---

<sup>i</sup> For many speakers *J Kodomo-ni gakkou-ni ika-se-ru* (child-dat. school-dat go-caus.-ind.) ‘let the child go to school’ seems to have a softer implication than *J Kodomo-o gakkou-ni ika-se-ru* (child-acc. school-dat. go-caus.-ind.) ‘make the child go to school’.

<sup>ii</sup> The suffix *-l-* in the latter two verb pairs is a causative (Pope 1954: 61). Semantically both *-l-* and *-ci-* derive causatives, but *-l-* puts fewer restrictions on the semantics of the preceding verb. An action like ‘drink’ (e.g. *uγu-* ‘drink’ => *uγul-* ‘give to drink’) that does not express a change of state cannot be the base verb for *-ci-* causatives.

<sup>iii</sup> In Old-Turkic the formative *-n-* occurs in reflexive-anticausative derivations, while *-š-* occurs in reciprocal verbs (Erdal 1991: 552-578, 584-634).

# Probabilistic OT approach to *sa*-Insertion in Japanese: Based on the corpus data

Shin-ichiro SANO

Sophia University  
7-1 Kioicho Chiyoda-ku Tokyo, Japan  
shinichirosano@gmail.com

## Abstract

This paper presents a Probabilistic OT analysis of the recent synchronic variation called *sa*-Insertion in Japanese, based on the corpus data. Firstly, I characterize the chronological change of the distribution of *sa*-Insertion based on the observed data. Secondly, I model and predict the change within the framework of Probabilistic OT. The result shows that a demand for one-to-one correspondence of form and content and a restructuring of conjugation paradigm by analogical leveling are the driving forces of the change: the chronological transition of the ranking values of constraints. I show that the change of *sa*-Insertion is explained by the interaction of the small set of constraints: OCP (morph), ParContrast, and AlloCorr.\*

**Keywords:** *sa*-Insertion, Optimality Theory, Probabilistic OT, language change, variation

## 1. Introduction

In this research, I conduct the analysis of the recent synchronic variation as well as the ongoing language change in Japanese causative forms involving a process called *sa*-Insertion from the perspective of Optimality Theory (henceforth OT; Prince & Smolensky 1993), based on the quantitative analysis. This process adds an extra *-as-* to the causative

\* I would like to thank Bruce Hayes and the members of the National Institute of Japanese Language for their valuable comments. Special thanks also go to Kenjiro Matsuda, Junko Hibiya and Frank Scott Howell for their help and support on this paper and on an earlier version of this paper. Any remaining faults are, of course, mine. This work was supported by Sophia University Open Research Center from MEXT.

morpheme, as in *yar-asase-ru* vis-à-vis the standard *yar-ase-ru* ‘let someone do’ and *hasir-asase-ru* vis-à-vis the standard *hasir-ase-ru* ‘let someone enter.’

As usual with any such variation, *sa*-Insertion has also been referred to as an example of *kotoba-no-midare* “language disturbance” by language purists and school teachers. Although Martin (1975: 287) refers to the phenomenon, it was not until Chen (2002) that its grammatical mechanism and sociolinguistic aspects were analyzed in a professional way. *Sa*-Insertion has, thus far, been analyzed based on the natural linguistic data and some properties of *sa*-Insertion have been revealed (Chen 2002, Okada 2003, among others). Although previous studies have elucidated the properties of *sa*-Insertion with respect to language-internal and -external factors such as the length of the preceding verb and the type of the following context, and with respect to language-external factors such as gender and style, as well as the interactions of the significant factors (Sano 2008, among others), formal aspects of the phenomenon remain to be explored. This research, therefore, aims to characterize the phenomenon quantitatively using a large-scale corpus and to give an OT account of the change of *sa*-Insertion.

The corpus employed is the Japanese Diet database, which is characterized by its large scale. It records all utterances of the members in any sessions and committees from the first Diet (May, 1947) to the present. The large scale enables one to analyze the chronological change of the phenomena over 60 years. I sampled 81 members of the Diet who come from Tokyo according to their birth-year; their utterances in all periods are in the scope of the present research. I collected a total of 317 causative forms with *sa*-Insertion, as opposed to a total of 4,708 standard causative forms; thus, the rate of *sa*-Insertion amounts to 6.31%.<sup>1</sup>

Based on the characterization of the variation in question, I explain the results of the quantitative analysis as well as the emergence and the course of the change of *sa*-Insertion by a Probabilistic OT model. I assume the Stochastic OT model and conduct the analysis using the Gradual Learning Algorithm (Boersma & Hayes 2001). I also predict the change of

---

<sup>1</sup> The Diet of Japan is comprised of the plenary sessions and the committees. The committees are further divided into permanent committees of each Ministry and select committees. Each member of the Diet belongs to either the House of Councilors or the House of Representatives (Oyama 2003).

*sa*-Insertion by means of evolOT (Jäger 2002). The result shows that a demand for one-to-one correspondence of form and content and a restructuring of conjugation paradigm by analogical leveling are the driving force of the change. I propose that *sa*-Insertion is an instance of language change for the optimization of the paradigm.

The discussion proceeds as follows. Section 2 firstly identifies the *sa*-Insertion phenomenon along with the introduction of the previous studies, and then introduces the Diet database as well as the sampling method. In Section 3, I characterize the chronological change of the distribution of *sa*-Insertion quantitatively based on the data. Section 4 conducts the OT analysis along with the introduction of the constraints. In Section 5, I conduct the Probabilistic OT analysis with these constraints. Section 6 concludes the discussion.

## 2. Methodological preliminaries

In this section, I firstly explore the *sa*-Insertion phenomenon in connection with the causative formation of Japanese.

### 2.1. *Sa*-Insertion

*Sa*-Insertion is a variation phenomenon in Japanese causatives. The Japanese causatives are formed by attaching causative suffixes to verb stems. Standard causative, which is the traditional variant, comprises the verb stem and the causative suffix *(s)ase*;<sup>2</sup> on the other hand, *sa*-Insertion, which is the innovative variant, comprises the verb stem and the causative suffixes *as*, *ase*. I present below some examples of *sa*-Insertion and standard causative observed in the Diet database.

---

<sup>2</sup> The Japanese causative suffix shows morphophonemic alternation, according to the types of verb stem: Consonant verb takes *ase*, as in *yar-ase*, while vowel verb takes *sase*, as in *tabe-sase* 'let someone eat.' I will mention the two types of Japanese verb (consonant verb/vowel verb) below.

## Standard causatives

- (1) hikooki-o mata tukur-ase-ru.  
airplane-ACC again make-CAUS-NONP  
“We let (the company) make airplanes again.”  
(Yoshio Namiki, Jun. 11 1952)
- (2) iroirona enzetu-o yar-ase-te-itadaita.  
various speech-ACC do-CAUS-TE-AUX.POL.PAST  
“I made various speeches.” (polite)  
(Keigo Oouchi, Jun. 7 1994)
- (3) gakkoo-ni ik-ase-nai.  
school-LOC go-CAUS-NEG.NONP  
“We allow (students) not to go to school.”  
(Hiroko Mizushima, Feb. 27 2004)

## Sa-Insertion

- (4) tyoosahookokusyo-o yom-as-ase-te-itadakimasita.  
investigation report-ACC read-CAUS-CAUS-TE-AUX.POL.PAST  
“I read the investigation report.” (polite)  
(Seiichi Mizuno, Sep. 27 1995)
- (5) situmon-o owar-as-ase-te-itadakimasu.  
question-ACC finish-CAUS-CAUS-TE-AUX.POL.NONP  
“Let me finish my question.”  
(Tatsuya Ito, Apr. 11 1997)
- (6) kono koosyo-o torihakob-as-ase-tai.  
this negotiation-ACC advance-CAUS-CAUS-DES.NONP  
“I want to let (someone) advance this negotiation.”  
(Sanzo Hosaka, Apr. 10 1998)

As exemplified above, each standard causative is formed by attaching *ase* to verb stems, while in *sa*-Insertion both *as* and *ase* attach to verb stems,

instead of only *ase*. Thus, *sa*-Insertion contains an extra *sa* in causative phrases, as opposed to the standard causatives.<sup>3</sup>

Among the previous studies, Inoue (2003) points out that *sa*-Insertion is restricted to consonant verbs, and it does not occur in vowel verbs. Japanese verbs are classified into two types, according to the stem-ending; one type is a consonant verb which ends in a consonant (e.g. *yar*-‘do’, *hair*-‘enter’), and the other type is a vowel verb which ends in a vowel (e.g. *mi*-‘see’, *tabe*- ‘eat’) (Bloch 1946).

Table 1. Distribution of causatives by verb type

verb type	stem	standard causative	<i>sa</i> -Insertion
consonant verb	<i>yar</i> -	<i>yar-ase</i> -	<i>yar-as-ase</i> -
	<i>hair</i> -	<i>hair-ase</i> -	<i>hair-as-ase</i> -
vowel verb	<i>tabe</i> -	<i>tabe-sase</i> -	* <i>tabe-sas-ase</i> -
	<i>mi</i> -	<i>mi-sase</i> -	* <i>mi-sas-ase</i> -

As Table 1 shows, standard causative can occur with either consonant- or vowel verbs, while *sa*-Insertion cannot occur with vowel verbs. Thus, \**mi-sas-ase*- or \**tabe-sas-ase*-, for instance, are impossible.

Based on this observation, Inoue claims further that the change of *sa*-Insertion would lead to the simplification of the conjugation of verbs in Japanese by analogical leveling (cf. Kiparsky 1978, Bybee 1985, among others).

Table 2. Distribution of causative suffix by paradigm

paradigm	verb type	causative suffix	
traditional	vowel verb	<i>sase</i>	(standard causative)
	consonant verb	<i>ase</i>	(standard causative)
innovative	vowel verb	<i>sase</i>	( <i>sa</i> -Insertion)
	consonant verb	<i>sase</i>	(standard causative)

<sup>3</sup> *Sa*-Insertion was dubbed based on a phonological aspect of Japanese. Japanese has an open-syllable sound pattern and in principle it does not allow codas. Thus, the sequence *yar-as-ase* is pronounced with CV structure as in *ya.ra.sa.se*. This results in the auditory perception of an extra *sa* rather than *as*. However, the morphosyntactic investigation revealed that *sa*-Insertion contains an extra causative suffix *as* (Okada 2003, Sano 2006), and the difference between standard causative and *sa*-Insertion cannot simply be attributed to the phonological aspect.

As illustrated in Table 2, the traditional paradigm, which consists of only standard causative, shows a morphophonemic alternation of the causative suffix between two allomorphs *ase* and *sase* according to the verb types to which it attaches. On the other hand, in the innovative paradigm, which consists of *sa*-Insertion and standard causative, the causative suffix in vowel verbs has changed from *ase* to *sase*. There is no such alternation in this paradigm, and the causative suffix uniformly takes the form *sase*, regardless of the types of the verb stem. Consequently, the difference in conjugation paradigm will disappear.<sup>4</sup>

Okada (2003) points out that; 1) the meaning of *sa*-Insertion is honorific, rather than causative; 2) *sa*-Insertion is double causative; 3) *sa*-Insertion serves to reinforce politeness, and the newly inserted causative suffix carries this function.<sup>5</sup>

Based on Okada's claim that *sa*-Insertion is a double causative, Sano (2006) proves that *sa*-Insertion is the productively formed causative which consists of two causative suffixes. Traditionally, the double causative is not allowed in Japanese and the occurrence of two causative suffixes leads to unacceptability. Instead, one of the causative suffixes is suppressed in double causative construction and a single causative surfaces (Shibatani 1973; Martin 1975; Kuroda 1993). As a result, double causative and single causative surface as an identical form: single causative. In *sa*-Insertion, however, two causative suffixes remain intact. Here exists the variation: If two suffixes remain intact, then the double causative (*sa*-insertion) arises, on the other hand, if one of the causative suffixes is suppressed, then the single causative (standard causative) arises.

## 2.2. Data

In this research, the Diet database is employed, which is characterized by its large-scale: It records all utterances of the members in any sessions

---

<sup>4</sup> This analysis, however, is problematic, because it is primarily based on the *Kana* spelling of Japanese. Although the name *sa*-Insertion is based on the *Kana* spelling, *Kana* is inappropriate for the detailed analysis of *sa*-Insertion, and the morphophonemic analysis needs to be done.

