acquisition, order of acquisition, and ultimate competence should be considered in order to judge the “difficulty.”

Third, counter-evidences reveal that similarity is not always a factor that hinders learners from acquiring native-like pronunciation (Munro 1993, Kwon 2007a). The English speaking Arabic subjects examined in Munro (1993) did not appear to have more success in learning to pronounce a new vowel when compared to similar vowels. Additionally, the new vowels produced by the experienced Korean speaking Japanese subjects were perceived as non-native vowels by Korean native speakers in Kwon (2007a), and the result failed to support the predictions of SLM.

SDRH, on the other hand, insists that both rate of acquisition and ultimate competence should be considered, unlike the previous standpoints, SLM and MDH, that attempt to account for difficulty of learning with a single variable. SDRH argues that dissimilar phones are acquired at a faster rate than similar phones, and markedness is a mediating factor that slows the rate (Major and Kim 1999).<sup>3</sup>

- Stage 1:  $x=40\%$ ,  $y=20\%$  (in accuracy)  
 Stage 2:  $x=50\%$ ,  $y=80\%$  (in accuracy)  
           ( $x$ : less marked,  $y$ : more marked)  
 Stage 3:                                    ?

---

3 Markedness Differential Hypothesis (MDH), proposed by Eckman (1977), is a hypothesis that maintains less marked phones are acquired earlier than marked ones, and it is verified in Major and Faudree (1996). MDH is said to be developed from the Contrastive Analysis Hypothesis (CAH), a simple hypothesis that there is a difficulty where there is difference between L1 and L2, and tries to predict the area of difficulty, the direction of difficulty, and degree of difficulty. MDH, however, does not consider similarity as a variable, and it fails to interpret the dilemma that “similarity and markedness” compete against each other (Major and Kim 1999). For example, there may occur a contradiction when deciding whether either /x/ or /ɣ/ in Arabic is more difficult for English learners of Arabic to learn based on the two models, SLM and MDH. First, SLM may predict that /x/ will be more difficult to learn than /ɣ/, since a voiceless velar, Arabic /x/, rather than Arabic /ɣ/, a voiced pharyngeal, is more similar to English /k/. On the contrary, MDH expects /ɣ/ should be harder than /x/ in that /ɣ/ is more marked than /x/.

In accordance with SDRH, *y* is acquired at a faster rate than *x* in the beginning stage (from Stage 1 to Stage 2) of learning L2 phones, since *y* is dissimilar to *x* as presented above. The rate of acquisition of the more marked phone, *y*, however, will slow down since markedness works as a mediator. SDRH, hence, predicts about Stage 3 with a point that given that *x* is less marked and *y* is more marked, the rate of acquisition of *y*, presumably, will slow down from a certain point although it is definite that that of *y* is faster than *x*.

SDRH notably stresses the rate of acquisition rather than a vaguely defined “degree of difficulty,” and SDRH assumes that dissimilar phones are acquired faster than similar phones, but it does not make any prediction about the ultimate results, unlike SLM or MDH. Phones of different levels of similarity in different degrees of markedness should be investigated in order to attest SDRH, but no empirical research on SDRH except Major and Kim (1999) has been done so far.

### **3. Hypotheses based on SLM and SDRH**

#### *3.1 Hypotheses*

The study seeks to examine validity of SLM and SDRH by establishing the hypotheses based on the two models and verifying them.

Hypothesis 1: Competence with less similar phones is higher than with more similar phones.

Hypothesis 2: Learners acquire less similar phones faster than more similar phones.

Hypothesis 3: Less similar phones are acquired more quickly than more similar ones. Given a similarity differential, a greater degree of markedness will decrease the rate of acquisition.

Hypothesis 1 and 2 are proposed to observe the effect of similarity on L2 phone acquisition. Dissimilar phones are easier to acquire than similar ones according to SLM, and “easier to acquire” should be analyzed in terms of order of acquisition, rate of acquisition, and ultimate competence. Hypothesis 1 concerns the effect of similarity on acquisition in different learning or experiencing levels. In order to coincide with Hypothesis 1, less similar phones should display better accuracy than more similar phones regardless of learning or experiencing period. Namely, less similar phones are acquired prior to more similar ones, and L2 learners are more likely ultimately to acquire native-like pronunciation in less similar phones. Hypothesis 2 also regards the

effect of similarity on acquisition, and it supposes less similar phones are acquired faster. Thus, it may be acceptable that validation of both Hypothesis 1 and 2 can verify the main arguments of SLM. Hypothesis 3 concerns the effect of similarity and markedness, and in the case that Hypothesis 3 is proven, SDRH could be validated.

### *3.2 Examination of the hypotheses*

The study tests the three hypotheses by examining the phonetic data produced by L2 learners, and the data of Kwon (2007b) will be utilized for the current study.<sup>4</sup>

The speech data of Kwon (2007b) is as follows: Speech production test on the 7 Korean simple vowels produced by Ks, BJs, AJs, and EJs and speech perception test on the 7 Korean simple vowels produced by Ks, BJs, AJs, and EJs are utilized. Subjects are 16 Korean native speakers (Ks), 16 Beginning Japanese learners of Korean (BJs), 16 Advanced Japanese learners of Korean (AJs) participated as subjects, and 16 Experienced Japanese learners of Korean (EJs). Ks were Korean graduate students in the Dept. of Korean Language and Literature, while BJs were Japanese learners of Korean who had studied Korean less than a half year, AJs for 1.5-2 years, and at least 1 year learning plus more than 5 years of experience in Korean.

To begin with, degrees of similarity among Japanese and Korean vowels are analyzed for four levels: Identical (I), High (H), Middle (M), and Low degree (L) based on the analysis of mean values of the F1 and F2 by t-test (Kwon 2007b) as Table 1 displays.<sup>5</sup> Each correspondent pair, the pair of the most closed counterpart of L1 and L2, is analyzed whether a correspondent pair is significantly different from each other in terms of F1 and F2. The study categorizes all the vowels into four categories in accordance with degree of similarity in order to enable comparative arguments on acquisition pattern (rate or order), although the study supposes that the correspondent pairs are laid on the continuum of similarity. When a correspondent pair does not display significant difference in both F1 and F2, the pair is categorized as an identical vowel (I). And, in case that a pair is not significantly different in either F1 or F2, it is classified into vowel with a High degree of similarity (H). The vowel that has a counterpart that is significantly different in both F1 and F2 is sorted as a vowel with a

---

<sup>4</sup> Kwon (2007b) was devoted to investigate the effect of similarity in learning L2 phone, and it indicated the possibilities of the effect of markedness, while the current study is more focused on examining the two models, SLM and SDRH by a clarified “degree of difficulty” and probing the roles of markedness with similarity and providing profound explanation.

<sup>5</sup> Vowel height is negatively correlated with F1, and vowel frontness is correlated with F2 (Ladefoged 2001, Johnson 2003).

Low degree of similarity (L). Additionally, the pair that does not differ significantly at the significance level of 0.05, but does significantly differ at the significance level of 0.1 is sorted as a vowel with a Middle degree of similarity (M). The classification is presented in Table 1.

Degree	Korean Vowels	Japanese Vowels
I	/e/	/e/
	/i/	/i/
H	/a/	/a/
	/o/	/o/
	/ɨ/	/ɯ/
M	/u/	/ɯ/
L	/ʌ/	/o/

Table 1. Four levels of similarity based on the analysis of mean values of the F1 and F2 by t-test

**Hypothesis 1: Competence with less similar phones is higher than with more similar phones.**

Table 2 demonstrates whether the learners have achieved Korean-like accuracy. ○ represents that learners are not significantly different from Korean native speakers in terms of F1 and F2, while X represents that the learners are significantly different from Korean. Namely, the groups marked with ○ are regarded to have achieved native-like competence, while the groups marked with X are not.

I: /i/, /e/				H: /a/, /o/, /ɨ/			
	BJs		AJs		EJs		
	I	e	I	e	i	e	
F1	○	○	○	○	○	○	
F2	○	○	○	○	○	○	
M: /u/				L: /ʌ/			
	BJs		AJs		EJs		
F1	X		○		○		
F2	X		X		X		
	BJs		AJs		EJs		
F1	X		X		X		
F2	X		○		○		

Table 2. Competence of the vowels in four levels produced by the three Japanese groups

All three Japanese groups could not achieve native-like competence in different similarity levels regardless of learning or experiencing period for the vowels in different degrees except the vowels of Identical group (I). Accordingly, it is problematic to judge

that either more similar or less similar phones are more likely to acquire native-like pronunciation in ultimate competence.

In addition, in terms of sequence of acquisition, the vowels of I are to be mastered in the very early stage of learning, and the vowels of H also are not significantly different from Korean native speakers in either F1 or F2 from the very beginning stage, probably as a result of the positive transfer from L1, although they still are significantly different from Korean speakers. /u/, M degree, and /Λ/, L degree, however, do not present any difference to Korean speakers in either formant frequencies until the learning or experiencing period has reached 18~24 months. Therefore, the higher the similarity between L1 and L2 is, the earlier the phones are acquired. Namely, the sequence of acquisition has a linear relationship with the degree of similarity.

Thus, Hypothesis 1 is falsified since the speech production of more similar phones shows more similarity with Ks in terms of F1 and F2 than do less similar phones. The result is contradictory with SLM's argument that adult learners will ultimately produce new L2 vowels more accurately than similar L2 vowels because they are more likely to establish additional phonetic categories for new vowels.

## **Hypothesis 2: Learners acquire less similar phones faster than more similar phones.**

The Figure 1 presents the result of the perception test of Korean listeners on the vowel data produced by BJs, AJs, and EJs, and it implies the acceleration of acquisition according to the learning or experiencing period.<sup>6</sup> As Figure 1, the listeners display the accuracy of almost one hundred percents in /e, i, a, o, ɨ/ across all the period levels, and they show lower accuracy in the beginning and significantly greater accuracy in long term in /u/ and /Λ/. It signifies that there is more acceleration in acquiring less similar vowels, /u/ or /Λ/ rather than more similar ones, /e/, /i/, /a/, /o/, or /ɨ/.

---

<sup>6</sup> The stimuli are randomly chosen from the data that are collected for production text, and 105 (7 vowels \* 3 groups \* 5 random samples) stimuli are used. The listeners are 10 Korean native speakers who are female graduate students in Korean Language and Literature whose ages ranged from 26 to 35. The ten listeners are asked to select the corresponding vowel on the answer sheets that are composed of 7 multiple choices (/a/, /o/, /Λ/, /ɨ/, /u/, /e/ and /i/) to each stimulus. Thus, 1,050 answers (10 listeners \* 105 questions) are given.

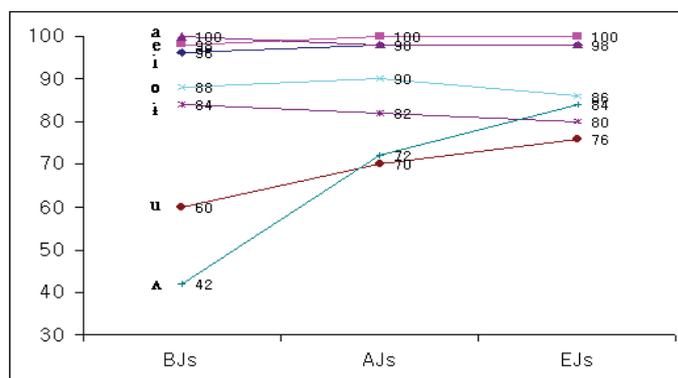

Figure 1. Result of the perception test on data of the three groups by Korean listeners<sup>7</sup>

	BJs	AJs	EJs
a	-0.64		1.2
e	0.6		0.8
i	1.09		0.5
o	2.8		1.38
ɪ	-1.18		0.7
u	18.7		8.45
ʌ	76.8		13.03

(scale: %)

Table 3. Rate of acquisition of seven vowels of Japanese Learners of Korean

The hypothesis 2 is verified since only the M and L display significant development according to the speech production test, and the results of the perception test also show the consistent analysis. It seems that learning, as a variable in acquiring L2 phones, has a greater effect on less similar phones than on more similar phones, and that is consistent with SDRH's argument.

**Hypothesis 3: Less similar phones are acquired more quickly than more similar ones. Given a similarity differential, a greater degree of markedness will decrease the rate of acquisition.**

Complexity Level	Korean Vowels
0	a
1	i u
2	e o ɪ
3	ʌ

Table 4. Complexity of Korean simple vowels based on marking conventions of Chomsky and Halle (1991)

It seems nearly impossible to make a hierarchy of various vowels of different language

<sup>7</sup> Cited from Kwon (2007b:182).

systems as Eckman (1977) attempted, thus this study adopts the complexity of Chomsky and Halle (1991)'s SPE in analyzing markedness of vowels, since it proves difficult to discuss the degree of markedness directly. The complexity of a system is equal to the sum of the markedness features of its members. It may be hard to say that the complexity levels exactly correspond to "the degree of markedness." Markedness constraints of SPE, however, consider the most commonly discovered vowels in natural languages like /a, i, u/ as the most economical systems (Jun 2004:230-231), and, hence, in case the complexity level of a certain phone is high, the phone is regarded to be less frequently observed, namely less marked. Therefore, the relationship of complexity and markedness appears feasible to estimate the degree of markedness of vowels.

In order to verify Hypothesis 3, five possible cases, which demonstrate different relationships between similarity and markedness from comparative perspectives are formulated and how similarity and markedness react in the L2 phone acquisition is scrutinized.

**[Case 1] similarity: A > B, markedness: A=B (A=/i/, B=/u/)**

Prediction: The degree of similarity of /i/ is higher than /u/, and the degree of markedness of /i/ is the same as /u/. Based on Hypothesis 3, the rate of acquisition of /u/ will be higher than /i/, but there will not be a noticeable change in the gap of the rate of the two phones.

Analysis: The rate of acquisition of /u/ was faster than that of /i/, and the gap did not make a significant change even though it gradually became smaller. Hypothesis 3, consequently, was validated with the analysis of Case 1.

**[Case 2] similarity: A=B, markedness: A > B (A=/o/, B=/a/)**

Prediction: The degree of similarity of /o/ is the same as /a/, and the degree of markedness of /o/ is higher than /a/. Based on Hypothesis 3, the rate of acquisition of /o/ will be similar to /a/, but the rate of acquisition of /o/ will be gradually slower than that of /a/.

Analysis: The rate of acquisition of /o/ is faster, and that of /o/ did not fall behind that of /a/. Hypothesis 3, consequently was validated with the analysis of Case 2.

**[Case 3] similarity: A=B, markedness: A=B (A=/o/, B=/ɨ/)**

Prediction: Both of the degrees of similarity and markedness of /o/ is the same as /ɨ/. Based on Hypothesis 3, the rate of acquisition of /o/ will be similar to /ɨ/, and there will not be a noticeable change in the rate of the two phones.

Analysis: The rate of acquisition of /o/ was not significantly different from that of /ɨ/, and it did

not make a significant change. Hypothesis 3, consequently, was validated with the analysis of Case 3.

**[CASE 4] similarity: A > B, markedness: A > B (A=/i/, B=/u/)**

Prediction: Degree of similarity of /i/ is higher than /u/, and the degree of markedness of /i/ is also higher than /u/ (Tables 1 and 4). Thus, based on Hypothesis 3, it is predicted that the rate of acquisition of /u/ will be faster than /i/, and the rate of /i/ will become slower compared to that of /u/, thus the gap of the rate of acquisition between the two phones will become greater.

Analysis: Referring to the results of the categorical judgments of /i/ and /u/ (Table 3), the rate of acquisition of /i/ was faster than that of /u/, but the rate of /u/, rather than that of /i/ began to decrease from a certain point, and the gap in the rate of the two phones became smaller. Hypothesis 3, consequently was not validated with the analysis of Case 4.

**[Case 5] similarity: A > B, markedness: A < B (A=/i/, B=/o/)**

Prediction: The degree of similarity of /i/ is higher than /o/ while the degree of markedness of /i/ is lower than /o/. Based on Hypothesis 3, the rate of acquisition of /o/ will be higher than /i/, and the rate of /o/ will become slower compared to that of /i/, thus the gap of the rate of acquisition between the two phones will become smaller.

Analysis: The rate of acquisition of /i/ is not significantly different from that of /o/, and it did not make a significant change in the rate. Hypothesis 3, consequently, was not validated with the analysis of Case 5.

The three cases, Cases 1~3, in which either degree of similarity or that of markedness was the same, coincided with Hypothesis 3, while the other two cases failed to validate it. However, it would be nearly impossible to observe the mediating effect of markedness for the Case 4 and Case 5, which compare phones that are high in both degree of similarity and that of markedness, since learners acquire native-like competence even in the very beginning stage.

#### **4. Conclusions and Discussions**

This study interrogated the validity of SLM and SDRH, and examined them empirically. The findings of the research are as follows: First, SLM is partially falsified. Similarity is closely related to the rate of acquisition, but it is not lineally related to ultimate competence or order of acquisition. As Flege (1996) demonstrates that adult L2 learners do not proceed inevitably towards successful production of new vowels, and as

additional research is needed to ascertain the basis for the striking differences between individuals observed, more research needs to be performed to prove SLM. Second, SDRH is verified for the most part. As SDRH argues, the most general principle involving dissimilarity and similarity turns out to be rate, and markedness does play a distinctive role as a mediating factor on the effect of similarity, even though the effect is not fully proportional.

The results of the current study seem partially compatible with the hypothesis of SLM and agreeable with SDRH on the whole, since similarity played a great role in terms of the learning speed, and markedness is found to be part of the factor that affects L2 phone acquisition. L2 phone acquisition, however, cannot be clearly generalized to be related with only a couple of factors such as similarity and markedness, and the study leaves some cases unexplained. Very complex factors seem to have an effect on L2 phone acquisition, just as Archibald and Young-Scholten (2003) argue that neither markedness nor equivalence classification nor reference to suprasegmental facts has been able to explain interlanguage segmental phonology fully.

## Abstract

In this study we use spoken and written corpora to examine the phenomenon of case marker dropping in Korean. We show that register (or genre) variation contributes to differences in case marker deletion. With an empirical data analysis, we classify regular patterns of case marker deletion and investigate semantic and pragmatic factors triggering case marker deletion and realization. These factors are important in recovering the information behind a missing case marker. In turn, this information is useful not only for deriving correct syntactic and semantic representations, but also for developing efficient computational processes of parsing, discourse analysis, machine translation, etc.

**Keywords:** annotation, case marker, particles, corpus, ellipsis, register

## 1. Introduction

In Korean, the syntactic and semantic relations of a noun phrase are represented by a case marker that follows that NP. Nominative case *이/가* *i/ka* marks subjecthood, and accusative *을/를* *ul/lul* marks objecthood, as in (1). Other case markers represent additional lexical meanings, such as locative, instrument, source, and goal.

- (1) 민수-(가)    교실-에서    피아노-로    음악-(을)    연주한다.  
Minsu-(ka)    kyosil-eyseo    piano-lo    umak-(ul)    yoncwuhanta.  
Minsu-Nom    classroom-in    piano-with    music-Acc    plays  
'Minsu plays music with a piano in the classroom.'

Our corpus-based research reveals that the rate of case dropping is, in fact, not evenly distributed in spoken and written Korean corpora. In an earlier pilot study with a 10,000 *eojeol*<sup>1</sup> spoken corpus, the total occurrence of nominative case markers corresponded to 88% overt markers and a dropping rate of only 12%. Interestingly, there was also a significant difference depending on register. In our spoken corpus, composed of informal personal conversations, the rate of the nominative dropping approximated 30%. Within the spoken corpus of formal debate, however, it was only 15%. Moreover, the written data showed a much lower rate, i.e., less than 10%. In general, it seems that the more informal dialogs are, the more often case markers are elided. Understanding such differences or similarities in register variation can be useful for efficient natural language processing and for language teaching, as well as for accurate linguistic analysis. For example, case marker ellipsis will be a more serious issue for computational modeling that incorporates informal spoken dialogs than computational processes on written texts. Even if a parser without a meaning resolution system for missing case markers can perform with high accuracy on written data, its performance will be downgraded with spoken data. In language teaching, case markers can be emphasized more for Korean writing and formal speaking based on their frequency in the given register.

In this study, we expand our data analysis to include large corpora with more than 50,000 *eojeol* and investigate if our earlier findings can be generalized. We test four different registers with respect to case marker ellipsis: two types of spoken texts and two types of written texts. The first two are divided into informal personal conversation and formal TV debate, and the latter two, into newspaper articles and scripts of public announcement. By comparing the rates of case marker deletion, we argue that formality of discourse does affect the occurrences of case markers. In addition, we examine the relevant morphosyntactic, semantic, and pragmatic factors affecting case marker realization and ellipsis.

## **2. Case Dropping Phenomena in Korean**

### *2.1. Korean Particles*

Korean is an agglutinative language in which a verb combines with various endings and

---

<sup>1</sup> *Eojeol* is a word level unit specific to Korean and based on spacing.

a nominal combines with a particle. At the level of morphosyntax, verbal endings and particles play a crucial role in connecting words or phrases in a sentence. Particles can be divided into two different classes that serve different functions: lexical case markers and discourse particles. Lexical case markers either represent the grammatical relation of a nominal or they add specific meaning to a nominal in a sentence. These two functions are referred to as structural case and inherent case, respectively. Discourse or modal particles come in various kinds and have functions that are closely tied to discourse properties. This class includes topic markers or delimiters.

**[1] Lexical Case Markers**

Structural Case: nominative(이/가 *ka/i*), accusative (을/를 *ul/lul*), genitive case (의 *uy*)

Inherent Case: dative(에게 *eykey*, 한테 *hanthey*), goal (으로/로 *ulo/lo*), locative (에 *ey*, 에서 *eyseo*), instrument (으로 *ulo*), etc.

**[2] Discourse/Modal Particles**

Topic (은/는 *un/nun*), Delimiters (도 *to*, 만 *man*, 조차 *cocha*, etc.)

Morphosyntactically particles can combine together. However, structural case markers cannot combine with certain discourse particles including topic marker 은/는 *un/nun* and delimiter 도 *to*. Particles are one of the most widely investigated topics in Korean linguistics in the past thirty years. Ever since Chomsky’s theory of generative grammar was introduced in the ‘80s, one of the common assumptions that syntacticians adopted was the clear distinction between structural and inherent case; structural case markers such as the nominative and the accusative mark grammatical relations without adding specific meaning to a nominal. In contrast, inherent case markers only add specific meaning to a nominal and serve no grammatical function. The evidence supporting this stance comes from case ellipsis. Korean is known to drop the nominative case marker 이/가 *i/ka* and accusative case marker 을/를 *ul/lul* relatively freely. In (1), these markers appear with parentheses to indicate this fact. In contrast, inherent case markers and discourse particles are rarely dropped, and they are marked without parentheses in (2).

(2)	민수-가	교실-에서/*Ø	피아노-로/*Ø	음악-을	연주한다
	Minsu-ka	kyosil-eyseo	piano-lo	umak-ul	yoncwuhanta.
	M-Nom	classroom-in	piano-with	music-Acc	play
	‘Minsu plays music with a piano in the classroom.’				

However, we doubt that the structural case markers can be dropped in any given context. For example, when a focus interpretation is added, the nominative or the accusative marker cannot be dropped.

- (3) a. A: 누가 너-를 좋아하니?  
 nuka ne-lul choahani?  
 who you-Acc like  
 ‘Who likes you?’  
 B. 존-이/\*-∅ 좋아해.  
 John-i choahay.  
 John-Nom like  
 ‘John likes (me).’
- b. A: 누가 너-를 좋아하니?  
 nuka ne-lul choahani?  
 who you-Acc like  
 ‘Who likes you?’  
 B. 존-이/\*-∅ 좋아해.  
 John-i choahay.  
 John-Nom like  
 ‘John likes (me).’

In addition, we note that case markers rarely disappear in formal spoken Korean such as broadcast news or announcements. This suggests that the phenomenon of case ellipsis needs to be more carefully explored.

## 2.2. Some Findings on Case Ellipsis in Previous Research

Kwon (1989) argued that the less lexical case markers are more likely to drop. This predicts that more nominative case markers are dropped than other case markers because nominative case is the least lexical case. He also provides the following hierarchy for case dropping in Korean.

### (4) Case Dropping Hierarchy

*Nominative > accusative > possessive > adverbial (temporal > instrumental > comparative)*

However, Kwon (1989) does not provide statistical data to support his argument. By analyzing the spoken language corpus of fourteen dialog segments from radio shows, Hong et al. (1998) provided such empirical data on case marker realization and ellipsis for Korean. In their analysis, they counted the number of noun phrases with and without elided case markers. They reported that 900 turns were exchanged between a show host and invited guests across the fourteen discourse segments from different radio shows, with a total time span of 60 minutes. In total 1,989 noun phrases were identified and 70.8% (1,408) of them were produced with an explicit particle. Noun phrases with elided particles corresponded to 27.7% of all the noun phrases, and within that group, 266 noun phrases appearing with delimiters were considered tokens of case marker ellipsis in their study. The rest of noun phrases were identified as errors. With respect to the structural case markers, they provided the following breakdown.

	Class I		Class II		Class III		Class IV		Total	Deletion Rate	
	Case Realized		Bare NP		Delimiter Replacement		Error			#	%
	#	%	#	%	#	%	#	%			
Nominative	388	65.9	43	7.3	154	26.1	4	0.7	588	197	33.4
Accusative	359	72.5	68	13.7	62	12.5	6	1.3	495	130	26.2
Genitive	67	39.2	101	59.1	2	1.2	1	0.6	171	103	60.3

Table 1. Realization and Ellipsis of the Structural Case Markers (Hong et al. 1998)

Although Hong et al.'s (1998) approach is valuable given that they used a corpus of real speech and provided a statistical analysis, a critical problem of their study is that the size of the corpus (with fewer than 2000 noun phrases) was too small to determine the actual case marker realization/ellipsis in Korean. Thus, from the perspective of a quantitative approach, their report on the overall distributions of particles including locative, temporal, predicative, etc. has limited implications. While considering the lack of computerized corpus data at that time, Hong et al. (1998) provided interesting statistics for the study of case markers and noun phrases in Korean

Similarly to Kwon (1989), Hong et al. (1998) reported that nominative case has a higher dropping rate than accusative case in Korean as in Table 1. In their analysis,

genitive case had the highest dropping rate of all. However, we claim that realization of the genitive case is controversial in Korean because of the complexity of complex noun phrases. In Korean, a complex noun phrase can be formed by combining more than two nominals. For example, 전국 학생 협의회 창립 기념 파티 *cenkwuk haksae yng hyepeuyhoy kinyem pathi* ‘nationwide student association establishment celebration party’ is a complex noun phrase composed of six nominals. In the structure of a complex noun, the genitive case marker tends to disappear, while theoretically it is possible to insert the genitive markers between each pair of nominals. Although it sounds awkward, 전국-의 학생-의 협의회-의 창립-의 기념 파티 *cenkwuk -uy haksae ng-uy hyeuyhoy-uy kinyem pathi* (nation-Gen student-Gen association-Gen establishment-Gen celebration-Gen party) is a grammatically possible construction. It has been controversial as to how to classify complex nouns and compound nouns and how to represent the exact structure of noun phrases in Korean. Linguistic intuitions about the positions of dropped genitive case markers and where they would occur if overtly realized vary among native speakers of Korean. Therefore, this study excludes ellipsis of the genitive case markers and focuses on realization and ellipsis of the other structural cases in Korean.

In contrast with Kwon (1989) and Hong et al. (1998), Kim and Kwon (2004) reports a higher dropping rate for the accusative case marker. Through our corpus study, we evaluate these contradictory conclusions and discuss relevant linguistic properties with respect to case annotation as well as realization and ellipsis.

### **3. Our Corpus Study**

#### *3.1. Data*

In this study, we use four different registers of spoken and written corpora in Korean and annotate case marking and dropping. The data consist of approximately 50,000 *ojeol* from the Sejong Corpora with morphological tagging. In order to maintain the desired balance of genre and text-type within our corpus data, the relevant data were extracted from a 1 million *ojeol* balanced corpora. Among the four different registers, the spoken corpus data include transcribed natural conversations on various topics and TV debates with morphosyntactic tagging on lexical category and morphological functions. The written corpus data include scripts of the public announcement of political issues and newspaper articles. The details of data are summarized as follows.

(5) Four Different Registers

Approximately 50,000 *Eojeol* from the Tagged Sejong Corpora (Spoken and Written)

Total: 48,985 *Eojeol*

- |  |                                |
|--|--------------------------------|
| [1] Informal Personal Conversation:                                  | 10,546 <i>eojeol</i> (Spoken)  |
| Conversations on Tourism and Disease & Health                        |                                |
| [2] Formal TV debate:  | 13,735 <i>eojeol</i> (Spoken)  |
| TV Broadcast of Nighttime Discussions                                |                                |
| [3] Public Announcement:   | 10,091 <i>eojeol</i> (Written) |
| Public Speeches on East Asia,<br>Relations between Korea and America |                                |
| [4] Newspaper Article:   | 15,613 <i>eojeol</i> (Written) |
| Editorials and articles published in 1996                            |                                |

It is worth noting that certain registers can be similar to one another even while belonging to different text-type categories. For example, the formal TV debate corpus (spoken) is similar to scripts from public announcements (written); this is because in terms of formality, TV debate is more formal than scripts from drama or movies.

We argue that case dropping needs to be more carefully examined by considering the properties of different registers. Although Korean is known as a language where case markers are easily dropped in speech, genre and formality of conversations seem to play a significant role.

For our case annotation, we used corpus data with specified morphosyntactic features that were established with a morpheme analyzer. We marked case realization and dropping in the arranged data with Microsoft Excel. An example from our annotated corpus appears as follows:

Original Text	Morpheme Analysis	Case Realized	Case Dropped	Comments
<s n=00016>				
또	또/MAJ			
앞으로	앞/NNG+으로/JKB	으로/JKB		
우리가	우리/NP+가/JKS	가/JKS

주시기	주/VV+시/EP+기/ETN			
바랍니다.	바라/VV+바니다/EF+./SF			

Table 2. An Example of Our Annotated Corpus

As shown in Table 2, case realization information is marked in the third column and dropping, in the fourth column. Additional information is added in the comment column. The data were hand annotated by the authors and the inter-annotator agreement rate was 92%. In this study, we marked only the nominative and the accusative case.

### 3.2. Structural Case Realization and Dropping in Korean

The statistical result from our annotated corpus is presented as follows:

		Spoken Corpus		Written Corpus		Total
		Conversation	TV Debate	Formal Address	News	
Nominative	Marked	68.3% (521)	87% (1133)	76% (530)	74% (1207)	77% (3391)
	Dropped	31.7% (242)	13% (169)	24% (164)	26% (424)	23% (999)
Accusative	Marked	36.9% (218)	62% (783)	54% (846)	36.9% (218)	47% (2065)
	Dropped	63.1% (373)	38% (475)	45% (746)	37% (724)	53% (2318)

Table 3. Case Realization and Dropping Rate of Structural Case in Korean

As we see in Table 3, the dropping rate of the accusative case (53%) is much higher than that of the nominative case (23%), an effect which holds across each of the four different genres. In addition, case dropping is more frequent in everyday conversations (47%) than in TV debate (26%), formal address (35%), and newspapers (32%).

With respect to our current statistical results, a notable point is that the dropping rate of the accusative case marker (53%) is unexpectedly higher than that of the nominative marker (23%). We believe that this may have resulted from our annotation method. For example, the accusative marker *을/를 ul/lul* tends not to appear with certain combinations of a verbal noun and the light verb *하다 hata* ‘do’ or *시키다 sikhita* ‘make’. In a light verb construction, a verbal noun contributes to the sentential structure by specifying an argument and the relevant subcategorization features like a predicate and the following light verb *하다 hata* or *시키다 sikhita* fills in the position of that predicate<sup>2</sup>. In a *하다 hata* light verb construction, the verbal noun can be accompanied by the accusative case *을/를 ul/lul*. However, it is more natural to drop the accusative case markers in the construction. For this reason there has been controversy regarding how to analyze in Korean grammar the combinations of a verbal noun and a light verb when the accusative case marker does not appear between them. Because a word unit does not allow lexical insertion inside of that unit, these combinations have been

<sup>2</sup> Lee (2003) examines the structure of light verb constructions and provides a syntactic representation of them within the frame work of Head-Driven Phrase Structure Grammar.

considered morphosyntactic combinations that are composed of two lexical items while behaving like single word units. Light verb combinations take the major parts of Korean predicates. Some light verb constructions take nominative case after a verbal noun (i.e. 되다 *toyta*). When counting light verb combinations as examples of case ellipsis, the case dropping rate increases dramatically. For example, among 724 tokens of accusative case dropping in the newspaper corpus, there are 665 tokens of N + 하다 *hata*, 25 tokens of N + 시키다 *sikhita*, and 4 tokens of N + 당하다 *tanghata*. When we exclude these tokens from the case dropping counts, only 30 tokens of the missing accusative case marker remain, which corresponds to a 2.3% dropping rate and 97.7% realization rate.

When light verb combinations are excluded from case ellipsis examples, the revised statistical result of case realization and ellipsis appears as in Table 4. In terms of the nominative case, some combinations of N + 되다 *toyta* have also been excluded from the case dropping cases in this table. Whereas Table 3 shows that the dropping rate of the accusative case marker (53%) is unexpectedly higher than that of the nominative marker (23%), Table 4 shows the expected pattern. The dropping rate of the accusative case marker (10%) is lower than that of the nominative marker (15%).

By considering the morphosyntactic properties of N+light verb combinations, which behave like single predicates, and the awkward interpretations of formations that overtly realize an otherwise missing case marker, we argue that case ellipsis does not need to be assumed for N + light verb combinations. This approach also supports the fact that case markers with light verb combinations developed historically to be added after a verbal noun rather than to be dropped from their original positions<sup>3</sup>. Therefore, we argue that the N + light verb combinations need not be counted as case ellipsis.

---

<sup>3</sup> This claim was also mentioned at our presentation at CIL 18 by an anonymous commentator. We agree that there is high probability for case insertion instead of case ellipsis. However, in order to solidify this argument, a more thorough examination of historical corpora is required with respect to N+ light verb combinations in Korean.

		Spoken Corpus		Written Corpus		Total
		Conversation	TV Debate	Formal Address	News	
Nominative	Marked	69% (521)	90% (1133)	88.8% (530)	86.5% (1207)	85% (3391)
	Dropped	31% (235)	10% (125)	11.2% (67)	13.5% (188)	15% (615)
Accusative	Marked	51% (218)	94.5% (783)	95% (879)	97.6% (1256)	90% (3136)
	Dropped	49% (209)	5.5% (45)	5% (46)	2.3% (30)	10% (330)

Table 4. Revised Realization and Dropping Rate of Structural Case in Korean

In summary, our findings show that the rate of case dropping is relatively low and varies according to different registers. Although it has been assumed that structural case marker dropping is very frequent in spoken Korean, the rates are really not very high in the spoken Korean in our corpora. Even in the everyday conversation genre, the nominative dropping rate is 31% and the accusative dropping rate is 49%. Across the remaining registers, the nominative and accusative dropping rates average 12% and 4%, respectively.