<sup>5</sup> This seems to be associated with the fact that the causative suffix originally carried the function as intensifier of the honorific/humble meaning in addition to the function as causative in old Japanese (cf. Sato 1977: 317-319, and references cited therein).

and committees from the first Diet held in May, 1947 to the present (It continues to be updated.). The large scale of the Diet database enables one to analyze the chronological change of the phenomena over sixty years.<sup>6</sup> The present research targets the utterances from May 1947 to April 2005.

In the Diet database, we search target strings by selecting the Diet number or the date of session/committee in the pull-down menu (this is obligatory) and adding search strings. The target can be specified by adding further information such as the name of a speaker or the session/committee. The target strings are displayed with detailed information per session/committee and we can directly download the information into our computer.

Based on the list of the members of the Diet by Nambu (2005), I sampled eighty-one members of the Diet who come from Tokyo; their utterances in all periods are in the scope of the present research. According to the member's birth-year, I selected one member for each year. Thus, the target of the analysis is the utterances of eighty-one members from Tokyo.<sup>7</sup> In the next section, I describe the change of *sa*-Insertion based on the collected data.

### 3. Chronological change

In this section, I characterize the chronological change of the distribution of *sa*-Insertion quantitatively. An exhaustive examination of the Diet database brought forth a total of 317 causative forms with *sa*-Insertion, as opposed to a total of 4,708 standard causative; thus, the rate of *sa*-Insertion ( $sa\text{-Insertion}/(sa\text{-Insertion} + \text{standard causatives}) * 100$ ) amounts to 6.31%, as shown in Table 3 below.

---

<sup>6</sup> Matsuda (2004) describes the possibility of the Diet database for Linguistics use.

<sup>7</sup> Sano (2008a, 2008b) describes the criterion concerning the status of *sa*-Insertion and standard causatives in the data extraction. According to the criterion of Sano (2008a), I excluded the examples which are not qualified as *sa*-Insertion or standard causatives from the extracted data.

Table 3. Distribution of causatives

	#
<i>sa</i> -Insertion	317
standard causatives	4,708
rate (%)	6.31

Based on these data, I considered the relation between the year-period and the occurrence of *sa*-Insertion, where *sa*-Insertions and standard causatives are sorted out by every five years. The distribution of *sa*-Insertion by five-year period is shown in Figure 1.

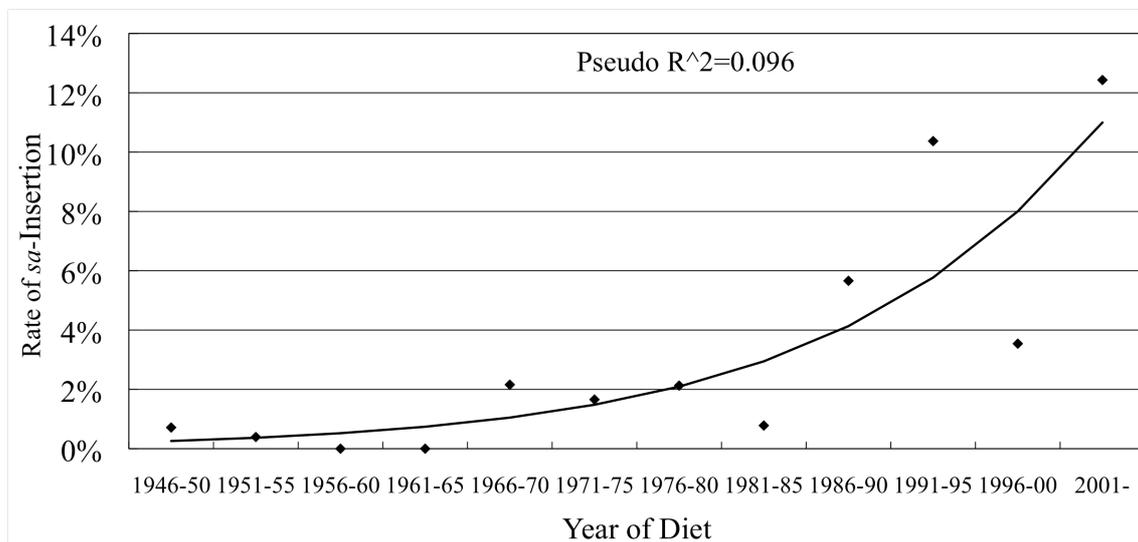

Figure 1. Chronological change of the distribution of *sa*-Insertion

In Figure 1, the dots which stand for the rate of *sa*-Insertion for each year of the Diet and the approximated curve are plotted. The rate of *sa*-Insertion is gradually rising from year to year. In the present data, *sa*-Insertion is first observed in 1949. From the first appearance, some *sa*-Insertion is observed (gradually increasing) until the 1980s; around 1990, *sa*-Insertion suddenly exploded. This shows that *sa*-Insertion is in the beginning of a language change, and the shape of the current curve exactly corresponds to the early stage of an S-curve (Bailey 1973, among others). Thus, it can be predicted that the change of *sa*-Insertion will proceed in an S-curve fashion.

#### 4. OT analysis

In this section, I conduct the OT analysis, introducing three constraints that govern the change of *sa*-Insertion: Obligatory Contour Principle (morph),<sup>8</sup> ParContrast, and AlloCorr.

##### 4.1. OCP (morph)

*Sa*-Insertion is a double causative, namely it contains two causative suffixes, while standard causative is a single causative (Okada 2003, Sano 2006). Based on this observation, I firstly introduce the constraint OCP (morph).

###### (7) OCP (morph)

No identical morphological categories are adjacent.

OCP (morph) blocks the occurrence of adjacent identical morphemes. I show how the double causative is suppressed to a single causative in terms of this constraint.

###### (8)

Input: /yar-as-ase/	OCP (morph)
a.ya.ra.sa.se	*!
☞ b.ya.ra.se	

As shown in (8), candidate (a) *ya.ra.sa.se* violates OCP (morph), since it contains two causative suffixes adjacently, on the other hand, the optimal candidate (b) *ya.ra.se* incurs no violation of OCP (morph). Thus, *sa*-Insertion, which contains two causative suffixes adjacently, is blocked by OCP (morph), and standard causative, which contains only one causative suffix, surfaces even if the input contains two causative suffixes.

---

<sup>8</sup> Obligatory Contour Principle (OCP), which bars consecutive identical features, was originally proposed by Leben (1973).

#### 4.2. Paradigm Contrast

As Okada (2003) claims, the meaning of *sa*-Insertion is honorific, rather than causative. *Sa*-Insertion plays a role in reducing the functional load with respect to these two meanings. To capture this observation in OT terms, I introduce the constraint Paradigm Contrast (Ito & Mester 2004).

(9) ParContrast (Paradigm Contrast, Ito & Mester 2004):

The cells of a paradigm are pair-wise phonologically distinct.

ParContrast requires a one-to-one correspondence between form and content. I illustrate the evaluation in terms of this constraint with the tableau.

(10)

Candidate paradigms for /yar-/	ParContrast
☞ a. causative: <i>ya.ra.se</i> (standard causative) honorific: <i>ya.ra.sa.se</i> ( <i>sa</i> -Insertion)	
b. causative: <i>ya.ra.se</i> (standard causative) honorific: <i>ya.ra.se</i> (standard causative)	*!

In paradigm (a), the meanings ‘causative’ and ‘honorific’ take distinct forms: ‘causative’ takes *ya.ra.se* which is standard causative, ‘honorific’ takes *ya.ra.sa.se* which is *sa*-Insertion. The paradigm (a) satisfies one-to-one correspondence between form and content. On the other hand, in paradigm (b), ‘causative’ and ‘honorific’ take the identical form *ya.ra.se*. In other words, *ya.ra.se*, which is standard causative, carries two meanings. This results in the higher functional load. The paradigm (b) does not satisfy one-to-one correspondence, and violates ParContrast. Thus, the paradigm (a), which includes *sa*-Insertion, is selected as the optimal candidate with no violation of ParContrast, and it follows that ParContrast is in favor of *sa*-Insertion.<sup>9</sup>

<sup>9</sup> The following question arises with respect to the meaning of *sa*-Insertion: Why the paradigm where *sa*-Insertion carries the meaning ‘honorific’ and standard causative carries the meaning ‘causative’ stands as the candidate, instead of the paradigm where *sa*-Insertion carries the meaning ‘causative’ and standard causative carries the meaning ‘honorific’? Both paradigms should satisfy one-to-one correspondence (Joe Pater, personal communication). As to the reason for this point, Japanese expresses

### 4.3. Allomorph Correspondence

As mentioned above, the causative suffix in Japanese shows allomorphy, namely, it undergoes morphological alternation according to verb types to which it attaches, either consonant verbs or vowel verbs. *Sa*-Insertion plays a role in eliminating the allomorphy by analogical leveling (Inoue 2003). To capture the analogical leveling in OT terms, I introduce the constraint AlloCorr.

(11) AlloCorr (Allomorph Correspondence, Ito & Mester 2004):<sup>10</sup>

Morphs in a relation of allomorphy are identical.

AlloCorr requires allomorphs to take the identical form. The AlloCorr evaluates the identity between forms within paradigms with respect to segments. I illustrate the evaluation in terms of this constraint with the tableau.

(12)

Candidate paradigms for /yar-/ and /tabe-/ ☞ a. consonant verb: ya.ra.sa.se (sa-Insertion) vowel verb: ta.be.sa.se (standard causative)	AlloCorr
b. consonant verb: ya.ra.se (standard causative) vowel verb: ta.be.sa.se (standard causative)	***!

The paradigm (a) which includes *sa*-Insertion and standard causative shows no allomorphy, namely, both consonant verb and vowel verb uniformly take the causative suffix *sase*. On the other hand, the paradigm (b), which consists only of standard causative shows the allomorphy, namely, consonant verb takes *se*, while vowel verb takes *sase*, and three segments do not have identical segments as their counterpart. This results in three violations of AlloCorr. Thus, the paradigm (a), which includes *sa*-Insertion, is selected as the optimal candidate with no violation of AlloCorr, and it

---

the honorific meaning by directing causation to the speaker, and the meaning is enhanced by attaching extra morphemes of causation. Therefore, the extra causative suffix may fit the honorific meaning. Along these lines, Okada (2003) claims that the extra causative suffix is the honorific booster.

<sup>10</sup> I slightly modified the original definition.

follows that AlloCorr is in favor of *sa*-Insertion.

In summary, OCP (morph) is against *sa*-Insertion, while ParContrast and AlloCorr are in favor of *sa*-Insertion. Assuming the standard OT, if ParContrast and AlloCorr dominate OCP (morph), standard causative is selected as the optimal candidate; on the other hand, if OCP (morph) dominates ParContrast and AlloCorr, *sa*-Insertion is selected as the optimal candidate. In the next section, I show how these constraints govern the changes of *sa*-Insertion interacting with each other.

## 5. Probabilistic OT analysis

Assuming the Stochastic OT model (Boersma 1998; Boersma & Hayes 2001), I conduct the analysis based on the collected data and the constraints. Firstly, I outline the Stochastic OT model, and then I move on to the analysis, followed by the prediction.

### 5.1. Stochastic OT

In Stochastic OT, the strength of each constraint is associated with numerical values (*ranking values*) along a continuous scale of real numbers, and each constraint takes the ranges of values characterized by a Gaussian distribution. The evaluation of Stochastic OT takes the forms of *stochastic evaluation*: at every speaking event, the random value, *evaluation noise*, is added to the ranking value and the final value of the constraint is determined. This value is called a *selection point*. The selection point of each constraint varies from evaluation to evaluation, and this is the locus of variation. Stochastic OT is accompanied by the learning theory: Gradual Learning Algorithm (henceforth GLA). GLA calculates and identifies the ranking values of each constraint based on the OT grammar and the learning data, and it in turn generates the distribution of variants based on the ranking values. While learning, GLA continues to promote and demote the ranking values of each constraint by a small step in order to come up with the grammar which can generate the frequency distribution consistent with the learning data.

## 5.2 Analysis

I implemented the analysis by means of GLA in Praat program (Boersma & Weenink 1992-2008). In the present analysis, I focused on three time periods: 1946-1950, 1986-1990, and 2000-2005. I classified the tokens of *sa*-Insertion and standard causative into each of these time periods. The frequency distributions of *sa*-Insertion and standard causative in each time period are shown in Table 4.

Table 4. Chronological change of the frequency of the causatives

	1946-50	1986-90	2000-05
<i>sa</i> -Insertion	1	9	200
standard causative	139	150	1409

I hypothesize that the chronological change of the distribution of *sa*-Insertion can be attributed to the change of the ranking values of each constraint. I derived the ranking values of each constraint in the three time periods based on the OT grammar and the frequency distribution.<sup>11</sup> After the learning, GLA has assigned the following ranking values to the constraints.