The case dropping rate in the TV debate spoken corpus (8%) is quite similar to that in the formal address (8%) and news (8%) written corpora. In contrast, the spoken corpus of everyday conversation shows much more frequent case dropping overall (40%). The fact that the overall ellipsis rate is higher for the nominative (15%) than the accusative (10%) parallels Kwon (1989) and Hong et al. (1998). However, it is worth noting that the accusative case is most frequently dropped in the spoken corpus of everyday conversation. This finding emphasizes the importance of including genre in any analytical account of case dropping.

We further emphasize that annotation criteria play an important role in identifying the exact rates of case realization and dropping. For instance, deciding whether to include light verb combinations or not was crucial to drawing conclusions regarding case ellipsis. This suggests that language specific properties of morphosyntactic combinations as well as idiosyncratic semantic and pragmatic features are to be

## [2] Idiosyncratic Combinations

Some syntactic combinations do not sound natural with the occurrence of a structural marker. The frozen combination “N + 말고” *malko* meaning ‘excluding N’ and “N + 가지고” meaning ‘as for’ behave as sort of fossilized expressions, like idioms. In these cases, it is grammatically unacceptable or awkward to insert the structural case between a nominal and the predicate form. We exclude these from case ellipsis examples. However, there are somewhat controversial cases. In the following idiosyncratic combinations, structural case markers are not completely disallowed, although they do not sound natural. Consider the following examples.

- (7) 동대문            그        쇼핑타운-(#이)            있잖아...  
Dongdaemun    ku        syophingthawun-(#i)        isscanha...  
Dongdaemun    that        shopping town-(Nom)        exist  
‘Speaking of the shopping town in Dongdaymun...’

The copular 있다 *issta* meaning ‘exist, have’ in Korean appears with one or two nominals with the nominative marker 이/가 *i/ka*. However, the combination of N + 있잖아 *isscanha*, which is an inflectional form of 있다 *issta*, sounds more natural without the nominative marker when it means ‘speaking of N’. It is the same for 아니다 *anita* ‘be not’. The combination N + 아니야 *aniya* is used as a confirming question meaning ‘isn’t it N?’ as in (8).

- (8) 대한문-(#이)            아니야?  
Dayhanmwun-(#i)        aniya?  
‘Isn’t it Dayhanwun?’

The sentence in (8) is more natural when the structural case marker does not appear. However, it is not completely awkward when the case marker is realized. We argue that these forms are in the process of lexicalization and should not be counted in as case dropping.

## [3] Idiomatic Chunks

Similar to the idiosyncratic combinations, the nominative and the accusative tend to disappear in idiomatic phrases as in (10)

(9) 뿌리-(가) 깊다	매듭-(을) 짓다	미역국-(을) 마시다
ppwuli-(ka) kiphtta	maytup-(ul) cista	miyekkwuk-(ul) masita
root-(Nom) deep	knot-(Acc) make	seaweed soup-Acc drink
‘inveterate’	‘finish’	‘fail (in exam)’

A notable difference between idiosyncratic combinations and idiomatic chunks in (10) is the recoverability of the case markers. In (10), the structural case markers can appear in the combinations without affecting grammatical judgment. By focusing on the recoverability without affecting grammaticality and meaning, we include these combinations as case ellipsis.

[Gerund Formations]

Similar to idiomatic chunks, the structural case markers tend to disappear in -음 -um or -기 -ki gerund formation. In particular, the accusative case 을/를 -ul/lul is more likely to be dropped as in (10).

(10) 역사(-를) 바로 알림-은 매우 중요한 과제이다.
yeksa-(lul) palo alli-m-un maywu cwungyoha-n kwacey-ita.
history-(Acc) correctly inform-Gen-Top very important-Rel assignment-Cop
‘Accurate knowledge of history is a very important assignment.’

The accusative case marker does not make the sentence unacceptable in (11). We count these gerund formations without a structural case marker as case ellipsis cases. However, we exclude some lexicalized combinations that work as single word units such as 영화 보-기 *yenghwa po-ki* ‘movie watching’, 그림 그리-기 *kulim kuli-ki* ‘picture painting’, etc. In these lexicalized combinations, inserting a case marker triggers ungrammaticality.

In summary, we used recoverability as our main annotation criteria for determining case dropping. Wherever it was allowed to recover the missing case marker without changing the grammaticality or meaning of a sentence, we assumed the existence of missing case markers.

4.2. Some Linguistic Properties of Case Dropping and Realization

While annotating the corpus, we found that there are some interesting linguistic factors involving in case dropping and realization. In this section, we discuss linguistic properties associated with case dropping and realization.

#### 4.2.1. Definiteness/Specificity

It is noteworthy that a structural case marker is likely to be dropped when the preceding noun is definite or specific. While dealing with ellipsis of nominative case, Kim (1991) also pointed out that nominative case dropping is related to definiteness and specificity. In (11), the nominative marker *이* cannot be dropped after the indefinite nominal *어떤 학생* *etten haksayng* ‘a student’. This contrasts with the fact that the first pronoun *나* and the definite expressions including *그 영화* *ku yenghwa* ‘that movie’ in (12) and *그 여배우* *ku yepaywu* ‘that actress’ in (13) appear without a case marker.

- (11) 길-에서 어떤 학생-이/\* $\emptyset$  나-에게 말-을 걸었다.  
 kil-eyse etten haksaeng-i/\* $\emptyset$  na-eykey mal-ul kelessta.  
 street-on some student-Nom/\* $\emptyset$  I-to talk-Acc started  
 ‘On the street, some student talked to me.’
- (12) 나- $\emptyset$  그 영화- $\emptyset$ /\*-가 굉장히 인상적이었어.  
 na- $\emptyset$  ku yenghwa- $\emptyset$ /\*-ka koyngcanghi insangjeokiesseo.  
 I- $\emptyset$  that movie- $\emptyset$  incredibly impressive.  
 ‘For me, the movie was incredibly impressive.’
- (13) A: 니콜 키드먼 있잖아....  
 Nicole Kidman issanha....  
 Nicole Kidman as for  
 ‘As for Nicole Kidman...’  
 B: 아, 나 그 여배우- $\emptyset$ /\**lul* 좋아해.  
 A, na ku yepaywu cohahay.  
 Ah, I that actress like  
 ‘Ah, I like that actress.’

The semantic property of pronouns as definite expressions is related to their frequent case dropping. A common pattern we found in the spoken corpus was  $[NP_i + Pronoun_i]$ , where a pronoun immediately follows its antecedent NP. In general, neither the NP or the pronoun takes a case marker. An example is shown in (15b).

- (14) a. A: 쌍생아-<sub>i</sub>-도 뭐.... 좀 우울해서 영화-가....  
 Ssangsaynga-to com wuwulhayseo yenghwa-ka  
 S-also little depressing movie-Nom  
 ‘The movie *Ssangsaynga* is a bit depressing...’

B: 포스터-Ø 보고 그거<sub>i</sub>-Ø 봤어.  
 poste-Ø poko kuke<sub>i</sub>-Ø pwasse.  
 poster saw it watched

‘(I) saw the poster and watched it (movie).’

- b. 제이-의 천밀밀-하는 거, 그거-Ø 봤-는데 그거-Ø 괜찰더라.  
 ceyi-uy Chemmilmil-hanun ke, kuke-Ø pwass-nuntey kuke-Ø kwaynchanhtela.  
 second Chemmilmil-called thing, it saw-and it good  
 ‘(I) saw the thing (movie) called the second *Chemmilmil* and it was good.’

#### 4.2. 2. Background Knowledge

Another interesting factor involving case ellipsis is a pragmatic feature that includes background knowledge (or familiarity) in the discourse. In the following example, it is more natural to use (15) without the accusative case when spoken in a store. In contrast, the accusative case seems to be required in (16) especially when the speaker comes to know a new fact without any background information. Furthermore, when a new entity 제 친구 *cey chinkwu* ‘my friend’ is introduced in the discourse, the case marker dropping rate seems to be low.

- (15) (in a store) 담배-를<sup>?</sup>/-Ø 주-세요  
 tampay-lul<sup>?</sup>-Ø cwu-seyyo.  
 cigarette-Acc give-imp  
 ‘Please give me a cigarette.’

- (16) (surprised at the news without background information)  
 제 친구-가 물건-을/\*-Ø 훔쳤어요?  
 cey chinkwu-ka mwulken-ul/\*-Ø humchyesseyo?  
 my friend-Nom thing-Acc stole  
 ‘Did my friend steal things?’

In addition, personal pronouns tend to appear without case markers. This is because the speaker and the hearer exist in the background. Although these pronouns are easily dropped in a pro-drop language like Korean, when they appear in a sentence, the nominative or the accusative case is likely to be missing as in (17).

- (17) a. 나 장사나 해 볼까 하구.....  
 na cangsa-na hay polkka haku....  
 I business-like do intend ....  
 ‘I intend to do business or something like that.’
- b. 너 외로워도 잘 버티잖아?  
 ne oyloweto cal pethicanha?  
 you lonely well stand  
 ‘Even if you are lonely, you stand it well, don’t you?’

#### 4.2.3. Valence of Predicates

Valence of a predicate is associated with case dropping in Korean. Kim (1991) claims that the fewer arguments the predicate allows, the easier dropping of the nominative case marker becomes. Also Park (2006) shows that the subject of an adjective, one place intransitive verb, or copula tends to appear without the case markers. Our data is consistent with their arguments with respect to the nominative case marker.

#### 4.2.4. Focus/Emphasis Interpretation with Case Realization

There are constructions in which a case marker appears even though it is not required. This is an addition phenomenon as opposite to a dropping one. In the following examples, a temporal expression is an adjunct and does not require any structural case marker. However, the accusative marker appears with the temporal adjunct phrase while adding a focus or emphasis interpretation on the phrase.

- (18) A: 나-도 한 시간 동안 떠드니까 목이 아파서....  
 na-to han sikan tongan ttetunikka mok-i aphase....  
 I-also one hour period spoke-since throat –Nom hurt  
 ‘Since I spoke for an hour, my throat hurts...’
- B: 왜 그래? 작업-도 한 시간-을 넘게 하면서...  
 way kulay? cakep-to han sikan-ul nemkey hamyense...  
 why do work-also one hour-Acc over do  
 ‘Why? You do work for more than one hour.’

Lee (2004) shows that the structural case markers can be added to adjunct phrases and argues that it depends on the specific meaning functions of the case markers in Korean. The focus interpretations with case addition can be found in the dependent noun phrases including 수 *su*, 바 *ba*, 줄 *cul*, etc.

(19) 계획-이 이루어질 수 있을지-에 대한 우려-를 떨칠 수-가 없다.  
 keyhoyk-i iluecil su issulci-ey tayhan wulye-lul ttelchyl su-ka epsta.  
 plan-Nom accomplish way possible- about worry-Acc remove way not exist  
 ‘(We) can’t get rid of the worry about whether the plan will be accomplished.’

The dependent noun combinations are similar to idiomatic chunks although they have more flexible inflectional variations. The nominative or accusative case is not required after these dependent nouns. However, when there is an emphasis on the whole meaning of the expression, 수 없다 *swu epsta*, a case marker can be added to the dependent noun as in (19).

## 6. Summary and Further Work

In this study, we conducted a corpus analysis for case marker realization and dropping with four different registers. A crucial finding is that the rate of case dropping in Korean is not as high as in the general assumption that case markers freely disappear in spoken Korean. The total case dropping rate for nominative case is about 15% and for accusative case is about 10%. A more important fact is that register plays a significant role in case dropping phenomenon. Within the spoken corpus, the case dropping rate varies depending on genre properties. In everyday conversation the accusative case dropping rate reaches 49%, whereas it is only 6% for TV debate. We claim that the implication of these findings is significant not only for linguistic theory, but also for applied linguistics including Korean pedagogy and language acquisition, language processing, and translation.

In our annotated corpus analysis, we presented our specific guidelines for case ellipsis and some relevant linguistic properties. Since our main focus was given to case realization and dropping of the nominative and the accusative, we did not include other particles such as topic marker and delimiters in this study. A further extensive statistical and theoretical approach to general realization and ellipsis with respect to particles is required for the future study.

## Abstract

In 2006, the National Institute for Japanese Language launched a five-year project for the compilation of a large-scale corpus of contemporary written Japanese. This 100 million words corpus is called the *Balanced Corpus of Contemporary Written Japanese* (BCCWJ). The most notable characteristic of the BCCWJ is its rigid sampling. The technique of random sampling is applied to two statistical populations that cover the production and circulation aspects of contemporary written Japanese. This paper describes how we designed these populations.

**Keywords:** BCCWJ, balanced corpus, representativeness, statistical random sampling

## 1. Introduction

Since 2006, the compilation of a 100 million words corpus of written Japanese has been underway at the National Institute for Japanese Language (NIJLA). This corpus is called the *Balanced Corpus of Contemporary Written Japanese* (hereafter, BCCWJ), and it is the first and long-awaited balanced corpus of contemporary written Japanese. The BCCWJ covers a wide range of texts including books, magazines, newspapers, white papers, textbooks, Diet minutes, materials on the Web, and so on.

In this paper, we describe the outline of the BCCWJ with particular focus on the corpus design. In section 2, we sketch the history of corpus linguistics in Japan. In section 3, we illustrate the corpus design issues regarding the BCCWJ, with special emphasis on the definition of statistical populations from which the samples of the BCCWJ are randomly chosen. In section 4, we present the detailed procedure of sample extraction. Finally, in section 5, we argue on the issue of corpus representativeness.

## 2. Corpus linguistics in Japan

### 2.1 Pioneering works

Since the release of *Brown Corpus* in 1964, various electronic corpora have been compiled and released. In the last few decades, in particular, diverse types of corpora have appeared: written corpora, spoken corpora, learner corpora, historical corpora, multi-lingual and parallel corpora, multi-modal corpora, and so on. The development of these corpora has enabled various applications such as analysis of polysemy, computation of word frequencies, quantitative analysis of grammatical expressions, corpus-based compilation of dictionaries, and not to mention, the use of corpora in natural language processing. There is no doubt that corpora will play a vital role in the linguistics of the 21st century.

NIJLA has been working on quantitative studies of contemporary Japanese since its establishment in 1948. For example, in the survey of *Vocabulary and Chinese characters in ninety magazines of today* published in 1962, a total of 440 thousand words were collected using statistical random sampling from the statistical population of 226,358 pages, which is the totality of pages in the 90 magazine titles published in 1956. The purpose of this survey was not only to describe the actual situation of contemporary Japanese at that time but also to obtain the list of “basic vocabulary” and that of Chinese characters that are frequently used in daily life.

A series of quantitative word surveys conducted by NIJLA in the 1960s can be regarded as pioneering works in corpus linguistics in Japan. However, data used in these studies were not made publicly available, and until recently, there was no consensus about the need for large shared corpora.

### 2.2 Recent works

Recently, NIJLA changed its traditional behavior and started to compile corpora that were designed to be publicly available. Until now, two corpora have been released: *Corpus of Spontaneous Japanese* (hereafter, CSJ) was released in 2004, and *Taiyo Corpus* was released in 2005.

CSJ is a large-scale richly annotated speech corpus: it consists of 661 hours, 7.52 million words of spontaneous speech (Maekawa, 2004). Its annotation includes two-way transcription, two-way parts of speech annotation, clause boundary labels, segment and intonation labels, speaker information, impressionistic rating data, and so on. CSJ has been widely utilized in the field of speech engineering for purposes such as

automatic speech recognition, speech summarization, and speech dictation. It has also been used in linguistics and psycholinguistics.

*Taiyo Corpus* is a collection of articles from the magazine *Taiyo*, one of the most popular magazines in prewar Japanese society. It includes 14.5 million characters of texts extracted from 3,400 articles published between 1895 and 1925. It was in this period that the writing style of Japanese changed drastically from a literary to a colloquial style. By analyzing *Taiyo Corpus*, it is possible to obtain detailed information on how that change took place.

Based on the experiences of these corpora, NIJLA has started a new five-year project for the compilation of the BCCWJ (Maekawa, 2007, 2008). Roughly speaking, the compilation procedure of the BCCWJ involves the following steps:

1. Corpus design: definition of the population and stratification
2. Sampling of texts to be included in the corpus
3. Copyright clearance
4. Text encoding and tagging by means of XML
5. POS annotation

In the following section, we illustrate the corpus design of the BCCWJ. In addition, our technique of statistical random sampling method is described; that is, how to define the population, how to stratify them, how to calculate the compositional ratio, and how to extract samples.

### **3. Corpus Design of the BCCWJ**

#### *3.1 Three component sub-corpora*

As shown in Figure 1, the BCCWJ consists of three sub-corpora that are called “Publication” sub-corpus, “Library” sub-corpus, and “Special-purpose” sub-corpus. The sizes of these sub-corpora are designed to be 35, 30, and 35 million words respectively as shown in the figure.

<i>Publication sub-corpus</i> Books, Magazines, and Newspapers published between 2001 and 2005 35 million words	<i>Library sub-corpus</i> Books published between 1986 and 2005, and registered in more than 12 public libraries in Tokyo 30 million words
<i>Special-purpose sub-corpus</i> White papers, Textbooks, Diet minutes, Web text (Internet Bulletin boards and blogs), Best-selling books, Verse, etc., published between 1976 and 2005 35 million words	

Figure 1 Inner structure of the BCCWJ

### 3.1.1 *Publication sub-corpus*

*Publication sub-corpus* (hereafter, PSC) is a component of the BCCWJ that aims to represent the actual state of the publication of contemporary written Japanese. We define the statistical population of PSC as the total number of characters printed in all the pages of books, magazines, and newspapers published between 2001 and 2005. Character is used as the basic unit of the computation of population, because it is not easy to determine the number of words involved in a given text. Japanese does not employ the writing convention of word spacing by means of a blank. Using the technique of stratified sampling, texts that were supposed to correspond to about 35 million words were extracted randomly from the population.

### 3.1.2 *Library sub-corpus*

Although PSC was designed based solely on the publication data that represents the “production” aspect of written Japanese, *Library sub-corpus* (hereafter, LSC) is a component that represents the “circulation” aspect of written Japanese. The statistical population for LSC is the set of books that are classified by the International Standard Book Number (ISBN), and registered in more than 12 public libraries of Tokyo metropolis. The size of population thus defined is almost the same as that of the book part of PSC. However, there is an important difference between LSC and the book part of PSC: the former does not include texts from the so-called “immoral” books.

### 3.1.3 *Special-purpose sub-corpus*

Some types of written text are of particular importance for some specific corpus-based analyses, but are rarely included in PSC or LSC. Examples include the texts of authorized textbooks and the text on the Web. *Special-purpose sub-corpus* is a component of the BCCWJ that has been specially designed to include this type of text. It includes texts from governmental white papers, authorized textbooks, Diet minutes, Internet bulletin boards, blogs, laws, verse, etc. Not all of these texts are necessarily chosen using the technique of random sampling.

### 3.2 *Two types of samples*

The next issue of corpus design is the length of individual samples. We defined two types of samples that differ in length. One of them is called *fixed-length sample* and consists of 1,000 characters; the other is called *variable-length sample*, and it covers the minimal structurally meaningful text unit such as a chapter, section, or paragraph with an upper limit of 10,000 characters. Fixed-length samples are necessary for various statistical inference purposes, while variable-length samples are useful for discourse analysis, linguistic studies with contexts, and stylistics.

Although variable-length samples will be provided in all three sub-corpora, fixed-length samples are provided only in PSC and LSC, which are assumed to be used for statistical inference purposes.

## 4. Sampling method of PSC and LSC

### 4.1 *Computation of the compositional ratio for PSC*

In this subsection, we illustrate how we defined the population of PSC, how we stratified it, and how we calculated the compositional ratio among the stratum.

First, we listed the titles of all the books, magazines, and newspapers published between 2001 and 2005. In the case of books, we used an online database called Japan Biblio Disc (*J-BISC*) as the source of data. *J-BISC* is a bibliographical catalog of the *National Diet Library*, which collects all the books published in Japan. We extracted records of 317,117 volumes including 74,911,520 pages from this database. Similarly, we identified 1,259 titles of magazines in 55,779 volumes including 10,414,955 pages, and 16 titles of newspapers in 49,625 volumes including 1,198,189 pages.

Second, we stratified these books into 11 categories according to the Nippon Decimal Classification (NDC), which is the book classification system by their subject

widely used in Japanese libraries. In the same vein, magazines were stratified into six categories by their genres, and newspapers were stratified into three categories by the extent of their distribution: nationwide, regional, and intermediate (semi nationwide).

The next step was the estimation of the total number of characters in each stratum. For this, we randomly selected 1,135 pages from 227 books, 265 pages from 53 magazines, and 211 pages from eight newspapers, and measured the printable area and the total number of characters printed for each of the sampled pages. As a result, we obtained a matrix showing the average numbers of characters printable in a page with a given area and the NDC. Part of the matrix is shown in Table 1. Non-italicized numbers are the average of the count, while italicized numbers are estimated by means of linear regression.

Table 1 Average number of characters printed in a page (Books, part)

NDC	Size	15 cm	16 cm	17 cm	18 cm	19 cm	20 cm	21 cm	22 cm
General		<i>410.8</i>	<i>442.0</i>	<i>473.3</i>	530.8	557.8	389.8	660.9	502.2
Philosophy		544.0	418.5	<i>473.3</i>	542.2	497.0	529.6	743.9	655.8
History		516.0	434.0	<i>473.3</i>	466.6	471.9	529.8	652.9	747.1
Social Science		413.8	<i>442.0</i>	<i>473.3</i>	456.0	602.5	603.0	618.6	885.9
Natural Science		<i>410.8</i>	<i>442.0</i>	290.8	457.0	469.1	631.6	680.8	801.1
Technology		430.4	396.0	<i>473.3</i>	340.8	409.9	539.0	672.8	815.5
Industry		<i>410.8</i>	<i>442.0</i>	<i>473.3</i>	558.8	513.9	511.6	448.3	1192.7
The Arts		503.6	492.8	<i>473.3</i>	451.2	573.4	654.5	667.1	638.8
Language		600.6	345.0	<i>473.3</i>	522.2	632.0	561.6	910.4	1052.0
Literature		435.2	487.2	<i>473.3</i>	482.8	447.8	501.4	753.3	585.3

In this way, we can estimate the total number of characters involved in each stratum or “genre” as shown in Table 2.

The total size of fixed-length samples was determined to be ten million words based on our prior knowledge about the series of NIJLA word surveys mentioned earlier. This size is considered sufficient for various statistical inference purposes. Since 1.7 characters correspond to a word in Japanese on an average, and a fixed-length sample consists of 1,000 characters, a total of 17,000 samples is required to obtain the material of ten million words. Table 3 shows the final compositional ratio of PSC. In addition to fixed-length samples, variable-length samples were also obtained. The average length of variable-length samples of books, magazines, and newspapers is estimated to be 3,900, 3,000, and 1,000 characters, respectively. The total size of PSC is then 34.7 million words as shown in Table 3.

Table 2 Number of Characters in each stratum of PSC

<i>Medium</i>	<i>Genre</i>	<i>Estimated Number of Characters</i>	<i>Compositional Ratio</i>	<i>Number of Samples</i>
<i>Books</i>	General	1,636,414,548	2.50%	425
	Philosophy	2,597,610,813	3.97%	675

	Block	1,296,592,154	1.98%	337
	Local	2,701,855,499	4.13%	702
	Subtotal	6,416,070,114	9.80%	1,666
<i>Total</i>		<i>65,471,677,099</i>	<i>100%</i>	<i>17,000</i>

Table 3 Compositional ratio of PSC

<i>Medium</i>	<i>Estimated Number of Characters</i>	<i>Compositional Ratio</i>	<i>Number of Words in Fixed-length Samples</i>	<i>Number of Samples</i>	<i>Number of Words in Variable-length Samples</i>
<i>Books</i>	48,539,925,351	74.14%	7,414,000	12,604	28,915,000
<i>Magazines</i>	10,515,681,634	16.06%	1,606,000	2,730	4,818,000
<i>Newspapers</i>	6,416,070,114	9.80%	980,000	1,666	980,000
<i>Total</i>	65,471,677,099	100%	10,000,000	17,000	34,713,000

#### 4.2 Computation of the compositional ratio for LSC

In this subsection, we describe the corpus design of LSC. As already noted, it was our design principle to make the population size of LSC nearly as large as the size of the book part of PSC. Consequently, it was expected that about 17,000 fixed-length samples would be obtained for LSC, and that there would be two comparable sets of book corpora, differing in their bibliographical attributes.

To achieve this aim, the statistical population of LSC should contain almost the same number of characters as the book part of PSC, i.e., 48,539,925,351 characters (see Table 2). By trial and error, we found that the best approximation was achieved when we chose the books registered in the public libraries of more than 12 wards and cities in Tokyo metropolitan area as the population for LSC. The population thus defined consisted of 335,721 volumes including 85,363,019 pages and 47,877,656,072 (estimated) characters. Table 4 compares the size of the populations of PSC and LSC, and Table 5 shows the estimated number of characters in each stratum of LSC. Lastly, Figures 2 and 3 compare the compositional ratios of the book samples of PSC and LSC with respect to the NDC.

Table 4 Population size of PSC (Books) and LSC

	PSC (Book)	LSC
Volumes	317,117	335,721
Pages	74,911,520	85,363,019
Characters	48,539,925,351	47,877,656,072

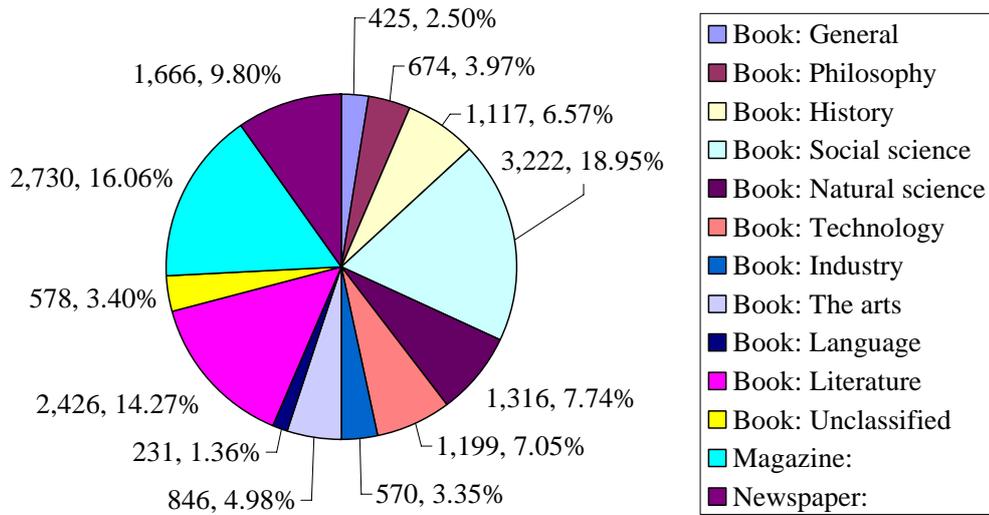

Figure 2 Compositional ratio of PSC

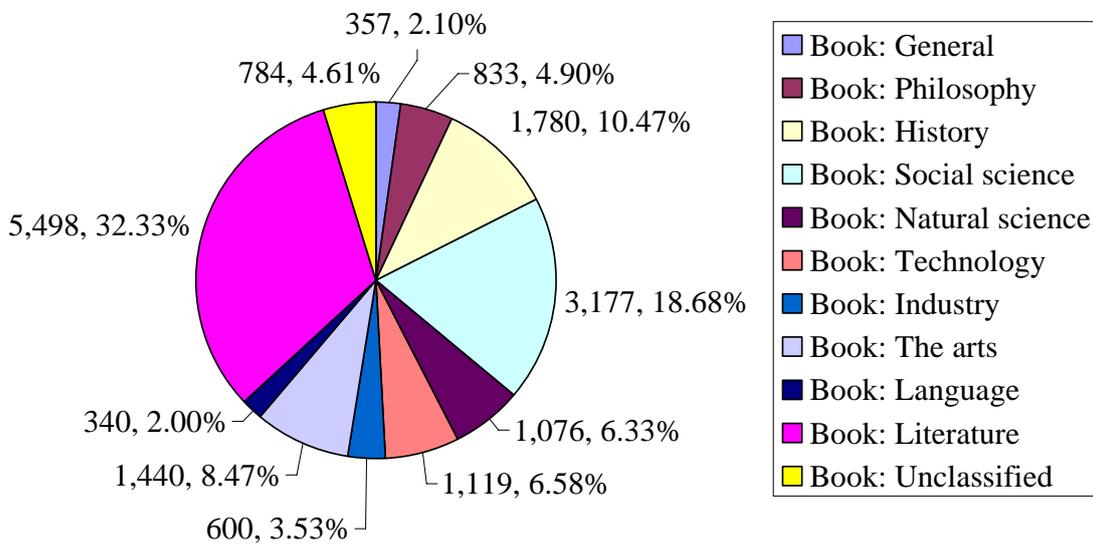

Figure 3 Compositional ratio of LSC

Table 5 Number of characters in each stratum of LSC

<i>Medium</i>	<i>Genre</i>	<i>Estimated Number of Characters</i>	<i>Compositional Ratio</i>	<i>Number of Samples</i>
<i>Book</i>	General	1,003,528,880	2.10%	357
	Philosophy	2,343,849,711	4.90%	833
	History	5,010,749,621	10.47%	1,780
	Social Science	8,946,058,392	18.69%	3,177
	Natural Science	3,028,276,363	6.33%	1,076
	Technology	3,149,144,051	6.58%	1,119
	Industry	1,690,150,481	3.53%	600
	The Arts	4,057,291,256	8.47%	1,440
	Language	956,625,910	2.00%	340
	Literature	15,485,091,056	32.34%	5,498
	Unclassified	2,206,890,351	4.61%	784
<i>Total</i>		47,877,656,072	100%	12,604

### 4.3 Extraction of samples

Once the compositional ratio has been determined, the next stage of corpus compilation is the extraction of samples from the printed materials. In order to guarantee the randomness of our sampling, all the characters of the population must have the same probability of being sampled.

To achieve this aim, we adopted the following sample extraction procedure. First, all pages in the population were randomized by computer and sequentially numbered. Second, if the number of samples to be extracted from the population was equal to N, the first N pages of the ordered set of pages were chosen for further processing. Third, one printed character was chosen randomly for each of the N extracted pages as the “sampling point.” Figure 4 shows how the selection was made. The target page was demarcated into 100 areas by applying a mesh of 10 by 10, and one of the 100 nodes (intersections) in the mesh was chosen randomly. The character that was closest to the chosen node (indicated by a red arrow in the figure) was chosen as the sampling point. Finally, 1,000 characters that followed the sampling point were chosen as the fixed-length sample. At the same time, the minimal structural unit such as a chapter, section, or paragraph was chosen as the variable-length sample.

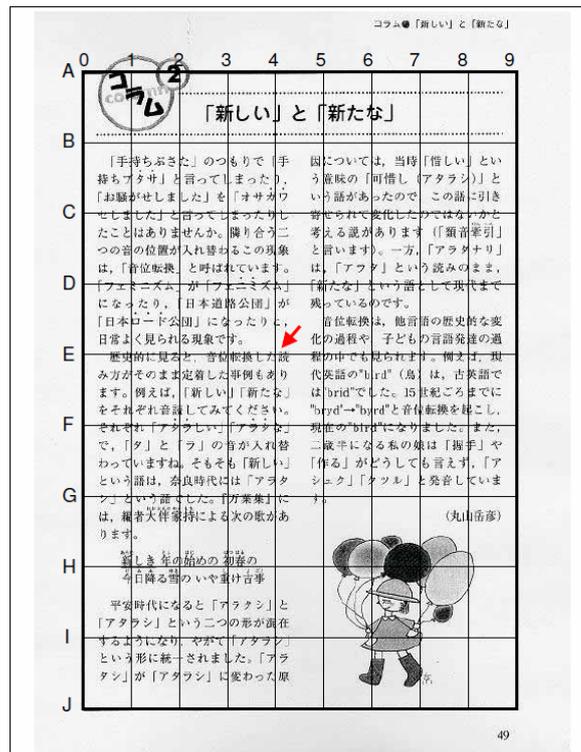

Figure 4 Selection of sampling point in a page

Figure 5 shows the sample extraction from a more complicated book page. The circled character on the left-hand page (note that this figure is a double truck image of a book) indicates the sampling point. The fixed-length sample starts with this character and ends somewhere on the following page (which cannot be seen in the figure). The variable-length sample, on the other hand, begins at the title of the section that is printed on the right-hand page, and is marked by a handwritten digit “1.” In this case, the variable-length sample involves a quotation in classical Japanese, which is deleted from the sample. The handwritten square with a criss-cross indicates the extent of the text to be omitted from the sample (note that the handwritten letter “d” is for “deletion”). There also is a figure in the left-hand page of Figure 5, which indicates that a non-verbal element such as this is to be omitted from the sample.

Most of the sample in the BCCWJ was selected in this way. The samples thus chosen (both fixed- and variable-length) are then fed into a computer using the UTF16 as the encoding scheme. Structural and POS tagging of the samples is done in the following stages of corpus compilation, but limited space requires us to omit the explanation of the tagging process.