Table 5. Chronological change of the ranking value of each constraint

	1946-50	1986-90	2000-05
OCP(morph)	103.821	102.676	102.045
ParContrast	96.179	97.324	97.955
AlloCorr	96.179	97.324	97.955

Table 5 illustrates the chronological change of the ranking values of each constraint. The ranking value of OCP (morph), which is against *sa*-Insertion, gradually decreases, on the other hand, the ranking values of ParContrast and AlloCorr, which are in favor of *sa*-Insertion, gradually increase along the time-line. The ranking values of each constraint come closer. As a result, the probability of the occurrence of *sa*-Insertion increases. Thus, the gradient approximation of the ranking values of each constraint caused the

<sup>11</sup> I set the representative parameters in learning as follows: Initial ranking: 100; Evaluation noise: 2.0; Ranking strategy: symmetric all; Initial plasticity: 1.0; Replications per plasticity: 100,000.

emergence and the gradual increase of *sa*-Insertion.

Next, I turn to the verification of the adequacy of the above analysis. GLA generates the frequency distributions of each variant (*output distributions*) according to the resulting grammar, namely, the ranking values of each constraint in Table 5. The output distributions for the above grammar are shown below.

Table 6. The observed distributions of causatives

observed	1946-50	1986-90	2000-05
<i>sa</i> -Insertion	1	9	200
standard causative	139	150	1409

Table 7. The predicted distributions of causatives

predicted	1946-50	1986-90	2000-05
<i>sa</i> -Insertion	1	11	207
standard causative	139	148	1402

Correlation coefficient = 0.999981

The observed frequency distributions of *sa*-Insertion and standard causative in the corpus data in each time period are repeated in Table 6; Table 7 shows the predicted frequency distributions of *sa*-Insertion and standard causative in each time period. The predicted distribution is consistent with the observed distribution. This is also supported by the extremely high correlation coefficient between the observed and predicted distributions. Thus, the analysis is verified to be adequate.

### 5.3. Prediction

Finally, I predict the chronological change of *sa*-Insertion. I employed evolOT (Jäger 2002). The evolOT predicts the transition of ranking values of each constraint over time, based on the OT grammar and the frequency distribution of the phenomena at a particular point, and it further generates a series of frequency distributions, according to the resulting ranking values. In the prediction simulated by evolOT, one cycle of learning (by means of

GLA) and production represents a single generation.<sup>12</sup> The result of the simulation is shown below.

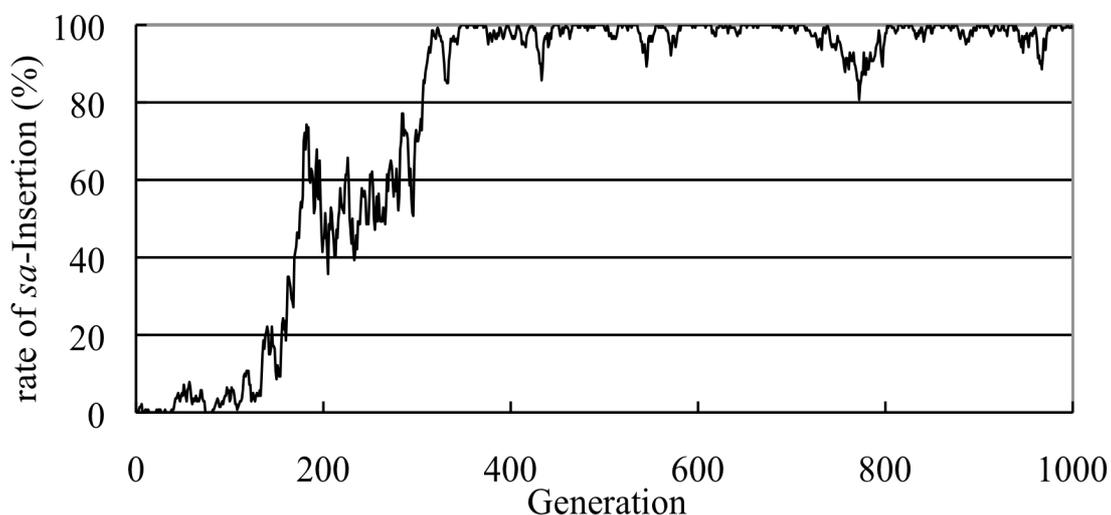

Figure 1. Prediction of the change of *sa*-Insertion

As Figure 2 illustrates, the evolOT predicts that the change of *sa*-Insertion proceeds in an S-curve manner. Furthermore, the beginning of the change of *sa*-Insertion illustrated in Figure 1 roughly corresponds to the generations from 0 to 150. Thus, the observed chronological change of the distribution of *sa*-Insertion and predicted one closely match.

At this point, I consider the reason why the rate of *sa*-Insertion increases in an S-curve manner, instead of remaining stable. Assuming a UG factor, such that at each cycle of learning, the raw ranking values get altered, with higher values for UG-favored constraints, this produces a slightly different distribution, which could then serve as the learning data for the next generation. Such a procedure could create an S-curve.<sup>13</sup>

## 6. Conclusion

In this research I conducted the Probabilistic OT analysis, based on the corpus data. The results show that *sa*-Insertion is first observed in 1949,

---

<sup>12</sup> I set the parameters as follows: Initial ranking = 0; Plasticity = 10; Noise = 20; Number of observations = 20,000.

<sup>13</sup> A suggestion by Bruce Hayes stimulated this idea.

and it is currently in the beginning of the language change. The demand for the optimization of the conjugation paradigm and for the reduction of the functional load is reflected in the gradient approximation of the ranking values of each constraint. This caused the emergence and gradual diffusion of *sa*-Insertion. The innovative paradigm which includes *sa*-Insertion satisfies these demands all taken together. The OT grammar I proposed was verified to be adequate. Finally, the evolOT predicts that the change of *sa*-Insertion will proceed in an S-curve manner. The result again matches the observed chronological change of the distribution of *sa*-Insertion. I propose that *sa*-Insertion is an instance of language change for the optimization of the paradigm. Although the change of *sa*-Insertion is affected by various language-internal and language-external factors, I showed that the change can be explained by the interaction of OCP (morph), ParContrast, and AlloCorr in a formal manner.

## Abstract

Resorting to Chinese philosophical and medical classics, this study explores the most general conceptual metaphor in the metaphorical system of anger in Chinese. QI, instead of HEAT, is the central metaphor in Chinese. From a historical viewpoint, *qi* used to refer to anger has nothing to do with heated gas but the essence that exists and circulates through the body. The conceptualization of *qi* causing anger or anger causing the hyperactivity of *qi* can be traced back to Warrior States (403-221 B.C.). It is affirmative that the physiological effects of *qi* serve as the underlying cultural model for the metaphorical system of anger. The cultural model exerts influence on language, which develops a large number of anger expressions associated with the lexeme *qi* in Han Dynasty (206 B.C.-220 A.D.). Diachronically, the sources of these two metaphors QI and FIRE are not two subversions of ANGER IS HEAT. It is the central metaphor ANGER IS QI that dominates the metaphorical use for anger expressions. The discourses drawn from Chinese classics distributed chronologically demonstrate that the compounds related to the lexeme *qi* are very productive. The compounds have undergone semantic extension and are referred to as metaphorical anger. In sum, the concept of *qi* plays a crucial role in the expressions of anger. The lexeme *qi* and the compounds related to *qi* indicating anger in contemporary Chinese are deeply rooted in Chinese conceptual system.

**Key words:** anger, *qi*, heat, metaphorical system, conceptual metaphor, cultural model.

## 1. Introduction

Lakoff and Kövecses (1983, 1987) propose that the physiological effects of anger such as body heat and internal pressure serve as the underlying cultural model for the metaphorical system of anger in English in which anger is characterized by the most general conceptual metaphor ANGER IS HEAT<sup>1</sup> (Kövecses 1986, 1990, 2000). The

---

<sup>1</sup> Capital letters stand for the metaphorical concepts.

metaphor ANGER IS HEAT has two subversions: ANGER IS THE HEAT OF A FLUID and ANGER IS FIRE. In this metaphorical system, there are a large number of anger expressions. For example, “You make my blood boil” and “I have reached the boiling point” tie to THE HEAT OF A FLUID. “Those are inflammatory remarks” and “She was doing a slow burn” tie to the FIRE metaphor. These are all conventionalized English anger expressions to describe a person who is angry.

Later, many studies have been conducted on Chinese anger expressions by making use of the methodology proposed by Kövecses and his associates in 1980s. Shyu (1989) and Cheng (1999) still treat the physiological effect of anger, body heat, as the underlying cultural model for the metaphorical system of Chinese anger expressions, in which ANGER IS HEAT is still the most general conceptual metaphor. What’s difference is that in Shyu’s categorization, she first introduces the concept of 氣 *qi* ‘air’<sup>2</sup> into the metaphorical system. Qi is translated as ‘air’ by Shyu and then the two subversions of HEAT become ANGER IS THE HEATING OF QI ‘AIR’<sup>3</sup> and ANGER IS FIRE. In other words, while English chooses FLUID and FIRE metaphors, Chinese uses QI ‘AIR’ and FIRE metaphors. There are a large number of conventionalized anger expressions which tie to the metaphorical system as shown in the following.

ANGER IS THE HEATING OF 氣 QI ‘AIR’

他有一股怨氣 *ta you yi gu yuan qi* “He has an angry air.”

別氣 *bie qi* “Don’t be angry.”

我心中有氣 *wo xin zhong you qi* “I have an air (anger) in my heart.”

ANGER IS FIRE

他發火 *ta fa huo* “He emitted fire.”

他冒火 *ta mao huo* “He spouted fire.”

我很火 *wo hen huo* “I become fiery.”

Yu’s (1998) analysis concerns the common cultural theories for Chinese anger expressions. Yu points out two Chinese traditional theories of 陰陽 *yin-yang* ‘yin-energy and yang-energy’<sup>4</sup> and 五行 *wu-xing* ‘the Five Elements’ as the

<sup>2</sup> Chinese discourses or phrases are illustrated in the following manner. Chinese characters are presented first. Italic types stand for transliteration: 漢語拼音 *Han Yu Pin Yin*. The translation is enclosed with either “” or ‘’: “” for discourse and ‘ ’ for phrase or word.

<sup>3</sup> The lexeme 氣 *qi* in classical Chinese encompasses various definitions: a form of energy, essence of the body, breath, and the force of life. Its modern counterpart has another definition: air or gas which is widely used in contemporary Chinese.

<sup>4</sup> In a survey of classical linguistic data, 先秦 pre-Qin, 秦 Qin and 漢 Han philosophical and medical

underlying cultural models for the metaphorical system of anger expressions. Yu proposes that the heated *qi* ‘air’ or ‘gas’ is formed by the *yang*-energy. Therefore, in this metaphorical system, the HEAT metaphor is still the most general conceptual metaphor in Chinese. Yu also identifies the central metaphor ANGER IS HEAT which has two subversions ANGER IS THE HOT QI ‘GAS’ and ANGER IS FIRE. It is noticed that Shyu translates *qi* as ‘air’ whereas Yu translates *qi* as ‘gas.’ They refer to the same thing in contemporary meanings. For instance, Shyu would translate the sentence 我心中有氣 *wo xin zhong you qi* as “I have an air (anger) in my heart.” Yu would translate it as ‘I have a gas (anger) in my heart. To sum, Yu’s two subversions are the same as Shyu’s. What’s difference is that Yu first introduces *yin-yang* and *wu-xing* as the underlying cultural models for the metaphorical systems of Chinese anger expressions and these two theories are utilized to account for the relationships among metaphors: the central metaphor HEAT and two subversions, QI and FIRE.

In general, previous studies on Chinese anger expressions converge on the following points. The researchers patch up Kövecses’ analysis of the cultural model of anger, draw upon Lakoff and Kövecses’ framework of metaphors in English anger expressions and come to the generalization that English and Chinese share the central metaphor ANGER IS HEAT that breaks into two subversions FIRE and AIR/GAS. Furthermore, the underlying cultural models *yin-yang* and *wu-xing* are utilized to provide a cognitive base for viewing ANGER IS HEAT as the central metaphor of anger in Chinese. However, the previous studies pose some problems. First, in our commonsense, the contemporary *qi* indicating AIR/GAS indeed can be viewed as a subversion of HEAT, since HEAT is a necessary condition of AIR/GAS (Yu 1998). Nevertheless, the lexeme *qi* can be traced back to 戰國時代 *Zhan Guo Shi Dai* ‘Warring States’ (403-221 B.C.). It didn’t refer to ‘air’ or ‘gas’ and was not a subversion of HEAT. Second, the effects of the theories, *yin-yang* and *wu-xing*, can also be traced back to ‘Warring States’ (403-221 B.C.) which encompass variable diachronic ingredients. These two theories are not supposed to be explained in a synchronic perspective. Yu uses diachronic models to explain the synchronic meaning of the lexeme *qi*. One way to solve the problem is to examine the linguistic data in a diachronic way and to ascertain whether the source of the lexeme *qi* and the concept of heat are related in classical Chinese.

---

works, 陰 *yin* and 陽 *yang* are two opposite forms of *qi* ‘energy’ existing and flowing in all things in the universe.

## 2. Goals

The goals of the present study are as the following:

1. To explore a cognitive base serving as the cultural model for the metaphorical system of Chinese anger expressions.
2. To ascertain the central metaphor in this metaphorical system.

I argue that from a historical perspective the physiological effects of *qi* can serve the underlying cultural model for the metaphorical system of Chinese anger expressions and that ANGER IS QI instead of HEAT is the most general conceptual metaphor in Chinese. The analysis in the next section begins with the definition of *qi* and the common cultural model of the physiological effects of *qi* demonstrated in classical Chinese.

## 3. The Definition of *Qi* and the Underlying Cultural Model in Chinese

The theory of *qi*, regarded as a basic concept in ancient Chinese, is pervasive in the conceptual system of Chinese (cf. Liu 1985, *Jing Shang Cong* 1997). It is found that in Chinese classics during Warring States (403-221 B.C.), the concept of *qi* with different definitions is well-demonstrated. Chinese philosophers regard *qi* as a form of energy possessed by all things in the universe such as human beings, birds and beasts, grass and trees as well as water and fire, as illustrated in the following discourse drawn from 荀子 *Xun Zi* ‘the works of *Xun Zi*’, written around Warring States (403-221 B.C.).

水火有氣而無生，草木有生而無知，禽獸有知而無義，人有氣、有生、有知，亦且有義，故最爲天下貴也。

*shui huo you qi er wu sheng , cao mu you sheng er wu zhi , qin-shou you zhi er wu yi , ren you qi ,you sheng ,you zhi ,yi qie you yi , gu zui wei tian xia gui ye .*

“Fire and water possess energy but are without life. Grass and trees have life but no intelligence. Birds and beasts have intelligence but no sense of duty. Man possesses energy, life, intelligence, and in addition, a sense of duty. Therefore, he is the noblest being on earth.” (Watson 1963: 45)

Furthermore, *qi* is a form of element that would influence a person’s cultivation of righteousness and reason, as shown in the following discourse drawn from 孟子 *Meng Zi* ‘the works of Mencius’, written around Warring States (403-221 B.C.).

其爲氣也，配義與道；無是，餒也。

*qi wei qi ye , pei yi yu dao ; wu shi , nei ye .*

“It is the mate and assistant of righteousness and reason. Without it, man is in a state of starvation.” (Legge 1992: 311)

Moreover, based on Chinese medical tradition, *qi* is the essence of the body that exists and flows through the body of every living being. The harmony of *qi* decides the source of life. It is the flourishing and declining of *qi* held in the internal organs that leads to the rising and falling of human physiology. The loss of *qi* in some human body parts would cause the interference or suspension of vitality of some organs (Cai 1997). “*Qi* influences the human physiology or leads to illness through inner structure of the human body and the mutual influence of the body and the external environment” (Cai 1997: 379). A discourse drawn from 莊子 *Zhuang Zi* ‘the works of *Zhuang Zi*’ demonstrates that *qi* is the essence of the body that would influence the human physiology.

莊子/外篇/卷七上/第十九達生

*Zhuang Zi/Wai Pian/Juan Qi Shang/Di Shi Jiu Da Sheng*

夫忿瀆之氣，散而不反，則爲不足；上而不下，則使人善怒；下而不上，則使人善忘；不上不下，中身當心，則爲病。

*fu fen xu zhi qi , san er bu fan , ze wei bu zu ; shang er bu xia , ze shi ren shan nu ; xia er bu shang ; ze shi ren shan wang ; bu shang bu xia , zhong shen dang xin , ze wei bing .*

“When the original breath within is scattered and will not reunite, then weakness follows. If it goes up but will not come down, it makes a man bad-tempered. If it goes down but will not come up, it makes a man very forgettable. If it goes neither up nor down, but canters upon the body, at the heart, then illness comes.” (Palmer 1996: 160-161)

The change of *qi* held in the viscera influences not only the human physiology but also the psychological states. More specifically, *qi* influences the emotional states. When the essences of the internal organs are exhausted, it may lead to the union of the spirits from the external environment, which results in various emotional states, as illustrated in the following discourse extracted from 黃帝內經 *Huang Di Nei Jing*

‘Yellow Emperor’s Classic of Internal Medicine’<sup>5</sup>.

黃帝內經素問/宣明五氣篇

*Huang Di Nei Jing Su Wen/Xuan Ming Wu Qi Pian*

五精所并：精氣并於心則喜，并於肺則悲，并於肝則憂〔怒〕，并於脾則畏〔思〕，并於腎則恐，是謂五并，虛而相并者也。

*wu jing suo bing : jing qi bing yu xin ze xi , bing yu fei ze bei , bing yu gan ze you [ nu ] , bing yu pi ze wei [ si ] , bing yu sheng ze kong , shi wei wu bing , xu er xiang bing zhe ye .*

“The five spirits are equal to the five essences. When they are united they caused joy to emanate from the heart; they cause pity to emanate from the lungs; they cause grief to emanate from the liver; they cause anxiety to emanate from the spleen; and they cause fears to emanate from the kidneys. This explains the unity of the spiritual essences. When the essences are exhausted then the spirits should unite.” (Veith 1982: 207)

On the contrary, the emotional states would cause *qi* to function abnormally, as shown in the discourse from Yellow Emperor’s Classic of Internal Medicine:

黃帝內經素問/舉痛論

*Huang Di Nei Jing Su Wen/Ju Tong Lun*

百病生於氣也，怒則氣上...。

*bai bing sheng yu qi ye , nu ze qi shang... .*

“Every kind of sickness results from qi; anger causes qi to rush upwards.”

If one wants to cease the state of agitation, he should comfort *qi* in the body, as exemplified in the following discourse extracted from the works of *Zhuang Zi*.

莊子/雜篇/卷八上/第二十三 庚桑楚

*Zhuang Zi/Za Pian/Juan Ba Shang/Di Er Shi San Geng Sang Chu*

出怒不怒，則怒出於不怒矣；出爲無爲，則爲出於無爲矣。欲靜則平氣，欲神則順心。

*chu nu bu nu , ze nu chu yu bu nu yi ; chu wei wu wei , ze wei chu yu wu wei yi .*

---

<sup>5</sup> That Yellow Emperor’s Classic of Internal Medicine is written around Warring States (403-221 B.C.) is regarded as the general opinion held by scholars. For a more detailed discussion, please refer to *Cai* (1997).

*yu jing ze ping qi , yu shen ze shun xin °*

“Anyone who expresses anger but is not really angry will exhibit non-anger. Anyone who acts yet is not really acting, his actions will be non-action. If he wants to be still (calm his *qi*), he must be at peace. If he wants to be spiritual, he must calm his heart.” (Palmer 1996: 208)

As exemplified in the discourses extracted from Chinese classics during Warring States, two points are singled out. First, in light of Chinese philosophy and medical tradition, the lexeme *qi* is a polysemy which encompassed various definitions during Warring States:

1. *Qi* is a form of energy in the universe.
2. *Qi* is an element influencing a person’s cultivation of righteousness.
3. *Qi* is the essence of the body influencing physiological states.
4. *Qi* is the essence of the body influencing emotional states.

Apparently, the definitions of *qi* have nothing to do with the concept of HEAT or with the heated gas.

Second, during Warring States, the lexeme *qi* related to anger has nothing to do with *yin-yang* or *wu-xing*, but has to do with the cultural theory of *qi*. The physiological effects of *qi* causing anger or the emotional states causing the hyperactivity of *qi* serve as the cognitive base of the common cultural model of anger. The underlying cultural model forms the metaphorical system in which ANGER IS QI is the most general conceptual metaphor. As illuminated in the discourses extracted from philosophical and medical classics during Warring States, it is safe to claim that the common cultural model for the metaphorical system of Chinese anger expressions is the physiological effect of *qi* itself. The conceptualization of *qi* from the discourses above is summarized as follows:

Being careless about one’s *qi* may cause the emanating of various emotional states, such as anger, happiness, sadness, fear and so on; in turn, emotional states would lead to the impediment, restriction, growing and nourishing of *qi*.

The next question is that if the physiological effects of *qi* serve as an underlying cognitive base for the metaphorical system of anger, then we have to survey the linguistic data to support the claim that there are a large number of conventionalized anger expressions which tie to the central metaphor ANGER IS QI instead of HEAT.

The conceptualization of *qi* indicating the emotion anger can be traced back to *Han* Dynasty (206 B.C.-220 A.D.), which will be expounded in the following section.

#### 4. The Metaphorical Use of the Lexeme *Qi* for Anger

A survey of philosophical and medical works of Warring States, and 漢 *Han* dynasties shows that *QI* instead of *HEAT* dominates the metaphorical use of anger expressions.

*Qi* stands in the prototypical meanings as a form of energy, an element, the essence of the body during Warring States. The semantic extension of the lexeme *qi* referring to anger is treated as its metaphorical use which occurred during *Han* Dynasty (206 B.C.-220 A.D.). As shown in the following discourses distributed chronologically, anger expressions associated with the lexeme *qi* are quite productive.

##### 1. Warring States (403-221 B.C.)

The discourses extracted from Chinese classics testify that *qi* regarded as an anger element in the body appeared around Warring States, as illustrated in 難經 *Nan Jing* ‘the works of 秦越人 *Qin Yue-ren*’.

難經/難經本義卷下/四十九難 論正經自病與五邪所傷之別  
*Nan Jing/Nan Jing Ben Yi Quan Xia/Si Shi Jiu Nan Lun Zheng Jing Zi Bing Yu Wu Xie Suo Shang Zhi Bie*  
恚怒氣逆上而不下則傷肝...  
*hui nu qi ni shang er bu xia ze shang gan*  
“If anger-qi goes up but does not come down, it will hurt the liver.”

##### 2. Warring States (403-221 B.C.) ~ *Han* Dynasty (206 B.C.-220 A.D.)

The following discourse extracted from 戰國策 *Zhan Gou Ce* is written around the declining years of Warring States but edited during *Han* Dynasty. The metaphorical *Qi* referred to as anger in the body occurred.

戰國策/卷十八~二一 趙策/卷二十一 趙四/趙太后新用事  
*Zhan Guo Ce/Juan Shi Ba~Er Yi Zhao Ce /Juan Er Shi Yi Zhao Si/Zhao Tai Hou Xin Yong Shi*  
...願見太后，太后盛氣而揖之。  
*...yuan jian tai hou , tai hou sheng qi er yi zhi 。*

“...hope to see the mother of the emperor. The mother of emperor is full of anger and waiting for him.”

### 3. Han Dynasty (206 B.C.-220 A.D.)

The lexeme *qi* metaphorically used to refer to anger appeared in the discourses of philosophical works during Han Dynasty, as presented in 淮南子 *Huai-nan Zi*.

淮南子/第十二卷

*Huai Nan Zi/Di Shi Er Juan*

忿心張膽，氣如涌泉

*fen xin zhang dan , qi ru yong quan*

“The heart is filled with hatred; anger comes up like a spring.”

Meanwhile, *Qi* indicating an anger element in the body intensively appeared during Han dynasty as shown in discourses from 春秋繁露 *Chun-qiū Fan-lu*, 說苑 *Shuo Yuan* and 吳越春秋 *Wu Yue Chun-qiū*.

春秋繁露/第十一卷/第四十四篇 王道篇

*Chun Qiu Fan Lu/Di Shi Yi Juan/Di Si Shi Si Pian Wang Dao Pian*

怒氣...，天與人所同有也

*nu-qi... , tian yu ren suo tong you ye*

“Anger-qi ... is possessed by heaven and human beings.”