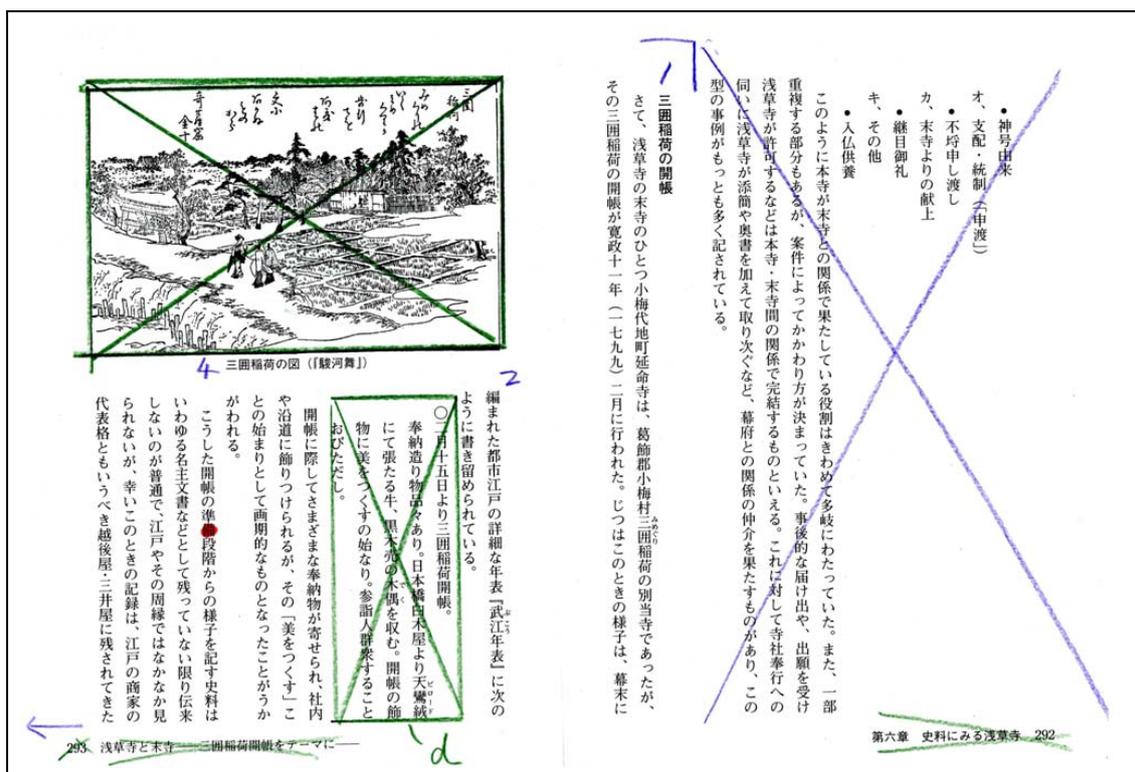

Figure 5 Example of sample

## 5. Concluding remarks

Biber (1993) claimed that if a corpus is to be used for any quantitative or statistical inference purposes, the population of the corpus must be carefully investigated and strictly defined before sampling. However, in the history of corpus linguistics so far, it seems that a rigid consensus about the concept of corpus balance is yet to be achieved by researchers. There is probably no unique solution to this problem, but this does not mean that we can do nothing to achieve better balance of a corpus. We can at least clarify the objective criteria used in the definition of corpus population as we have tried to do in this paper. Given the criteria of corpus population, there is some possibility of evaluating the successfulness of corpus sampling. In this respect, we would like to point out that most of the currently available “balanced” corpora, including famous ones like Brown Corpus and BNC, are far from being satisfactory.

Needless to say, the final evaluation of a corpus can only be made after its public release, because the effectiveness of a corpus will vary depending on the purpose for which it is used, and it is not easy to predict, before its public release, the way in which a corpus will be used.

The public release of the BCCWJ is scheduled for the year 2011. The ultimate evaluation of the corpus should be provided by the users of the corpus who, we expect, include not only linguists but also researchers and practitioners in diverse related fields.

## Abstract

The issues this paper addresses are the sonority conversion, which is defined as different ranking of sonority in a certain language, and the case taken from a variety of English. While Rhotic has larger sonority value than Lateral and Nasal in the general ranking, in Present-Day American English the tap, a rhotic, is less sonorous than the lateral and nasals but more sonorous than obstruents. In addition to attested phonological and phonetic nonrhoticity, the sonority-based criteria on the former involve syllabic consonant formation, tautosyllabicity of clusters, segments preceding syllabic consonants and the ban on the sequence of three sonorant consonants and those on the latter the least satisfaction regarding the Syllable Contact Law and the restriction on syllable-final tapping.

Keywords: the sonority conversion, tap, lenition, tongue movement, the Maximum Coda Principle

## **1. Introduction**

Classical phonology established general sonority scale, in the sense that the ranking holds to every language. There exists, however, different ranking of sonority in a certain language, which is referred to as the sonority conversion. Previous research has provided only limited cases on this subject: those between semivowels and liquids. It is the purpose of this paper to uncover a different sort of the sonority conversion: the lower sonority of Present-Day American English (henceforth AmE) taps relative to the lateral and nasals.

AmE taps are a widespread allophone derived from underlying /t/ or /d/:

(1) better, city, water, party, center, gulty, atom, daddy

Consonant lenition or consonant weakening is grounded in the phonetic motivation that effortful consonants shift to effortless ones and gives rise to reduction in constriction degree or duration (Kirchner 2001, 2004).<sup>1</sup> While consonant lenition (e.g. /t/ → [ʔ], /f/ → /v/) is typical to intervocalic positions, some, not all, of the

AmE tapings are equal to the generalization (cf. those in 1).

AmE has both flap and tap (e.g. Ladefoged 2006: 171). Phonetically, the former requires the tongue to be curled up beforehand, while the latter does not. Phonologically, 'r'-coloured vowel in the rhyme is pronounced as the former, while intervocalic consonant, for the most part, in the coda as the latter. This paper is concerned with the tap in AmE. It belongs to rhotic like those in other languages (e.g. Trask 1996: 350), but, in my assertion, the tap has smaller sonority value than the lateral and nasals, contrary to the general hierarchy. This fact therefore functions as a piece of evidence with respect to the sonority conversion.

The present paper is structured as follows. Section 2 introduces previous research and objective criteria on the sonority conversion. Section 3 examines related phonological and phonetic phenomena, according to which the AmE tap differs from the majority of rhotics. Section 4 adduces four pieces of evidence on the less sonorous tap than the lateral and nasals and section 5 two pieces of evidence on the more sonorous tap than obstruents. Each of the six conditions is, by and large, sonority-based. Section 6 gives concluding remark.

## **2. The Sonority Conversion**

Sonority means relative loudness of segments. Important works on sonority include Selkirk (1984), Clements (1990), Rice (1992), Blevins (1995), Zec (1995) and de Lacy (2004). Other things being equal, a segment with higher sonority has more loudness than the other with lower sonority. The opposite ranking of sonority is referred to as consonantal strength (Murray and Vennemann 1983, Vennemann 1988). The general sonority hierarchies for both consonants and vowels (see de Lacy 2004 and Kenstowicz 2004 for that for the latter) are demonstrated independently of each other and High Central Vowel has higher sonority relative to Semivowel by the distance of one:

(2) The general sonority scale for consonants

Semivowel > Rhotic > Lateral > Nasal > Voiced Fricative > Voiceless Fricative > Voiced Stop > Voiceless Stop

(3) The general sonority scale for vowels

Low Vowel > Mid Peripheral Vowel > High Peripheral Vowel > Mid Central Vowel > High Central Vowel

In the rankings in (2) and (3) Semivowel and Low Vowel are the most sonorous,

respectively. In order to clarify this scale, pronounce, for instance, coronal semivowel, coronal nasal, coronal voiceless fricative and coronal voiceless stop in your language. Incidentally, the four segments have crosslinguistically high frequency and the sonority conversion has not been observed between each of the consonants. The ranking of sonority below shows the general one of semivowels and liquids in the level of each segment (/j/ has the largest value):

(4) /j/ > /w/ > /r/ > /l/ (e.g. Kiparsky 1979: 432)

The sonority conversion tends to happen between semivowels and liquids, as claimed in Hankamer and Aissen (1974: 137-139).<sup>2</sup> The one that, for example, /r/ is more sonorous than /w/ suggests a case of the sonority conversion owing to the different ranking from the general one:

(5) Sanskrit  
/r/, /j/ > /w/ > /l/ (Steriade 1982: 329)

(6) Early West Germanic  
/j/ > /r/ > /l/ > /w/ (Suzuki 1989, 1996: 297-307)

I observe that the cases of the sonority conversion like above are assumed to rather commonly occur in other languages than Sanskrit and Early West Germanic under the conditions of, for semivowels and liquids, a wide variety of variations and changes and the difference between onsets and rhymes. The former make the segments, in some cases, more vocalic and, in others, more consonantal. In the latter, on the basis of syllabic generalizations, the segments become more consonantal in the onset and more vocalic in the rhyme. I use the term the sonority conversion when discussing the current issue. This paper defines *the sonority conversion as different ranking of sonority in a certain language, in comparison with the general ranking.*

Then, it must be considered whether the analysis of the sonority conversion is built on experimental phonetics or phonological pattern. The one based on experimental phonetics does not give correct analysis due to the following three reasons; (a) sonority differs among speakers so that others give rise to different result; (b) it also diverges for every speech and can not be valued correctly; (c) it becomes different between the onset and the coda, for consonants, or between stressed and unstressed syllables, for vowels. For some consonants and vowels which occur in both of the environments, sonority differs according to the positions. For instance, in PDE, the sonority of /l/ differs between stressed and unstressed syllables and that of plain [t] between the onset and the coda. The former is ascribed to the much stronger pronunciation in stressed syllables and the latter

stems from the difference between released stops in the onset and both released and unreleased ones in the coda. The one in the stressed vowel and the one in the onset are more sonorous for each segment, respectively.

The sonority conversion is highly relevant to syllables and after the notion of syllables was established, the research on the sonority conversion began. Needless to say, this line of research necessitates the prerequisite that phonologists have intuitions on sounds, but the objective criteria for the sonority conversion must be based on phonological generalizations relevant to sonority. More specifically, the following become the key factors on this issue: the Sonority Sequencing Principle, the Syllable Contact Law, the Nucleus Constraint, sonority-based syllabification, all of which being sonority-based and deriving possible or impossible patterns from the highest or the lowest limit; the case is that a sonority-based phenomenon occurs, if a segment is, say, more sonorous than Voiced Fricative or less sonorous than Rhotic. Phonological derivations (i.e. strengthening and weakening processes, derivations and crosslinguistic patterns) and phonetic difference (e.g. lip-opening for vowels and movement and posture of the tongue for consonants) are added to another pieces of evidence. Needless to say, the Sonority Sequencing Principle, the Syllable Contact Law and the Nucleus Constraint are based on syllables and the sonority. The Sonority Sequencing Principle specifies the rise and fall of sonority for consonants preceding or following syllabic nuclei. The second one defines the preference of higher sonority of final segment in the preceding syllable and of lower sonority of initial in the following syllable. The third gives the generalization that nuclei are occupied by a more sonorous segment than onsets and codas. The claim that the sonority conversion is based on phonological generalizations related to sonority is justified due to the fact that the evidence is considered to be objective, definite and accountable for it. In terms of accountable evidence following the intuition on sounds, pattern-oriented generalizations for the sonority conversion are compared to allophonic distributions for syllabifications.

### **3. Phonology and phonetics of AmE taps**

#### **3.1. Phonological derivations**

As stated, AmE taps are derived from an alveolar stop as a phonetic variant:

(7) /t, d/ → [ɾ]

The derivation in (7) stems from the following facts; since AmE speakers might possibly pronounce the alveolar stops in the same environments as those of the tap, the underlying /t/ or /d/ makes sense (simple derivation, including identical form between input and output, is one of the factors to analyze underlying forms); the tap commonly appears in intervocalic position, where consonant lenition processes, like that in (7), have high frequency both in English and crosslinguistically.

In (7), there is much distance of the sonority in comparison with other types of consonant lenition. Providing the tap has the sonority as the rhotic in the general ranking in (2), both of the sounds differ by the degree of 5 or 6. Many other consonant lenition processes have the difference by the degree of 1 or 2 (e.g. /t/ → [d], /k/ → [x]). This means that, given the general sonority hierarchy, the derivation of the AmE tap is unusual.

Taps in many languages outside English are derived from /r/. The languages contain, for instance, Japanese (Kubozono 1999: 47), Norwegian (Kristoffersen 2000: 24), Modern and Present-Day British English (Wells 1982: 43), the Indo-Aryan language Marathi (Pandharipande 1997: 542) and many others. The four languages above do not refer to all of the ones with the derivation, but represent only some examples.

Owing to the fact that taps belong to rhotic, the taps derived from /r/ are considered to be more natural than those derived from coronal stops. Derivations are likely to have cause and effect. As a matter of fact, a relevancy between the sonority conversion and derivation is observed in other case. In Early West Germanic /w/ was less sonorous than /r/ and /l/, as shown in (6), and obstruents were historically derived from /w/. The /w/ in /wr, wl/ clusters in Early English and the phoneme itself in other Early West Germanic languages underwent the phonological change:

(8) Early English

/wr, wl/ → /br, bl/

/wr/ → /vr/

(Minkova 2003: 367 and others)

(9) West Germanic languages other than English

/w/ → fricative

(Suzuki 1989: 33 and others)

The /w/ in Early West Germanic constitutes the input and the AmE tap the output. Be that as it may, the derivation of the Early West Germanic /w/ is related to the consonants with lower sonority and the /w/ has lesser sonority value. It is the first step, therefore, that since the AmE tap is derived from the consonants with lower

sonority, the tap is expected to be less sonorous than other rhotics.

The lenition from coronal stop(s) to rhotic, like the AmE tap, holds, in total, to 16 languages all over the world (Kirchner 2001: 80). This type of derivation is involved in Late Modern and Present-Day British English (cf. Wells 1982, Broadbent 2008), but there is no clear evidence that this rhotic shows an example of the sonority conversion. It is not the case that all of the languages with the phonological process relate to the sonority conversion. In particular, the British tap may have phonological evidence, but not phonetic one in the literature. Thus, the phonological aspect does not adduce the enough evidence and the phonetic aspect must be examined.

### 3.2. Phonetic movements

The tap and coronal stops in AmE share the articulator of alveolar ridge, but have different manner of articulation. Thus, they are predicted to have some articulatory difference. The tap in AmE is different from those in other languages and may or may not be identified with voiced /t/ (Wells 1982: 248-252). Although flaps and taps do not have identical articulation, de Jong (1998) focuses on the AmE flapping and observes that the motion of the tongue is very similar between flap and [d]. This paper expects the phonetic characteristic to be grounded in the following articulation of the general sounds at issue and the AmE tap; while, for tap and flap, the front of the tongue moves rapidly to the alveolar ridge and returns to the neutral position, for [d], it firmly attaches to the alveolar ridge or the dental; in this articulatory way, the AmE tap is approximately between the rhotic in general and the coronal voiced stop in general; the AmE tap has the tongue contact between the quick and firm attachments on the alveolar ridge. The articulatory way sounds not only like a rhotic, but also like a voiced stop (e.g. the pronunciation of the AmE tap in the words *better* and *city*). The AmE tap therefore sounds like between rhotic and coronal voiced stop in other languages.<sup>3</sup> This makes a sharp contrast with the central approximant of /r/, which is phonetically identical to schwa except for the obstruction of air flow (Gick 2002).

It is therefore predicted that AmE taps are not exactly a rhotic consonant in terms of sonority scale.

In the remainder of this article several pieces of sonority-based evidence on the language-specific ranking of AmE taps will be posited.

#### 4. The smaller sonority value than the lateral and nasals

##### 4.1. The nonsyllabicity of the tap

The nuclei of a syllable are highly relevant to sonority since, assuming a basic syllable theory, they must have larger sonority scale than the onset and the coda. The following constitutes one of the syllable-based generalizations:<sup>4</sup>

(10) HNuc (The Nuclear Harmony Constraint)

A higher sonority nucleus is more harmonic than one of lower sonority. (Prince and Smolensky 2004: 20)

Sonority plays an essential role in the status of nucleus. Basically, all vowels occupy the nuclei of a syllable and have larger sonority value than all consonants. Sonorant consonants have much more possibilities of syllabicity than obstruents due to the higher sonority and the mid sonority of sonorant consonants has a clue to the analysis in this section.

Let us observe the examples showing the relevancy between sonority and syllabic nuclei in AmE:

(11) a. how      b. way  
      [hæw]    [wej]

(12) a. /w/ quality, dwell  
      b. /j/ beauty, huge

(13) a. near      b. cure  
      [nɪr]      [kjʊr]

First, the semivowels in (11) occupy the second elements of the diphthongs (e.g. Roach 2000:125). The AmE notations differ from the corresponding British ones. The semivowels have the largest sonority value among consonants (see the hierarchy in 2). Second, semivowels occur also in the onset either as singleton or as the prevocalic consonant of clusters. Concerning the latter semivowels as in the words in (12), /j/ constitutes a part of the nucleus and /w/ a part of the onset (cf. Davis and Hammond 1995) and /j/ is more sonorous than /w/ in the sonority hierarchy of the individual segments in (4). Thus, the more sonorous one becomes a part of the nuclei. Third, the examples in (13) show that /r/ occupies the second element of the diphthongs. Rhotic has the second largest consonantal sonority following semivowels and consonants with lesser sonority than rhotic are banned in the position. The generalization of more sonorous nuclei, therefore, holds to the sonorant consonants in AmE.

Next, we turn to observe the following pairs of pronunciations. AmE speakers implement the syllabic consonants in (14), but not those in (15) (cf. Wells 2008 for the nonsyllabic taps in AmE):

- (14) a. fishery    b. struggle    c. oftn    d. happen    e. broken  
           [r]            [l]            [n]            [m̩]            [ŋ]
- (15) a. density    b. syllabicity    c. specifity  
           \*[ɹ]            \*[ɹ]            \*[ɹ]

Then, the relevancy between the phonetic implementation of each syllabic consonant and the sonority hierarchy must be examined on the basis of the facts that syllabic consonants occupy the nuclei of a syllable and that segments with higher sonority are more suitable for the nuclei.

On the one hand, all of liquids and nasals are capable of occupying a syllabic status. Among the segments that might become syllabic consonants, rhotics are the most sonorous and the lateral has the second largest sonority. In AmE, the close connection between higher sonority and syllabic nuclei is manifested in very frequent syllabic [r]. As other piece of evidence (Hammond 1999), stressed syllabic consonants consist of, for the most part, [r] or [r̩] (e.g. your, first, stir) and, with fewer frequencies, [l] (e.g. bull, mull). On the other hand, the AmE taps in (15) do not become syllabic, despite the environment of syllabic consonants of underlying schwa plus a liquid in unstressed syllables and of the less sonorous preceding segments. The nonsyllabic status of the AmE taps is shared by the majority of obstruents. While syllabic consonants occupy the nuclei of a syllable, the status of the tap differs from other sonorants.

Some phonological phenomena are grounded in phonetics (e.g. movement and posture inside oral cavity and duration), not in phonological ones (e.g. sonority and the OCP). As well as phonetically based phonological constraints (Boersma 1998, Flemming 2002, Hall 2004, Hayes and Steriade 2004, Kirchner 2001, Pater 1999, among others), some phonological changes have phonetic bases: Anglian Smoothing (Howell and Wicka 2007) and vowel syncope in Mussan (Blevins 2008). According to Oda (2008a), the increase and nonincrease of syllabic consonants in the history of English is accounted for by phonetic, not phonological, motivations. However, this does not mean that all aspects of English syllabic consonants are phonetically motivated. The argument in this section is what consonant occupies syllabic nuclei, different from the increase and nonincrease. The sonority of the former is irrelevant to the increase since the distribution of syllabic consonants remains similar throughout the every period of English.

## 4.2. Coda consonants

Syllable-based generalizations state that nonsyllabic consonants occur in the onset and the coda and that some, in particular allophones, are restricted to either position. As many phonologists (e.g. Kahn 1980, Selkirk 1982, Borowsky 1986, Gussenhoven 1986, Rubach 1996) have suggested, aspirated voiceless stops (i.e. [p<sup>h</sup>, t<sup>h</sup>, k<sup>h</sup>]) and the devoicing of sonorant consonants (e.g. [w̥, l̥]) are confined to the onset and glottal stops (i.e. [ʔ] derived from /t/) and the deletion and epenthesis of alveolar stops to the coda. The AmE tap occurs in coda-final positions (cf. the five papers above), although it is the correct expression that the tap appears in non-foot-initial positions (Jensen 2000, see also Kiparsky 1979).<sup>5</sup> All of the underlined segments in (16) are pronounced as the tap and syllabified in general to the coda:

(16) a. put it on    b. sent a letter    c. city    d. water

The tap is preceded by a vowel or by a vowel plus a sonorant consonant (cf. Kahn 1980, Selkirk 1982, Picard 1984, Borowsky 1986, Gussenhoven 1986, Wells 1990 and Rubach 1996). The majority of the examples in (16) demonstrate the taps preceded by a vowel. When the tap follows a sonorant consonant, the sonorant consonant is a rhotic (17a), the lateral (17b) or the alveolar nasal (17c):

(17) a. party    b. gilty    c. center

The underlined clusters have crosslinguistically very rare existence. Given the general sonority hierarchy in (2), those in the coda lateral plus rhotic and nasal plus rhotic violate the Sonority Sequencing Principle since the rhotic becomes more sonorous than the lateral and the alveolar nasal. Dimoraic rhymes in stressed syllables (the Stressed Syllable Law) hold to the majority of stress languages, but PDE has some, not all, stressed syllables with more than two morae. While the Stressed Syllable Law has the priority for some cases, other condition is superior for others. There is the agreement that AmE taps appear definitely in the coda unless the Stressed Syllable Law is used. It is therefore asked why the coda-final taps in (17) are allowed to occur despite the violation of the Stressed Syllable Law (i.e. three or four, rather than two, morae). Whether or not maximum syllabifications work is the clue to the violation.

Tautosyllabicity and sonority profile correlate with each other due to the Sonority Sequencing Principle. In Polish some marked onset clusters appear as phonotactic constraints and those like /rt/ and /lk/ in the onset violate the Sonority Sequencing Principle owing to the more sonorous first consonant:

(18)a. rtec ‘mercury’    kar.ty ‘cards’    b. lkac ‘sob’    pal.ka ‘stick’

When the onset clusters with the worse sonority profiles occur word-medially, they become heterosyllabic (Rubach and Booij 1990: 122). The profiles militate against the Maximum Onset Principle, which specifies that if phonotactic patterns of consonants are allowed, the consonants are maximally syllabified to the onset.

The second evidence in the same line stems from PDE. The Maximum Onset Principle tends to hold to the ones with good sonority contour like /dr/, but not to the ones with bad contour like /st/ (Treiman and Zukowski 1990) despite the fact that both are regarded as English phonotactic patterns:

(19) a. Madrid      b. estate  
      [mə'drɪd]      [ɪs'teɪt]

Present-Day English has the effect of the Maximum Coda Principle as well as the Maximum Onset Principle. The Maximum Coda Principle is suggested by Hammond (1999: 134) and Wells (1990) and supported by some pieces of allophonic evidence, but may operate only for some, if not all, examples and only for some speakers. Compare the underlined sequence in (20a) and that in (20b):

(20) a. helper      b. strengthen  
      ['hɛlp.ə]      ['strɛŋkθ.n]

I consider that, in that sense, if sonority profile is better, Max-Coda has higher effect and that the underlined segments in (20a) receives more possibility of the maximum syllabification than those in (20b). It is because the former has a good sonority profile but because the latter definitely does not. The examples in (18)-(20) converge to illustrate that the tautosyllabicities, more or less, are ascribed to the good sonority profiles. The examples with a sonorant consonant plus the tap in AmE are repeated below:

(21) a. party      b. guilty      c. center      = (17)

There is the crosslinguistic preference of the Stressed Syllable Law, but the examples with syllable-final tap in (21a-c) militate against it despite the rare coda cluster sonorant consonant plus tap. The reason why the Maximum Coda Principle has the priority over the Stressed Syllable Law stems from the account that the less sonorous tap than the lateral and nasals and other sonorant consonants render the Maximum Coda Principle applicable due to the satisfaction of the Sonority Sequencing Principle.

### 4.3. Less sonorous segments preceding syllabic consonants

The Sonority Sequencing Principle specifies that sonority scale decreases between two syllabic nuclei due to the larger sonority of them. In parallel, when a segment precedes a syllabic consonant, the preceding segment must be less sonorous than the syllabic consonant in view of the principle. In the following examples, each of the syllabic one is more sonorous than the preceding one by the degree of one (cf. 2):

- (22) a. even      b. final  
      ['i:vŋ]      ['fam]

By way of comparison, the following syllabic consonants are much rarer or never: the syllabic nasal preceded by the lateral and the syllabic lateral preceded by the central approximant of /r/ (cf. Wells 2008), both of the syllabic consonants, if implemented, being less sonorous than the preceding ones by the distance of one:

- (23) a. sullen                      b. laurel  
      ['sʌləŋ]    \*['sʌlŋ]      ['lə:rəl]    \*['lə:r]

The words in (23) have underlying schwa plus a nonsyllabic consonant like those in (22), but the syllabic consonant formation is inapplicable. As argued in section 4.1., syllabic nuclei are grounded in higher degree of sonority. In principle, the ban on the syllabic consonant formations in (23) is accounted for by stating that even if satisfied, they are counted as worse patterns on the basis of the sonority demotion (i.e. /l/ > /n/, /r/ > /l/).

The only one kind of exception is a sequence of two syllabic consonants, but there is the difference between nonsyllabic and syllabic consonants. It leads to different syllabic analysis: for the former, syllable margin and for the latter, syllable nucleus. Due to the explicit syllable break, the more sonorous preceding [r] relative to the following [ŋ] is irrelevant to the analysis of the sonority at issue:

- (24) reference  
      ['refrŋs]

Now examine the cases in which the tap precedes a syllabic consonant. Following the tap, AmE speakers pronounce syllabic [l] and syllabic [m], instead of the corresponding form with schwa:<sup>6</sup>

- (25) a. little      b. bottle  
      ['lɪr]      ['bɑr]
- (26) atom  
      ['ærm]

In these cases, if the taps have the sonority scale as Rhotic in the general ranking, the syllabic [l] and the syllabic [m] would not be pronounced in view of the syllable theory mentioned above. There exists no or almost no example where a preceding consonant, in either the onset or the coda, has larger sonority scale than the following syllabic consonant. The sequence tap plus syllabic [l] or [m] does not represent much rarer cases, but AmE speakers tend to pronounce them. Provided the taps are less sonorous than the lateral and nasals, the syllabic consonants in (25) and (26) function as the nuclei.

#### 4.4. The phonotactic constraint on triconsonants

When dividing consonants into obstruents and sonorant consonants on the basis of the sonority in broad terms, three types of diconsonantal clusters become possible: an obstruent plus a sonorant consonant (e.g. /pr/), an obstruent plus an obstruent (e.g. /st/) and a sonorant consonant plus a sonorant consonant (e.g. /mj/). Sequences of two sonorant consonants have a marked status (e.g. McMahon 1990: 221). The markedness is accounted for by the OCP, the ban on adjacent similar elements, and the sonority, with an obstruent plus a sonorant consonant highly valued. Instead of both of them, a cluster is grounded in articulatory phonetics. The marked cluster rhotic plus coronal glide (i.e. /rj/) stems from incompatible articulation and durational difference (Hall 2003, 2004). In AmE there exist three tautosyllabic clusters that consist of two sonorant consonants:

- (27) a. onset /mj/ (e.g. music)  
b. coda /lm/ (e.g. film), /ln/ (e.g. kiln)

The disonorants in (27) are thought of as marked clusters. First, only some everyday words include them. Second, in the diachronic view, the coda /lm/ appeared in Middle English and the other two sequences in Modern English (cf. Nakao 1985: 462-464). By contrast, the clusters such as /pl, kr, sp/ have the diachronic stability in English and have more causations for the relative unmarkedness. Third, they have crosslinguistically limited occurrences.

Assuming the markedness of the diconsonantal sonorants, partly because of the sonority, I predict that PDE has no sequence within a morpheme that consists of three sonorant consonants, although the clusters across the boundary of either a morpheme or a word appear (e.g. filmmaker, soul music). Both onset and coda clusters lack them and it is an impossible phonotactic pattern that a syllabic consonant is preceded and followed by a sonorant consonant within a morpheme.

Then, look at the following phonetic descriptions in (28). At first glance, the underlined segments consist of the sequence of the three sonorant consonants due to the alveolar nasal plus the tap plus, after the syllable break, the syllabic [r]:

- (28) a. center      b. international  
           [nr.ɾ]      [nr.ɾ]

It seems to be true that AmE does not have other case of the sequence of three sonorant consonants within a morpheme. This phonotactic constraint (i.e. the one banning the clusters, say, like /mlj/ and [n̩lm]) is posited in AmE and other varieties of English and, like diconsonantal sonorants, has the motivation of sonority. Both of the sequences shown above are made impossible due to the close distance of the sonority. The large difference of sonority in both cases makes the profiles allowed (e.g. [stj]upid, ta[b̩lz]). When the number of sonorant consonants changes from three into two, legal sequences also appear: a[mj]usement, fi[n̩]. To put it simply, my supposition is the following order of sonority: Vowel > Sonorant Consonant > Tap > Obstruent. In this view, the underlined segments in (28) consist of a sonorant consonant plus the tap plus a syllabic sonorant consonant, but not the sequence of three sonorant consonants. The pronunciations become legal due to the fact that the AmE tap has the lower sonority value than the lateral and nasals and differs from sonorant consonants in terms of the sonority scale.

## 5. The larger sonority value than obstruents

### 5.1. The Syllable Contact Law

One of the reasons for the more sonorous tap than obstruents stems from the Syllable Contact Law. The definition, slightly different from the earlier version, is cited from Murray (2000: 222):

- (29) the Syllable Contact Law

The preference for a string ...  $\sigma_x \sigma_y$  ... increases as the right edge sonority of  $\sigma_x$  increases and the left edge sonority of  $\sigma_y$  decreases.

In order to discuss the issue of whether a syllable contact is better or worse, look at the following examples (Although English syllabifications are well-known for the inconsistency, those in the following do not become controversial):

- (30) a. cowboy                      b. construction  
           ['kæw.bɔɪ]                      [kən'strʌk.tʃn̩]

(30a) represents better contact and (30b) worse one. The semivowel /w/ is much more sonorous than the voiced stop /b/ by the degree of six. The voiceless stop /k/ is less sonorous than the voiceless fricative /ʃ/ by the degree of two. (See the general hierarchy in 2.) Other things being equal, the satisfaction of the Syllable Contact Law renders a segment at issue have better profile than the violation of it.

With regard to the Syllable Contact Law, the AmE tap represents the preceding syllable-final. When we cope with the following syllable-initial, segments across word-boundary originate in irrelevant environment and therefore cases without word-boundary should be dealt with. As demonstrated in (31), the following syllable-initial contains unstressed high front tense vowel, ‘r’-colored schwa, syllabic [r], syllabic [l], syllabic [m] and, possibly, the corresponding form with (‘r’-colored for 31c) schwa of each syllabic consonant:

- (31) a. daddy    b. better    c. center    d. little    e. atom  
           [ˈdæɹ.i]    [ˈber.ə]    [ˈsɛnɹ.r̩]    [ˈlɪr̩l̩]    [ˈærm̩]

Given one of the syllable-based generalizations, onset-initial alveolar stops turn into the rhyme-final tap (Kahn 1980, Selkirk 1982 and others in this line of research). In the case of the former, the preceding syllable-final is occupied by a vowel or by a sonorant consonant and the following syllable-initial by an alveolar stop. In the case of the latter, the tap becomes the preceding one and a vowel with low sonority or a syllabic sonorant consonant the following one. Generally speaking, coda-final tends to be more sonorous than onset-initial. If, like my assumption, the AmE tap is between nasals and voiced fricatives in terms of the sonority, it is less sonorous than the following syllable-initial by the degree between one (the syllabic nasal in 31e) and seven (the high peripheral vowel in 31a). This implies, more or less, the violation of the Syllable Contact Law, but such violations are likely to happen in AmE:

- (32) a. erudite    b. topmost    c. footlight    d. aqua  
           [r̩.j]            [p.m]            [ʔ.l̩]            [k.w]

In the order of (32a, b, c, d) the preceding syllable-final is less sonorous than the following syllable-initial by the degree of one, four, five and seven in the general ranking in (2), respectively. The examples like above lead me to claim that the lesser sonority of the preceding syllable-final than the following syllable-initial is permitted, but that the smaller sonority value of the former is, at most, seven in the general ranking. It is taken into account that in contrast to the highly common case of the less sonorous tap than the following syllable-initial [i] by the degree of seven, as in the words *city*, *pity* and *daddy*, the following violations of the Syllable

Contact Law by the distance of eight do not happen and are, at the least, very rare: voiceless fricative – mid central vowel, nasal – low vowel. If the tap is less sonorous than voiced fricatives, contrary to my assumption, it means a crucial violation of the Syllable Contact Law and the lesser sonority scale does not work. That is why the AmE tap has the sonority between nasals and voiced fricatives.

## 5.2. The ban on tapping

Like other allophones, the AmE tap has some restrictions for the occurrence. One of them specifies preceding segments. (Other restrictions contain stressed or unstressed syllables, the onset or the coda and the following segments). The tap is preceded by either a vowel, as in (33), or a vowel plus a sonorant consonant, as in (34), but not by a vowel plus an obstruent, as in (35). Despite the same phonological environments preceded by a stressed syllable and followed by an unstressed vowel, those in (35) is pronounced as the corresponding voiced stops and not replaced by the tap, as Wells (2008) describes (see also the papers on syllabic analyses in the second paragraph in section 4.2.):

(33) a. little	b. bottle	c. city	
[ˈlɪr.ɫ]	[ˈbɑr.ɫ]	[ˈsɪr.i]	
(34) a. center	b. guilty	c. party	
[ˈsɛnr.ɾ]	[ˈɡɪlr.i]	[ˈpɑrr.i]	
(35) a. actor	b. laughter	c. loved Ann	d. bathed in
[ˈæktə]	[ˈlæftə]	[lʌvd]	[beɪðd]
*[ˈækrə]	*[ˈlæfrə]	*[lʌvr]	*[beɪðr]

Syllabic analyses state that the allophonic tap is restricted within the coda-final (cf. the literature in the first paragraph in section 4.2.). On the basis of the sonority hierarchy suggested in this paper, those in (33) and (34) satisfy the Sonority Sequencing Principle and the Maximum Coda Principle is applied to the ones in (34). (The latter is meant to apply to more than one consonant.) Conversely, if the tap is phonetically implemented, the coda taps in (35) violate it owing to the larger sonority than obstruents. The Maximum Coda Principle is one of the characteristics for PDE syllabifications, but the occurrence of the tapping in (35) makes the principle unworkable. The reason why the violation of the principle is blocked in (35) is that such syllable-edge segments occur within coronal obstruents, which have a different status from the tap.

## 6. Conclusion

The phenomenon that AmE tap has lesser sonority value than the lateral and nasals presents a different case from that in previous research. With respect to accountable evidence, this paper has suggested four pieces on the less sonorous tap than the lateral and nasals and two pieces on the more sonorous tap than obstruents. All of the six pieces relate AmE taps to the phenomena relevant to sonority such as the Nucleus Constraint, sonority-based maximum syllabifications, the Sonority Sequencing Principle and the Syllable Contact Law. They, in fact, correspond to the phonetic facts and the phonological phenomena, both of which converge to support my view.

Footnote

<sup>1</sup> Both consonant lenition and consonant weakening refer to the identical sound patterns from effortful to effortless ones. The AmE tapping corresponds to the generalization due to the fact that the tap has limited air turbulence relative to the alveolar stops. They are not grounded in sonority promotion, a phonological one, since the consonant lenition, say, from a voiced fricative to a nasal does not occur.

<sup>2</sup> According to Oda (2008b), the sonority conversion happens not only within sonorant consonants but also between vowels. In the general ranking in (3), Mid Central Vowel has lesser sonority value than High Peripheral Vowel. However, PDE has the following language-specific ranking on them:

(i) Present-Day English

/ʌ/ (TURNED V, a mid central vowel) > High Peripheral Vowel  
> (other segments of) Mid Central Vowel

On the one hand, it is worth noting that the sonority conversion takes places in the cases other than those in the sense of Hankamer and Aissen. On the other hand, I observe that such less common cases do not have a very wide distribution.