說苑/第十九卷 脩文

*Shuo Yuan/Di Shi Jiu Juan Xiu Wen*

粗厲猛賁之聲動人，而怒氣應之；

*cu li meng bi zhi sheng dong ren , er nu-qi ying zhi ;*

“To touch people with rough and violent sound would cause anger-qi.”

吳越春秋/句踐伐吳外傳第十/句踐二十一年

*Wu Yue Chun Qiu/Gou Jian Fa Wu Wai Zhuan Di Shi/Gou Jian Er Shi Yi Nian*

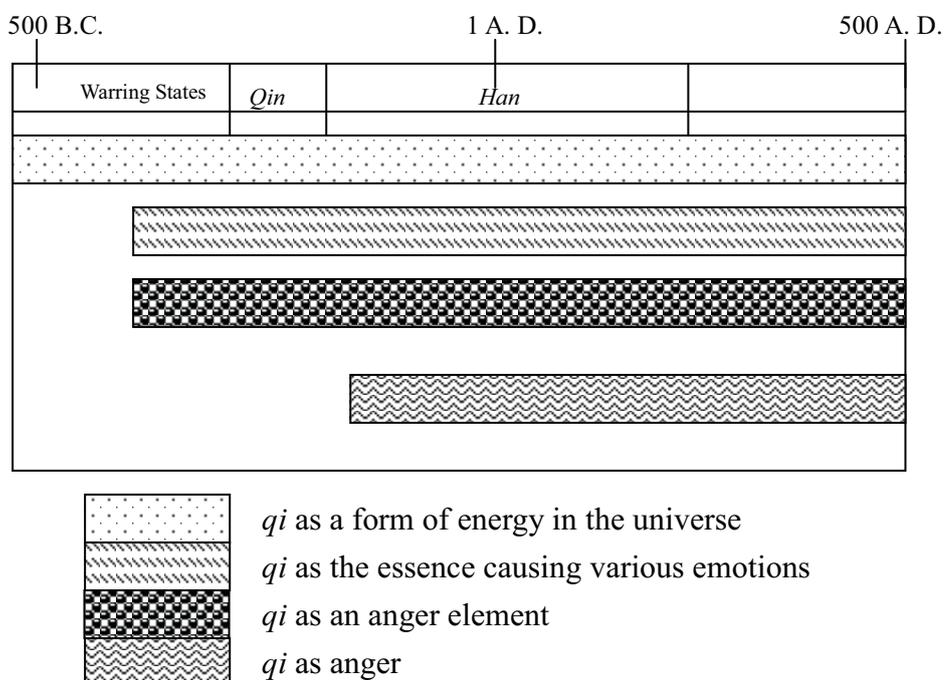

見敵而有怒氣... ·

*jian di er you nu-qi*

“One is anger-qi because of seeing the enemy.”

The historical development of the lexeme *qi* from a prototypical meaning as a

form of energy of all things to a specific one indicating anger itself is roughly schematized as below.

**Figure 1. The historical development of different senses of *qi*.**

As Figure 1 shows, *qi* is a polysemous lexeme during Warring States. Its prototypical meanings stand in a form of energy, an element and the essence of the body. The metaphorical use of anger expressions associated with the lexeme *qi* occurred during *Han* Dynasty. Therefore, it is safe to claim that ANGER IS QI is the central metaphor of anger in Chinese culture in light of a diachronic perspective.

To conclude, the discourses from Warring States to *Han* Dynasty illustrated above support the claim that diachronically the metaphor ANGER IS QI dominates a large number of anger expressions. Anger expressions tied to body HEAT are not found in Chinese classics before *Han* Dynasty. *Qi* originally functions as a lexeme meaning a form of energy possessed by all things in the universe. Then *qi* is specified as the essence circulating in the body where the impediment of the essence would cause the emanating of various emotional states. It is the conceptualization of *qi* causing anger that motivates the development of the lexeme *qi* indicating energy to the metaphorical use as anger.

## 5. Compounding of X + the Lexeme *Qi*

The central metaphor ANGER IS QI is extremely productive in that the compounding of a preceding word in combination with the lexeme *qi* can elaborate the conceptual metaphor. In other words, there are a large number of anger expressions related to the compounding of X + the lexeme *qi* which tie to the metaphor ANGER IS QI. The compound 生氣 *sheng-qi* ‘generate *qi*; active *qi*’ or 受氣 *shou-qi* ‘receive *qi*’ is a good example.

### 5.1 The compound 生氣 *sheng-qi*

Besides a free noun, the lexeme *qi* can form compounds in combination with a preceding word. The lexeme 生 *sheng* means either ‘generate’ or ‘active.’ The compound 生氣 *sheng-qi* ‘generate *qi*; active *qi*’ is construed as the most general form used to express anger in contemporary Chinese. Chronologically, its prototypical meaning is related to the cultural theory of *qi*.

#### 1. Warring States (403-221 B.C.)

The following discourse is from Yellow Emperor’s Classic of Internal Medicine. The compound is used to indicate ‘the spirit of life’ (Veith 1982: 104) in the body.

黃帝內經素問/四氣調神大論篇

*Huang Di Nei Jing Su Wen/Si Qi Tiao Shen Da Lun Pian*

唯聖人從之，故身無奇病，萬物不失，生氣不竭...

*Wei sheng ren cong zhi , gu shen wu qi bing , wan wu bu shi , sheng-qi bu jie...*

“The sages followed the laws [of nature] and therefore their bodies were free from strange diseases; they do not lose anything (which they has received by nature) and their spirit of life was never exhausted.” (Veith 1982: 104)

#### 2. South and North Dynasties (420-589 A.D.)

The compound *sheng-qi* indicating the external spirit in some circumstances occurred in 後漢書 *hou han shu* ‘the Book of Eastern Han Dynasty’ written around South and North Dynasties.

後漢書/列傳/卷五十一

*hou han shu/lie zhuan/Juan Wu Shi Yi*

孤兒寡婦，哭號空城...雖含生氣，實同枯朽。

*gu er gua fu , ku hao kong cheng...sui han sheng qi , shi tong ku xiu 。*

“The orphans and the widows are crying in the deserted city...It may contain the spirit of life but in fact, it is decayed and rotten.”

### 3. Yuan Dynasty (1206-1370 A.D.) ~ Ming Dynasty (1368-1644 A. D.)

The compound *sheng-qi* has undergone a semantic extension and takes on the metaphorical meaning ‘ruffle’ or ‘be angry’ occurring in the novel 三國演義 *San Guo Yan Yi* written around the Yuan Dynasty (1206-1370 A.D.), but edited during Ming Dynasty (1368-1644 A. D.):

三國演義/第五十一回

*San Guo Yan Yi/Di Wu Shi Yi Hui*

程普恐瑜生氣

*Cheng Pu kong Yu sheng-qi*

“*Cheng Pu* is afraid that *Yu* would ruffle [be angry].”

### 4. Qing Dynasty (1644-1911 A.D.)

The compound *sheng-qi* metaphorically used to refer to ‘ruffle’ or ‘be angry’ intensively appeared in the novels during Qing Dynasty (1644-1911 A.D.).

醒世姻緣/第二回

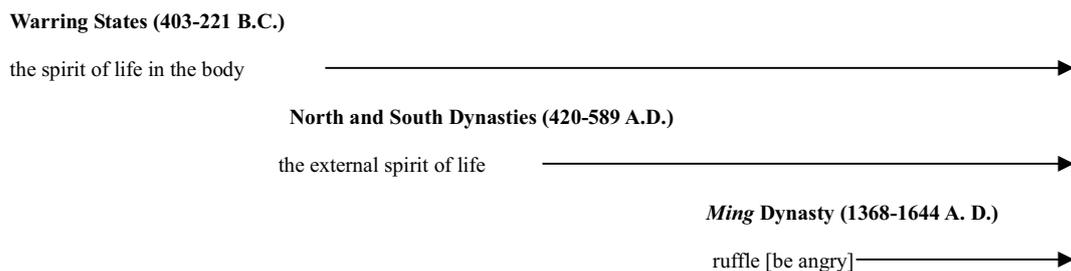

*Xing Shi Yin Yuan/Di Er Hui*

...要我生氣，我倒沒有這許多閒氣生來。

*yao wo sheng-qi , wo dao mei you zhe xu duo xian qi sheng lai*

“...to make me ruffle [be angry]. I have no surplus anger to generate.”

The compound *sheng-qi* becomes the most general form to express anger. It is also viewed as a colloquial form in contemporary Chinese. The historical development of the compound *sheng-qi* from a prototypical meaning related to the spirit of life to a specific one indicating anger is roughly shown as below.

**Figure 2. The historical development of different senses of *sheng-qi***

### 5.2 The compound 受氣 *shou-qi*

Another compound 受氣 *shou-qi* is also a general form to express anger in contemporary Chinese in which the lexeme 受 means ‘receive.’ Its prototypical meaning is also related to the cultural theory of *qi*.

#### 1. Warring States (403-221 B.C.)

As illustrated in the following examples during Warring States, *shou qi* was a verb phrase indicating ‘receiving energy’ from *Yin Yang* or the internal organs ‘receiving the life-giving force.’

莊子外篇/卷六下/第十七 秋水

*Zhuang Zi Wai Pian/Juan Liu Xia/Di Shi Qi Qiu Shui*

受氣於陰陽

*shou qi yu yin yang*

“receive energy from Yin Yang”

黃帝內經素問/玉機真藏論

*Huang Di Nei Jing Su Wen/Yu Ji Zhen Zang Lun*

肝受氣於心，傳之於脾，氣舍於腎，至肺而死。心受氣於脾，傳之於肺...

*gan shou qi yu xin , chuan zhi yu pi , qi she yu shen , zhi fei er si , xin shou qi yu pi , chuan zhi yu fei...*

“When the liver receives the life-giving force from the heart, it is from there transmitted to the spleen, whence it is passed on to the kidneys; here it reaches its utmost, so that it meets death when it arrives at the lungs. When the heart receives the life-giving force from the spleen, it is from there transmitted to the lungs...”(Veith 1982: 179)

## 2. Ming Dynasty (1368-1644 A. D.)

The verb phrase *shou qi* ‘receive *qi*’ connected with the emotion anger meaning ‘receive one’s anger’ is found to occur in the novel 三遂平妖傳 *San Sui Ping Yao Zhuan*:

三遂平妖傳/第七回

*San Sui Ping Yao Zhuan/Di Qi Hui*

老爺出廳了，你快些躲避，莫累我們受氣。

*lao ye chu ting le , ni kuai xie duo bi , mo lei wo men shou qi 。*

“The venerable sir is coming to the hall. Hide yourself out of his sight so that we won’t receive his anger.”

## 3. Qing Dynasty (1644-1911 A.D.)

The compound *shou-qi* is metaphorically used to indicate ‘ruffle’ or ‘be angry’ intensively occurred in the novels during Qing Dynasty such as 桃花扇 *Tao Hua Shan* and 醒世姻緣 *Xing Shi Yin Yuan*.

桃花扇/卷三/第二十二齣 守樓

*Tao Hua Shan/Juan San/Di Er Shi Er Chu/Shou Lou*

知你拒絕田仰，動了大怒...下官怕你受氣，特爲護你而來。

*zhi ni ju jue tian yang , dong le da nu...xia guan pa ni shou-qi , te wei hu ni er lai 。*

“I know you refuse *Tian Yang* and are very angry...I am afraid you ruffle [are angry] and come to protect you.”

醒世姻緣/第七十六回

*Xing Shi Yin Yuan/Di Qi Shi Liu Hui*

...孩子不是他公公骨血...狄員外因此受氣

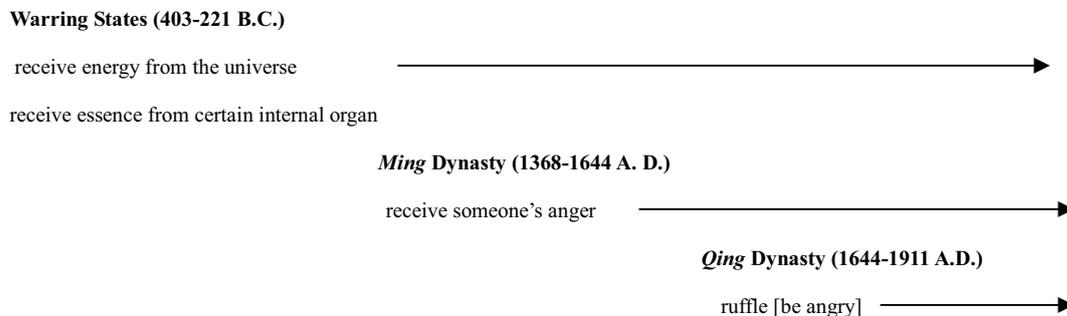

*...hai zi bu shi ta gong gong gu xie...di yuan wai yin ci er shou-qi*

“The officer *Di* ruffles [is angry], for the child is not his.”