<sup>3</sup> This is based on my judgment in Japanese sounds, which have both the tap and the voiced coronal stop.

<sup>4</sup> The constraint in (10) does not mean a Prince and Smolensky's (2004) finding, but constitutes one of the general syllable theories. In this line of research, see Vennemann (1988), Clements (1990) and some others.

<sup>5</sup> Jensen's (2000) prosodic approach is partly based on foot-initial and non-foot-initial positions. While the former undergoes strengthening processes,

# Georg von der Gabelentz' *Manual for Recording Foreign Languages* (1892) – Origins, Aims, Methods, Effects

Wilfried Kürschner

University at Vechta (Germany)  
Dohlenstr. 7, D-49377 Vechta  
kuerschner-vechta@t-online.de

## Abstract

The main works of Georg von der Gabelentz (1840–1893) have had, and still have, a fruitful reception in Chinese (especially his *Chinese Grammar*, 1893) and general linguistics (especially his *Linguistics: Aims, Methods, Results*, 1891, 2nd ed. 1901). In contrast, his *Manual for Recording Foreign Languages*, which was commissioned by the Colonial Department of the German Foreign Office and was published in 1892, remained virtually unknown.

The aim of this paper is to place this work into its context of origin (German and European colonial policy) and outline its range of contents (phonetics including transcription, vocabulary) plus Gabelentz' ideas concerning the methods of recording data from indigenous languages. Furthermore, the effectiveness of the manual is examined (e.g., Schmidt 1900, 1901).

**Keywords:** colonial linguistics, Georg von der Gabelentz, history of linguistics, lexicology, linguistic fieldwork

## 1. Georg von der Gabelentz: A few remarks on his work and life

In the history of linguistics, Georg von der Gabelentz is not renowned for the booklet we are going to deal with in this article, but rather for two other works, namely, among sinologists for his *Chinese Grammar* (first published in 1881), and even more among general linguists for his textbook *Linguistics: Aims, Methods, Results* (1891). Because of the doctrines he laid down in the latter book, Gabelentz is seen by some as a forerunner of Ferdinand de Saussure in certain respects: he distinguishes, as Saussure did later, between *langue* (“Einzelsprache”), *langage* (“menschliches Sprachvermögen”) and *parole* (“Rede”: “Human language is the articulated expression of thought by sounds” [„Menschliche Sprache ist der gegliederte Ausdruck des Gedankens durch Laute“], 1891: 3). Furthermore, Gabelentz made a distinction between synchronical and diachronical study of language.

He lived from 1840 to 1893, working as a professor of linguistics first in Leipzig, having positive and negative contacts with the proponents of the Neogrammarian school (“Junggrammatiker”) there and elsewhere in Germany. Later he moved to the University of Berlin, where he finished his famous book on linguistics mentioned above and where he published, just one year before his early death, his last work, namely the *Manual* under consideration.

## 2. The *Manual* in context

### 2.1. *Word lists*

The *Manual* is related to a category of linguistic aids Gabelentz calls “Collectanea”. These are corpora of linguistic materials of different kinds collected more or less systematically. Their historical origins are word lists, also called vocabularies. Some of them became very famous, for instance the *Linguarum totius orbis vocabularia comparativa* by Peter Simon Pallas, published in St. Petersburg in 1786–89. Another item is the word list contained in the *Catálogo de las lenguas de las naciones conocidas, y numeración división y clase de éstas según la diversidad de sus idiomas y dialectos* by Lorenzo Hervás, published in six volumes in Madrid from 1800 to 1805. Finally, Gabelentz’ father, Hans Conon von der Gabelentz, should be mentioned who in the first half of the nineteenth century published quite a number of grammars of diverse languages, relying on collectanea compiled by himself and others.

### 1.2 *Germany’s colonial policy: Linguistic implications*

As the title of the book indicates, the *Manual* was a commissioned book he worked out for the Colonial Department of the German Foreign Office. To my knowledge, no research has yet been made in the archives to find out how this commission came about, but it can safely be placed into the context of the German Empire’s efforts to establish itself as a colonial power beside the other European nations that had started their colonial policies decades, if not centuries before: Portugal, Spain, England, France, the Netherlands, even Belgium, Denmark, and Sweden, to name just the more important ones. Germany at that time was a “belated nation” in general, lagging behind the more advanced nations in many respects, including the conquest of overseas claims or “Schutzgebiete”, protectorates, as they were called. There were only a few German pro-

tectorates, namely in Africa: German Southwest Africa (now Namibia), the first colony acquired in 1883, German East Africa (acquired in 1884, now Tanzania, Rwanda and Burundi), Cameroon, and Togo (now parts of Ghana and Togo – both of them acquired in 1884/85); in Asia: the Bay of Kiautschou (China, acquired in 1898); and finally, in the South Seas: German New Guinea (acquired in 1885), consisting of Emperor William's Land and the Bismarck Archipelago, the Solomon Islands, the Marshall Islands (acquired in 1885), the Caroline, Marian and Palau Islands, and German Samoa (all of them acquired in 1899).

It was the Foreign Office's task to take care of the administration of these protectorates, which was done by German military and civil servants. As we can figure out, these persons did not speak the languages of the occupied countries, which could easily run to a multitude of tribal languages including dialects. An interest in these languages most certainly was not an intrinsic one in learning them in order to communicate with the indigenous population. It was rather a scientific interest, as we are told in many contemporaneous sources, an interest in the vast multitude of human languages spoken on this globe, in addition powered in Germany by the search for "worldviews" incorporated in languages, an idea which goes back to Wilhelm von Humboldt. On the scientific side, there were, moreover, explorers interested in broadening geographical, biological and anthropological knowledge. In order to guide and assist scientific observations of these and other kinds on journeys, there was a special handbook edited by Georg von Neumayer which also contained a practical article by Carl Meinhof (1906). Thirdly, there was a more practical interest in language stemming from efforts to do Christian missionary work. German missionaries were eager to convert native people to Christendom not only in the German protectorates, but in many other places around the world, too. Concerning language and languages, here we have a combination of colonial and missionary interests, with the missionary aspect being more practical, namely translating the Bible and catechistic literature like prayer books and hymn books, plus having the ability to speak and preach to people in their own language.

It is these three groups mentioned – colonial civil servants, missionaries and explorers („Kolonialbeamte, Missionare und Forschungsreisende“, p. 1) – that Gabelentz addresses in the introduction („Einleitung“) of the *Manual*, plus all other persons, as he writes, who while in distant countries have time and pleasure to promote their knowledge of language („die ... Zeit und Lust haben, die Sprachkunde zu fördern“, *ibid.*). This might evoke the image of the well-to-do voyager with time and leisure enough to record linguistic data just like others collect plants or hunt for butterflies. Gabelentz compares these travellers to professional linguists who, alas, seldom have the opportu-

nity to collect materials on the spot („Sprachforscher vom Fach kommen selten in die Lage, an Ort und Stelle Materialien sammeln zu können“, *ibid.*). With these travellers in mind, for whom the experience of collecting words, sentences and texts of different sorts can become a passion („... erleben, dass auch das Sammeln von Wörtern, Sätzen und allerlei Texten zur Passion werden kann“, *ibid.*), Gabelentz formulates the aim of the *Manual*: to make collecting easier for them and provide linguistic science with useful, reliable and, because of their uniformity, clear works („Dies Sammeln soll ihnen erleichtert, und der Wissenschaft sollen brauchbare, zuverlässige, dabei durch eine gewisse Uniformität übersichtliche Arbeiten zugefügt werden“, *ibid.*).

To be quite clear about it: the final destination of the lists Gabelentz hopes to be provided with, is the science of language. From his textbook, we can safely infer that mere collecting of data from different languages would not be considered an aim in itself, but rather it should be made practical by writing grammars and dictionaries of these languages. We will come back to this point later on.

## **2. Contents and organisation of the *Manual***

A few words on the physical character of the book. It is in landscape format with a length of 17.5 centimetres and a height of 11.5 centimetres, thus not too bulky. It is bound in moleskin, a kind of cotton, and at one side there is a case for a pencil. The number of pages is 272 (with pages 199–272 ruled) plus 16 pages in Roman numerals at the beginning filled with an alphabetical list of all the words used in the *Manual* referring the user to their place in the word lists themselves. The book is not too thick and can easily find a place in the traveller's outfit.

### *2.1. Languages to be investigated*

The object of Gabelentz' interest is clearly confined to the languages spoken in the protectorates of the German Empire. What could be judged and presumed up to the time when the *Manual* was published –this happened, as pointed out above, in 1892, nine years after the acquisition of the first protectorate, German Southwest Africa – Gabelentz characterizes these languages as not too difficult („nicht besonders schwierige Sprachen“, p. 1). From his textbook and other works, we know that Gabelentz was highly interested in assessing the value of languages, what he calls the determination of their value („Wertbestimmung der Sprachen“, 1891/1901, p. 387). Al-

though, as has been noted, the traveller will be confronted with relatively easy languages, Gabelentz provides him with some practical hints concerning the method of elicitation of data, mainly words, and the recording of phonetic details. One example must suffice. Imagine, you want to elicit your informant's equivalent for the word *hand* and hold out your hand to him. It might happen that his answer does not render hand in general but *your hand* because, as Gabelentz surmises, the savage cannot think of hand in abstract (p. 3). Alternatively, he could answer *palm* or *flat of the hand, out-stretched hand* or *It is white*. I just quoted from Gabelentz' text where he calls indigenous people *savages* („Wilde“ in German, p. 3); one page later he equates the informants with *children* („Kinder“, p. 4). Their languages are “raw” („rohe Sprachen“, p. 4), they often lack words for general concepts like “brother” and can only name the elder brother, or the younger brother, that is the species, but not the genus („... nur Namen der Arten, aber keinen Namen der Gattung“). This should not be overestimated, I think, but it is in conformity with European thinking and talking about indigenous people at the turn of the nineteenth to the twentieth century. Evidence for this can be taken from Gabelentz' admonition to the data collector:

You should stick to the principle that each savage speaks his mother tongue correctly, at least as a rule more correctly than a European does. Where we think something is wrong, the mistake will probably be in our understanding. The people just think differently from us and through their language we want to find out how they think (Sonst aber halte man sich an den Satz, dass jeder Wilde seine Muttersprache richtig spricht, jedenfalls in der Regel richtiger als ein Europäer. Wo uns also etwas fehlerhaft vorkommt, da wird wahrscheinlich der Fehler in unserem Verständnisse liegen. Die Leute denken eben anders als wir, und durch ihre Sprache wollen wir erfahren, wie sie denken; p. 5).

## 2.2 Organisation and content of the data sheets

The contents of the data sheets and their arrangement go back to a former work by Georg von der Gabelentz and Adolf Bernhard Meyer, called “Contributions to the Knowledge of the Melanese, Micronese and Papuan Languages” („Beiträge zur Kenntnis der melanesischen, mikronesischen und papuanischen Sprachen“), published in 1882, that is ten years before the *Manual* was published. The lists consist of words, sometimes of word combinations. They are arranged according to the parts of speech schema of traditional grammar, if appropriate with subgroups again following the traditional

subdivisions. A somewhat less comprehensive scheme than the one used in the *Manual* can be found in the textbook where Gabelentz mentions that he had once tested its suitability („Ein Schema für ein solches Wörterbuch, dessen Bequemlichkeit ich erprobt habe [...]“, 1891, p. 177/178, 1901, p. 166/167).

The order of the word classes is not the traditional one but starts with pronouns with personal pronouns at the beginning. As can be seen from the appendix where the categories Gabelentz uses are given plus some examples, already here Gabelentz prepares the collector to ask for concepts not lexicalised in German nor in English: we do not have words for *we two*, *we three*, let alone *we two: me and you* in contrast to *we two: me and him*, etc. Pronouns are followed by nouns both concrete and abstract, arranged in the way of a thesaurus. That is, words are grouped together according to their semantic connections in, as we might say, word fields and word families. The noun list aptly starts with words having to do with God and Heaven, and it finishes, as many such lists do, with the embarrassing category general or miscellaneous (“Allgemeines”). Some of the groupings are rather astonishing. Have a look at number 271 to 275 in the appendix: The words *spirit*, *shadow*, *name*, *voice* and *word* are put at the end of the category *Other parts of the body, excretions!* The order of adjectives starts with the concept “large” etc. and finishes with “general or miscellaneous” just like the nouns do. Adverbs are subcategorized according to the traditional subgroups of adverbs of time, of place and so on. Conjunctions and prepositions do not show any known pattern. It is with verbs that the method of thesauring clearly comes to its limits. Starting with *Verba dicendi*, verbs of saying, known from Latin and other grammars, the list quickly comes to category F. “Other verbs (in alphabetical order)” from *abreissen* ‘tear off’ to *ziehen* ‘pull’. The typographical design of inserted ruled lines and whole ruled pages are meant to encourage the data collector to think of more and other concepts or to be more realistic, to think of German words and elicit the indigenous term for them, in this case verbs.

Gabelentz’ interest in these lists clearly concentrates on the lexical aspects. Grammar is not totally neglected, although for instance in the connection with possessive pronouns there is no hint to retrieve data on how possession as a concept that exceeds traditional word class boundaries is grammaticalised in the language under consideration. Concerning nouns, the ways of marking plurals or comparable concepts are not taken care for in the lists themselves but in the section on “How to use the word lists” („Anweisung zum Gebrauch des Wörterbuchs“, p. 19/20). There Gabelentz urges the explorer to add the plural forms, if appropriate. The same applies to different verb forms – the explorer is urged to busy himself in collecting them or else to demonstrate by examples (sentences) that verbs are invariant in the language under consideration. As to

adjectives, Gabelentz asks for combinations of them with nouns, e.g., *the white stone, three high trees, the stone is white, the trees are high* („Auch bei den Adjektiven sollte man of Verbindungen mit Substantive anführen: ‚Der weisse Stein, drei hohe Bäume, der Stein ist weiss, die Bäume sind hoch‘ u. s. w.“, p. 20). Concerning auxiliaries (prepositions, postpositions, genitive or object particles, conjunctions etc.), Gabelentz again asks for examples by which their “meaning” can be explained. This is necessary, he says, because these words in German are mostly indeterminate. („Die Bedeutung der Hülfsörter [Prä- und Postpositionen, etwaiger Genitiv- oder Objektspartikeln, Konjunktionen] muss nothwendigerweise durch Beispiele erläutert werden; denn die deutschen Wörter sind mehrentheils viel zu unbestimmt. Füllt hier der Sammler den ihm gelassenen freien Raum fleissig aus, so arbeitet er einem wichtigen Theile der Grammatik vor“, p. 20). By doing this, the explorer helps to prepare an “important part of the grammar”, whose construction, as has been pointed out above, is beside the dictionary a vital aim of the linguist.

Thus we can say that a copy of the *Manual* filled with data from a certain language is not just a kind of nomenclature of a part of its vocabulary, but ideally a grammatically enriched and informed list. Moreover, Gabelentz describes the empty pages at the end of the book as places where sayings, proverbs and other sentences, if possible texts, stories, tales and songs can be written down, thus going far beyond the level of pure words („Die leeren Blätter am Ende des Wörterbuchs sind für gebräuchliche Redensarten und sonstige Sätze, womöglich auch für zusammenhängende Texte, Erzählungen und Lieder aus dem Munde der Eingeborenen bestimmt“, *ibid.*).

### **3. Effectiveness of the *Manual***

As far as we know, Gabelentz’ *Manual* did not become very influential. It is referred to in a larger work by Father Wilhelm Schmidt, a member of the Societas Verbi Divini, better known as *Steyley Missionare*, a catholic order of brothers and priests. Father Schmidt wrote in 1901/1902 on the linguistic situation in the then German part of Papua-New Guinea, partially using Gabelentz’ word list to compare data from several languages and dialects. He mentions that the book is often used by civil servants and missionaries (Schmidt 1901, p. 357). He refers to the records of the languages of Tami, Jabim, Karkar and Kake-dong (Kai) made by filling out the book (p. 373). It cannot be ascertained if these have been used for dictionary or grammar construction. Maybe it is in libraries of monasteries that we could be lucky enough to find the original records or

copies. However, we should not be surprised if these books were weeded out as simple consumer goods not worthy of archiving. There are only a few libraries in Germany and the rest of the world where copies of the *Manual* are still available, e.g., the German and the Austrian National Libraries and the British Library. In the Gabelentz archives in his native city of Altenburg, Thuringia there are two copies, one without any entries and the other one relatively completely filled with entries from the Basque language, probably from Georg von der Gabelentz' own hand.

A quick look at the bibliographies in the newer surveys of the languages of the world or parts of it shows that Gabelentz' book did not reach the attention of these authors. Thus, maybe it is not unfair to state that among Gabelentz' works, the *Manual* stands in an isolated position. It does not achieve the width and depth of Gabelentz' other work and can, I think, as a commissioned work safely be placed among his lesser achievements. Nevertheless, it aptly fits into the theme "Unity and Diversity of Languages" of the 18th International Congress of Linguists and helps us to gain a more complete and multiperspective picture of Gabelentz' work as a whole.

# Viability of VOT as a Parameter for Speaker Identification: Evidence from Hong Kong<sup>1</sup>

Winnie H.Y. Cheung      Lian-Hee Wee

Hong Kong Baptist University  
[winniehtc@gmail.com](mailto:winniehtc@gmail.com)

## Abstract

This research explores VOT as a speaker-specific property within the context of English-Cantonese bilingualism in Hong Kong. Utterances collected from five individuals for /p, t, b, d/ vary over two languages and four emotional states. Results show that VOT means by themselves appear to be generally useless as a speaker-specific property because there is as much inter-speaker variation as there is intra-speaker. However, in this paper, we have been able to show that the profile of VOT shifts of each phoneme across the two languages is speaker-specific. Extrapolating from this, profiles of VOT shifts across other parameters like emotional states and even vowel adjacency would be likewise speaker-specific. Herein lies the viability of VOT for speaker-identification.

**Keywords:** VOT shifts, speaker identification, bilingual, Hong Kong English, Cantonese.

## 1. Introduction

Speakers are rarely conscious of the synchronicity (or lack thereof) of vocal fold vibration and the release of plosives phones. This makes Voice Onset Time (VOT) a likely candidate for forensic speaker identification. Thus motivated, we investigate correlations between four variables which are likely to affect VOT values: speakers, moods, languages and the voicing contrast of plosives within each language.<sup>2</sup> The hypothesis is that VOT values should vary significantly across these variables and that there should be a systematic correlation between the VOT values and the variables, with particular reference to speaker-specificity if VOT is to have forensic applications. The results of this research show that for bilinguals, the VOT shift of the same plosive phoneme across the languages commanded by that speaker is potentially speaker-specific. As such, the viability of VOT for speaker-identification is stronger for polyglots than for monolinguals, an area of forensic phonetic studies hitherto rarely explored (but see Kilpatrick 2003 for a closely related study on VOT of English and Spanish bilinguals).

Section 2 explains the experimental design and data collection. Section 3 presents our results and provides a brief discussion on what the results indicate. Section 4 explains the implications and limitations of the work, before ending with a conclusion.

---

<sup>1</sup> This work is supported by FRG/06-07/I-34. The authors are grateful to the informants (names withheld for anonymity) for being such willing subjects. The authors are heavily indebted to Julian H.Y. Kam for her immense contribution as research assistant, *sine qua non*.

<sup>2</sup> The investigation of language variation is motivated by Moosmuller (1997), who argues that phonological backgrounds are prone to individual variation in speaker identification.

## 2. Design of Experiment

In this research, we consider monosyllabic words involving single plosive onsets which VOTs are measured under variation of (i) speakers, (ii) moods, (iii) languages and (iv) the voicing contrast of plosives within each language. The last of these four is well-documented and require no further elaboration. Tokens are set in a carrier frame for naturalness and for ease of identifying the boundaries of the plosives under study. One-way ANOVA<sup>3</sup> is used to test if the other three variables also have significant effects on mean VOT values.

### 2.1 Languages Tested

Since Hong Kong is essentially bilingual in English and Cantonese, these two languages are chosen for study. English and Cantonese both make a two-way distinction in voicing. However, Shimizu (1996:13) reports that the VOT boundary value of English plosives is about 20-40ms, which means that below 20ms, the plosive would be certainly perceived as voiced, and above 40ms as voiceless. Lisker & Abramson (1964) [cited in Cho & Ladefoged 1999] present the distinction in Cantonese as 9-34ms for one category and 79-98ms for the other, so that the boundary value is 35-78ms, significantly higher than that of English. This means that what is voiced for Cantonese would probably sound very much like unvoiced for English, prompting various linguists to claim that Cantonese makes an aspirate-unaspirate distinction while English makes a voice-voiceless distinction.

Thus, a natural question would be on the VOT for a Cantonese-English bilingual. Since both languages make a two-way distinction, would such a bilingual have a VOT divide that matches English or Cantonese, both or neither?<sup>4</sup> The choice of languages here would serve to address this question. In any case, Hung (2000) reports that speakers of English in Hong Kong have a distinct accent. Specific to plosives, the English spoken in Hong Kong (or Hong Kong English, HKE) appears to be more like Cantonese than English. As will be shown in section 3, this is sometimes the case for some speakers and for some phonemes.

In this paper, the English studied would be HKE.

### 2.2 Subjects

Five individuals (two males and three females) are used in this study. Their details are provided in the table (1):

(1) List of subjects used in this study

Informants	Sex	Age	Education Level
CY	M	19	University
MW	M	21	University

<sup>3</sup> ANOVA is a hypothesis-testing procedure used to evaluate the mean differences between two or more treatments (Woods et al 1986; Gravetter & Wallnau 2000). ANOVA is useful in this research as we look at the differences in VOT values with respect to speakers, mood and language (i.e. three treatments).

<sup>4</sup> Hung (2000), for example, claims that the English spoken in Hong Kong has a VOT contrast that is fundamentally similar to Cantonese.

AH	F	22	University
JK	F	23	University
WC	F	21	University

Only tertiary educated subjects are chosen here because of their more balanced command in both Cantonese and English (for issues on impact of bilingualism on VOT, see Kilpatrick 2003:Chapter 2). More accurately though, the English spoken in Hong Kong is not phonetically identical with standard varieties such as General American or Received Pronunciation. Nonetheless, because Cantonese has such a dominant presence in Hong Kong, the bilingual subjects exhibit dominant bilinguality (definition in (2)) with a preference for Cantonese. This is very typical of the Hong Kong people. The subjects chosen are thus reasonably representative of Hong Kong.

(2) Dominant Bilinguality (Hamers & Blanc 2000:368)

A state of bilinguality in which competence in one language is superior to the competence in the other; note that dominance is not equally distributed for all domains and functions of language.

2.3 *Phoneme and Selection of Words*

As mentioned above, the two languages studied (English and Cantonese) make a two-way distinction on the voicing contrasts of plosives. As such, our selection of phonemes include the labials /b/~p/ and the alveolars /d/~t/. We have left out the set of velars for want of resources, although our results later will show that our conclusions can be easily extended to cover the velar plosives.

In this research, we set up a list of monosyllabic words involving the plosives /p, t, b, d/ as single onsets across the two languages. For each phoneme, there are six token words to be read three times so that an average value may be obtained. The six tokens are equally divided amongst three cardinal vowels [high, front], [low], and [high, back, round] so that our averages would not be skewed by effects of vowels that immediately follow the plosives. Below, (3) and (4) are our list of test words. The phonetic forms in (3) correspond to pronunciations in Hong Kong, and may not coincide with dictionary entries.

(3) List of English Words

plosives	Following vowel	closed syllable	open syllable
p	i	pig [p ik]	pea [p i]
	o	pot [p ot]	paw [p o]
	a	part [p art]	par [p ar]
t	i	tick [t ik]	tea [t i]
	o	top [t op]	tall [t o]
	a	tart [t art]	tie [t ai]
b	i	big [pit]	bee [pi]
	o	bob [pob]	ball [po]
	a	bark [park]	bar [par]
d	i	dig [tik]	D [ti]
	o	dot [tot]	door [do ]
	a	dark [tark]	die [tai]

(4) List of Cantonese Words<sup>5</sup>

plosives	Following vowel	closed syllable	open syllable
p	i	[p <sup>h</sup> ik]	[p iu]
	o	[p ok]	[p o]
	a	[p ak]	[p a]
t	i	[t ip]	[t iu]
	o	[t ok]	[t o]
	a	[t at]	[t a]
b	i	[pik]	[piu]
	o	[pok]	[po]
	a	[pak]	[pa]
d	i	[tik]	[tiu]
	o	[tok]	[to]
	a	[tat]	[tai]

Because vowels are known to affect VOT values (Shimizu 1996:27, 55, 111), we have tried to factor out their effects by balancing each phoneme with equal number of entries for each of three cardinal vowels: [high, front], [low] and [high, back].

2.4 *Carrier frame*

The English words and the Cantonese words are put into a carrier frame such that the plosive is preceded by a sonorant. This would allow us to see clearly where the plosive begins. The carrier frames are as given in (5).

- (5) a. Carrier frame for English  
I am going to say \_\_\_ once.
- b. Carrier frame for Cantonese  
ŋɔ: wui kɔŋ \_\_\_ jət ts<sup>h</sup>i.

2.5 *Speaker Moods*

Because part of our study is to examine the viability of VOT for speaker identification, we decided to factor in emotional states to see if there is any covariation with VOT values that might be speaker-specific. To this end, each speaker is required to utter each word (in their carrier frames) across four different emotional states: neutral, happy, sad and angry. Because different individuals might have different “renditions” of the same emotional state, this part of the experiment is somewhat uncertain. However, it should be quite reasonable to assume that variation of moods would either be manifest in the intensity or the pace of utterance, both which would have a direct impact on VOT.

2.6 *Tokens*

This experiment involves a total of 2880 tokens are taken (=6 words\*4 phonemes\*5 speakers\*3 readings\* 4 moods\*2 languages). See above sections for details.

---

<sup>5</sup> Glosses and tones omitted, since selected words that are natural to Cantonese do not lend themselves easily to translation.

## 2.7 Data Collection

Subjects were asked to utter the stimuli words in their carrier frames separately in a quiet setting where the utterances are also recorded. The software used is Praat (version 4.4.30, but see Boersma & Weenink 2008 for a more updated version) at a sampling frequency of 22050Hz. Because of the large number of tokens required, recordings are made over a period of no more than two days<sup>6</sup> each with intermittent breaks every 15-20 minutes. Recordings for each language are collected separately to avoid having the subjects having to switch between codes. Within each language, every token word is collected for all emotional states (mood) before moving on to another word. While this means that subjects have to switch emotional states back-and-forth, it helps prevent a building up of intensity of moods. For instance, if a subject is required to constantly keep an angry mood, the mood may feed itself so that the intensity of anger would grow over each repetition.<sup>7</sup>

## 3. Results and Discussion

This section presents the results obtained from measuring the VOT values of recordings collected under the experiment design given in the previous section. One-way ANOVA is used for calculating F-ratios, all at a significance level of  $p < 0.05$ , giving us an error of less than 5%.

In (6) below, we present the results for the VOT contrasts that set apart the two-way voicing distinction for Hong Kong English (HKE).

(6) F-ratio and F-dist. of HKE across four moods

/p, t/	Mean HKE VOT value(s)				F-ratio	F-dist	Significance	
	Neutral	Happy	Sad	Angry				
C.Y.	0.0843	0.0796	0.0927	0.0801	1.7624	2.8387	N	
M.W.	0.0626	0.0591	0.0708	0.0625	1.4767		N	
A.H.	0.0542	0.0435	0.0547	0.0620	3.0165		Y	
J.K.	0.0727	0.0644	0.0723	0.0715	0.9752		N	
W.C.	0.0635	0.0489	0.0682	0.0446	6.4146		Y	
/b, d/								
C.Y.	0.0218	0.0217	0.0259	0.0208	3.7030		Y	
M.W.	0.0142	0.0175	0.0210	0.0240	5.1858		Y	
A.H.	0.0168	0.0127	0.0178	0.0137	1.0237		N	
J.K.	0.0097	0.0107	0.0091	0.0049	0.8190		N	
W.C.	0.0117	0.0055	0.0113	0.0047	6.2485	Y		

Table (6) provides the mean VOT values of each speaker (listed along the first column) across four emotional moods (listed along the top row) when in HKE utterances. The phonemes are divided for the voicing contrast, so that the set of VOT values for the upper half applies to the voiceless phonemes (/p, t/ in this case, having left out /k/ in this research). The lower half of the table is for the VOT values of voiced phonemes (/b, d/

<sup>6</sup> We keep things to within this time frame for fear that a longer stretch of time would bring in other complications such as memory lapses.

<sup>7</sup> A method often used in realistic acting first advocated by Constantin Stanislavski.

in this case). The F-ratio is then calculated (with  $df=3, 44$ , where  $df$  refers to degrees of freedom)<sup>8</sup> to see if VOT variation across moods for each individual speaker is significant.<sup>9</sup> The results are summarized in the final column, where one can see that for C.Y., VOT variation is insignificant across moods for both voiceless plosives, but not voiced plosives. For A.H, variation across moods is significant for voiceless plosives, but not for the voiced ones. There is no obvious pattern when the variation is significant for each speaker within or across the two kinds of plosives.

Ideally, if VOT is useful for speaker-identification, then there should be systematically no significant variation for each speaker across moods for at least one set (either /p, t/ or /b, d/) of the phonemes. This is clearly not the case given the results in (6), which undermines the feasibility of VOT as a speaker-specific parameter.

Moving on to Cantonese, table (7) presents the results for the VOT contrasts that set apart the two-way voicing distinction (again,  $df=3, 44$ ).

(7) F-ratio and F-Dist. of Cantonese across four moods

/p, t/	Mean Cantonese VOT value(s)				F-ratio	F-dist	Significance	
	Neutral	Happy	Sad	Angry				
C.Y.	0.0757	0.0594	0.0651	0.0583	1.5771	2.8387	N	
M.W.	0.0696	0.0528	0.0711	0.0576	6.0910		Y	
A.H.	0.0405	0.0325	0.0412	0.0330	2.1276		N	
J.K.	0.0628	0.0744	0.0608	0.0311	4.8038		Y	
W.C.	0.0474	0.0320	0.0364	0.0341	2.1927		N	
/b, d/								
C.Y.	0.0188	0.0183	0.0205	0.0196	0.0728		N	
M.W.	0.0209	0.0115	0.0146	0.0113	2.6395		N	
A.H.	0.0111	0.0087	0.0155	0.0065	6.3932		Y	
J.K.	0.0149	0.0087	0.0147	0.0051	6.7450		Y	
W.C.	0.0075	0.0055	0.0095	0.0036	2.3656	N		

Table (7) is read the same way as table (6). As can be seen from the results in (7), there is no systematic pattern in when moods make significant variation on the VOT means of each speaker, which corroborates with the results in (6). Again, this undermines the feasibility of VOT as a speaker-specific parameter.

Although (6) and (7) do not appear very supportive, it is nonetheless possible that the applicability of VOT for speaker-identification is confined at the level of the phoneme and could be language specific. The results in (8)<sup>10</sup>, allows us to check if this may be so for the case of HKE.

<sup>8</sup>  $df = x,y$ , where the first value is the degree of freedom between treatments (in this case the moods), while the second value is the degree of freedom within-treatments (in this case the number of utterances that produced the VOT means). On how to calculate  $df$ , see Woods et al (1986) or Gravetter & Wallnau (2000) for an excellent explanation.

<sup>9</sup> In order to see if moods have impact on each individual speaker, the four emotional states are compared using only one informant each time. By this, one could treat each informant as a separate sample. Hence in this case, an independent measures design is chosen over repeated measures design. One could also notice that since F-ratio is calculated each time using only one speaker. We would therefore have five outcomes (five values of F-ratios). The same thing could be said of the results of table (7).

<sup>10</sup> As we want to see if individuality would impact on the VOT means for a given phoneme, speakers (individual conditions) now become the variable or factor that is being examined. Phonemes /p,t,b,d/

(8) F-ratio and F-Dist. of HKE across five speakers

	Speakers	Mean <sup>11</sup> VOT HKE (s)	F-ratio	F-dist	Significance
/p/	C.Y.	0.0801	16.5218	2.4500	Y
	M.W.	0.0562			
	A.H.	0.0495			
	J.K.	0.0691			
	W.C.	0.0590			
/t/	C.Y.	0.0883	17.5216		
	M.W.	0.0713			
	A.H.	0.0578			
	J.K.	0.0714			
	W.C.	0.0535			
/b/	C.Y.	0.0208	12.6636		
	M.W.	0.0177			
	A.H.	0.0098			
	J.K.	0.0116			
	W.C.	0.0073			
/d/	C.Y.	0.0243	51.6274		
	M.W.	0.0206			
	A.H.	0.0208			
	J.K.	0.0057			
	W.C.	0.0093			

In table (8), we compare the VOT means of each individual across the four chosen phonemes of HKE. Here the results appear to be more encouraging in that there are significant differences ( $df = 4, 115$ , where 4 is  $df$  based on number of speakers, and 115 is  $df$  based on number of utterances) for all four phonemes across the speakers as indicated by the “Y” in the last column. However, one has to be cautious of jumping to conclusions here since the comparison is made for all five speakers, not for any given pair of speakers. In other words, the “Y” could be simply the result of having one very deviant speaker while the remaining three have mutually indistinguishable VOT values. To check that for any pair of speakers, there is a significant difference in the VOT values, the Tukey’s Honesty Significant Difference (HSD, again see Gravetter & Wallnau 2000 for explanation) post hoc test is needed. If the mean difference of any pair exceeds the critical value (i.e. Tukey’s HSD, calculated with the formula in (9)), one can conclude that pair is significantly different.

(9) Tukey’s Honesty Significant Difference (HSD)

$$\text{HSD} = q \sqrt{\frac{\text{Variance within treatments}}{\text{number of scores in each treatment}}}$$

, where  $q$  is a table value called a Studentized range statistic.

The Tukey’s HSD is applied to all possible pairings (which is  $C_2^5 = 10$ ) of all five speakers. The results are summarized in table (10).

---

become the control factors. Each time only one phoneme is considered, so there are four F-ratios altogether for comparison. Table (11) is understood the same way as here.

<sup>11</sup> The means are calculated for all utterances across four emotional states.

(10) Pairwise HSD across speakers on HKE /p, t, b, d/

Phoneme	Speakers	M.W.	A.H.	J.K.	W.C.
/p/	C.Y.	✓	✓	✗	✓
	M.W.	Grey	✗	✓	✗
	A.H.	Grey	Grey	✓	✗
	J.K.	Grey	Grey	Grey	✓
/t/	C.Y.	✓	✓	✓	✓
	M.W.	Grey	✓	✗	✓
	A.H.	Grey	Grey	✓	✗
	J.K.	Grey	Grey	Grey	✓
/b/	C.Y.	✗	✓	✓	✓
	M.W.	Grey	✓	✗	✓
	A.H.	Grey	Grey	✗	✗
	J.K.	Grey	Grey	Grey	✗
/d/	C.Y.	✗	✗	✓	✓
	M.W.	Grey	✗	✓	✓
	A.H.	Grey	Grey	✓	✓
	J.K.	Grey	Grey	Grey	✗

In (10), each pairing is shown on the table by matching each row to each column. The corresponding cell is marked ✓ if the pair is significantly different, but ✗ if not. Grey cells indicate that the pair has already been considered. From the random spread of ✗, it is clear that not all the differences are significant for any given pair of speakers. VOT as a speaker-specific property is unviable even when confined to the level of the phoneme for a specific language. This claim is further supported by the results in (11) when one moves on to investigate Cantonese ( $df= 4, 115$ ).