As shown in the discourses, the verb phrase *shou qi* ‘receive *qi*’ has undergone a semantic extension and becomes polysemous. In modern Chinese, it connotes either an action in which someone receives another’s anger or ‘ruffle’ itself. Diachronically the verb phrase ‘receive *qi*’ takes on the metaphorical use meaning ‘ruffle’ during Qing Dynasty (1644-1911 A.D.).

The lexeme 受 *shou* ‘receive’ functioning as a verb combines with the lexem *qi*

‘energy’ and then becomes a compound used to indicate anger, as roughly schematized as below:

**Figure 3. The historical development of different senses of 受氣 *shou-qi*.**

We have delved into the chronological distributions of the common compounds used to indicate anger in modern Chinese. The points singled out here are as in the following:

1. The compounds become conventionalized and are metaphorically used to refer to anger in the novels written around *Ming* and *Qing* dynasties.
2. The source of the compound is relevant to the cultural theory of physiological effects of *qi* in the body. The underlying cultural theory of *qi* provides a cognitive base for the metaphorical use of the lexeme *qi* in construction with a preceding word.
3. The central metaphor ANGER IS QI is extremely productive in that the compounding of a preceding word in construction with the lexeme *qi* elaborates the central metaphor.

## 6. Conclusion

Different from previous studies on Chinese metaphors of anger (Shyu 1989, Yu 1998, Cheng 1999), we have verified the central metaphor ANGER IS QI based on the philosophical and traditional medical works. The multiple definitions of the lexeme *qi* are manifested in the classics during Warring States. The prototypical meaning of the lexeme *qi* has nothing to do with heated gas but the essence that exists and circulates through the body. Based on the discourses extracted from the classics, it is also found that the physiological effects of *qi* ‘the essence of the body’ exerts influence on a person’s emotional state and vice versa, anger would cause the hyperactivity of *qi*. The

conceptualization of *qi* as the essence of human physiology causing variable emotional states associated with anger feelings is prevailing in Chinese culture. It is affirmative that the physiological effects of *qi* serve as the underlying cultural model for the metaphorical system of anger in Chinese in which ANGER IS QI is the most general conceptual metaphor. Diachronically, the sources of two metaphors QI and FIRE are not two subversions of ANGER IS HEAT. ANGER IS QI, instead of ANGER IS HEAT, is the central metaphor in the metaphorical system. Based on the data current during 403 B.C. to 1900 A.D., beginning in Warring States and continuing through *Han*, *Song*, *Yuan*, *Ming* dynasties to *Qing* dynasty, we have shown that the metaphorical use of the lexeme *qi* referring to anger is found to occur during *Han* dynasty. The underlying cultural model of physiological effects of *qi* exerts influence on language, which develops a number of anger expressions associated with the lexeme *qi* which tie to the central metaphor ANGER IS QI. Therefore, it is QI, instead of HEAT, dominates the metaphorical use for anger in Chinese.

In light of the discourses drawn from Chinese classics and novels distributed chronologically, the compounds related to *qi* indicating anger are also related to the cultural theory of *qi* and are very productive. The compounds undergo semantic extension and are referred to as metaphorical anger. In sum, the cultural theory of *qi* plays a crucial role in the expressions of anger. In Chinese, it is common for anger to be metaphorized as QI. The lexeme *qi* referring to anger and the compounds related to the lexeme *qi* indicating anger in contemporary Chinese are deeply rooted in Chinese conceptual system.

# Kaingang and Austronesian – Similarities between Geographically Distant Languages

Vladimir Pericliev

Mathematical Linguistics Dpt., Institute of Mathematics & Informatics,  
Bulgarian Academy of Sciences, bl.8, 1113 Sofia, Bulgaria  
peri@math.bas.bg

## Abstract

The paper shows that significant similarities exist between two geographically distant language families: the Kaingang family, comprising Xokleng and Kaingang, spoken in South Eastern Brazil, on the Atlantic, and Austronesian, spoken in the Pacific. These similarities pertain to kinship semantic patterns, structural features and lexicon. In the paper, I sketch kinship and grammatical similarities and discuss in more detail the lexicon, paying special attention to various modes of arguing for significant similarity. One plausible explanation of the results found is a distant relationship between these families, a conclusion corroborated also by some extralinguistic facts. If such a hypothesis turns out to be true, one important implication would be some prehistoric contact between these distant parts of the world.

**Keywords:** Austronesian-Kaingang relationship hypothesis, Oceanic and South American contacts, language prehistory and classification, languages and migrations.

## 1. Introduction

The Southern-Ge Kaingang people, comprising the Xokleng and the Kaingang, presently reside in the states of Santa Catarina, São Paulo, Paraná, and Rio Grande do Sul in south-eastern Brazil, and speak two closely related languages, forming the Kaingang language family. No external relationship of the Kaingang people, or their language, with peoples or languages outside of Ge, or Amerind(ian) more generally, has so far been suggested. In this paper, I will describe substantial similarities between the Kaingang language family and the Austronesian family, in particular its Oceanic/Polynesian branch. First, I will sketch significant kinship pattern and structural similarities between the families. Then, I will present lexical parallels with sound correspondences, placing special emphasis on the comparison of “non-random word sets”, like synonyms, homonyms, paronyms, lexical fields, etc. which impart additional plausibility to the comparisons.

## 2. Kinship similarities

A database of the kinship terminological patterns of 566 societies (Murdock 1970) was computationally explored with the goal of finding statistically significant similarities between pairs of societies speaking languages belonging to *different* language families according to the standard language classification source *Ethnologue*. The database has eight attributes with a total of 192 values. The attributes are the eight relatives: grandparents, grandchildren, uncles, aunts, nephews and nieces, siblings,

cross-cousins and siblings-in-law. The values for attributes are so-called “kinship patterns” such as, for the kin grandparent, “Bisexual Pattern” (having two terms, distinguished by sex, which can be glossed as “grandfather” and “grandmother”), “Merging Pattern” (having a single undifferentiated term, which can be glossed as “grandparent”), etc. The pair-wise society comparison revealed that Xokleng (the language representing the Kaingang family in the database) had 7 matching kinship patterns with the Amis (Taiwan) and 6 matching kinship patterns with both the Chuukese (Micronesia) and the Ulithian (Micronesia). These were the most significant results in comparison to all other investigated society pairs, at levels of  $p = 0.005$ ,  $p = 0.002$  and  $p = 0.008$ , respectively. Xokleng thus, quite unexpectedly, turned out to follow an Austronesian type of kinship patterning, showing also substantial kin pattern overlaps with other Austronesian languages like Rotuman, Samoan, and Māori. Checking the original files for Xokleng of the contributor of the database, anthropologist G. P. Murdock, showed his opinion about the similarity expressed in labeling Xokleng’s system as “Normal Hawaiian”. Further details can be found in Pericliev (2007: 42-48).

### **3. Structural similarities**

Some structural features of the Kaingang language family (for Xokleng, cf. Henry 1935, 1948, Urban 1985, 1986, Gakran 2005; for Kaingang cf. Wiesemann 1972, 1978, 1986) were then tested against a set of typically Austronesian features that have been proposed (Klamer 2002) as a heuristic for suggesting the affiliation of a language (i.e. whether it is Austronesian or not). The Kaingang languages turned out to share Austronesian properties of both phonology and grammar.

Like Austronesian languages, and especially their Oceanic branch, which are known to have lost the voicing contrast in obstruents and to have developed prenasalized consonants in opposition to plain consonants, the Kaingang languages also do not have plain voiced obstruents, but contrast plain voiceless with prenasalized voiced consonants.

Many Austronesian languages prefer roots of CVCV type, and so do the Kaingang languages. Specifically, according to Henry (1948: 196), in Xokleng the CVCV pattern is prevalent and amounts to 35% of all root patterns in Xokleng (CV patterns being 14%, CVC 13%, CVCVC 12%, CVCCV 12%, CCV 5%, and CVCVCV 5%). As seen from these numbers, other typically Austronesian features of Xokleng are the “dropping” of final consonants (word-final consonants being present in only 25% of the patterns) and a dispreference for consonantal clusters (occurring in only 17% of the words). Besides, the possible final consonants and consonantal clusters are subjected to further restrictions we need not discuss here. The situation is similar in Kaingang.

Another, and related, phonological similarity is the insertion of paragogic vowels word-finally in both language families in order to open the syllable.

Similarly to many Austronesian languages, Xokleng forms emotional expressions by Verb + body part noun, in which the Experiencer of the emotion is the Possessor of the body part. E.g. Xokleng’s expression for “I am angry” literally means “My heart splits (in several places)” (Henry 1935: 213).

Like many Austronesian languages, Xokleng’s numerals seem to behave like

verbs in that they act like verbal predicates and take the same predicating particles as the verbs.

Also, like other Austronesian languages mainly in Eastern Indonesia, but also scattered elsewhere in Western and Eastern Austronesian languages (e.g., Malagasy, Manobo, Hawaiian, Batak, etc.), Xokleng (cf. Urban 1986) employs parallelism in narratives, myths, poems and songs, a verbal art form in which semantically synonymous pairs/triples etc. of words and phrases are used in parallel utterances.

Finally, we note two other typically Austronesian features not mentioned by Klamer (2002), which are possessed by the Kaingang languages, viz. the affixing and reduplication as productive devices, and operating basically on verbs, and the fundamental verbal distinction in both Austronesian and the Kaingang languages between stative verbs and dynamic, or active, verbs.

#### 4. Some lexical data and sound correspondences

A 100-item basic vocabulary list was compiled, and pair-wise comparisons were computationally made between Xokleng and Kaingang on the one hand, and the reconstructed Proto-Austronesian and five major extant Austronesian languages (Tagalog, Malay, Fijian, Samoan and Hawaiian) on the other hand. Standard similarity criteria for matching two word forms were used: generally, two identical consonants, or an identical consonant and a vowel plus a phonetically “similar” consonant. The method, which follows closely that of Oswalt (1991) was tested against pairs of languages with well understood relationships, both positive and negative. All comparisons were significant at levels shown below (with accuracy up to four decimal places).

	Proto-AN	Tagalog	Malay	Fijian	Samoan	Hawaiian
Xokleng	0.0000	0.0000	0.0002	0.0022	0.0003	0.0000
Kaingang	0.0087	0.0004	0.0179	0.0014	0.0000	0.0000

The preliminary computational approach to lexicon was suggestive and I proceeded with manual lexical comparison between the Kaingang and the Polynesian family, the latter being the “closest” geographically.

In the following, our data for Xokleng comes from different sources (Gensch 1908; Henry 1935, 1948; Gakran 2005), and for Kaingang from the dictionary Wiesemann (2002) and Wiesemann (1972). The data on cognate sets for Polynesian are based on Biggs & Clark (2006), Blust (1995), and the *Austronesian Basic Vocabulary Database*, but Tregear (1891), Williams (1957), Pukui & Erbert (1986), and Andrews (1865) are also consulted.

Table 1 shows the familiar sound correspondences (e.g., Biggs 1973, Tregear 1891) in the Polynesian languages Māori (New Zealand), and Hawaiian, alongside with those that are known to hold for the Kaingang family (Wiesemann 1978).

The following similarity sets are illustrations of the sound correspondences. Each similarity set has a gloss, giving a general meaning, which may be further specified for some languages if somewhat different from gloss. The items in one language family that are similar to those of the other family are separated by equality “=”. A dash “-“

indicates a relatively clear word division in the Kaingang languages, segmenting stem from morphological endings (-*m*, -*n*, -*r*, -*y*, etc.). Brackets “()” enclose forms that are not part of the comparison (e.g. the verbal forms *ke*, *he* ‘to say’ in the Kaingang languages, which, when parts of larger verbs, simply indicate direct speech). A slash “/” stands for “or”, and according to context may indicate a paragogic vowel at the end of a Kaingang word, or a doublet form. Note that a paragogic vowel in both Kaingang languages is the same or a more central vowel added after word final *r*; *v*; *y*; in Kaingang orthography, the paragogic vowel is not written, while in Xokleng an investigator like Henry (1935, 1948) and earlier linguists write these vowels and they may appear in my description below. Note also that a plus sign “+” after a Xokleng word below designates a word whose source is the early investigation by Gensch (1908), who does not make some phonological distinctions (e.g. central vs. non-central vowels) that are recognized today, which results in some indefiniteness in his description (in other respects pretty reliable). Finally, in the sequel, the Kaingang languages are written in their usual phonemic transcription, and the Austronesian languages in the way of their respective sources, with only minor and obvious changes (e.g. I use “?” in place of the more common apostrophe “ ’ ”).