(11) F-ratio and F-dist. of Cantonese across five speakers

	Speakers	Mean <sup>12</sup> VOT Cantonese (s)	F-ratio	F-dist	Significance
/p/	C.Y.	0.0591	6.3382	2.4500	Y
	M.W.	0.0579			
	A.H.	0.0386			
	J.K.	0.0680			
	W.C.	0.0424			
/t/	C.Y.	0.0702	42.1360	2.4500	Y
	M.W.	0.0676			
	A.H.	0.0350			
	J.K.	0.0466			
	W.C.	0.0318			
/b/	C.Y.	0.0152	2.1968	2.4500	N
	M.W.	0.0130			
	A.H.	0.0114			
	J.K.	0.0122			
	W.C.	0.0084			
/d/	C.Y.	0.0233	17.1836	2.4500	Y
	M.W.	0.0166			
	A.H.	0.0094			
	J.K.	0.0095			
	W.C.	0.0046			

<sup>12</sup> Like (8) above, the means are based on all utterances across the four emotional states.

Table (11) is read the same way as table (8). From table (10), although VOT variation is significant for voiceless phonemes and /d/ across five speakers, it is not so for /b/, which makes it unnecessary to run the Tukey's HSD.

There remains one last hope for the viability of VOT as a speaker-specific property. Since we are working with bilinguals (recall that Hong Kongers are larger English-Cantonese bilinguals), one possibility is that VOT variation for the same phoneme across the two languages commanded by each speaker is specific to that individual. In other words, for speaker X who commands languages  $L_a$  and  $L_b$ , the same phoneme /p/ could have VOT variations across the two languages, that is different from some other speaker Y. This possibility is available only to bilingual individuals, but not an option for monolinguals. In (12)<sup>13</sup> below, we make the comparisons of VOT means<sup>14</sup> for each phoneme /p, t, b, d/ across HKE and Cantonese.

(12) F-ratio and F-dist. between HKE and Cantonese

	Speakers	Mean VOT (s)		F-ratio	F-dist.	Significance
		HKE	Cantonese			
/p/	C.Y.	0.0801	0.0591	10.9560	4.0400	Y
	M.W.	0.0562	0.0579	0.1740		N
	A.H.	0.0495	0.0386	10.8294		Y
	J.K.	0.0691	0.0680	0.0173		N
	W.C.	0.0590	0.0424	16.3281		Y
/t/	C.Y.	0.0883	0.0702	15.9234		Y
	M.W.	0.0713	0.0676	1.2872		N
	A.H.	0.0578	0.0350	24.8831		Y
	J.K.	0.0714	0.0466	31.9538		Y
	W.C.	0.0535	0.0318	24.6337		Y
/b/	C.Y.	0.0208	0.0152	10.2729		Y
	M.W.	0.0177	0.0130	2.9164		N
	A.H.	0.0098	0.0114	0.8815		N
	J.K.	0.0116	0.0122	0.0455		N
	W.C.	0.0073	0.0084	0.3241		N
/d/	C.Y.	0.0243	0.0233	0.0918	N	
	M.W.	0.0206	0.0166	3.3538	N	
	A.H.	0.0208	0.0094	39.6752	Y	
	J.K.	0.0057	0.0095	4.7846	Y	
	W.C.	0.0093	0.0046	0.0003	N	

In (12), each phoneme is studied separately and the VOT means for each speaker for each language is tabulated. The F-ratio ( $df= 1, 46$ , where 1 is the  $df$  based on number of languages and 46 on utterances) together with the F-distribution show no obvious pattern at first blush. However, a careful study will reveal that the profile of VOT shifts for each plosive phoneme across languages appears to be speaker-specific. Before, we continue, we define VOT shift in (13).

<sup>13</sup> Similar to the calculations of F-ratios across four moods, each speaker is being studied separately.

<sup>14</sup> The means here are taken across all four emotional states.

(13) VOT L-Shift

VOT L-shift is the change in the mean VOT of any given phoneme across two languages.<sup>15</sup>

For current purposes, the actual value of the VOT L-shift is not quite as important as if the shift is significant. That said, consider C.Y. and M.W. for example (see Table 14).

(14) Comparing VOT L-shift of C.Y. and M.W.

		Mean VOT (s)		F-ratio	F-dist.	Significance
		HKE	Cantonese			
C.Y.	/p/	0.0801	0.0591	10.9560	4.0400	Y
	/t/	0.0883	0.0702	15.9234		Y
	/b/	0.0208	0.0152	10.2729		Y
	/d/	0.0243	0.0233	0.0918		N
M.W.	/p/	0.0562	0.0579	0.1740	4.0400	N
	/t/	0.0206	0.0166	3.3538		N
	/b/	0.0177	0.0130	2.9164		N
	/d/	0.0713	0.0676	1.2872		N

In (14), the final column would inform us if the VOT L-shift is significant. There is no significant VOT L-shift for M.W. for all the phonemes /p, b, d, t/. VOT values across all four phonemes remains fairly stable when he switches between Cantonese and HKE, possibly this means M.W. has only one set of plosives for both languages. However, for C.Y. this is not the case. Except for /d/, changing between Cantonese and HKE affects the VOT significantly. This distinguishes C.Y. from M.W. as two different individuals.

With only four phonemes studied here, and two possibilities with regards VOT L-shift (either significant or not), there are 16 ( $=2^4$ ) possible profiles. Thus for a HKE~Cantonese bilingual, with these four phonemes, speakers can be divided into 16 categories depending on the profile of what VOT-L-shifts are significant. This means that there is a 6.25% (1/16) chance that any two HKE~Cantonese bilinguals agree in their VOT L-shift profiles for /p, b, t, d/. In the case of the five speakers studied here, it turns out that all five have different VOT L-shift profiles, tabulated in (15) for ease of comparison.

<sup>15</sup> Thus (13) does not apply to changes in VOT across plosive phonemes in the same language.

(15) Comparing VOT L-shift profiles for all five speakers

		VOT L-shift Significance
C.Y.	/p/	Y
	/t/	Y
	/b/	Y
	/d/	N
M.W.	/p/	N
	/t/	N
	/b/	N
	/d/	N
A.H.	/p/	Y
	/t/	Y
	/b/	N
	/d/	Y
J.K.	/p/	N
	/t/	Y
	/b/	N
	/d/	Y
W.C.	/p/	Y
	/t/	Y
	/b/	N
	/d/	N

Evidently, VOT L-shift profiles are constrained by the number of phonemes and by the number of languages commanded by the bilingual (or rather multi-lingual). This is because the number of VOT L-shift profiles is given by the formula in (16).

(16) Number of VOT L-shift profiles =  $2^P C_2^L$   
 , where P = number of phonemes; and L = number languages > 1

The formula in (16) factors into account the possibility of multilingualism, where if there are 3 languages commanded by an individual, then it follows that there can be three sets of VOT L-shift profiles: one set between L<sub>A</sub> and L<sub>B</sub>; between L<sub>B</sub> and L<sub>C</sub>, and between L<sub>A</sub> and L<sub>C</sub>.

**4. Implication and Limitations**

*4.1 Increasing viability of VOT L-shift Profile*

The results in section 3 imply that the viability of VOT as a parameter for forensic speaker-identification is not entirely useless. At the very least, with respect to bilinguals, it would be useful for narrowing down possibilities when there is a match in VOT L-shift patterns.

In this research we have investigated only four phonemes, and by the formula in (16), the chances of a VOT L-shift. Profile match would be only 6.25%. However, HKE and Cantonese both have six plosive phonemes. Extrapolating from the results of our experiment, the number of VOT L-shift profiles would increase to 64 (=2<sup>6</sup>), so that there

is only a 1.56% chance<sup>16</sup> of a perfect match on VOT L-shift profiles. Increasingly, Hong Kongers are becoming trilingual (adding Putonghua to their repertoire of languages), which would reduce the chance of match to 0.52%. Though not anywhere as rare as two identical snowflakes, two identical DNA samples or two identical thumbprints, a 0.52% chance of perfect match is itself quite useful, it means the test is 99.48% accurate.

Further, since more and more people are learning foreign languages (Japanese, French, German, Korean, Italian and Spanish are among the favorite foreign languages in Hong Kong), the potential for using VOT L-shift profile increases exponentially.<sup>17</sup>

#### 4.2 Collapsing of phonemes to their voicing categories

There are, however, a number of limitations in the present report. The most obvious one is that the velars have been left out. Also, in studying VOT variation across moods, we have not separated out each phoneme, collapsing /p, t/ into one category and /b, d/ into another. The unpromising results in (6) and (7) could well be due to this. As such, it may well be that, contrary to our claim, VOT remains useful for speaker identification across a range of moods, notably by way of something parallel to VOT L-shift. In this case, what is needed would be shift of VOT values across moods (M-shift). If this turns out to be viable, then it would be even more useful than appealing to VOT L-shift profiles since VOT M-shift would apply to monolinguals as well. When applied to bilinguals, the number would be further multiplied by the number of languages in command for intra-language mood-shift.

$$(17) \text{ VOT M-shift profiles} = 2^P C_2^M L$$

, where M = number of emotional states > 1.

By (17), a monolingual would have a 0.26% chance of a perfect match when calculate over four emotional states.<sup>18</sup> It would be useful for polyglots too, and would significantly increase reliability, since the total number of profiles would increase to the formula given in (18) where L-shifts would also be applicable.

$$(18) \text{ Number of VOT shift profiles} =$$

$$\text{VOT L-shift profiles} + \text{VOT M-shift profiles}$$

For bilinguals, for example, there would only be 0.12% of a perfect match for bilinguals (assuming a set of six plosives over 4 emotional states).<sup>19</sup> This gives a 99.88% accuracy.

There is but one difficulty on working with emotional states. These states are highly subjective and difficult to discern. In our study, four states (neutral, happy, sad and angry) are chosen, but it is very hard to decide if these can serve as cardinal

---

<sup>16</sup> Chance of a perfect match is derivable by a simply dividing 1 by the total number of possible combinations, then multiplied by 100%.

<sup>17</sup> This of course assumes that different languages have differing VOT values, which is empirically supported by such works as Shimizu (1996) and Kilpatrick (2003).

<sup>18</sup> Calculated from  $2^6 C_2^4 * 1$

<sup>19</sup> Calculated from  $2^6 C_1^2 + 2^6 C_2^4 * 2$ , see (18).

reference states the same way cardinal vowels are used in phonetics or cardinal points are used in a compass.

#### 4.3 *Impact of vowels on VOT*

It is well-known that the quality of vowels that immediately follow the plosive affects the VOT values (Shimizu 1996:27, 55, 111). In this research, the VOT of each plosive is obtained by averaging the values for plosives immediately preceding a high, front vowel; a low vowel; and a high, back vowel. Thus for any plosive P, we have equal tokens of Pi, Pa and Pu profiles, which are then averaged for the mean VOT of that plosive. This effectively masks the individual effect of vowels on plosives (recall section 2.3). Given that VOT L-shift profiles can be speaker-specific, one can envisage the possibility of VOT V-shift where for each speaker, the impact of vowels on the VOT value of each plosive would be different. Again, since vowel quality differs across languages, the formula for VOT V-shift profiles would look very much like (17), given here as (19).

$$(19) \text{ VOT V-shift profiles} = 2^P C_2^V L$$

, where V = number of different vowels > 1.

We have not made calculations in this regard, but if useful, the formula in (19) would have to be revised as (20).

$$(20) \text{ VOT shift profiles} =$$

L-shift profiles+M-shift profiles+V-shift profiles

Evidently, this would make it a lot harder for there to be a perfect match in VOT shift profiles, making the use of VOT a viable and easy tool for forensic speaker identification. The formulae for VOT L-shift, M-shift and V-shift can of course be further fine-tuned. For example, in (16), we have conflated all four emotional states and all vowel differences to obtain the VOT L-shift. This need not be so, which would increase the total number of profiles by a factor of V and M. Likewise, in VOT M-shift, we have conflated the vowel differences and in VOT V-shift we have conflated the emotional state differences.

Alternatively, one can imagine simplifying the formulae for VOT M-shift and V-shift by conflating the language differences so that L=1 for all cases. We are not sure how best to approach this at this point. As in all research that relies on statistics, there are limitations in the sample size, sample range and sample type. In these areas, we invite anyone interested to join us.

## 5. **Conclusion**

This research begins with the assumption that since speakers cannot consciously manipulate VOT, it is potentially useful for forensic speaker identification. To this end, data for four plosives / p, t, b, d/ across two languages (Cantonese and Hong Kong

English) are collected from five bilingual individuals. Results show that intra-speaker variation of VOT values often overlap with inter-speaker variation, making any simplistic use of VOT measurements for speaker identification naïve. However, if one looks into profiles of VOT shifts across languages, then one arrives at a speaker-specific property. This would, of course, apply only to people with command over at least two languages. This implies that similar approaches may be used to study VOT shifts across other parameters such as emotional states or vowel environments. If applicable, then tabulating VOT shift profiles would be useful for monolinguals as well.

# Some Insights into the Cultural History of Europe as provided by the *Atlas Linguarum Europae* (ALE)

Wolfgang Viereck

University of Bamberg  
Obere Dorotheenstr. 5a; 96049 Bamberg/Germany  
wolfgang.viereck@uni-bamberg.de

## Abstract

The *Atlas Linguarum Europae* is, primarily, an interpretative word atlas. Its most original aspect is motivational mapping. This procedure asks for the causes or the motives in designating certain objects. The motivations, however, should be transparent. Only then can formal differences between languages be disregarded and the focus placed solely on semantic parallelism. As religion is the basis of every culture, the frame of reference is the history of religions. The geolexical data show that the cultural history of Europe is not made up of random elements and events but follows a unified, well-structured pattern where three separate layers can be distinguished, one historical layer and two pre-historical ones. These are illustrated with a number of examples.

**Keywords:** History of religions, Christian and Muslim layer, anthropomorphic layer, zoomorphic layer, motivational mapping.

## 1.0. Introductory Remarks

The *Atlas Linguarum Europae* (ALE) has been in existence since 1970. The seventh fascicle has just been published (Viereck 2007 [2008]), thus bringing the number of published maps and commentaries to eighty. The ALE can be called a linguistic atlas of the fourth generation, being preceded by regional and national atlases as well as by atlases of language groups. Atlases of the fifth type, i.e. on entire language families such as Indo-European, or of the final type, namely a world linguistic atlas, do not exist as yet, although interesting work has recently been made available with *The World Atlas of Language Structures* (Haspelmath et al. 2005). The ALE is the first continental linguistic atlas. Its frontiers are neither political nor linguistic but simply geographic. The choice of the continent has nothing to do with Eurocentrism but only follows from the present state of research.

The ALE maps distinguish between six language families: Altaic, Basque, Caucasian, Indo-European, Semitic and Uralic. In these language families, 22 language groups in total, such as Romance and Slavic, can be counted. These, in turn, consist of many individual languages. It thus becomes apparent that the demands on scholars to interpret the heterogeneous data collected in 2,631 localities from Iceland to the Ural mountains are very high indeed. It is always the oldest vernacular words that are looked for in the various languages. These are, then, put on symbol maps and interpreted either synchronically or diachronically, as the cases require.

As regards the ALE, insights into Europe's cultural past follow less from loanwords and from reconstructed roots, although the project also has important contributions to its credit in these two areas. Loanwords usually belong to the historical period and are thus too young. Reconstructed roots involve very early periods but are usually

motivationally opaque and thus not very revealing for a cultural analysis. ALE's main concern then is to ask for the causes or motives in designating certain objects. These motivations should be transparent as only then can formal differences between languages be disregarded, so that the focus rests solely on semantic parallelism. Motivational mapping is an innovative kind of interpreting geolexical data. Only in a large-scale project such as the ALE can this approach be successfully pursued. When the area to be investigated is too small this approach will not be productive.

Also insights into the ethnolinguistic origins of Europe are expected from the ALE. This is a most lively and controversially debated field at present where archaeologists and geneticists join forces with linguists. In the Uralic area the Continuity Theory, first advanced by archaeologists then by linguists, seems now accepted by the majority of the specialists. According to this theory, Uralic peoples and their languages have lived in their present historical territories since the Mesolithic Age. A similar approach was fairly recently adopted for Indo-European arguing that there has never been an Indo-European invasion and that Indo-European languages have followed the same diffusion patterns as the Uralic languages.

## **2.0. Cultural History and Religion**

As religion is the basis of every culture, the frame of reference is the history of religions. As any class of realia such as plants, animals and natural phenomena including planets is magic, they thus have a magico-religious character whose earliest form manifests itself in totemism, in totemic relationships with various classes of realia. In so-called primitive societies this is still observable today. This relationship assumes different manifestations, as will be shown later.

The geolexical data show that the cultural history of Europe is not made up of random elements and events but follows a unified, well-structured pattern where three separate layers can be distinguished. The layer that can be recognised and dated most easily belongs to history, namely to Christianity and Islam. Within this layer Christian motivations appear much more often than Muslim ones, thus mirroring the difference in the areal spread of the two religions in Europe. In the pre-historical period two levels can be distinguished, one, anthropomorphism, characterised by 'supernatural', 'superhuman' pagan figures, and the other by still earlier zoomorphic and kinship representations. The basic structure has remained the same from pre-historical to historical times. While dating the first-mentioned layer is unproblematic, anthropomorphic representations of reality are connected with socially stratified societies, typical of the Metal Age, while zoomorphic and kinship representations are connected with more primitive societies of the Stone Age. Unlike vertical dead archaeological stratigraphies, linguistic stratigraphies as presented on ALE motivational maps are horizontal and all the above layers are still alive. In the following sections these three layers are illustrated with a number of examples.

### *2.1. The Christian and Muslim Layer*

With regard to animals, the butterfly is interesting. The *Oxford English Dictionary* (1989, s.v. 'butterfly') surprisingly notes "The reason of the name is unknown".

However, in the Germanic area the belief was widespread that witches in the appearance of butterflies stole butter, milk and cream. Compounds with *butter-* occur most often, see Dutch *botervlieg*, German *Butterfliege*, both ‘butterfly’, and English *butterfly*. Dutch *boterhex*, *boterwif*, both ‘butterwitch’, clearly point to the belief in witches. Whereas this aspect is, of course, pre-Christian, the butterfly is christianised in Europe, too, mainly in the South as ‘little angel’ or, in Greece, as ‘the pope’s wife’ (priests in the Greek Orthodox Church are allowed to marry before their ordination as deacons), but also in Finland as ‘Brigit’s bird’.

The lady-bird also yields a rich harvest everywhere in Europe. Most commonly a Christian or Islamic religious being or notion is associated with another animal, such as a bird (cf. English *lady-bird*), a hen (Danish *marihøne* ‘Mary hen’, French *poulette au bon Dieu* ‘good God’s young hen’, Basque *jinkoilo* ‘God’s hen’), a cock (Norwegian *marihane* ‘Mary’s cock’), a cow (English *cow-lady* or *lady-cow*, Polish *boża korówka*, Russian *bozhia korovka*, both ‘God’s cow’, French *vache à Dieu* ‘God’s cow’, Italian *vaccheta de la Madonna* ‘young cow of the Holy Virgin’), an ox (Spanish *buey de Dios* ‘God’s ox’), a beetle (German *Marienkäfer* ‘Mary’s beetle’, English *lady-bug*) or, more generally, a little animal (Dutch [*Onze*] *Lieveheersbeestje* ‘Our Lord’s little animal’, Galician *palomina de Dios* ‘God’s little dove’). The religious being or notion can be ‘God’, in addition to the examples above see Spanish *arca de Dios* ‘God’s chest’, ‘angel’ (Breton *elik doue* ‘God’s little angel’), ‘Jesus’ (Swedish *Jesu vallflicka* ‘Jesus’ shepherd’), ‘(Virgin) Mary’ (Swedish *jungfru marias nyckelpiga* ‘Virgin Mary’s key servant’, Italian *anima della Madonna* (soul of the Holy Virgin’) or the names of saints such as, in Italy, *San Martino*, *San Gioani*, *San Nicolà*, in France, *Saint Jean*, *Saint Jacques*, *Sainte Catherine* and, in Spain, *San Antón*. In the Muslim area we find ‘Allah’, ‘mosque’ and ‘Fatimah’, the name of Mohammed’s daughter, for the lady-bird.

For plants the religious motivations are more numerous. The proof that language can so accurately reflect the history of religions is best seen with regard to the world of plants. This is thanks to the founder of modern botany, the Swedish scholar Carl von Linné, whose 300th birthday was celebrated in 2007. He laid down the rules for naming plants and decided to keep all those names of plants that had been named after kings, gods or Christian saints. The daffodil (*Narcissus Pseudo-Narcissus*) is *Saint Peter’s bell* in Wales, and *Saint Peter’s herb* is an expression for the cowslip (*Primula veris*) in parts of England; this plant is called *Sankt Pers nycklar* ‘Saint Peter’s key’ or *jungfru Marie nycklar* ‘Virgin Mary’s key’ in Sweden. Among the plants named after Christian saints may also be noted Latin *herba sancti Johannis* ‘Saint John’s wort’, German *Johanniskraut* ‘John’s wort’, English *Saint John’s wort* (*Hypericum*). The milk thistle (*Silybum marianum*) is *Lady’s thistle*, *Marian thistle*, *Saint Mary thistle* in English and *Mariendistel* ‘Mary thistle’ in German. *Galium verum* is called *Lady’s bedstraw* in English and *jungfru Marie sänghalm* ‘Virgin Mary’s bedstraw’ in Swedish. Swedish (*jungfru*) *Mariékåpa* ‘(Virgin) Mary’s habit’ is English *Lady’s mantle* for the *Alchemilla*.

Natural phenomena also testify to a Christianisation and Islamisation in Europe. The classic example of the ALE is the rainbow. Everywhere in Europe we find compounds with, for example, ‘belt’, ‘bow’, ‘bridge’, ‘ring’ plus a religious motivation such as ‘God’s belt’, ‘Noah’s bow’, ‘Saint Barnaby’s crown’ or ‘Allah’s bow’. An example from Latvian (*dieva juosta* ‘God’s belt’) must suffice here. Once the basic structure of the classificatory system had been worked out, it became clear that the rainbow had

been considered sacred by European peoples and that, with the advent of the new religions, lexical innovations were coined expressing the same relationship that had existed earlier. Even Christmas belongs to the natural phenomena as the pre-Christian winter solstice underlies the Christian feast. Not unsurprisingly, therefore, only a few names for Christmas have a Christian motivation, such as ‘Christ’s mass’, ‘Christ’s birth’, ‘Christ’s day’, attested in Albanian, Basque, Dutch, English, German, Greek, Sardinian, Spanish and Polish *Boże Narodzenie* ‘God’s birth’, i.e. ‘Christ’s birth’.

Apart from the names that refer to God and Christ themselves, ‘Easter’ is also of Christian origin, mostly attested as ‘Little Easter’ in southern Europe. Here the pre-Christian influence becomes noticeable, as in pagan times there were two important feasts in the course of the year. To call Christmas ‘Little Easter’ shows that the more important of the two was that in spring and summer, the real Easter.

In parts of Italy, for instance, *ceppo* ‘log’ also means Christmas. This is, of course, pre-Christian. It denoted the fires to celebrate the winter and summer solstice. Of these mainly the fires lit on St. John’s Day have remained today in many parts of Europe. Since Christianisation was more successful with the winter solstice, such fires are encountered today much more rarely. Expressions such as English *Yule-log* and German *Christusklotz* ‘Christ’s log’ for Christmas point to that old custom and are a sign of the mixing of different religious conceptions.

## 2.2. The Anthropomorphic Layer

The same notions that provide examples for the other layers can be drawn upon for this middle layer, which is both pre-Christian/pre-Islamic and post-zoomorphic.

The butterfly appears in Austria as ‘forest’s elf’ and in Russian as *babočka*, in Belorussian as *babačka* (from the goddess *Baba* ‘Old Woman’). The lady-bird is associated with the Finno-Ugrian god *Ukko* ‘Old Man’, in Frisian with the elf *Puken* ‘puck’, in southern Italy with the elf *Monachello*, in Romanian with *Paparuga* and ‘witch’ and in Greek with the *Moirai*.

In the case of plants, the motivation ‘fairy’ occurs in England for the cowslip (*Primula veris*) as *fairy cups*, the dwarf or purging flax (*Linum catharticum*) as *fairy flax* and the purple foxglove (*Digitalis purpurea*) as *fairy cap* or *fairy thimble*. The latter is also attested in Ireland and Scotland together with *fairy finger*. The bending of the tall stalks of this plant is believed to denote the unseen presence of supernatural beings.

Among the natural phenomena, the rainbow has anthropomorphic representations everywhere in Europe. In the Turkic area they are associated with Kalmuk *Taengri*, in the Uralic area with *Ukko* and *Tiermes*, in the Indo-European area with *Laume* (in the Baltic region), *Iris*, ‘Old Woman’ (in the Romance and Slavic regions) and *Soslan* in Ossetian, often together with ‘bow’, ‘belt’ or ‘ribbon’. For thunder as well as for lightning one encounters the Celtic storm-god *Taranos*, Germanic *Thor*, Lithuanian *Perkūnas*, the Finno-Ugrian *Ukko*, the Lapp *Tiermes* and the Slavic *Perun*; in the Finno-Ugrian area ‘Old Man’ was also repeatedly attested for thunder and lightning.

### 2.3. The Zoomorphic Layer

In the most archaic layer, i.e. the zoomorphic and totemic layer characteristic of egalitarian societies, the realia investigated appear in the form of either an animal or a kinship name. As this is the oldest layer, the evidence is, quite naturally, less overwhelming than for the two younger layers.

Coming to animals, Riegler (1937/2000) had already interpreted wild animals and insects as relics of a totemistic view of the universe in which they would be our closest relatives. This relationship, similar to kinship, is consequently expressed by kinship terms. Propp (1946) noted that the totem animal in its original form is embodied by the ‘mother’ and by matrilinear kins. This is indeed what we most often find in European dialects. The butterfly as a relative appears as *mammadonna* ‘grandmother’ in Rhaeto-Romance, as ‘mother’ in German and Sardinian and as ‘(grand)father’ in the Uralic area. Many kinship names were recorded also for the lady-bird: ‘grandmother’ in, for example, Polish, Russian, Serbian, Croatian, Mordvin, Udmurt, Finnish and Komi-Zyryan, ‘mother’ in, for example, Romanian, Belorussian, Tatar, Bashkirian and Livian, ‘aunt’ in German and Italian, ‘bride and spouse’ in, for example, Turkish, Albanian, Macedonian, Italian, ‘sister-in-law’ in Bulgarian. ‘Grandfather’ occurs in Swedish, Komi-Zyryan and Maltese and ‘uncle’ in Albanian for the same notion lady-bird.

Compared with animals, plants do not seem to play the same role in totemism. Some plants are given kinship names, others are associated with animals. The pansy (*Viola tricolor*) is called *Stiefmütterchen* ‘little step mother’ and *Stiefkind* ‘step child’ in German. In Ukrainian the pansy has both kinship and animal names: ‘brothers’, ‘brother and sister’, ‘orphan’ and ‘cuckoo birds’. *Dziad* ‘grandfather’ occurs in Polish for the blackberry (*Rubus fruticosus*).

As to natural phenomena, thunder is called ‘grandfather’, ‘father’ and ‘dear father’ in the Finno-Ugric area and lightning ‘grandfather’ in Mordvin and Udmurt and ‘dear father’ in the Finno-Ugric area. This relationship is clearly totemic. In this class of realia animals occur rather often. For the rainbow we have ‘dragon’, ‘snake’, ‘ox’, ‘cow’, ‘fox’ and ‘drinking animal’ in many European dialects and languages.<sup>1</sup> Other zoomorphic representations appear with thunder, namely ‘dragon’ and ‘serpent’ and with lightning, ‘whale’ and ‘dolphin’ (in France and Italy). The same phenomenon occurs in Africa, where lightning is often perceived as an animal, usually a quadruped or a bird (cf. Lagercrantz 2000).

Also designations for bread, names of diseases and children’s rhymes follow the same pattern (cf. K. Viereck & W. Viereck 1999 on names of diseases, W. Viereck 2000 on names of bread and W. Viereck 2003 on children’s rhymes). Unfortunately, the ALE has only one notion in the area of diseases whose responses are, moreover, irrelevant for this model.

### 3.0. Conclusion

In the process of the cultural development of Europe, we thus find recurrent structural patterns: the same reality was first given kinship and zoomorphic names to be followed by anthropomorphic names and finally by Christian and Islamic names – and this across

all language and dialectal borders. If peoples did not migrate, then, no doubt, concepts did.

The three periods mentioned, of course, do not end and begin abruptly. Archaeological finds show that there were fluid transitions also between the Stone Age, on the one hand, and the Metal Age, on the other, and that anthropomorphic representations were known also in the Neolithic period (cf. Müller-Karpe 1998). Also Riegler noted: “Remarkable are the many transition phases that led from the theriomorphic to the anthropomorphic apperception” (1937/2000: 826f.; translated from German). That the transitions between the pagan and the Christian layer can be better documented can be explained with the greater temporal proximity to us. Up to the early 4th century the Christian church had been an underground church – Constantine I (272 - 337) was the first Christian Roman emperor who, in 313, issued the Edit of Milan legalizing Christian worship - and it took many centuries until the Christian faith had penetrated the whole of Europe. In the North of Europe heathendom and Christianity had co-existed down to the 11th century (cf. Capelle 2005, who calls his book characteristically “heathen Christians”). Just as earlier pagan places of worship had turned into Christian places of prayer, so Christian churches later turned into mosques. The best-known example of such a transformation is no doubt the Hagia Sophia in Istanbul. There are also examples of mosques converted into Christian churches, as the Shrine of our Lady of Europe in Gibraltar shows that the Spaniards converted into a chapel in 1462. Also Jewish synagogues were consecrated as Christian churches. A good example where the change was even kept in the name is the Sinagoga Santa Maria la Blanca in Toledo that became a Christian church already in 1405 long before the Jews had been expelled from Spain in 1492.

With new religious beliefs a wave of new designations followed, yet the old conceptions often remained the same. To take just one example out of many:

When Christianity came to Britain [in the late 6th and during the 7th century], the bright yellow flowers of the plants in the *Hypericum* family that had been associated with the golden brightness of Baldur the sun-god came to be called St. John's wort, as Baldur's Day became St. John's Day. The plant continued to be thought a cure for wounds and on St. John's Eve good Christians wore a sprig of it to ward off evil spirits and especially to protect themselves against the stray thunderbolts of the gods (Ashley 1974: 116).

St. John's Day is the Christian equivalent of the summer solstice, one of the most important events in pre-historic times. In the early Christian period pagan thought was alive and well. However, examples of this can easily be found today: The initials of Caspar/Kaspar + Melchior + Balthasar + the year are still written on the entrance doors of people's houses in Catholic areas in Germany, Italy and Poland on Epiphany, January 6, to protect the people from evil of any kind and small pictures of Christopher are hung up by car drivers as a protection in many countries, such as Germany and Ukraine. Apparently Enlightenment had no effect on people's piety.

The ALE is naturally based on European dialects. The adopted motivational approach has uncovered some important pieces in the mosaic of the cultural development of Europe. Their implications, no doubt, transcend the frontiers of the European continent. In the light of the complementary nature of world cultures, it would

be highly desirable if the picture presented here were systematically complemented by insights gained in other cultures.<sup>2</sup>

## Notes

<sup>1</sup> The rainbow as a drinking animal is attested also beyond Europe in Japan and in China. In Chinese culture it is a double-headed dragon drinking water on both sides of the river.

<sup>2</sup> I am thinking of work similar to that carried out by Frobenius who, in 1929, was concerned with the gender of the sun and the moon and presented three cosmogonic groups with insightful maps world-wide in which the sun and the moon were linked with ,man and wife', with ,brother and sister' and with ,twin brothers'. The last-mentioned was to him the oldest view of life. Unfortunately, some of Frobenius' interpretations were tied to the prevailing thoughts of the time and can thus not be accepted.- I gratefully acknowledge the following additions made by members of the audience in Seoul: 'God hammering' for thunder in Japanese and *mu-dang* 'lady + evil spirit' (!) for the lady-bird in Korean.

# **A Study on Parsing Strategies of the Consonant-Clusters in Taiwan Mandarin Loanwords**

**Wu, Chinwei**

Associate professor, Department of Chinese  
National Taiwan Normal University  
jean\_ww@hotmail.com

## **Abstract**

In this study, a corpus of Taiwan Mandarin loanwords translated from English is set. There are about five hundred loanwords. The percentages for the different strategies to parse the consonant clusters and the percentages of occurring in the syllabic positions would be calculated and listed. The final results would tell the coda/onset asymmetry and epenthesis/deletion asymmetry. That is, the onset seems to be more important than coda and the epenthesis is a better strategy for preserving every perceived element. And some segment such as the fricative [s] is always preserved. It tells the effect of perception. The perception seems to be the key point during the parsing.

**Keywords:** consonant-cluster, loanword, parsing strategy, deletion/epenthesis

## **1. Introduction**

This paper aims at the parsing strategies of the consonant-clusters in Taiwan Mandarin Chinese loanwords from English. In loanword phonology, if the native language does not allow some kinds of consonant clusters in the syllables, and then the permissible parsing strategies might be: the first is adjustment or change of phonological features; the second, deletion of some consonant; the third, epenthesis of some segment, such as vowel to create a new syllable. All these parsing strategies are due to not to violate the phonotactic constraints in the native language. The complex onsets and complex codas are not allowed in n Taiwan Mandarin syllables. In Mandarin loanword phonology, it is proposed that those strategies are often used to translate the borrowing words, but especially the epenthesis strategy is a better one than deletion. That is, most of the segments in the native words are parsed out in loanwords, especially in the onset positions. Besides, some segment such as /s/ would always be parsed out no matter what position it's in. It is also proposed that the preference for the onset

segments and some segments such as /s/ is due to the perceptual factors. The more beneficial for perception the segment in input is, the more probable to be parsed out the segment in output is. We tried to analyze these phenomena in the Optimality Theory (Prince & Smolensky 1993, McCarthy & Prince 1993, 1994) framework. The relevant constraints are grounded according to the Perception-Map model (Côté 2000, Jacobs & Gussenhoven 2000, Kenstowicz 2001, 2003, Lombardi 1999, 2000, 2002, Steriade 1997, 1999a, 1999b, 2000a, 2000b, 2001).