**Table 1.** Sound correspondences between Xok(leng), Kai(ngang), Māo(ri), and Haw(aiian).

<i>Nos.</i>	<i>Xok/Kai/Māo/Haw</i>	<i>Examples Nos.</i>

24. Throw: X *pãŋ*, K *pěŋ* = M *panga*, H *pana*.
25. Hand/touch: K *pě* = M *pā*, H *pā*.
26. Finish: X *kaŋ*, K *kã-n* = H *kā*.
27. Dig: K *kōkō-m* = M *kōkō*, H *ʔōʔō*.
28. Turn, reverse: K *wĩrĩ-n* = M *wiri* ‘twist’, H *wili*.
29. Carry: X *mɔ*, K *ma* = M *mau*, H *mao*.
30. Tree, forest: X *wæ+*, K *wã-n* = M *wao*, H *wao*.
31. The (def. art.): X *te*, = M *te*, H *ke*.
32. Moist: X *tuy/u*, K *tuy* ‘trickle intensely’ = M *tōi*, H *kōi* ‘flow, spurt’.
33. Heart: X *ðe*, K *ʔe* ‘heart, chest, breast’ = M *ate* ‘liver, heart’, *ateate* ‘bosom’, Tuamotan *ate* ‘heart’.
34. Shell: X *kɔða* ‘shell’, *kɔðan* ‘strip embira bark’ (*kɔtĩ* ‘smooth’), K *kuʔēn* ‘to peel, to shell’, *kĩʔe* ‘knife’ = M *kota* ‘cockle shell, anything to scrape or cut with’, PPn

\**qota* ‘dregs, residue’.

35. Wash clothes: X *ḍaŋ*, K *Φā*, = H *kā*, Samoan *tā*.

36. Rash (of skin): K *tuŋa* ‘rash’ = Rarotongan *tunga* ‘scabbed, weevily; covered with sores’, Tokelau *tunga* ‘pimple’, Pn *tunga* ‘blemish, imperfection’.

37. Hand, arm: X *nēŋa*, K *nīŋε* (or *niŋā*) = M *ringa*, Fijian *liga-* ‘hand, forearm’, PMP \**liŋa* ‘hand, arm’. (*l* ~ *n* is a common alternation within Polynesian languages, e.g. *lima* ~ *nima* ‘five, hand’).

38. Ashes: X *mlā*, K *mrēj* = Pukapuka *malamala*, H *malamala* ‘small piece of any substance broken from a larger’, PPn \**mala(mala)* ‘chip, splinter, fragment’.

39. Pierce: X *pati* = M *pātia* ‘spear’, Penrhyn, Rarotongan, Tahitian *pātia* ‘stab, thrust; spear, lance’, Central-Eastern Pn *pā-tia* ‘pierce’.

40. Stone: X *kaḍu+* = M *whatu*, H *haku*, Mangarevan *ʔatu*, Pn *fatu*.

As seen from the above list, the sounds (vowels and consonants) of each Kaingang-family wordform, with only a small number of exceptions, are totally predictable from the Polynesian-family wordforms, according to the correspondences from Table 1. More illustrations of the correspondences follow in the next section.

## 5. More data (non-random lexical sets) and additional levels of evidence

By a “non-random lexical set”, I will understand a set of words sharing a similarity in meaning, form, or perhaps in some other way. Familiar examples based on shared meanings are lexical fields such as body parts, kinship terms or lower numerals, and the classical example of a non-random lexical set, formed on this basis, is the basic vocabulary, whose elements (body parts, kinship terms, etc.) are themselves non-random word sets. There are also other non-random word sets, perhaps less commonly used in historical/comparative linguistics, which I will also compare below. Such comparisons provide an additional level of evidence over the traditional comparative method, and used complementarily to it, can lend further credibility to the comparisons, because a concentration of similarities within an antecedently fixed and limited (i.e. non-random) domain are generally less likely to be due to mere chance than the same number of matches in an open domain.

In the following, I slightly relax the strict conditions for counting a match used earlier, especially as regards vowels, and occasionally admit comparanda outside of the Polynesian family, for the following reasons. The first reason is methodological and has been nicely phrased by Campbell in the following manner:

Where the intention is to call attention to a possible, but as yet unattested connection, one often casts a wide net in order to hold in as much potential evidence as possible. When the intention is to test a proposal that is already on the table, those forms admitted initially as possible evidence are submitted to more careful scrutiny. (Campbell 2004)

The second reason is empirical and has to do with the considerable presence of doublet forms involving vowels for the Kaingang family, not all of which may be registered in the sources I am using, and for which very strict sound matching criteria can turn out to be much too restrictive. E.g., as reported by Wiesemann (1972, 1978), in Kaingang there exist a number of free vowel alternations: *a* ~ *ə*, *ā* ~ *a*, *ã* ~ *ε*, *ā* ~ *ɔ*, *ε* ~ *e*,

o ~ o (e.g. *kāgra* ~ *kāgrə* ‘picture’, *kā* ~ *ka* ‘tree’, etc.).

### 5.1. Synonymous sets

If a single word from a set of synonyms in one language may resemble a word from a synonymous set in another language by pure chance, the event in which other words from both sets also resemble each other is much less likely to occur by chance. The higher the number of resembling words, the less likely the event, and hence the stronger the evidence for the existence of some link between the compared languages. By “synonyms” I understand both words with exactly coinciding and such with close meanings, and examples of both types are used as illustrations below.

#### (1) NEAR

Near1: K *kakā* = M *tata*, H *kaka* ‘fruits growing in clusters’, Pn *tata* ‘near’.

Near2: X *la*, K *rā* = M *rā*, H *la* ‘there, yonder’.

#### (2) RAIN

Rain1: X *ugua*+ (? *ukua*) = M, H *ua*, Rapanui, Rennell Is. (Solomons) *ʔua* (POc \**quzan*).

Rain2: X *kuta* ‘fall (rain)’, K *kutē* ‘fall (rain)’, *ta kutē* ‘rain’ = Pwamai (New Caledonia) *kuta*, Jawe (New Caledonia) *kut*.

Rain3: X *tə*, K *ta* = Woleai (Micronesian) *uta*, Lau, Longgu (Solomon Islands) *uta*.

Rain4: K *kə* (*he*) ‘drizzle’ (also *ta kə*) = M *tō* ‘fall (of rain)’, Pn \**tō* ‘fall (of rain)’.

Rain5: K *kəkə* (*he*) ‘drizzle’ = M *totō* ‘to ooze, to trickle’, H *koko* ‘reddish rain’

(Andr).

#### (3) HIT/STRIKE

Hit/strike1: K *pē* ‘hand, arm’ = H *pā*, Niue *pā* ‘slap, strike, touch, clap’.

Hit/strike2: X *puke*, K *pə ke* = Niue *poki* ‘slap’.

Hit/strike3: K *tā-n* ‘kill, beat to death’ = Niue *tā* ‘strike, kill, adze’.

Hit/strike4: X *tunʒe*, K *tag ke* = Niue *tuki* ‘knock, pound, mash’.

#### (4) TREE/WOODS

Tree/woods1: X *kə*, K *ka* = POc \**kayu* ‘stick, wood’, Fijian (Bau) *kau*, M *mā/kau*, Namakir (Vanuato) *ka*.

Tree/woods2: X *kute*, K *kute* ‘capão (flora), forming a type of flowers in southern Brazil, consisting of a group of tree vegetation’ = POc \**qutan* ‘woods, forest’, Mota *uta*.

Tree/woods3: X *wæ*+, K *wā-n* = M *wao*, H *wao*.

Tree/woods4: X *bekud*+ = PAn \**binjudu*, Paiwan *vukid* (Blust 1995).

#### (5) WATER

Water1: X *ɲoy-waig*+ ‘river, stream’, K *war* ‘flood of water’ = POc \**wair*, M *wai*, *awa* ‘river, stream’, H *wai*.

Water2: X *ɲoy*, K *ɲoy* = H *nō* ‘seepage, to leak’.

Water3: K *kayā* ‘salty’ = M *tai*, H *kai* ‘salty water’.

Water4: K *wāya* ‘mixture (with water)’ = Fiji *vai-na* ‘mixture with water’.

Water5: K *ɲunɲən* ‘liquid’ = M *ngongi*, H *nono* ‘oozing, seepage’, Macassar *njonjo* ‘liquid; to drip’.

Water6: K *ēkə-r* ‘sour water’ = M *ehu* ‘muddy’, H *ehu* ‘dusty, disturbed’.

Water7: K *ku-pe* ‘wash’ (*ku-* prefix) = Vanua Lava (five dialects) *pe*; Mota *pei*; *pii* ‘sprinkle water’, *pia* ‘foam from soap’.

Water8: K *me* ‘liquid’ = Mergen *me* ‘water’.

Water9: K *run* ‘carry, fetch water’, *runya* ‘vessel for water’ = M *ranu-a* ‘mix with liquid’, Tongan *lanu* ‘wash in fresh water’, POc \**danum* ‘fresh water’.

Water10: X *ɲoy* (*be?*)*lele*+ ‘falling of water’ = M *rere* ‘waterfall’ (Tr), H *wai lele* ‘waterfall’.

(6) BREAST/SUCK

Breast/suck1: X *-kum(b)e*+ ‘female breast’ = M *kōuma* ‘breastbone’, Tuamotan *kōuma* ‘chest, breast, bosom’, PPn \**uma.a* ‘breast, chest’.

Breast/suck2: K *ũ-n ũ-n* (*he*) ‘suck’ = M, H *ū* ‘female breasts’, Tongan *huhu* ‘female breasts, to suck’.

(7) FIRE

Fire1: X *pē*, K *pī* = POc \**api*, M, H *ahi*, Anuta *api*.

Fire2: X *akpunu*+ ‘burn’, K *kaprūn* ‘line of fire, much fire in the firewood’ = M *kapura*.

Fire3: X *δai-kəlɔ* ‘kindle fire’ = M *toro* ‘to burn, a flame, burning’ (also M *kora* ‘fire’), Tongan *tolo* ‘to rub, to ignite’.

Fire4: K *pūn* ‘burn’, *pūr* ‘burnt’ = Proto-Central Pacific \**pula* ‘burn’, Proto-Micronesian \**pwula* ‘burn’, Rotuman *pula* ‘burn’, H *pula* ‘kindling’, Waya (western Fiji) *bula-n* ‘burn’.

Fire5: K *wāpūn* ‘burn with big fire’, *wāpūr* ‘burnt to garbage’ = M *māpura* ‘fire’.

Fire6: K *kupūn* (= *hupūn*) ‘to light up’, *hupūr* ‘illuminated with fire’, *kupūr* ‘burn in fire’ = Central-Eastern Polynesian *kō-pura* ‘flash’, PPn \**pula* ‘shine’, M *kōpura* ‘flash, flicker, glance’, Tahitian *opura/pura* ‘to be flashing obscurely as fire’, Tuamotu *kōpura/pura* ‘to emit sparks, to glow or shine with unsteady light’.

Fire7: K *kəm* (*ke*) ‘light fire, light’, *kəm kəm* (*ke*) ‘to flash, to shine’ = Tahitic *koma* ‘spark’, M, Tuamotu *koma*.

## 5.2. Polysemous/Homonymous sets

If a monosemous word in one language happens to resemble another monosemous word in another language by chance, the event in which a polysemous (or homonymous) word resembles a polysemous (or homonymous) word, is less likely to be merely coincidental, because it involves several meaning matches, rather than only one. The higher the number of meaning matches, and the more “unusual” the meanings of the polysemous/homonymous word, the less probable this event is, and hence the stronger the evidence for a non-chance link between the compared languages.

(1) In the following example, the compared forms have four meanings, the last two of which are “unusual” in that they seem quite divergent from the “basic meaning” of the form:

Sun: X *la*, K *rā* = M *rā*, H *lā*; cf. No.7.