Here is a brief introduction about Taiwan Mandarin Chinese phonotactics. As for the syllable types, there are just four slots at most in Mandarin Chinese syllables. One consonantal onset (C), a prenuclear glide (G), one vowel (V) and one coda (Co). Only the nucleus vowel must occur, others are not requested. Only one segment is allowed to be the onset, and one for the prenuclear glide and one for the coda. Therefore the allowing syllable forms in Taiwan Mandarin are: CGVCo, CGV, CV, CVCo, GV, GVCo, VCo and V. There are 21 consonants such as labials /p, m/, coronals /t, l/, dorsals /k, x/ allowing to be as the onset. The three glides /y/, /w/, /ɥ/ could be as the prenuclear glides. The coda segments are restricted the 4 ones /y/, /w, n, ŋ/. The Mandarin loanwords translated from English are according to the phonotactic constraints above.

The subparts in this paper are: the first part is introduction, the second is the literature review about the loanword phonology; the third is the descriptions of Mandarin loanwords from English; the fourth is the analysis of the strategies; and the final is the conclusion.

## **2. Literature review**

Loanword phonology has attracted much attention in the literatures, such as Silverman (1992), Yip (1993), Kenstowicz (2000, 2001, 2003) and many others. For it reveals some interesting patterns observed not in normal data. In a rule-based derivational framework such as Hyman (1970), Wingstedt & Schulman (1984), loanword phonology has to be considered as consisting of some intermediate levels; and some rules especially suggested for processing loanwords. This framework would have confronted the difficulties: some rules are necessary at some intermediate level processing loanwords but might disappear at later levels. Bauer (1985) and Yip (1993) argue that loanwords would conform to the already existing structures, and also maintain the structure of the incoming loans as much as possible. The change is only for increasing well-formedness (Yip 1993). The conflicts of adjustment and maintenance in

loanwords could be solved in a constraint-based analysis.

In loanword phonology, prosodic structure adjustment and phoneme substitutions are the most common patterns. Chao (1976:185) observed the tendency that the sounds within the inventory of the native language are used to approximate the sounds of foreign words in Chinese loanwords. Some studies such as Chao (1976), Wu (1988) list many loanwords in Mandarin. Most of their data are analyzed from the morphological perspective. Here the phonologically-translated loanwords would be the main focus.

Cheung (1986) describes the phonological patterns of Cantonese loanwords transliterating from English. Deletion or epenthesis of a segment into the consonant clusters makes the disyllabic form. The adjustment does not violate the phonotactic system in Cantonese. The disyllabic form is the preferred type. At the suprasegmental level, the primary stress syllable in English is mapped with the high-level tone in Cantonese. Silverman (1992) extends the results of Cheung (1986) and suggest the bi-level model for loanword phonology. The loanwords would be multi-scanned at the Perceptual level and the Operative level. Later Yip (1993) analyzes the prosodic structures of Cantonese loanwords in OT. The adjustment is made to produce an optimal output respect to the universal constraints, e.g. the constraint *MINIMAL-WORD* for the tendency towards disyllabic form<sup>1</sup>. Guo (1998) analyzes the Mandarin loanwords focusing on the prosodic structure and phoneme substitution. He finds the onset-coda inconsistency in Mandarin loanwords. The coda cluster in English source words is not always faithfully parsed. The unsalient segments such as liquids would undergo deletion. More studies on other languages, such as Broselow (2000), the adjustment in loanword phonology is accounted for through the output constraints ranked above the faithfulness constraints. And loanwords are accounted for by the same grammar for the native words.

As mentioned above Cheung (1986) and Silverman (1992) do not ignore the mapping relation between the stress and the high tone in Cantonese loanword phonology. Chao (1976:181) also observed that the Cantonese use high tones for indicating stress in the names transliterating from English. In Japanese, the loanwords transferring from English the stress position are with the high accent (Chen 1998). Tsao (2000) observes that Taiwanese speakers transfer the Japanese pitch accent (the stress position) as the high tone. Actually the tone is carried over the stress in Mandarin words. However in loanwords the relationship of tone and stress is found in Mandarin as well as in other

---

<sup>1</sup> Chao (1976: 182) mentioned that Chinese transliteration of foreign names avoids monosyllables, which are felt somehow to be too short for place names. And a monosyllabic surname is usually broken into two syllables possibly because a monosyllabic form does not sound like a free word.

languages (Rivera-Castillo 1998). In terms of OT the relationship between the two suprasegmental features might have a better explanation.

In this paper the processing strategies of consonant clusters would be the focus. The OT analysis for loanword phonology is expected to have the economic explanation the loanword patterns are accounted for by the ranking of constraints. The analysis would provide more insights about the inner system.

### 3. Data descriptions

#### 3.1 Mandarin loanword data

First of all, I set a database of Taiwan Mandarin loanwords, collected from the dictionary, the names of new products and the commercial brands .....etc. There are three kinds of Mandarin loanwords. The first kind of loanwords is semantically-translated, such as “electric-mail” [tien tsɿ you tɕien]. The second kind is phonologically-translated, such as “blog” [pu luo kɤ]. The third kind is phonologically-semantically translated, such as “beer” [p<sup>h</sup>i] ([tɕiou]), in which the second syllable means wine. I checked about 1150 phonologically-translated loanwords from English. Then I chosed 435 English words with consonant clusters among them. There are 106 consonant clusters in the initial position; 300 consonant clusters in the medial position; 92 consonant clusters in the final position. I observed the parsing strategies of the consonant clusters in three word positions: initial, medial, final. In Table. 1, the English words are with initial complex onsets and the onset consonants are parsed out in loanwords. In Table.2, the English words are with medial consonant clusters. A vowel is epenthesized between consonants to make a new syllable in (1-2-a). A consonant (the stop sound) is deleted in (1-2-b). The lateral is changed to a retroflex vowel in (1-2-d) but is deleted in (1-2-e). Moreover the medial nasal is parsed as the nasal coda of the first syllble, such as (1-1-b),(1-2-a)(1-2-b).

	English	Mandarin Loanword
1-1-a	Blog	[pu luo kɤ]
1-1-b	brandy	[pai lan ti]
1-1-c	Bruce	[pu lu st]

1-1-d	Chris	[k <sup>h</sup> ʃ li sɪ]
1-1-e	trust	[t <sup>h</sup> uo la sɪ]
1-1-f	Truman	[tu lu mən]

[Table. 1]

	English	Mandarin Loanword
1-2-a	England	[iŋ kʏ lan]
1-2-b	Scotland	[su kʏ lan]
1-2-c	Ashley	[ai ʃi li]
1-2-d	alpha	[a ə fa]
1-2-e	Albert	[ia po t <sup>h</sup> ʃ]

[Table. 2]

In Table. 3, the English words are with final consonant clusters. The coda segments are parsed in (1-3-a)(1-3-b), for one of them is a nasal, which is as the nasal coda. The other is as the onset of the following syllable. In (1-3-c), one (the stop sound) of the final cluster is deleted. In (1-3-d)(1-3-e) both consonants are parsed out; one as the nasal coda, the other is /s/ sound and parsed as the onset of the new syllable (1-2-a)(1-2-b).

	English	Mandarin Loanword
1-3-a	<b>pump</b>	[pɑŋ p <sup>h</sup> u]
1-3-b	tank	[t <sup>h</sup> an k <sup>h</sup> ʃ]
1-3-c	<b>England</b>	[iŋ kʏ lan]
1-3-d	<b>Hopkins</b>	[xuo p <sup>h</sup> u tʃin sɪ]
1-3-e	<b>Williams</b>	[wei lien sɪ]

[Table. 3]

### 3.2 the results

	epenthesis	deletion	adjustment
initial	77.35%	4.72%	81.13%
medial	39.66%	3%	39.33%
final	27.17%	67.39%	15.21%

[Table. 4]

By comparing epenthesis in the three word positions, epenthesis of vowel in word-initial position is the highest, 77.35% and much higher than the others. It is due to all the consonants are parsed out in loanwords. By comparing deletion in the three word positions, deletion in word-final position is highest and also higher than the others. It is often to delete one coda segment in the word-final positions, especially the loanword is above bi-syllabic. By comparing adjustment in the three word positions, adjustment of phonological features in word-final position is lowest, for some segments are deleted. adjustment of phonological features in word-initial position is highest, for some English consonant such as /r/ is not allowed in Mandarin.

Most of the time only one of the word-medial consonant to be the coda and the other to be onset in the following syllable. Logically speaking, consonant clusters could be resyllabified as onset/coda in case of inserting vowels. However I did not find the consonant clusters in initial and final positions to be resyllabified as onset/coda in syllables. In fact the segments in word-initial position are as the onset and the consonants in word-final positions are as the onset or deleted.

By comparing the strategies in word-initial position, epenthesis is much higher than deletion. By comparing the strategies in word-medial position, epenthesis is higher than deletion, too. By comparing the strategies in word-final position, deletion is higher than epenthesis.

Generally speaking, there is an epenthesis/deletion asymmetry. Epenthesis is the better strategy than deletion in parsing the consonant cluster in Mandarin loanwords from English. Another asymmetry is in the initial/final positions. Most of the segments in the initial position might be always parsed out; the ones in the final position might not be necessarily pared. Besides, the third asymmetry is for the medial consonants, only medial consonants could be as the onset or the coda in the syllabic level of the borrowing words. The information of the syllabic roles could be parsed out in the loanwords.

From the data, I tried to give some discussions about several kinds of consonants. In

Mandarin loanwords the nasals are parsed no matter what positions. For the phonotactics, only labial nasal codas are adjusted to coronal or velar nasals such as (1-3-a). Most of the stops are parsed in initial and medial positions but the stops might be deleted in word-final position, such as (1-3-a). For the phonotactics, the voiced stops are not allowed in Mandarin and adjusted to the voiceless ones. Fricatives are always parsed and seldom deleted no matter what positions. The /f/ sound is parsed in initial, medial, final positions, including ph /f/ sound. The /s/ sound is also parsed, such as (1-c-c)(1-2-b)(1-3-e). The liquid /l/ sound in initial position is parsed out mostly but the medial /l/ might be deleted. Mostly the /l/ sound is adjusted to the retroflex vowel /ʎ/, such as (1-2-d). Another liquid /r/ sound is parsed as the affricate or deleted. As for the consonantal categories the asymmetry for consonants (stop/fricative) in peripheral positions is that initial stops are parsed out but final stops are not; however, initial/final fricatives are parsed. It could be explained that when parsing borrowing words, the friction would be easily perceived in initial or final positions; conversely, the initial plosives are clear but the final unreleased stops are not perceived.

Comparing /r/ and /l/ parsing, for /r/ sound is not allowed in Mandarin Chinese, this segment has to be deleted or adjusted to other segments, such as /z/, /l/ etc. The /l/ sound is allowed to be an onset of a syllable. If the /l/ in the initial cluster then it is always parsed as an onset. Only the medial /l/ would be changed to /ʎ/.

In a sum here the asymmetries proposed are listed in (1-4):

(1-4-a) Asymmetry I: Epenthesis is the better strategy than deletion in parsing the consonant cluster in Mandarin loanwords.

(1-4-b) Asymmetry II: Most of the segments in the initial position are always parsed out ; the ones in the final position are not necessarily parsed.

(1-4-c) Asymmetry III: only the medial consonants could be as the onset/coda in the syllabic level of the borrowing words.

(1-4-d) Asymmetry IV: in peripheral positions, initial stops are parsed but final stops not; however, initial/final fricatives are parsed. The key factor is the perception of the friction

## **4. The Optimality Theory Analysis**

### *4.1 Analysis of Insertion in Loanwords*

In this section, the Mandarin Chinese loanwords would be analyzed with the ideas

of the Optimality Theory. As mentioned above Optimality Theory proposes the set of outputs of a given input are evaluated by the ranking of universal, violable constraints in parallel (Prince & Smolensky 1993, McCarthy & Prince 1994, 1995). If violations are inevitable, the highly ranked constraint must be satisfied. If two representations violate the same constraint, the better one is with lesser violations. The conformity or modification in loanword phonology is attributed to the constraint rankings. There are two forces engaged to form the loanword surface structures. There are two conflicting forces within the grammar: M<sub>ARKEDNESS</sub> constraints and F<sub>AITHFULNESS</sub> constraints. The faithfulness constraints require the correspondence between input and output. If faithfulness constraints are ranked above markedness constraints, the Mandarin loanwords to be identical to the English source words. According to the Correspondence Theory (McCarthy & Prince 1995), the relevant faithfulness constraints are M<sub>AXIMALITY</sub> (henceforth M<sub>AX</sub>) and D<sub>EPENDENCY</sub> (henceforth D<sub>EP</sub>) and I<sub>DENT</sub> (F).

(1-5-a) M<sub>AX</sub>: no deletion

Every segment in input has a correspondence in output.

(1-5-b) D<sub>EP</sub>: no insertion

Every segment in output has a correspondence in input.

(1-5-c) I<sub>DENT</sub> (F) : the distinctive features of corresponding segments are identical.<sup>2</sup>

The constraint D<sub>EP</sub> in (1-5b) bans insertion of any segment, while M<sub>AX</sub> in (1-5a) militates against deletion of any segment. The constraint (1-5c) I<sub>DENT</sub>(F) asks the feature values of two correspondences in input and output to be identical. For example, changing the voicing value between two correspondences has a violation of this constraint. If the three constraints are ranked above other output constraints, loanwords are identical to the source words. Actually loanwords are asked to change for nativisation. The more important reason why loanwords are forced to change is to form universally well-formed linguistic structures, e.g. the CV unmarked syllable type, or the unmarked foot structure---a disyllabic prosodic word. That is, there are conflicting forces mentioned above. The markedness output constraints ranked above faithfulness constraints make the conformity of loanwords.

The markedness output constraints concerning with the syllable structure are introduced below. Since the CV syllable type is the most common structure and is the possible in every language. There is an undominated constraint N<sub>UCLEUS</sub> (henceforth N<sub>UC</sub>), requiring every syllable must have a nucleus (Prince & Smolensky 1993). This undominated c

---

<sup>2</sup> This constraint would be discussed in the following sections.

constraint asks a syllable to have the nucleus. In Taiwan Mandarin syllables vocalic segments as the sonority peak within syllable is necessary. Owing to this constraint the inserted segment in loanwords is the vowel but not others. This is an undominated constraint, which I do not list in every tableau below but it is obeyed.

(1-5d) NUCLEUS: every syllable must have a nucleus.

(1-5-e) CC CON: except Cj or Cw, no consonant cluster is allowed within a syllable.

It is due to the output constraint \*COMPLEX, which bans the CC consonant clusters within a syllable. The repair strategies to avoid the violation of this constraint might be deletion or insertion. What kind of the CC sequences tolerated among languages is different. The consonant cluster tolerated within a Mandarin syllable must be two consonants maximally; the CC sequence of is only allowed to be in the initial position; the second consonant must be the glides /j/ or /w/. The constraint concerning with Mandarin syllable structure in (1-5e), the CONSONANT CLUSTER CONDITION (henceforth CC CON), is defined below. This constraint ranks above the faithfulness constraints. The tableau 8 shows the conformity of loanwords.

**Tableau 5**

Ranking: CC CON >>MAX >> DEP

Input: /p<sup>h</sup>Λmp/      Output: [paŋ. p<sup>h</sup>u.]

/p <sup>h</sup> Λm <sub>1</sub> p <sub>2</sub> /	CC CON	MAX	DEP
5a. p <sup>h</sup> Λm <sub>1</sub> p <sub>2</sub> .	*!		
5b. p <sup>h</sup> Λm <sub>1</sub> .		*!	
5c. p <sup>h</sup> Λp <sub>2</sub> .		*!	
☞ 5d. paŋ <sub>1</sub> . p <sup>h</sup> <sub>2</sub> u.			*(u)

The constraint CC CON outranks the faithfulness constraints. The sequence /mp/ in (5a) is not in the initial position and not one of the allowable CC sequence, so (5a) has the fatal violation (\* indicated as the violation and ! indicated as the fatal violation). Although one of the two segments is deleted in (5b, 5c) to avoid the violation of the higher constraint, yet they violate the high-ranked MAX. The optimal candidate (5d) (indicated by the pointing finger) is selected because it violates only the lowered constraint DEP.

**Tableau 6**

Input: /braun/ Output: [pu. lɑŋ]

/b <sub>1</sub> r <sub>2</sub> aun/	CC CON	MAX	DEP
6a. p <sub>1</sub> aun.		*!/r/	
6b. r <sub>2</sub> aun.		*!/b/	
6c. p <sub>1</sub> r <sub>2</sub> aun.	*!		
☞ 6d. p <sub>1</sub> u.l <sub>2</sub> ɑŋ			*/u/

The ranking in Tableau 6 is the same as in Tableau 5. The input is a monosyllabic word with the initial consonant cluster. Any deletion /b/ or /r/ would violate MAX<sup>3</sup>. Therefore the candidates (6a) (6b) are ruled out. The candidate (6c) is fatal by having a consonant cluster /pr/ within a syllable (the bold dot indicated as the syllabic boundary). Inserting a vowel /u/ into the initial cluster to form a disyllabic word in (6d) would violate DEP. However the candidate (6d) is selected as the optimal candidate because it has the minimal violation among the candidates.

The restrictions on the onset and the coda vary from language to language. Prince & Smolensky (1993) propose Onset/Coda Licensing Asymmetry, defined that there are languages in which some possible onsets are not possible codas, but no languages in which some possible codas are not possible onsets. In Japanese, only the nasal is the allowable coda. In Mandarin the obstruents and the liquid /l/ are allowed to be the possible onsets but not codas. Only one of the four segments /n,ŋ,j,w/ are possible choices appearing in the final syllabic coda position. The output constraint, CODACONDITION (henceforth CODACON) requires only one of the four segments, /n,ŋ,j,w/.

#### 4.2 Analysis of Deletion in Loanwords

As mentioned above the repair strategies of loanwords might be deletion or insertion of segments. It seems to be due to the ranking of the faithfulness constraints, MAX and DEP. Actually there is an output constraint *MINIMALWORD*, which requires a prosodic word to be disyllabic minimally. This constraint forces loanwords to be disyllabic minimally by deletion or insertion. The Prosodic Hierarchy proposed by Selkirk (1980), Foot-Binarity taken together derive the notion “Minimal Word” (Prince 1980, Broselow 1982, McCarthy & Prince 1986, 1990, 1991). According to the

<sup>3</sup> In Mandarin the voiced obstruents are not allowed. Therefore the voiced obstruents would change to voiceless segments otherwise they would be deleted. The phonotactic rules are not relevant and not discussed more in this paper.

Prosodic Hierarchy, any instance of the category Prosodic Word must contain at least one foot. By Foot-Binarity, every foot must be syllabic. By transitivity, a PrWd must contain at least syllables. Observed word minimality restrictions therefore follow from the grammatical requirement that a certain morphological unit, often Stem or Lexical Word, must correspond to a Prosodic Word (McCarthy & Prince 1993). Because of the MINIMAL WORD restriction (Yip 1993), the loanwords might be augmented or truncated to satisfy the constraint.

(1-5-f) MINIMALWORD: a lexical word must be disyllabic.

(1-5-g) FOOT-BINARITY: a foot must be binary under syllabic or moraic analysis<sup>4</sup>.

(1-5-h) PARSE-σ: every syllable belongs to a foot (McCarthy & Prince 1994).

The three constraints require the templatic restrictions on the prosodic structure of loanwords e.g a disyllabic binary foot. The constraints triggering deletion or epenthesis in loanwords implies that this constraint ranks above the faithfulness constraints (Guo 1998) and also outranks the two output constraints, CC CON, CODACON.

**Tableau 7**

Input: /braun/ Output: [pu laŋ]

/braun/	MINWORD	CC CON	CODACON	MAX	DEP
7a. pawn.	*!			*(r)	
7b. rawn.	*!			*(b)	
7c. prawn.	*!	*(pr)			
☞ 7d. pu.laŋ					*/u/

The input is a monosyllabic word with the initial consonant cluster. Any deletion /b/ or /r/ would violate MAX. A monosyllabic word would violate MINWORD. Therefore the candidates (7a) (7b) are ruled out. The candidate (7c) is fatal by having a consonant cluster /pr/ within a syllable and it is a monosyllabic word. Inserting a vowel /u/ into the initial cluster would form a disyllabic word, such as in (7d). Thus the candidate (7d) is the optimal candidate.

<sup>4</sup> The ranking of this constraint will be discussed later.

**Tableau 8.**

Input: /pʌmp/      Output: [pəŋ p<sup>h</sup>u]

/pʌmp/	MINWORD	CC CON	CODACON	MAX	DEP
8a. pəŋ.	*!			*(p)	
8b. pəŋ.p <sup>h</sup> u			*!(m)		*(u)
8c. pəmp.	*!	*(mp)	*(mp)		
☞ 8d. pəŋ.p <sup>h</sup> u					*(u)
8e. pə.mu.p <sup>h</sup> u					**!(u)

Since both the candidates (8a), (8c) are monosyllabic words thus they are ruled out. Both the candidate (8b), (8d) with an epenthetic vowel are the disyllabic word and they do not violate MAX. The candidate (8d) is the winner for (8b) has a prohibiting labial nasal coda. Both (8d) and (8e) do not violate the constraint MINWORD. The candidate (8e) with two vowels inserted has one more violation than (8d). Therefore the candidate (8d) is selected as the optimal candidate by the minimal violation. The ranking of MINWORD and DEP gives the explanation of the restricted size of the loanwords.

**Tableau 9**

Input: /bændɪdʒ/      Output: [pəŋ tai]

/bændɪdʒ/	PARSE-σ	FT-BIN	MINWORD	CC CON	CODACON	MAX	DEP
9a. (bæn. dɪdʒ)					*!(dʒ)		
9b. (bæn .dɪ.dʒɪ)		*!					*(ɪ)
9c. (bændʒ.)		*!	*	*(ndʒ)		*** (dɪdʒ)	
☞ 9d. (pəŋ. tai)						*(dʒ)	
9e. (bæn.dɪ) dʒɪ	*!(dʒɪ)						*(ɪ)
9f. (bæ.dɪn.)						*(n)	*!(n)

The input is a disyllabic CVN.CVC word. All the candidates with the nasal coda of the first syllable would not violate CODACON so the nasal coda is not needed to delete. However the candidate (9a) with an ungrammatical affricate coda /dʒ/ violates CODACON fatally. (9c) is ruled out for deleting segments /d, ɪ, dʒ/ violates MAX and the result of being a monosyllabic word would have a fatal violation of MINWORD. The candidate (9b) is a trisyllabic word and does not violate MINWORD. However the foot structure (the parenthetic marks indicated as the foot domain) is not binary. There is an unparsed syllable /dʒɪ/ in (9e), so (9e) is ruled out. There are two steps of repairing the candidate (9f): deletion of the nasal coda of the first syllable and change the final

affricate to a coronal nasal. Thus the candidate (9f) has one more violation than (9d). The candidate (9d) with a binary foot structure is the optimal candidate in spite of the minimal violation of MAX. The preference of the disyllabic structure makes the choice of deleting final coda rather than epenthesis. The three constraints PARSE- $\sigma$ , FT-BIN, MINIMALWORD give the explanation of the preference.

## 5. Conclusion

This paper aims at the parsing strategies of the consonant-clusters in Taiwan Mandarin loanwords. In this study, a corpus of Taiwan Mandarin loanwords translated from English is set. There are about five hundred loanwords. The percentages for the different strategies to parse the consonant clusters and the percentages of occurring in the syllabic positions would be calculated and listed. The final results show the four asymmetries. Asymmetry I: Epenthesis is the better strategy than deletion in parsing the consonant cluster in Mandarin loanwords. Asymmetry II: Most of the segments in the initial position are always parsed out ; the ones in the final position are not necessarily parsed. Asymmetry III: only the medial consonants could be as the onset/coda in the syllabic level of the borrowing words. Asymmetry IV: in peripheral positions, initial stops are parsed but final stops not; however, initial/final fricatives are parsed. The key factor is the perception of the friction. The perception seems to be the key point during the parsing.

## Abstract

We deal with various uses and meanings of *com*, which means ‘a little’ in Korean. This study interprets *com* with some exceptional examples from the standpoint of sense and the standpoint of force in an attempt to enlarge the general scope of *com*. Moreover, we will find how this lexicon is conventionally used. Sadock (1978) observed that conversational implicature can become conventionalized. Also, Davis (1998) defines ‘conversational implicature convention’ as a conventional way of conversationally implicating things, and distinguishes it from ‘conventional implicature’. Various figures of speech seem to start from non-conventional expressions and become conventional expressions in the course of time. This paper offers an ad hoc conclusion to these issues of semantics and pragmatics.

**Keywords:** conversational implicature convention, conventional implicature, hedge, figures of speech, lexicalization.

## 1. Introduction

This paper consists of the various uses and meanings of *com*, which means ‘a little’ or ‘a bit’ in Korean, in the context of Korean language. This study will examine *com* with some exceptional examples from the standpoint of sense and the standpoint of force in order to enlarge the general scope of *com*. In addition, we will find how this lexicon is used conventionally, rather than literally.

In discourse, *com* functions as a general modifier that lessens the quantity of the predicate to as a conveyer, thereby conveying various peculiar meanings in Korean context. *Com* reveals the speaker’s attitude towards a proposition. Moreover, *com* makes indirect speech acts. In this respect, one of the purposes of *com* is to lighten a burden among conversation participants, in hopes of minimizing conflicts. Of course, some of the cases in this study show that *com* does not occasionally match with those

common characteristics. The special use of *com* will be mostly discussed in Chapter Three. It should also be noted that this paper presupposes the euphemistic aspect of *com* as it leads to polite speech. While *com* is generally understood as an abbreviated form of *cokum*, it can also be considered as an adverb of manner to the effect that *com* decides the ways of speech. In other words, it greatly affects aspects and manners of utterance.

In Chapter Two, we will examine the previous studies with relation to the general meanings of *com*. In Chapter Three, we will deal with the unique uses of *com*. We will discuss the examples and presume why and how *com* is used in those manners. The content of the Chapter Three largely consists of discussion concerning the following three characteristics of *com*:

- (1) *com* used in euphemism or litotes

*com*            hanta

a little        do

+> “do quite well.”

- (2) *com* used in ellipses

kuken        *com*

that        a little

+> “I hesitate to say it, but I disagree.”

- (3) *com* used in movement and repetition

*com*            kuman            *com*

a little        stop            a little

“Please, stop, please.”

Finally, in the fourth and final chapter, this study puts those expressions discussed in Chapter Three into the scope of convention, that is, we will find the possibility of expanded lexicalization of *com* in Korean. (cf. All the examples in this paper follows the Yale Romanization.)

## 2. *Com*

### 2.1. *Previous Studies on Meanings of com*

*Com* is generally considered as an abbreviated form of *cokum*. As a noun, *cokum* means ‘small quantity’ or ‘short period’. As an adverb, it also means ‘a little in amount’

or 'in a short time'. However, when *cokum* is abbreviated to *com*, this noun usage disappears, and the new meaning of 'the expression used in order to soften the speech when one makes a request' is added. Moreover, *com* occasionally means 'fairly and considerably' or 'how much' when used in interrogative sentences or ironic expressions. The focus of this paper is an investigation of these additional meanings of *com*, as well as an interpretation of the meanings of *com* to which *com* is peculiarly confined.

Kim (1984: 39) regards *com* as a modifier of quantifiers. *Com* is distributed in front of quantifiers and defines the range of the quantifiers or the boundary of the quantifiers. In other words, it is considered as a sort of auxiliary degree adverb. According to meaning characteristics, *com* could be divided into two parts; an intensifier and an emphaser. Moreover, according to morphological characteristics of quantifiers, *com* could also be divided into two parts; *com* with verbal quantifiers and *com* with noun quantifiers. In this study, it is mainly shown as an intensifier which confines the range of quantifiers and as a coexisting modifier with verbal quantifiers.

Seo (2005: 57) tries to make a subdivided part of speech with relation with *com*. He argues that *cokum* and *com* are "a partly non-universal quantity adverb" among "restriction adverbs." So to speak, *com* should be regarded as an adverb which coexists with declinable words in a restricted range. It is an item of confined quantifiers and represents small amount. In addition, it is regarded as a degree adverb modifying adjectives. In this use, it modifies adjectives and controls the degree of modification.

Lee (1988) explains meaning characteristics and syntactic characteristics of *com*. In this paper Lee separates *com* from *cokum* and *yakkan* in an attempt to account for the modality of *com*. In explaining *com*, he points out that *com* is used in time expressions and degree expressions. Furthermore, the study contains some modal properties of *com*; consequently, he asserts that, as an adverb of manner, *com* makes requests in imperatives and reveals irony in interrogatives. According to Lee (1988) in contrast to *cokum* and *yakkan*, *com* particularly has a property of modality.

Among many studies, Son (1998) shows quite notably detailed work on *com*. Having consistent pragmatic point of view, Son (1998) deals with various situational meanings of it. The main point of his paper is that the meanings of *com* could be differentiated according to situation. Conclusively he argues that *com* has largely three aspects; politeness, emphasis, and negation.

## 2.2. *Com* in Polite Speech

Leech (1983: 132) comprehensively deals with substantial arguments on politeness according to Politeness Principle with Tact Maxim, Generosity Maxim, Approbation Maxim, Modesty Maxim, Agreement Maxim, and Sympathy Maxim. According to Leech (1983: 36-40), conversation is basically a goal-directed problem-solving strategy. Then, the participants in conversation would achieve the goal by using the Politeness Principle in the strategy. Politeness Principle has to be indispensable in interpreting *com* in a sense that *com* basically gets the meaning of politeness from its original meaning of understatement.

However, the problem is that interpretation of the understatement from the meanings of *com* is not always applied to Politeness Principle. Kim (1997) also points out that we need to reconsider *com* to the effect that PP cannot complete the interpretation of *com* as a politeness marker in Korean. In other words, some interpretations of *com* do not satisfy the Cost-benefit Scale (Leech, 1983: 107) and Indirectness of politeness. In this respect, we need to associate PP with other basic principles such as Cooperative Principle in order to better understand *com* as Leech (1983: 80) points out.

On the other hand, Korean hedge *com* is based on its literal meaning of understatement since *com* originally means 'a little' in Korean. In this light, we need to consider Brown and Levinson's comments on understatement as a polite way of speech. Brown and Levinson (1987: 139) point out that the use of hedges especially in polite speech such as *please* is appeared in a different manner in different cultures. They provide a case with reference to Tamil equivalent of sentence-initial *please* insertion - *koncam* insertion. As both adjectives and adverbs, *koncam* means literally 'a little,' but it usually occurs in circumstances where it cannot have its literal meaning. In this light, we can have a good opportunity to compare *koncam* in Tamil and *com* in Korean as well as *please* in English:

- (4) inta paattiratt-le neriya *koncam* teeva paTutu  
 this vesell-in much a little need is felt  
 “This plate needs much more, please.”

(Brown and Levinson, 1987: 140)

In this case, *koncam* functions as an adverb on the highest performative verb, where its literal meaning seems to carry over naturally as a hedge on illocutionary force: 'I request you a little.' In this respect, *koncam* in Tamil has a very similar function to *com* in Korean; namely, they both function as a hedge especially to make a polite way of requests. Brown and Levinson (1987: 177) directly point out that the word for 'a little' in

many other languages such as Tzeltal and Malagasy also functions like *please* in English.

In Korean, minimizing the imposition using *com* would be almost always the polite way of speaking, while in English imposing an acceptance to the hearer can possibly be polite, as we have seen the case of *please*. The words for 'a little' are basically used for polite speech to the effect that these words tend to have the function of minimizing the imposition of requests; at the same time, the speaker and the hearer are able to avoid FTA(Face Threatening Act).

They additionally assert that this kind of violation of the maxims of Quantity is conducive to lessening the pressure among conversational participants in that understatements are able to generate implicatures by saying less than is required.

### 2.3. *Com as a Hedge*

Hedge is a concept which retains or reduces the proposition. Generally, the main characteristics of hedges are vagueness, politeness, and modality. Among others, the hedge is well known as a 'politeness marker' of the speaker, which functions as a passive way of utterance. At the same time, however, using hedges could be a speech strategy which is conducive to persuasion and strengthens the relationship with the hearer. Lakoff (1972: 471) points out that the hedges are words whose job is to make things more or less fuzzy. For example, sort of, rather, largely, very etc. could be hedges. It could also be considered as softening of statement in order to reduce the riskiness of what one says.

Kim (1997) focuses on pragmatic functions of *com*. It particularly deals with *com* in ellipsis phrases in accounting for meaning relationship with some verbs. The distinguishing point of her study is that she understands *com* as a 'hedge' in Korean contexts. In other words, when *com* appears without the relationship with verbs, it fences off the speech flow from the presupposition of negation and brings about indirect request; thus, she insists that *com* should be considered as a hedge in some cases.

All in all, the argument about *com* as a hedge in Kim (1997) is convincing since *com* seems to function as a hedge. First of all, 'vagueness' of hedges is also shown in uses of *com* as we have seen in the introduction of this paper:

- (5) kuken *com*  
that a little  
+> "I hesitate to say it, but I disagree."

Regardless of the literal meanings of each word in the sentence, this expression clearly reveals characteristics of vagueness in *com*. Lakoff (1972) points out that the hedges blur the speaker's judgment on the proposition. The second characteristics of *com* could be 'politeness' since it is widely known as politeness marker in many studies (Kim, 1997; Son, 1998; Joo, 2000). The explanation of this property of hedges is in Brown and Levinson (1987) saying that hedges would be very effective in saving the hearer's face. For example, when the speaker has an opposite opinion to the hearer, "I think it's a bit incorrect." would be more polite than "I disagree." Lastly, *com* also has another characteristics of hedges; 'modality'. Lee (1988) focuses on the modality of *com* in a sense that it particularly has a property of modality in contrast to other lexical items which have similar literal meanings to *com*.

Hedges are used to reveal the speaker's subjective attitude towards the relation between utterance and reality. It is through representing the speaker's judgment on the proposition that the 'attitude' of the speaker comes in the utterance. House and Kasper (1981) divides 'modality markers' into three classes; 'hedges'(kind of, sort of, etc.), 'understater'(a little bit, not very much, etc.), and 'downtoner'(possibly, perhaps, etc.). In my opinion, *com* could be in all three classes of modality markers to the extent that the literal meaning of *com* is 'a bit' or 'a little'.

Attaching importance to speech situation, Joo (2000) focuses on situational aspects using *com*. Even though Joo (2000) has some distinguished points especially on pragmatic view, it might be said to be too broad to catch the specific characteristics of *com* in that different people may call it different things. In particular, there seems to be problems in selecting some examples. Joo (2000: 78) points out that we could find the stubborn or repeated action before the speech in the example "kuman *com* haseyyo." meaning "Stop, please." and it varies according to speech situation. It might be possible that we may expect the speaker's annoyance or repeated action from this example, but it could also be possible that we may presume that there is some irritated or repeated actions before the speech when we hear "kuman haseyyo." even without *com*; thus, her argument is somewhat problematic to the extent that the speaker's attitude can also be shown through stress or intonation regardless of *com*.

However, Joo (2000: 82) also points out that *com* has some characteristics of hedges to the extent that the uses of *com* are divided into two parts; one is the use of *com* which is the same as *cokum*, and the other is the use of *com* is pragmatic contexts. From this classification, we can have an idea that the latter would be the case related to the hedges.

### 3. Some Unique Uses of *com*

#### 3.1. *com hanta*

In this case, *com* is used in euphemism or litotes. In common speech, one uses this expression in order to understate one's abilities or strong points. Interestingly, however, we cannot assert that this is truly the case of litotes in the sense that it can actually be used in compliment both of the speaker and of the listener. Moreover, this litotes seems to be possibly used by young people to elders. Let us consider this example:

- (6) a. ne        *com*        hanta  
      you     a little     do  
      +> "You do quite well."  
      b. komawe  
          thanks  
          "Thanks."

If you are a Korean speaker, this conversation is so natural that we cannot even recognize the literal meanings in it. At this point, we have to think about it carefully. If someone tries to understate your abilities, it would be natural for you to be irritated or depressed. However, we do not feel angry when we face this kind of utterance.

According to Politeness Principle suggested by Leech (1983: 132), to maximize benefit to other (Tacit Maxim) and to maximize praise of other (Approbation Maxim) would result in polite speech. Unfortunately, these basic rules of politeness cannot be applied to the example (6). Why is it so?

From the fact that this expression is naturally used even when describing elders, we have to suspect that it is far from the literal meaning. Someone might say that it should not be regarded as a part of litotes anymore. Therefore, this paper strongly argues that this expression with *com* is out of the literal meaning of it; so to speak, it is now in the scope of convention.

#### 3.2. *kuken com*

Now, we will deal with another particular use of *com*. This is the case when *com* is used in ellipses. Let us first see below example:

- (7) a. wuli     dulama     polkka?  
      we        drama        see

“Shall we watch the drama?”

b. *kuken com* (...)

that a little

+> “I hesitate to say it, but I don’t want to watch it.”

In (7b)’s reply, just after *com*, there must be an ellipsis which implicates that the speaker does not want to watch the drama. In a polite manner, (7b) tries to convey the meaning of refusal. Even though it is commonly used in everyday conversation, the meaning of the expression is far from the literal meaning of *com*. Ellipsis using *com* could possibly convey several meanings such as “I don’t like it,” “I am not sure of it,” or “I can’t do it.” Nevertheless, the conveyed meanings with *com* are quite enough to be understood in most conversations. Moreover, as Agreement Maxim of Politeness Principle points out that “Minimize disagreement between self and other,” the speaker may want to control the risk of disagreement. That is to say, in the case when it is difficult for a conversation participant to openly oppose to the other’s opinion, we are inclined to use this kind of expression with the meaning of the soft refusal or euphemistic opposition. By using an indirect utterance of refusal, the speaker of (7b) shows politeness. Therefore, it is the case where the conversation using *com* is consistent with the preexistent theory.

On the other hand, as discussed in Chapter Two, this usage of *com* is also considered as a hedge by some scholars in the sense that we can find the “vagueness” of it in this case. Whether it is considered as a hedge or ellipsis, it is obviously unique in that the literal meaning of *com* does not let us easily presume this confined use of it.

### 3.3. *com kuman com*

This is the case when *com* is used in movement and repetition. It usually appears in front of verb since it is basically an adverb. However, we can easily find some data from conversation where *com* is used after the verbs or where it is used more than once. This paper considers the former as a movement and the latter as a repetition. Let us first take an example:

(8) *com kuman com*  
a little stop a little  
“Please, stop, please.”

In the case of (7), *com* is repeatedly used as well as moved after the verb. Interestingly, the repetition of it seems to strengthen the requests. Moreover, we could feel some irritation or anger from the speaker. From the fact that we could feel the eagerness of the speaker, it should be considered as an exceptional use of *com*. Joo (2000: 78) also points out that we could find the stubborn or repeated action before the speech from the example "kuman *com* haseyyo." Likewise, we can think of some other examples which are commonly used in everyday conversation in Korea. Of course, the effect of the speech is very similar to (7). Let us look at the below example:

- (9) ceypal      *com*      wulci      *com*      maseyyo.  
*please*      a little      cry      a little      stop  
 "Please don't cry, please."

Now, let us focus on the movement:

- (10) a. mwun      *com*      yelecwuseyyo.  
          door      a little      open  
          "please open the door."  
       b. mwun      yelecwuseyyo      *com*.  
          door      open      a little  
          "?please open the door."

In (9b), hearers do not naturally accept it as a polite speech in that 'yelecwuseyyo' is stressed due to the movement of *com*; as a result, this utterance sounds rather impolite. Also, it is possible for hearers to think that the speaker might be irritated by some negative situations. For example, it is completely possible that the speaker has requested the hearer to open the door, but it was rejected. Then, the speaker once again requests the hearer to do with a certain stress; namely, it is a movement of *com*. Consequently, the utterance does not sound polite though the basic function of it consists of polite speech as mentioned in Chapter Two.

#### 4. Conventionalization of *com*

##### 4.1. Conventionalization about Language

Morgan (1978) clearly presents cultural diversity in convention about language with reference to the examples of "Have you eaten?" in Korean vs. "How are you?" in

English. According to him, there are two kinds of language-related conventions: 'conventions of language', that jointly give rise to the literal meanings of sentences, and 'conventions about language' which govern the use of sentences for certain purposes.

By the term 'conventional,' it is the relation between linguistic form and literal meaning, which is 'arbitrary,' a matter of knowledge of language or culture. For example, we do not reason out from the word 'apple' that it is used to refer to a kind of fruit; thus, it is arbitrary and we should understand the knowledge of English. Then, Morgan (1978) distinguishes between conventions 'of' language and conventions 'about' language. In particular, the latter, conventions about language is the conventions of the culture that uses their own language. In short, conventions 'of' language is the characteristics of language itself as mentioned above in the example of 'apple,' whereas conventions 'about' language is about the cultural differences to use different ways of language.

Sadock (1978) also observed that conversational implicature can become conventionalized. With a similar point of view, Davis (1998) defines 'conversational implicature convention' as a conventional way of conversationally implicating things, and distinguishes it from 'conventional implicature'. Various figures of speech seem to start from non-conventional expressions and become conventional expressions in the course of time.

Morgan (1978), finally, suggests we need "short-circuited implicature" in accounting for our direct understanding of conveyed meanings. The representative example of "Do I look like a rich man?" helps understand his explanation. Suppose that you have a friend, and when asked for a loan, he replies, "Do I look like a rich man?" intending the implicature of a refusal. Suppose again, that he comes to use that sentence for refusing loans as a habit; it conveys a refusal indirectly and is a part of your background knowledge. Then, it could be entirely possible that this habit of refusal spreads so that it is common throughout the community to refuse loan; thus, it becomes a common knowledge for most of the members of the community. Finally, an indirect refusal from the utterance "Do I look like a rich man?" becomes a short-circuited implicature armed with common knowledge; consequently, the utterance immediately indicates that the request is refused.

In other words, short-circuited implicature is the implicature that is used so often and naturally in a given culture that we do not even need to use our inference to interpret the sentence or utterance. That is to say, it becomes a convention. Likewise, in the case of *com* in Korean language and culture, there are certain possibilities for it to be in the scope of conventionalization. We will discuss them in the next section.

#### 4.2. One Possible Process of Conventionalization of *com*

As mentioned in above section, Sadock (1978) and Morgan (1978) both observed that conversational implicature can become conventionalized. Also, Davis (1998) defines ‘conversational implicature convention’ as a conventional way of conversationally implicating things. According to Davis (1998: 148), a lot of figures of speech start from non-conventional expressions and then become conventional expressions in the course of time in a certain society.

In this section, we will examine how an expression using *com* loses its literal meaning and gets conventionalized in the course of time in our everyday conversation. It would be convincing that some procedures in a society make it change. Recall that *com* can be used in litotes:

- (11) *com*            *hanta*  
a little            do  
+> “do quite well”

Now, let us think of the possible process of meaning change in this expression. It was possibly made in order to express some understatements of the speaker if we think about the literal meaning of the expression. First of all, pragmatic intrusion might happen in this expression by implicatural contribution to "what is said" (Levinson, 2000: 172). Then, the pragmatic meaning of it could often precede the semantic or literal meaning of it in the course of time. Secondly, it could be through I-Implicature suggested by Levinson (2000: 122) that conversation participants in a society come to use this expression “stereotypically” with the pragmatic meaning. As time goes by, it becomes so fixed that almost all the members of the society could understand and use it in this manner. Finally, as Morgan (1978) suggested, this expression is ultimately a part of "short-circuited implicature" with our direct understanding of conveyed meanings. In other words, this expression becomes a short-circuited implicature armed with “common knowledge” of our society. When, hearing this expression, we do not have to use our inference to interpret the meaning to the effect that short-circuited implicature is the implicature that is used so often and naturally in a culture; consequently, it becomes a convention.

It evidently reminds us of Morgan’s (1978) representative example of "Do I look like a rich man?" intending the implicature of a refusal. Yes, it is very similar to the example of “*Com hanta.*” intending the implicature of compliment rather than litotes; in other words, the meaning has been changed dramatically in the course of time.

Namely, the implicature generated by some uses of *com* are short-circuited and culturally conventionalized as a sort of rule of conversation. It is a matter of convention that one uses these particular forms. As mentioned before, the convention 'of' language is the arbitrariness of language in general, whereas the convention 'about' language is the convention of each culture's linguistic facts. The latter is, thus, closely associated with cultural difference in linguistic use. The special uses of *com* could possibly be applied in the concept of the convention 'about' language. Finally, if a given expression has already in the short-circuited implicature, then, I think it should be in the lexicon which is in a different layer from the literal meanings of it. For instance, the expression “*Com hanta*” could be in a lexicon so that it should let the language users know its peculiar meaning.

Conclusively, it would be convincing that the use of *com* could be explained by a convention about language because it is defined by culturally conventionalized forms of conveying the meanings. We have thought of a hypothetical procedure of *com* being a conventionalized expression; namely, “a literal meaning”=> “pragmatic intrusion”=> “I-Implicature”=> “short-circuited implicature”. Of course, this process does not seem to be fixed or ultimate at all. As a result, anyway, it becomes conventional to use the expression in this 'way.' For example, in American culture, using the expression “You do a little.” does not seem to be polite nor be functioned as a compliment. That should be the reason for the diversity of expressions according to culture.

## 5. Conclusion

We have examined *com* with some exceptional uses as well as general meanings in this paper. In Chapter Two, we have examined the previous studies with relation to the general meanings of *com*. In Chapter Three, we have looked at some unique uses of *com* and discussed the three representative examples in an attempt to presume why and how *com* is used in those manners. Finally, in Chapter Four, we have tried to interpret *com* in the scope of conventionalization according to some scholars' opinions and theories.

As we have discussed, *com* is generally considered as an abbreviated form of *cokum*. As a noun, *cokum* means ‘small quantity’ or ‘short period’. As an adverb, it also means ‘a little in amount’ or ‘in a short time’. An interesting thing is that we could not simply understand *com* as the abbreviation for *cokum* as we have discussed in this paper. First of all, unlike *cokum*, *com* cannot be used as a noun. Furthermore, there is much

room for presumption that *com* could be considered as a part of idiolects, due to the fact that individual differences exist in the frequency deviation. In explaining general meanings of it, we have also pointed out that it is used both in polite speech and in hedging expressions.

Politeness Principle which was suggested by Leech (1983) seems to be important in interpreting *com* in a sense that *com* basically gets the meaning of politeness from its original meaning of understatement 'a little'. However, as we have seen above chapters, the problem is that interpretation of the understatement from the meaning of *com* is not always applied to Politeness Principle. In other words, some interpretations of *com* do not satisfy the Cost-benefit Scale (Leech, 1983: 107) and Indirectness of politeness. I think this is why interpretation of *com* is interesting and why we need to think about the phenomena more carefully.

From the data shown in Chapter Three, we have found that some expressions using *com* is not consistent with the existent theories such as Politeness Principle. In this respect, how do we interpret the expressions in our everyday language without a critical misunderstanding? Do we need brand new theories to account for them?

As the arguments of Morgan (1978) and Davis (1998), there are conventions and some fixed meanings in our language. However, we still do not know where the scope of convention starts and ends. On the other hand, we still have other questions such as "What if the short-circuited implicature does not work well among people?" Then, can we call it the short-circuited implicature? On the other hand, if a certain expression has already in the short-circuited implicature, then, I think it is a good idea for it to be in the lexicon which should be in a different layer of the literal meanings of it. That is, actually, this paper's suggestion.

Conventionalized expressions are different from implicature. However, the argument in Davis (1998) is, at least partially, convincing to the extent that some parts of implicature obviously rely on the convention. According to Davis (1998: 164), figures of speech including hyperbole and euphemism are from the nonce implicature to the part of language convention. Hence, he tries to regard implicature as "implicature convention". For example, the fact that we produce the implicature "some +> not all" (not "some +> maybe all") may result from our conventional use of it in the course of time. Accordingly, it would be possible for *com* to start from the literal meaning and reach the field of convention; consequently, it becomes so natural that we do not have to interpret the hidden meaning of it. Even though I cannot support all of his ideas relating to implicature, his argument would be convincing in some points.

In conclusion, we have examined some unique uses of *com* as well as general meanings of it. This paper tries to find the reason for its exceptional uses in “convention about language”. While *com* is generally understood as an abbreviated form of *cokum*, it can also be considered as an adverb of manner to the effect that *com* decides the ways of speech. In other words, it greatly affects aspects and manners of utterance. Furthermore, we have discussed some particular phenomena when it is used in litotes, ellipsis, movement, and repetition. Finally, in this study, we have considered one possible process where an expression which uses *com* could be conventionalized in the course of time. It would be great for this study to be able to give some thought-provoking ideas to future studies relating to *com*. In all these respects, it is necessary for us to broaden the possibility of pragmatic approach in order to better understand *com*.

## Abstract

The purpose of this paper is to show that Subjectivization and Objectivization in Korean are A-Movement. First, we show that the first Nominative NP in Multiple Nominative Construction (MNC) is in A-position. There are many pieces of evidence that the first Nominative NP in MNC is in A-position: (1) There is a corresponding topicalized construction for MNC. The existence of a corresponding topicalized construction for MNC shows that the first Nominative NP in MNC is not in A'-position but in A-position. (2) Subject Honorification shows that the first Nominative NP in MNC is a subject, and hence that it is in A-position. (3) Reflexivization shows that the first Nominative NP in MNC is a subject, and hence that it is in A-position. Second, we show that the first Accusative NP in Double Accusative Construction is in A-position. Third, we show that the objectified NP created after Objectivization is the direct recipient of the agent's action.

**Keywords:** Subjectivization, Objectivization, A-Movement, Multiple Nominative Construction, Double Accusative Construction, Topicalization.

## 1. Introduction

The purpose of this paper is to show that Subjectivization and Objectivization in Korean are not A'-Movement but A-Movement, that is, a newly-created subject and a newly-created object are in A-position.

There are many pieces of evidence that the first Nominative NP in Multiple Nominative Construction (MNC) is in A-position. First, there is a corresponding topicalized construction for MNC. The existence of a corresponding topicalized construction for MNC shows that the first Nominative NP in MNC is not in A'-position but in A-position. Second, Subject Honorification shows that the first Nominative NP in MNC is a subject, and hence that it is in A-position. Third, Reflexivization shows that the first Nominative NP in MNC is a subject, and hence that it is in A-position.

Lee (1988) argues that the first *ul/lul*-marked NP in Double Accusative Construction (DAC) is a topicalized one. But his claim is not tenable for two reasons. First, there exists an independent topicalized construction, apart from DAC. Second, there exists a passive construction which is derived from DAC. The existence of a passive construction which is derived from DAC, first, shows that the first *ul/lul*-marked NP in DAC is in A-position, not in A'-position and that the topicalization analysis of objectivization has a serious problem from the viewpoint of movement. According to the topicalization analysis of objectivization, the first *ul/lul*-marked NP in DAC is in TOPIC position, which is A'-position. But the subject position of a passive construction is A-position. Hence, the topicalization analysis of objectivization assumes that an NP in A'-position moves to A-position. In a normal movement, an NP in A-position moves to A-position or to A'-position. Because movement from A'-position to A-position is, in principle, not allowed, the topicalization analysis of objectivization cannot be maintained. Then, we present an analysis which is an alternative to the

topicalization analysis, in which the first *ul/lul*-marked NP in DAC is in A-position.

And finally, we show that the objectified NP created after Objectivization is the direct recipient of the agent's action.

## 2. Subjectivization is A-Movement

Let us consider Subjectivization first. There are many pieces of evidence that the first Nominative NP in Multiple Nominative Construction (MNC) is in A-position.

First, there is a corresponding topicalized construction for MNC:

- (1) a. Chelswu-ka apeci-ka sacang-i-ta.  
NOM father-NOM president-be-DEC  
'It is Chelswu whose father is a president.'  
b. Chelswu-nun apeci-ka sacang-i-ta.  
TOP father-NOM president-be-DEC  
'As for Chelswu, his father is a president.'
- (2) a. Munmyengkwuk-i namca-ka swumyeng-i ccalp-ta.  
Civilized country-NOM man-NOM life span-NOM short-DEC  
'It is civilized countries where men—their life span is short.'  
b. Munmyengkwuk-un namca-ka swumyeng-i ccalp-ta.  
Civilized country-TOP man-NOM life span-NOM short-DEC  
'As for civilized countries, men—their life span is short.'
- (3) a. Ku kongcang-i kwulttwuk-i yenki-ka sikhemeh-ta.  
the factory-NOM chimney-NOM smoke-NOM dark black-DEC  
'It is the factory whose chimney—its smoke is dark black.'  
b. Ku kongcang-un kwulttwuk-i yenki-ka sikhemeh-ta.  
the factory-TOP chimney-NOM smoke-NOM dark black-DEC  
'As for the factory, its chimney—its smoke is dark black.'
- (4) a. New York-i kochung kenmul-i manh-ta.  
NOM high rise blds.-NOM many-DEC  
'It is New York where there are many high-rise buildings.'  
b. New York-un kochung kenmul-i manh-ta.  
TOP high rise blds.-NOM many-DEC  
'As for New York, there are many high-rise buildings.'

The existence of a corresponding topicalized construction for MNC shows that the first Nominative NP in MNC is not in A'-position but in A-position.

At this juncture, someone may argue that the first Nominative NP in MNC is not in A-position but in A'-position, because (a)-sentences in (1)~(3) are derived from the following Genitive Construction (GC):

- (1) c. Chelswu-uy apeci-ka sacang-i-ta.  
GEN father-NOM president-be-DEC  
'It is Chelswu's father who is a president.'
- (2) c. Munmyengkwuk-uy namca-uy swumyeng-i ccalp-ta.  
Civilized country-GEN man- GEN life span-NOM short-DEC  
'It is civilized countries' men's life span that is short.'
- (3) c. Ku kongcang-uy kwulttwuk-uy yenki-ka sikhemeh-ta.  
the factory-GEN chimney-GEN smoke-NOM dark black-DEC  
'It is the factory's chimney's smoke that is dark black.'

But this claim is not tenable, because there exist MNC which are not derived from GC and which still have their corresponding topicalized constructions:

- (5) a. Enehak -i chwycik -i elyep -ta.  
 linguistics-NOM employment-NOM difficult-DEC  
 ‘It is linguistics in which employment is difficult.’  
 b. Enehak -un chwycik -i elyep -ta.  
 linguistics-TOP employment-NOM difficult-DEC  
 ‘As for linguistics, employment is difficult.’  
 c. \*Enehak -uy chwycik -i elyep -ta.  
 linguistics-GEN employment-NOM difficult-DEC  
 ‘It is linguistics’ employment that is difficult.’
- (6) a. Cwungkwuk-umsik-i paythal -i na-ki(-ka)\_ swyp-ta.  
 Chinese cuisine-NOM stomach disorder-NOM occur(-NOM) easy-DEC  
 ‘It is Chinese cuisine by which stomach disorders occur easily.’  
 b. Cwungkwuk-umsik-un paythal -i na-ki(-ka)\_ swyp-ta.  
 Chinese cuisine-TOP stomach disorder-NOM occur(-NOM) easy-DEC  
 ‘As for Chinese cuisine, stomach disorders occur easily.’  
 c. \*Cwungkwuk-umsik-uy paythal -i na-ki(-ka)\_ swyp-ta.  
 Chinese cuisine-GEN stomach disorder-NOM occur(-NOM) easy-DEC  
 ‘It is Chinese cuisine’s stomach disorders that occur easily.’

The ungrammaticality of (5 c) and (6 c) shows that (5 a) and (6 a) cannot be derived from (5 c) and (6 c), but must be base-generated. And the fact that (5 a) and (6 a) have their corresponding topicalized constructions, (5 b) and (6 b), shows that the first Nominative NP in MNC is not in A’-position but in A-position.

Second, Subject Honorification shows that the first Nominative NP in MNC is a subject, and hence that it is in A-position. Consider the following examples:

- (7) a. Kim-sensayng-nim-kkeyse kohyang-i  
 teacher HON-NOM(HON) hometown-NOM  
 ipwuk-i-si-ta.  
 northern part-be-HON-DEC  
 ‘It is Teacher Kim whose hometown is the northern part of Korea.’  
 b. \*Kim-sensayng-nim-uy kohyang-i ipwuk-i-si-ta.  
 Teacher-HON-GEN hometown-NOM northern part-be-HON-DEC

In (7 a), the first Nominative NP triggers Subject Honorification and the honorific marker *-si* is attached to the verbal stem. As an inanimate NP, the second Nominative NP, *kohyang*, cannot trigger Subject Honorification; hence the ungrammaticality of (7 b). In (7 b), ‘Teacher Kim(HON)’ is used as a Genitive NP, and thus cannot trigger Subject Honorification.

Third, Reflexivization shows that the first Nominative NP in MNC is a subject, and hence that it is in A-position. Consider the following examples:

- (8) a. Chelswu<sub>i</sub>-ka caki<sub>i</sub>-uy cip -eyse ay.in-i casalha-ess-ta.  
 NOM self-GEN house-at love-NOM commit suicide-PAST-DEC  
 ‘It is Chelswu<sub>i</sub> whose love committed suicide at self<sub>i</sub>’s house.’  
 b. Chelswu<sub>i</sub>-uy ay.in<sub>j</sub>-i caki<sub>\*i,j</sub>-uy cip -eyse casalha-ess-ta.  
 GEN love-NOM self-GEN house-at commit suicide-PAST-DEC  
 ‘Chelswu<sub>i</sub>’s love<sub>j</sub> committed suicide at self<sub>\*i,j</sub>’s house.’

In (8 a), the first Nominative NP triggers Reflexivization. This shows that the first Nominative NP in MNC is a subject because *caki*, a reflexive pronoun, takes a subject as its antecedent. This, in turn, shows that the first Nominative NP in MNC is in A-position. But, in (8 b), *Chelswu* cannot be *caki*’s antecedent, since it is not a subject, but a Genitive NP.

### 3. Objectivization is A-Movement

This time, let us consider Objectivization. Consider the following examples:

- (9) a. Chelswu-ka Yenghuy-lul son-ul cap-ess-ta.  
 NOM ACC hand-ACC catch-PAST-DEC  
 ‘Chelswu caught Yenghuy by the hand.’  
 b. Chelswu-ka Yenghuy-uy son-ul cap-ess-ta.  
 NOM GEN hand-ACC catch-PAST-DEC  
 ‘Chelswu caught Yenghuy’s hand.’
- (10) a. Chelswu-ka cip -ul cey chay-lul ci-ess-ta.  
 NOM house-ACC three unit-ACC build-PAST-DEC  
 ‘It was houses that Chelswu built three units.’  
 b. Chelswu-ka cey chay-uy cip -ul ci-ess-ta.  
 NOM three unit-GEN house-ACC build-PAST-DEC  
 ‘Chelswu built three units of houses.’
- (11) a. Chelswu-ka Yenghuy-lul chayk-ul cwu-ess-ta.  
 NOM ACC book-ACC give-PAST-DEC  
 ‘It was Yenghuy that Chelswu gave a book.’  
 b. Chelswu-ka Yenghuy-eykey chayk-ul cwu-ess-ta.  
 NOM to book-ACC give-PAST-DEC  
 ‘Chelswu gave a book to Yenghuy.’

Syntactically, in (9 a) both *Yenghuy* and *son* are direct objects of the verb, while in (9 b) *son* is the only direct object of the verb.

Lee (1988) argues that the first *ul/lul*-marked NPs in (9 a), (10 a), and (11 a), are topicalized ones. But his claim is not tenable for two reasons. First, there exist independent topicalized constructions, apart from (9 a), (10 a), and (11 a). Consider the following examples:

- (12) a. Chelswu-ka Yenghuy-nun olun son-ul cap-ko Swunhuy-nun oyn  
 NOM TOP right hand-ACC catch-and TOP left  
 son-ul cap-ess-ta.  
 hand-ACC catch-PAST-DEC  
 ‘As for Yenghuy, Chelswu caught her by the right hand and as for Swunhuy,  
 he caught her by the left hand.’  
 b. Chelswu-ka Yenghuy-lul olun son-ul cap-ko Swunhuy-lul oyn  
 NOM ACC right hand-ACC catch-and TOP left  
 son-ul cap-ess-ta.  
 hand-ACC catch-PAST-DEC  
 ‘Chelswu caught Yenghuy by the right hand and Swunhuy by the left hand.’
- (13) a. Chelswu-ka tantok cwuthayk-un cey chay-lul ci-ess-ko  
 NOM single house-TOP three unit-ACC build-PAST-and  
 yenlip cwuthayk-un twu chay-lul ci-ess-ta.  
 tenement house-TOP two unit-ACC build-PAST-DEC  
 ‘As for single houses, Chelswu built three units and as for tenement houses, he  
 built two units.’

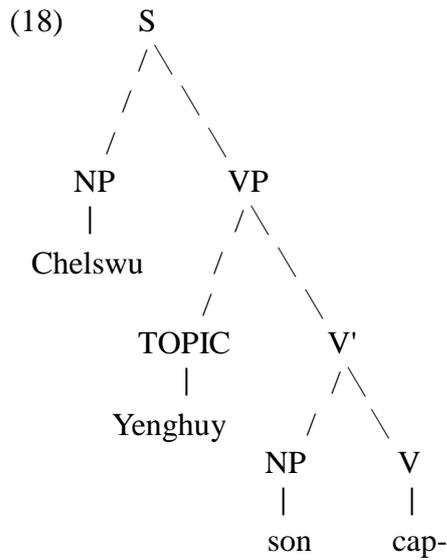

- b. Chelswu-ka tantok cwuthayk-ul cey chay-lul ci-ess-ko  
 NOM single house- ACC three unit-ACC build-PAST-and  
 yenlip cwuthayk-ul twu chay-lul ci-ess-ta.  
 tenement house-ACC two unit-ACC build-PAST-DEC  
 ‘Chelswu built three units of single houses and two units of tenement houses.’
- (14) a. Chelswu-ka Yenghuy-nun chayk-ul cwu-ko Swunhuy-nun  
 NOM TOP book-ACC give-and TOP  
 kongchayk-ul cwu-ess-ta.  
 notebook-ACC give-PAST-DEC  
 ‘As for Yenghuy, Chelswu gave a book and as for Swunhuy, he gave a notebook.’
- b. Chelswu-ka Yenghuy-lul chayk-ul cwu-ko Swunhuy-lul  
 NOM ACC book-ACC give-and ACC  
 kongchayk-ul cwu-ess-ta.  
 notebook-ACC give-PAST-DEC  
 ‘Chelswu gave Yenghuy a book and Swunhuy a notebook.’

The existence of (12 a), (13 a), and (14 a), shows that the first *ul/lul*-marked NPs in (9 a), (10 a), and (11 a), are not topicalized ones, but are in A-position.

Second, there exist passive constructions which are derived from (9 a), (10 a), and (11 a), respectively. Consider the following examples:

- (15) a. Yenghuy-ka Chelswu-eykey son-ul cap-hi-ess-ta.  
 NOM by hand-ACC catch-PASS-PAST-DEC  
 ‘Yenghuy was caught her hand by Chelswu.’
- b. Yenghuy-ka Chelswu-eykey son-i cap-hi-ess-ta.  
 NOM by hand-NOM catch-PASS-PAST-DEC  
 ‘Yenghuy was caught by the hand by Chelswu.’
- (16) a. cip-i cey chay-ka ci-e-ci-ess-ta.  
 house-NOM three unit-NOM build-PASS-PAST-DEC  
 ‘Three units of houses were built.’
- b. \*cip-i cey chay-lul ci-e-ci-ess-ta.  
 house-NOM three unit-ACC build-PASS-PAST-DEC  
 ‘Three units of houses were built.’
- (17) a. Yenghuy- ka Chelswu-ey uyhaye chayk-i cwu-e-ci-ess-ta.  
 NOM by book-NOM give-PASS-PAST-DEC  
 ‘Yenghuy was given a book by Chelswu.’
- b. \*Yenghuy- ka Chelswu-ey uyhaye chayk-ul cwu-e-ci-ess-ta.  
 NOM by book-ACC give-PASS-PAST-DEC  
 ‘Yenghuy was given a book by Chelswu.’

The existence of passive constructions which are derived from (9 a), (10 a), and (11 a), first, shows that the first *ul/lul*-marked NPs in (9 a), (10 a), and (11 a) are in A-position, not in A'-position. The existence of passive constructions which are derived from (9 a), (10 a), and (11 a), also shows that the topicalization analysis of objectivization has a serious problem from the viewpoint of movement. According to Lee's (1988) claim, (9 a) is assumed to have the following tree diagram:

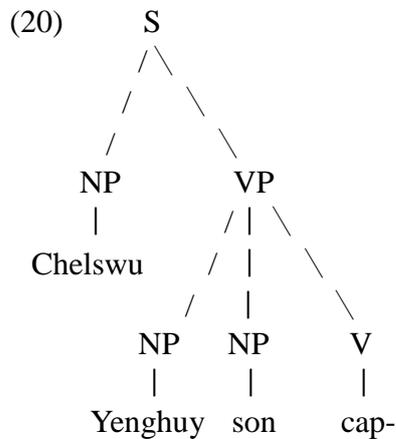

According to the topicalization analysis of objectivization, the first *ul/lul*-marked NPs in (9 a), (10 a), and (11 a), are in TOPIC position, which is A'-position, as shown in (18). But the subject position of passive constructions is A-position. Hence, the topicalization analysis of objectivization assumes that an NP in A'-position, *Yenghuy* in (18), moves to A-position, *Yenghuy* in (15 a) and (15 b). In a normal movement, an NP in A-position moves to A-position or to A'-position:

(19) [argument NP] → [argument NP] or [adjunct NP]

Because movement from A'-position to A-position is, in principle, not allowed, the topicalization analysis of objectivization cannot be maintained.

Now, let us present an analysis which is an alternative to the topicalization analysis. What is important at this juncture is that the first *ul/lul*-marked NPs in (9 a), (10 a), and (11 a) are in A-position and that they are direct objects of the relevant verbs. Reflecting this point, we present the following tree diagram for (9 a):

In (20), both *Yenghuy* and *son* are assigned [+Accusative] by a dynamic verb, *cap-*, under the following Direct Case Assignment (DCA):

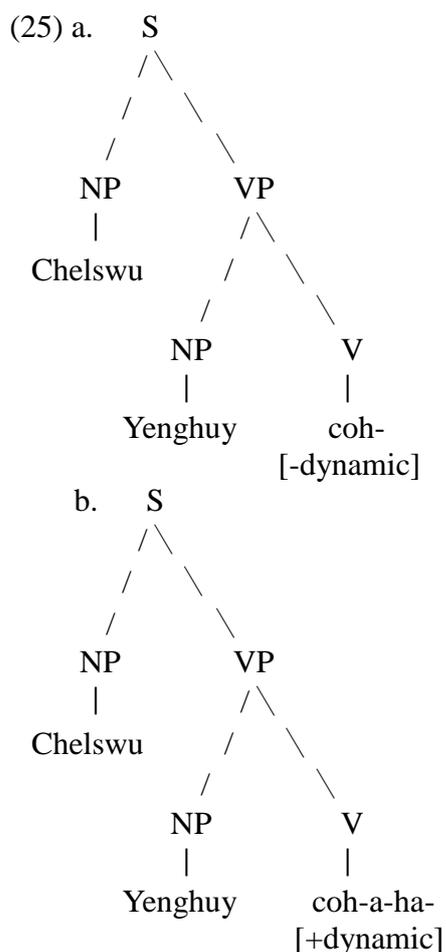

- (21) a. An NP-argument which is a sister of a dynamic verb is assigned [+Accusative].  
 b. All the other NPs are assigned [+Nominative].

The DCA, (21), well explains the contrast between (a)-sentences and (c)-sentences in the following examples:

- (22) a. Chelswu-ka Yenghuy-ka coh -ta.  
           NOM      NOM be fond of-DEC  
           ‘Chelswu is fond of Yenghuy.’  
 b. \*Chelswu-ka Yenghuy-lul coh -ta.  
           NOM      ACC be fond of-DEC  
 c. Chelswu-ka Yenghuy-lul coh-a-ha-n-ta.  
           NOM      ACC fond of-do-PRES-DEC  
           ‘Chelswu likes Yenghuy.’  
 d. \*Chelswu-ka Yenghuy-ka coh-a-ha-n-ta.  
           NOM      NOM fond of-do-PRES-DEC
- (23) a. Chelswu-ka puin-i musep -ta.  
           NOM wife-NOM be afraid of-DEC  
           ‘Chelswu is afraid of his wife.’  
 b. \*Chelswu-ka puin-ul musep -ta.  
           NOM wife-ACC be afraid of-DEC  
 c. Chelswu-ka puin-ul musew-uey-ha-n-ta.  
           NOM wife-ACC afraid of-do-PRES-DEC  
           ‘Chelswu is afraid of his wife.’  
 d. \*Chelswu-ka puin-i musew-uey-ha-n-ta.  
           NOM wife-NOM afraid of-do-PRES-DEC
- (24) a. Halapeci -ka kohyang -i kuliw -si -ta.  
           grandfather-NOM hometown-NOM pine for-HON-DEC  
           ‘My grandfather is pining for his hometown.’  
 b. \*Halapeci -ka kohyang -ul kuliw -si -ta.  
           grandfather-NOM hometown-ACC pine for-HON-DEC  
 c. Halapeci -ka kohyang -ul kuliw-uey-ha-si-n-ta.  
           grandfather-NOM hometown-ACC pine for-do-HON-PRES-DEC  
           ‘My grandfather pines for his hometown.’  
 d. \*Halapeci -ka kohyang -i kuliw-uey-ha-si-n-ta.  
           grandfather-NOM hometown-NOM pine for-do-HON-PRES-DEC

(a)-sentences in the above examples have a transitive adjective, *coh-*, *musep-*, or *kulip-*, as their predicate, respectively, while (c)-sentences in the above examples have a *ha*-verb, *coh-a-ha-*, *musew-uey-ha-*, or *kuliw-uey-ha-*, as their predicate, respectively. The contrast between the grammaticality of (a)-sentences and the ungrammaticality of (b)-sentences in the above examples shows that the object of a transitive adjective is assigned [+Nominative], not [+Accusative]. And the contrast between the grammaticality of (c)-sentences and the ungrammaticality of (d)-sentences in the above examples shows that the object of a *ha*-verb is assigned [+Accusative], not [+Nominative].

(22 a) and (22 c) have the following tree diagram, respectively:

*coh-*, ‘be fond of’, is a non-dynamic verb and hence its sister NP-argument cannot be assigned [+Accusative], but is assigned [+Nominative], under the DCA, whereas *coh-a-ha-*, ‘like’, is a dynamic verb and hence its sister NP-argument is not assigned [+Nominative], but is assigned [+Accusative], under the DCA. Hence, the DCA well explains not only the contrast between (a)-sentences and (c)-sentences in (22)~(24) but also the contrast between the grammaticality of (a)-sentences and the ungrammaticality of (b)-sentences in (22)~(24) and the contrast between the grammaticality of (c)-sentences and the ungrammaticality of (d)-sentences in (22)~(24).

#### 4 The Semantics of Objectivization

The semantic difference between (9 a) and (9 b) is that in (9 a) *Yenghuy* is the direct recipient of the agent’s action, while in (9 b) *son* is the direct recipient of the agent’s action. This kind of semantic difference between (9 a) and (9 b) is shown by their passive counterparts. The passive counterparts of (9 a) and (9 b) are as follows, respectively:

- (26) a. Yenghuy-ka Chelswu-eykey son-ul/i cap-hi-ess-ta.  
 NOM by hand-ACC/NOM catch-PASS-PAST-DEC  
 ‘Yenghuy was caught her hand by Chelswu.’/‘Yenghuy was caught by the hand by Chelswu.’
- b. Yenghuy-uy son-i Chelswu-eykey cap-hi-ess-ta.  
 GEN hand-NOM by catch-PASS-PAST-DEC  
 ‘Yenghuy’s hand was caught by Chelswu.’

The ungrammaticality of the following examples also shows that *Yenghuy* in (9 a) and (11 a), not *son* in (9 a) or *chayk* in (11 a), is the direct recipient of the agent’s action:

- (27) a. \*son-i Chelswu-eykey Yenghuy-lul cap-hi-ess-ta.  
 hand-NOM by ACC catch-PASS-PAST-DEC
- b. \*chayk-i Chelswu-ey uyhaye Yenghuy-lul cwu-e-ci-ess-ta.  
 NOM by ACC give-PASS-PAST-DEC

The following cleft constructions once again show that *Yenghuy* in (9 a) and (11 a) and *cip* in (10 a) are the direct recipients of the agent’s action:

- (28) a. Chelswu-ka son-ul cap-un salam-un palo Yenghuy-i-ta.  
 NOM hand-ACC catch-REL person-as for just be-DEC  
 ‘The person whom Chelswu caught the hand is just/exactly Yenghuy.’
- b. Chelswu-ka cey chay-lul ci-un kes-un palo cip-i-ta.  
 NOM three unit-ACC build-REL thing-as for just house-be-DEC  
 ‘The thing which Chelswu built three units is just/exactly a house.’
- c. Chelswu-ka chayk-ul cwu-n salam-un palo Yenghuy-i-ta.  
 NOM book-ACC give-REL person-as for just be-DEC  
 ‘It was Yenghuy whom Chelswu gave a book.’

*Yenghuy* in (28 a) and (28 c) and *cip* in (28 b) are the direct recipients of the agent’s action.

## 5. Conclusion

We have shown that Subjectivization and Objectivization are not A’-Movement but A-Movement, and that the objectived NP created after Objectivization is the direct recipient of the agent’s action.

# A Diachronic Corpus Study on ‘Be + to-infinitive’\*

Young-Se Kang, Jong-Yurl Yoon & Keun-Chul Chang

Kookmin University  
861-1 Jeongneung-Dong, Seongbuk-Gu, Seoul 136-702, Korea  
yskang@kookmin.ac.kr, jyoon@kookmin.ac.kr, [gmstone@kookmin.ac.kr](mailto:gmstone@kookmin.ac.kr)

## Abstract

The purpose of this study is to show, by using the diachronic corpus, that ‘be to’ of ‘be + to-infinitive’ is a semi-auxiliary or a quasi-modal like ‘be going to’ and ‘be able to’.

**Keywords:** be + to-infinitive, diachronic corpus, semi-auxiliary, quasi-modal.

## 1. Introduction

The aim of this study is to show that ‘be to’ of ‘be + to-infinitive’ is a semi-auxiliary or a quasi-modal like ‘be going to’ and ‘be able to’. ‘be to’ appears in the same position as ‘be going to’ and ‘be able to’:

- (1) a. thys unhappy soule ... *was goying to* be broughte into helle for the synne and onleful lustys of the body (1482 *Monk of Evesham* (Arv.) 43.)
- b. feithful men, whiche schulen *be* also *able to* teche other men (c1380 Wyclif)
- c. Ther ben of suche ... That *ben* noight *able* of hemselve *To* get love. (c1390 Gower, *Confessio Amantis*)
- d. You will *be to* visit me in prison with a basket of provisions. (1816 Austen, *Mansfield Park* I . xi v. 135)
- e. None of them had been completely finished, the painting and papering *being* yet *to* be done. (1885 Sir J. Bacon in *Law Times Rep.* (N.S.) LII. 569/2 [OED])

‘be to’ can be analyzed as a semi-auxiliary or a quasi modal because it appears in the same position as ‘be going to’ and ‘be able to’.

## 2. Auxiliary of Modality

(modality < modal < mode < mood < OE *mód* = OFris *môd*, OHG *muot*, ON *móðr*: a frame of mind or state of feelings; one’s humor, temper, or disposition at a particular time)

### 2.1. Distinctive qualities of modal auxiliaries

Modal auxiliaries are more restricted than primary auxiliaries (periphrastic auxiliary ‘do’; aspectual auxiliary ‘have’; passive auxiliary ‘be’) in morphological or syntactic aspects. Modal auxiliaries have the following characteristics:

- (2) a. A bare infinitive comes after them: ( i ) I *can* go. ( ii ) \*I *hope* go.
- b. They do not have nonfinite forms: ( i ) \**to can* ( ii ) \**canning* ( iii ) \**canned*

- c. They do not have present singular forms: ( i ) \*She *can*s come.  
( ii ) She *hopes* to come.
- d. They have abnormal time reference, not past time: You *could* leave this evening.  
(Quirk *et al.* (1985: 137))
- e. They do not co-occur: \*He *may will* come. (Palmer (1979: 9))

It is controversial whether modal auxiliaries with this meaning existed in Old English and, if so, how many modal auxiliaries existed in Old English. There were verbs which had the meaning of auxiliaries in Modern English: ‘be’ *beon, wesan, weorþan*; ‘have’ *habban*; ‘will, would’ *willan*; ‘must’ *motan*; ‘shall, should’ *sculan*; ‘may, might’ *magan*; ‘can’ *cunnan*, etc. In the Old English period they had independent meanings. But with changes of time, they are now used as auxiliaries which must be combined with main verbs. Therefore it is difficult to distinguish modal auxiliaries from modal idioms, semi-auxiliaries, or catenatives. Quirk *et al.* (1985: 137) classifies modal auxiliaries, modal idioms, semi-auxiliaries, and catenatives in accordance with the scale of modal function:

- (3) a. central modals: can, could, may, might, shall, should, will, would, must
- b. marginal modals: dare, need, ought to, used to
- c. modal idioms: had better, would rather, would sooner, **be to**, have got to, etc.
- d. semi-auxiliaries: have to, **be able to**, **be going to**, **be about to**, be bound to, be obliged to, be supposed to, be willing to, etc.
- e. catenatives: appear to, happen to, seem to, get +-ed, keep + -ing, etc.
- f. main verb + nonfinite clause: hope + to-infinitive, begin + -ing, etc.

Lightfoot(1974, 1979, 1988, 1991) argues that original modal main verbs were restructured as auxiliaries in the Early Modern English period. Examples of roundabout phraseology (Lightfoot(1979), Denison(1993)) are as follows:

- (4) a. he told him he *had* not *to* beleeve, that the couetousness of Virginio ... had moved Ferdinand (1579 Geoffrey Fenton, *Guicciard* (1618))
- b. we *have* ... *to* strive with a number of heavy prejudices (1594 Richard Hooker, *Of the Law of Ecclesiastical Polity* I i I )
- c. thys unhappy soule ... *was goying to* be broughte into helle for the synne and onleful lustys of the body (1482 Monk of Evesham (Arv.) 43.)
- d. to *be abill to* wed hure (1440 *The Gesta Romanorum*, ed. S. J. H. Herrtage(1879), p. 269)
- e. faithful men, which schulen *be* also *able to* teche other men. (a1425(c1395) *WBible*(2) II. Tim. 2.2)
- f. for if they do look to the bottom and see the King's case, they think they *are* then bound to give the King money; (1667 Pepys, *Diary* VIII 572.4 (8 Dec))
- g. and now the King would have the Parliament give him money, when they are in an ill humour and will not *be willing to* give any, nor are very able; (1667 Pepys, *Diary* VIII 591.24 (27 Dec))

But Allan(1987) and Plank(1984) claim that ‘be to’ and ‘have to’ began to be used in the Old English period. Also they claim that *gan/gangan* ‘go’ in OE is similar to ‘be going to’ in

Modern English. Allan claims that *beon* (*h*)*able* was used with the modal sense when it was borrowed from French. Some examples of *be to*, *have to*, *gan/gangan* and *be able to* are as follows:

- (5) a. þone calic þe ic **to** drincenne **hæbbe** ‘the chalice which I have to/will drink’ (OE *Gospel St. Matthew*)  
 b. **Hæfst** ðu æceras **to** erigenne? ‘Do you have fields to plough/have to plough fields?’ (*Æ Gram*)  
 c. hwæ ðer he **hæbbe** hine **to** full fremmenne ‘whether he had to perfect himself’ (OE *Gospel St. Luke*)  
 d. Grammaire ferste hath forto teach To speke upon congruite (c1390 Gower, *Confessio Amantis*)  
 e. Ic **geongo to** cunne ða ilca ‘I go to know/find out that’ (*Lindisfarne Gospel*)  
 f. gif þu **gest** herof **to** disputinge ‘if you hereof proceed/turn/are going to dispute’ (1250 *Owl & Nigh.*)  
 g. feithful men, which schuln **be** also **able to** teche other men (c1380 Wyclif)  
 h. the haeve **was** not **able to** dwelle in wynter (*ibid.*)  
 i. Ther ben of suche ... That **ben** nocht **able** as of hemselve **To** get love (c1390 Gower, *Confessio Amantis*)  
 j. It is a feble leche þat ca not helpe þat is able to be holpen (c1400 Lanfranc)

The above examples weaken Lightfoot’s(1974, 1979) claim that modal main verbs are changed as the modal auxiliaries through a restructuring process in the 16<sup>th</sup> century. And the examples in (5) suggest that syntactic changes progressed gradually.

## 2.2. Be + to-infinitive

‘Be + to-infinitive’ can be construed in many ways. Some examples from Palmer(1974) are given in (6):

- (6) a. He’s **to** come tomorrow.  
 b. You **are to** be congratulated.  
 c. They **are to** be married next week.  
 d. They **were to** have come today.

Denison(1998) call ‘be’ of these structures ‘modal BE’. Warner(1990) argues that ‘BE’ in these structures is meaningless and that it can be omitted. Some examples are discovered in the early part of the 19<sup>th</sup> century. They are given in (7).

- (7) a. You will **be to** visit me in prison with a basket of provisions. (1816 Austen, *Mansfield Park* I . xi v . 135)  
 b. N.B. No snuff **being to** be had in the village she made us some. (1818 Keats, *Letters* 78p. 189)  
 c. None of them had been completely finished, the painting and papering **being yet to** be done. (1885 Sir J. Bacon in *Law Times Rep.* (N.S.) LII. 569/2 [OED])  
 d. But new problems may **be to** come.

### 3. Diachronic Corpus of ‘Be to’

#### 3.1. Be, v.

- 1) the original Aryan substantive verb with stem *es-*, Skr. *as-*, *ś-*, Gr. *ἔσ-*, L. *es-*, *ś-*, OTeut. *\*es-*, *ś-*;
- 2) the verb with stem *wes-*, Skr. *vas-* to remain, OTeut. *wes-*, Gothic *wis-an* to remain, stay, continue to be, OS., OE., OHG. *wesan*, OFris. *wes-a*, ON. *ver-a*;
- 3) the stem *bew-* Skr. *bhū-*, *bhaw-*, Gr. *φν-*, L. *fu-*, OTeut. *\*bew-*, *beo-*, OE. *béo-n* to become, come to be.

##### a. 1 sing. *am*

## Abstract

The properties of a sentence with floating quantifier/numeral classifier crucially depend on the semantic properties of the quantifier/numeral involved: whether it is proportional or not and whether it is strong or not. In this sense, we claim that there are two different groups of proportional quantifiers-- *taypupun*, *motwu*, etc. on one hand and *pan isang*, *celpan*, *kwabanswu*, etc. on the other. The former is the same as numeral classifiers in certain respects. But the latter is not the same as numeral classifiers in behavior in the sense that these strong proportional quantifiers show dependency across intervening objects. The weaker ones in this group are naturally similar to numeral classifiers, which are inherently weak.

**Keywords:** quantifier floating, information structure, proportional quantifiers, non-conservative reading

## 1. Introduction

Quantifier floating appears in various languages. The quantifier *all* can occur at both pre-nominal position and post-nominal position as in (1).

- (1) a. All students drank beer.  
b. The students all drank beer.

Similarly, quantifiers in Korean can be separated from host-NP and appear various positions in the sentence.

- (2) a. *haksayng(tul)*    *sey myeng-i*    *yek-ey*    *tochakha-yessta.*  
Student(s)    3 CL – NOM    station-AT    arrive - PAST  
“Three students arrived at the station.”  
b. *haksayng(tul)-i*    *sey myeng*    *yek-ey*    *tochakha-yessta.*

c. *haksayng(tul)-i yek-ey sey myeng tochakha-yessta.*

In addition, proportional quantifiers can be separated from their host-NP as well.

(3) a. *haksayng(tul) taypwupwun/celpan/panisang-i yek-ey tochakha-yessta.*

Student(s) most/half/more than half-NOM tation-AT arrived

‘Three students ate apples.’

b. *haksayng(tul)-i taypwupwun/celpan/panisang yek-ey tochakha-yessta*

c. *haksayng(tul)-i yek-ey taypwupwun/celpan/panisang tochakha-yessta*

(3a) is non-floated sentence and (3b) and (3c) are floated sentences. Floating proportional quantifiers in Korean, however, differ from floating numeral classifiers in various respects. The previous studies have pointed out that there are structural differences between them. However, the syntactic behaviors of a sentence with floating quantifier depend on the type of the quantifier.

In this sense, this paper will concentrate on the semantic properties of the floating proportional quantifiers *taypwupwun* ‘most’, *motwu* ‘all’, *panisang* ‘more than half’ etc. Especially, it will focus on the relation between numeral classifiers and proportional quantifiers.

This paper presents two classes of proportional quantifiers in Korean to examine these properties. – (i) *taypwupwun*, *motwu* etc. and (ii) *panisang*, *celpan* (half) etc. The former is different from the numeral classifiers and the latter is similar to them.

## 2. Floating Quantifiers in Korean

There are several forms of classifiers in Korean as in (4).

(4) a. [*sey myeng-uy haksayng(tul)-i ecey yek-ey tochakha-yessta*

3 CL-POS Student(s) – NOM yesterday station- AT arrived

‘Three students arrived at the station yesterday.’

b. [*haksayng(tul) sey myeng]-i ecey yek-ey tochakha-yessta*

c. *haksayng(tul)-i ecey sey myeng tochakha-yessta*

It is generally assumed that (4a) and (4b) are non-floated forms (fundamental form). But here we assume that the fundamental form of numeral classifier is a post-

nominal type as in (4b). The pre-nominal form shows a denotational meaning. It presents the property of a host-NP. The post-nominal form, however, has a quantificational meaning. It shows the quantity of a host-NP. Likewise, (4b) is a non-floated sentence and (4c) is a floated sentence.

### 3. Differences between Numeral Classifiers and Proportional Quantifiers

#### 3.1 Subject-Object asymmetry

First difference between numeral floating classifiers and proportional floating quantifier is related to so-called ‘Subject-Object asymmetry’ problem. Previous studies observed that the object cannot intervene between the subject and a subject-oriented numeral classifier. Thus the following sequence is allowed as in (5a); Obj.<sub>i</sub>-Subj.-FNC<sub>i</sub>. In contrast, the sequence ‘Subj.<sub>i</sub> -Obj.- FNC<sub>i</sub> is blocked, as in (5b).

- (5) a. *sakwa-lul haksayngtul-i sey kay mek-ess-ta.*  
 apple-ACC Student-NOM 3 CL ate  
 ‘Students ate three apples.’
- b. \**haksayngtul-i sakwa-lul sey myeng mek-ess-ta*  
 Student(s)- NOM apple-ACC 3 CL ate  
 ‘Three students ate apples.’

In the previous literature, it was asserted that syntactic structure gives rise to the difference. The previous studies have pointed out that there are structural differences between them. It, however, seems to me that the syntactic behaviors of a sentence with floating quantifier depend on the semantic nature of the quantifier. So, in this paper, we want to demonstrate with some pieces of evidence that the difference between them results from semantic properties of the quantifiers and information structural factors involved.

In the sentence (6a), it is impossible that the sentence is interpreted as ‘Three police officers caught a thief’. However, the sentence with proportional quantifier *taypupun* ‘most’ can have not only ‘Subject-oriented meaning’ but also ‘Object-oriented meaning’. In other words, sentence (6b) means that ‘Most police officers caught a thief.’ And it means ‘Police officers caught most thieves.’ as well.

- (6) a. *kyengchal(tul)-i totwuk-ul sey myeng jap-ass-ta.*  
 the police-Nom thief-Acc 3 CL caught  
 \*Subject-oriented reading √Object-oriented reading
- b. *kyengchal(tul)-i totwuk-ul taypwupwun jap-ass-ta.*  
 the police-Nom thief-Acc most caught  
 √Subject-oriented reading √Object-oriented reading

On top of that, acceptance degree differ depend on the type of proportional quantifiers as in (7).

- (7) a. *kyengchal(tul)-i totwuk-ul celpan jap-ass-ta.*  
 the police-Nom thief-Acc half caught  
 \*Subject-oriented reading √Object-oriented reading
- b. *kyengchal(tul)-i totwuk-ul pan isang jap-ass-ta.*  
 the police-Nom thief-Acc more than half caught  
 ??Subject-oriented reading √Object-oriented reading
- c. *kyengchal(tul)-i totwuk-ul taypwupwun jap-ass-ta.*  
 the police-Nom thief-Acc most caught  
 √Subject-oriented reading √Object-oriented reading

(7a) only means that ‘police officers caught half of the thieves.’ That is, it doesn’t have subject-oriented reading. (7b) means that ‘police officers caught more than half of the thieves.’ And ‘subject-oriented reading’ is not relevant. In contrast, (7c) have both meanings perfectly. Likewise, *celpan*, *panisang*, and *taypwupwun* are all proportional quantifiers but there are differences between them. It means that the differences are caused by semantic properties of quantifiers.

### 3.2. Restriction of predicates problems

Nakanishi’s (2003) states that numeral classifiers cannot be floated from the subject NP of the Individual-level predicates, but it can be floated from the subject NP of the Stage-level predicates.

This property also appears in Korean. Non-floated quantifier can appear with Individual-level predicate *ttokttokha-ta* ‘smart’ as in (8a), but floated quantifier cannot appear with Individual-level predicates as in the sentence (8b).

- (8) a. *haksayng(tul) sey myeong-i tooktokha-ta.*  
 student(s) 3 Cl -Nom smart  
 'Students are three persons smart.'  
 b. \**haksayng(tul)-i sey myeng ttoktokha-ta.*

Nakanishi explained that individual-level predicate cannot have event arguments because it reveals continuous attribute of certain entity.

However, when it comes to proportional quantifiers, the judgment of sentences varies from quantifier to quantifier. *taypwupwun* 'most' is far more relevant than others as in (9c).

- (9) a. ??*haksayng(tul)-i pan isang ttoktokha-ta.*  
 student(s)-Nom more than half smart  
 b. ??*haksayng(tul)-i celpan ttoktokha-ta.*  
 student(s)-Nom half smart  
 c. *hacksayng(tul)-i taypwupwun ttoktokha-ta.*  
 student(s)-Nom most smart

### 3.3 Restriction of predicates

According to Chungmin Lee(2000), semantic differences between quantifiers are related to "unaccusative effect". Numeral quantifiers can be appear with unaccusative predicate *tochakhata*, but they cannot be shown with transitive verb such as *milta* 'push' or *masita* 'drink' etc.

- (10) a. *haksaying-i sey myeng tochak-hay-ss-ta.*  
 student -NOM 3 CL arrived  
 'Three students (FNC) arrived.' --- UNACCUSATIVE  
 b. ??*haksaying-i sey myeng wus-ess-ta.*  
 student -NOM 3 CL laughed  
 'Three students (FNC) laughed.' --- UNERGATIVE  
 c. *haksaying-i sey myeng maykcwu-lul masi-ess-ta.*  
 student-Nom 3 Cl beer-Acc drank  
 'Three students (FNC) drank beer.' --- UNERGATIVE

According to Chungmin Lee(2000), floating numeral quantifiers undergo a kind of adverbialization. That is, since quantifier became a kind of adverb through floating, it is more natural that it appears with unaccusative predicate close to verb.

Note that, in this case, relevance of sentence is depends on the quantifier.

- (11) a. ?? *haksaying-i celpan wus-ess-ta*  
 student -NOM half laughed  
 'Half of the students(FPQ) laughed.' --- UNERGATIVE
- b. *haksaying-i taypwupwun wus-ess-ta*  
 student -NOM most laughed  
 'Most students(FPQ) laughed.' --- UNERGATIVE

The quantifier like *pan isang* 'more than half' can not appear with unergative predicate *wusta* 'laugh', but *taypwupwun* 'most' can appear with all kinds of predicates.

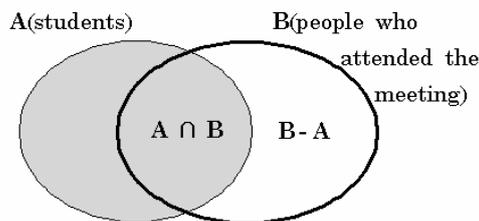

### 3.4. Non-conservative representation

Quantifiers fundamentally have 'conservativity'. However, some proportional classifiers lose its conservativity under the following conditions:<sup>1</sup>

<sup>1</sup> **Conservativity and non-conservativity reading:**

- (1) *haksayng(tul)-i taypwupwun hoyuy-ey chamsekha-yess-ta* [conservative reading]  
 student(s)-Nom most meeting-at attended  
 (i) Most students attended the meeting.  
 (ii) \*Most attendants were students.(=People who attended the meeting were mostly students)'
- (2) [[*haksayng(tul)-i*]<sub>F</sub> *taypwupwun hoyuy-ey chamsekha-yess-ta*]<sub>IP</sub> [non-conservative reading]  
 (i) \*'Most students attended the meeting.'  
 (ii) 'Most attendants were students.(=People who attended the meeting were mostly students)'

Sentence (1) is true iff  $1/2|A| < |A \cap B|$ . So we do not need to check the relative complement. That is, the truth value of the sentence is determined in set A. However, (2)'s 'most' quantify over attendants. Therefore we should check both set A and B.

(12) Conditions on the loss of conservativity of the proportional quantifier:

- 1) The quantifier must be floated.
- 2) There must be a focal accent on the subject.

The sentence with proportional quantifier can't have conservative reading under the conditions of (12), as in (13)

- (13) a. [ *taypwupwun* ]<sub>IP</sub> # [ [*haksayng(tul)-i*]<sub>F</sub> *hoiyuy-ey cahmsekha-yess-e.* ]<sub>IP</sub>  
b. [ [*haksayng(tul)-i*]<sub>F</sub> *taypwupwun hoiyuy-ey chamsekha-yess-e.* ]<sub>IP</sub>  
c. [ [*haksayng(tul)-i*]<sub>F</sub> *hoiyuy-ey taypwupwun chamsekha-yess-e.* ]<sub>IP</sub>  
d. [ *hoiyuy-ey* ]<sub>IP</sub> # [ [*haksayng(tul)-i*]<sub>F</sub> *taypwupwun chamsekha-yess-e.* ]<sub>IP</sub>

As in (13), there is focal accent on the subject and there is no term from the focal word to the end of the sentence. And then it's representation is 'people who attended the meeting were mostly students'. Likewise, in these sentences, the set of people who attended the meeting is quantified by *taypwupwun*.

However, it is not the case that all quantifiers can get non-conservative reading.

- (14) a. [*haksayng(tul)-i*]<sub>F</sub> *sey myeng hoiyuy-ey chamsekha-yess-e.*  
b. [*haksayng(tul)-i*]<sub>F</sub> *celpan hoiyuy-ey chamsekha-yess-ta.*  
\* 'Half of the attendants were students.'  
c. [*haksayng(tul)-i*]<sub>F</sub> *pan isang hoiyuy-ey chamsekha-yess-ta.*  
'More than half of the students attended the meeting.'  
?? 'More than half of the attendants were students.'  
d. [*haksayng(tul)-i*]<sub>F</sub> *taypwupwun hoiyuy-ey chamsekha-yess-ta.*  
\* 'Most students attended the meeting.'  
'Most attendants were students.'  
(=People who attended the meeting were mostly students)

As we can find in (14), non-conservative reading depends on their semantic property. The quantifier *taypwupwun* can have 'non-conservative meaning' as the sentences in (14d). However, some other proportional quantifiers cannot have non-conservative interpretation as in (14b). Similarly, the numeral classifiers cannot have non-conservative reading.

## 4. Quantifier Floating and Information Structure

### 4.1 contrastiveness

Now that we've covered several differences between quantifiers, let's move on to the reason. To solve this problem, we should know the core meaning of quantifier *taypwupwun* 'most', because it is totally different from numeral quantifiers and it is freely floated in any conditions.

Anna Papafragou & Naomi Schwarz(2005)'s observation enable us to know the lexical meaning of *taypwupwun* 'most'.

They state that when people hear the word 'more than half', it is important for them whether it is over 50% or not. However, in the case of 'most', they focus on the ratio, and they also concerned about the number of remains in the whole.

(15) Anna Papafragou & Naomi Schwarz (2005)

- more than half: It is important for the speakers whether it is over 50% or not.
- most: It focuses on the ratio, and it also concerned about the number of remains.

Martin Hackl & Ben Acland (2006) also states that there is a difference between two quantifiers as in (12).

(16) Martin Hackl & Ben Acland (2006)<sup>2</sup>

- more than half(A) (B) = 1 iff  $|A \cap B| > 1/2|A|$
- most(A) (B) = 1 iff  $|A \cap B| > |A-B|$

In Korean, *pan isang* 'more than half' and *taypwupwun* 'most' have different meaning as in (17).

(17) a. *pan isang-uy khatu-lul mence kacinun salam-i wusungca-ta.*

more than half-of card-ACC early have person-NOM winner

'The person who gets more than half of the card first is winner.'

b. *#taypwupwun-uy khatu-lul mence kacinun salami wusungcaipnita.*

---

<sup>2</sup> M&B(2006) pointed out that there is semantic difference between more than half and most. It, however, could not easily caught by formal semantics because two logical meanings are the same.

(17a)'s interpretation is 'the person who gets more than half of the card first is winner' and (17a) is relevant but (17b) is not, it doesn't make sense. In case of *pan isang* we can judge truth value before the game finished. However, in case of *taypwupwun*, we cannot judge truth value until the game finished: because we have to compare the number of cards each players have.

With reference to these observations, we can expect *taypwupwun* originally have 'contrastiveness'. And other proportional quantifiers also have contrastive-ness but not strong. Fractions or percent expressions have discrete quantity and the expressions like 'more than half' or *panisang* have a reference point, so they don't need to compare related entities with other alternatives. And numeral classifiers do not have contrastive-ness originally. (Sometimes they can be interpreted as contrastively according to contexts).

#### 4.2 Contrastiveness and event quantification

Event quantification is derived like this.

(18) [*yecatul-i*]<sub>F</sub> *taypwupwun sewulyek-ey tochakhayssta*.

- Focal element NP [*yecatul-i*]<sub>F</sub> constitutes the set of alternatives: {women, men}
- The domain of quantifier *taypwupwun*: extends from a set of women to a set of people who arrived.

In contrast, since other quantifiers do not have contrastiveness the domain of quantifiers cannot be extended to a set of people who arrived.

(19) \**[yecatul-i]*<sub>F</sub> *sampwunuy il sewulyek-ey tochakhayssta*.

- Focal element [*yecatul-i*]<sub>F</sub> constitutes the set of alternatives: {women, men}
- The domain of quantifier *sampwunuy il* is not extended.

(20) \**[yecatul-i]*<sub>F</sub> *sey myeong sewulyek-ey tochakhayssta*.

- Focal element [*yecatul-i*]<sub>F</sub> constitutes the set of alternatives: {women, men}
- The domain of numeral classifier *sey myeong* is not extended.

## 5. Solution for ‘Subject-object asymmetry’

As mentioned before, semantic properties of quantifiers give rise to restriction of floating.

(5) a. *sakwa-lul haksayng(tul)-i sey kay mek-ess-ta*  
apple-ACC Student-NOM 3 CL ate  
‘Students ate three apples.’

b. \**haksayng(tul)-i sakwa-lul sey myeng mek-ess-ta* .  
Student(s)- NOM apple-ACC 3 CL ate  
‘Three students ate apples.’

In contrast to (5b), a Contrastive Topic (CT) marked numeral classifiers and NOM-marked numeral classifiers can freely float, as exemplified in (15).

(21) a. *haksayngtul-i sakwalul sey myeng-un mek-ess-ta*.  
Student- NOM apple-ACC 3 CL-CT Marker ate  
b. *haksayngtul-i sakwa-lul sey myeng-i mek-ess-ta*.  
Student- NOM apple-ACC 3 CL-Case Marker ate

Sentence (21a) is relevant as a result of attaching CT-marker *-(n)un* to classifier *sey myeng*. As many previous studies asserted, *-(n)un* is ‘Contrastive Topic marker’ in Korean. Then, (21a) means ‘at least three students ate apples (but not more than that)’. (21b) certainly has contrastiveness and scalarity.

On the other hand, (21b) means ‘the number of students who ate apples is three and not other numbers’. (21b), like (21a), brings about contrastive meaning, Contrastive Focus (CF) this time. Given these interpretations, we can assume that acceptance of (21a) and (21b) is due to its ‘Contrastiveness’. The floating quantifiers acquire contrastiveness by CT-marker or CF structural case-marker (NOM here). As a result, they get into Nuclear Scope of information structure from the restrictor position.

Consider now the floating quantifier without NOM-marker. It can avoid the Subject-Object asymmetry when it has the specific intonation pattern (H\*) as in (21b). Kang B. (2000) explains that the classifier without any marker can be floated when the context puts greater importance on the quantity.

(22) {How many students ate apples?}

A: haksayng(tul)-i sakwa-lul [sey myeng H\*]CF mek-ess-e.  
Student- NOM apple-ACC 3 CL ate

(23) a. haksayng(tul)-i sakwa-lul sey myeng-**man** mek-ess-ta

Student- NOM apple-ACC 3 CL-CT Marker ate [-**man** ‘only’ = focalizer]

b. haksayngtul-i sakwa-lul sey myeng-**ina** mek-ess-ta

[-**ina** ‘as many as’ = surprise]

Let us now turn to (5a) above. How come (5a) is relevant? The classifier *sey kay* in (5a) can easily be focused because it is originated from the object. In other words, object has potential focus in the sentence.

(24) a. sakwa sey kay-lul haksayng(tul)-i mek-ess-ta.

Apple 3 CL-ACC students-NOM ate

“Students ate three apples.”

b. ?sakwa-lul sey kay haksayng(tul)-i mek-ess-ta.

As we saw in example (24), the object oriented classifier *sey kay* can not be floated. Because object oriented classifier can not be focused on the position as in (24b).

Let us now return to proportional quantifiers. Why do they can be floated on the same condition? It is due to the semantic property of proportion. Proportional meaning has certain ratio comparing with others in a set. However, relevance differs from quantifier to quantifier, depending on the degree of strength in quantification as in (25).

(25) a. ??haksayng(tul)-i sakwa-lul **sampwunuy il** mek-ess-ta [‘1/3’]

b. ?haksayng(tul)-i sakwa-lul **panisang** mek-ess-ta. [‘above half’]

c. \*haksayng(tul)-i sakwa-lul **sasip-phulo** mek-ess-ta [‘40%’]

d. \*haksayng(tul)-i sakwa-lul **celpan** mek-ess-ta [half]

## 6. Conclusion: Classification of Quantifiers

We have examined the differences between numeral classifiers and proportional quantifiers. We argued that the differences are not because they have different syntactic structures but because they have different semantic and information structural properties.

Numeral classifiers do not have contrastiveness. This property results in subject-object asymmetry and conservative representation. In contrast to numeral classifiers, proportional quantifiers, if strong, have contrastiveness fundamentally. Thus they do not have the asymmetry problem and they lose their conservative reading with contrastively focused numeral element, quantifying over event-related null nominal domain.

Finally, there are several grades between numeral classifiers and proportional quantifiers in strength. Some weaker proportional quantifiers behave similarly to numeral classifiers.

Floating Quantifiers	Numeral classifiers	Proportional Quantifier 1		Proportional quantifier 2
		Discrete quantity	Present of a datum point	Non-discrete quantity
Quantity	Accurate numbers			
Degree of Contrastiveness	<-----1-----2-----3-----4----->			
Subject-Object asymmetry	$\sqrt{\text{Obj.}_i\text{-Subj.}-\text{NC}_i}$ * $\text{Subj.}_i\text{-Obj.}-\text{NC}_i$	$\sqrt{\text{Obj.}_i\text{-Subj.}-\text{FNC}_i}$ * $\text{Subj.}_i\text{-Obj.}-\text{FNC}_i$	$\sqrt{\text{Obj.}_i\text{-Subj.}-\text{FNC}_i}$ ? $\text{Subj.}_i\text{-Obj.}-\text{FNC}_i$	$\sqrt{\text{Obj.}_i\text{-Subj.}-\text{NC}_i}$ $\sqrt{\text{Subj.}_i\text{-Obj.}-\text{NC}_i}$
Non-conservativity	*	*	*	√
Restriction of Predicate	?*/*	??	?	√
Language expressions	<i>han myeong</i> (1), <i>twu kay</i> (2), <i>sey mari</i> (3) ...	Percents (40%,50% ...)