Day: X *la* (K *kurā*) = M *rā*, H *lā*; cf. No.8.

Near: X *la*, K *rā* = M *rā*, H *la* ‘there, yonder’.

Below: K *rā* = Fijian (Bau) *e rā*, Fijian (Navosa) *ra*.

Besides, the Kaingang form *ra* ‘hot’ and Xokleng *lɔ* ‘hot’, apparently related to *rā* and *la*, respectively, also have the same correlative word *rā/lā* ‘hot’ in Polynesian.

(2) This example exhibits three meanings, the last of which seems “unusual”:

Cloth, clothes: X *kul/u*, K *kur/u* = H *hulu* ‘cloth; fur, wool’.

Blanket: X *kul/u*, K *kur/u* = H *huluhulu*.

Colour: ? X *kul/u* = Paumotan *huru* ‘colour’, H *hulu* ‘colour, nature, kind’; but cf. Section 6(3).

Compare also the different, but apparently related, Kaingang forms:

Hair: ? X *kren-kula-*+ (= ‘head’-*kula*) = M *huru* ‘hair, coarse hair (properly, of the body, but sometimes used for the hair of the head’; cf. *uru*, the head; a single hair), Rarotongan *uro*; cf. 6(5).

Fibre: K *kurē* (or *kurā*) ‘internal fibre of taquara’ = H *pulu* ‘coconut fibre’, cf. *hulu-hulu* ‘body hair, hair of eyelashes, fleece, fur, hairy’, PAn *\*bulut* ‘hairy filaments of certain plants, husk’, Niue *pulu* ‘fibre’.

(3) This example shows the instrumental metonymy “tree-stick”, which is typical for Oceanic languages, where the instrumental prefix *ka(i)-* has developed from *\*kayu* ‘tree’, cf. Lynch et. al. (2002: 70):

Tree: X *kɔ*, K *ka* = POc *\*kayu* ‘stick, wood’, Fijian (Bau) *kau*, M *mā/kau* ‘handle’, Namakir (Vanuato) *ka*.

Stick: X *kɔ*, K *ka* = Fijian (Bau) *kau*.

### 5.3. Polysemous/Homonymous and paronymous sets

By “paronyms”, here I understand words in one language that are very close in form. Paronymous sets normally involve some derivational pattern. If the different meanings of a polysemous/homonymous word in one language are rendered by a paronymous set in another language, this would be an unlikely event, since normally we would expect a random set of words, rather than some derivational pattern, to do the job. The higher the number of meanings of the polysemous/homonymous word rendered by paronyms, the less likely the event, and hence the stronger the evidence for a non-chance link between the compared languages. Below are examples of paronymous sets in the Kaingang family that correspond to the different meanings of polysemous/homonymous sets in Polynesian.

(1) The Kaingang paronymous set  $\{t\tilde{a}, (\delta/\Phi)\tilde{a}, k\tilde{a}\}$  matches the Polynesian polysemous word *tā*:

Break (as wood): K *tā* = H *kā* ‘to split or break wood’, M *tā* ‘strike’, Samoan *tā* ‘to break firewood, to break up a dry tree’, Fijian *tā* ‘chop’.

Kill: X *tajn*, K *tā-n* ‘kill, beat to death’ = H *kā* ‘murder’, Rennell Is. (Solomons) *tā* ‘hit, strike, cut, kill’, Sikaiana (Solomons) *tā* ‘kill, hit, kick’, Luangiua (Ongtong-Java, Solomons) *kā* ‘hit, kill’.

Wash clothes: X *đag*, K *Φā* = H *kā*, Samoan *tā*.

Beat (maize): K *Φān* = H *kā* ‘to thrash out grain’.

Finish: X *kaŋ*, K *kā-n* = H *kā*.

It is important to notice that the sound pattern of forming the paronymous set in Kaingang, viz. the alternation  $t \sim \delta/\Phi \sim k$ , coincides with all the Kaingang sounds that correspond to Polynesian *t*, thus giving additional support to the three rules Nos. 2, 3, and 6 from Table 1. Notice also that the same alternations are additionally observed within Kaingang itself, e.g.: Xokleng *kɔđa* ‘shell’, *kɔđan* ‘strip embira bark’, but *kɔtī* ‘smooth’, Kaingang *ti* ‘he/it’; *Φi* ‘she’, Xokleng *ti* ‘he/it’; *đi* ‘she’.

(2) The following example shows a correspondence between a paronymous set in Kaingang and a paronymous set in Māori and a homonymous set in Hawaiian.

Throw: X *pāŋ*, K *pēŋ* = M *paŋa*, H *pana*.

Shoot: X *pænū* or *paŋ*, K *penū* = M *whana*, H *pana*, PPn \**fana* ‘shoot with a bow’.

Bow/arrow: X *puŋ* = H, Marquesan *pana* ‘bow’.

#### 5.4. Lexical fields

##### (1) BODY PARTS

Head1: X *klē*, K *krī* = PPn \**qulu*, M *uru*, East Futuna, Tongan, East Uvea *ʔulu* ‘head’.

Head2: X *paʔi*, K *pāʔi* = M *u/poko*, H *poʔo*.

Hand/arm1: X *nēŋa*, K *nīŋā* or *nīŋe* = M *ringa* ‘hand, arm’, Fijian *liga* ‘hand, forearm’, PMP \**linga* ‘hand, arm’.

Hand/arm2: K *pē* = M, H *pā* ‘touch’, Ra’ivavai *pā* ‘to touch with’.

Leg/foot: K *wagwag* ‘to limp’ (*wag (ke)* ‘to pass to the other side’) = M *wae/wae*, H *wawae*.

Eye: X *kāna* ‘eye, to look at’, K *kanē* ‘eye, to look at’ = M *kana* ‘stare wildly’, Tuamotan *kana* ‘stare’, Central-Eastern Pn *kana* ‘stare at’ (M, Penrhyn *kanohi* ‘eye’).

Breast: X *-kum(b)e+* ‘female breast’ = M *kōuma* ‘breastplate’, Tuamotan *kōuma* ‘chest, breast, bosom’ (cf. also K *ū-n ū-n (he)* ‘suck’ = M, H *ū* ‘female breasts’).

Heart/liver: X *de*, K *Φe* ‘chest, breast, heart’ = M *ate* ‘liver, heart’, H *ake* ‘liver’, Tuamotan *ate* ‘heart’.

Chin: X *lɔ*, K *ra* ‘jaw’ = M *rae*, H *lae* ‘any projecting substance as a prominent forehead’, Tongan *lae* ‘forehead’, Samoan *lae* ‘beardless chin’.

Bone: X *koko+* ‘bone, knuckle’, *kuka*, K *kuka* = PAn \**kukut* ‘bone’, \**kuku* ‘node, joint, knuckle’, H *kuʔe* ‘joint, the nuckles’.

Mouth/lips: X *-kuʔo* (from *-kuso+*) ‘lips’ = Fijian *gusu-na*, Samoan, Tongan, Nieu *ngutu*, PAn \**ŋusu*.

##### (2) KINSHIP TERMS

Xokleng’s kinship terminology is discussed by Henry (1941: 175-80) and Kaingang’s by Wiesemann (1974). The comparisons below seem to show substantial similarity of Kaingang terms with Micronesian languages (viz. the terms for wife, husband, and mother). Note that we found (Section 2) the best match in kinship semantic patterns between Xokleng and the Micronesian languages Chuuk and Ulithian. The entry for ‘elder sibling’ is interesting, especially if the forms for ‘younger siblings’ could also be conceived as “similar”. The entry for “family” is a remarkable resemblance both formally and semantically, and further allows us to tentatively explain the meaning of Xokleng *kəŋŋəŋ* and Kaingang *kaŋŋəŋ* ‘an Indian, a Kaingang’, previously unexplained as far as I know, as meaning ‘one of our family’ by reference to the respective words for ‘family’, viz. *kəi ka* and *kaŋkã*. The entry for ‘child1’ notes a similarity with a cognate set in some Solomonian languages, while those for ‘father’ and ‘child2’ show likeness with words in isolated New Guinea languages, for which no cognate sets are proposed in the *Austronesian Basic Vocabulary Database*.

Wife+woman: X *plū*, K *prū* = Proto-Chuukic \**p<sup>w</sup>p<sup>w</sup>ulú* ‘spouse’, \**p<sup>w</sup>ulú-wa* ‘married’, Satawalese *pulú-wa-(n)* ‘his wife’, Marshallese (Eastern Dialect) *pālee-*.

Husband+man: X *man* (or *mən*), K *mən* = Proto-Micronesian, Proto-Chuukic \**m<sup>w</sup>aane* ‘man, male’, Satawalese *m<sup>w</sup>áán*, As, Minyaifuin (Gebe, New Guinea) *man*

‘husband’.

Father: X *yug*, K *yɔg* = Kaulong (Au Village, New Guinea) *iyok*.

Mother: X *n̄ɔ̄*, K *-n̄ɔ̄* = PAN *\*t-ina*, POc, Proto-Micronesian *\*tina*, Samoan *tinā*, Mokelese (Micronesia) *ina-(a)* ‘his mother’, Mortlockese (Micronesia) *ina-*.

Child1: X *η̄l̄/e*, K *η̄r* = Kwara’ae *ngela*, Lengo, Ghari *η̄gari*, Mbaungguu *η̄wele*, Fataleka *η̄wele* (all Solomonian).

Child2: K *kɔsin* = Sengseng (New Guinea) *po-kusan*.

Elder sibling: X *kake* ‘relative’, K *kāke* (or *kāke*) ‘elder brother’, *kāke Φi* (*Φi* = female) ‘elder sister’ = PMP *\*kaka* ‘elder sibling’. (Blust 1995 notes that there can be no doubt that in PMP *\*kaka* referred to elder siblings, while another word, *\*huaji*, to younger siblings; Kaingang’s meaning correspondences to the latter term have the forms X *yawi*, K *yāwi* (*Φi*) ‘younger brother/sister’.)

Family: X *kai ka* (*he*) ‘relatives, people with the same body paint, family’, K *kajkã* ‘family, parents’ = Pn *kāiga* ‘kin, family, relative’, Tuvalu (Ellice Is.) *kāiga* ‘family, relative’, East Futuna (Horne Is.) *kāiga* ‘relative, family, parent’, East Uvea (Wallis I.) *kāiga* ‘parent, friend’, Pileni (Solomons) *kaega* ‘clan, family’, Samoan *ʔāiga*. ‘elementary family; family, lineage, kin, relatives’, Tokelau *kāiga* ‘kin, relative’, Tongan *kāinga* ‘relation, relative’.

### (3) NUMERALS

Kaingang’s numerals, according to Wiesemann, are *pir* ‘one’, *reŋre* (or *reŋre*) ‘two, second’, *tāntū* ‘three’, *wēŋ-kāŋra* ‘four’, [*šiko*] ‘five’. Contemporary Xokleng has a base-two system, *pil* ‘one’, *leŋle* ‘two’, forming higher numerals by their combination: *leŋle to pil* ‘three’ *leŋle to leŋle* ‘four’, etc. (Greg Urban, personal communication). Henry (1945) lists *pil* ‘one’ and *leŋle* ‘two’, as well as one word involving the number four, viz. *ɔ̄ɔ̄ipa* ‘four-cornered’, but says that the Xokleng have no “real numbers”, presumably because e.g. *leŋle/reŋre* mean ‘companion, friend, co-spouse (Xokleng), brother (Kaingang)’. An early investigation (Gensch 1908) lists what seems to be a quinary numeral system: *toktenúnlo+* ‘one’, *nunengláeglo+* ‘two’, *lenglæmú+* ‘twice’, *umarikélko+* ‘three’, *umpétko+* ‘four’, *undupélemo+* ‘five’ (stress is marked).

One: X *pil/i*, K *pir*, *pipir* ‘few’, (*wēŋ*) *pānpir* ‘reunited’, *pānpin* ‘group together long objects’ = M *piri*, H *pili* ‘united, joining’, Marquisan *piʔi* ‘unite, kindred’. The Austronesian languages usually do not express quantity with the term, cf. however the related Tahitian *piti* with the same meaning ‘to join, to unite with another’ used as “two” in counting.

Two: K *rərə* ‘fight by twos’, *rən* ‘grapple’, *to rə* ‘fight’ (i.e. *rərə* probably *rə-rə* lit. ‘grapple, fight + two’) = Pn *rua* ‘two’, Tahitian *aro-rua* ‘the second in a combat’, or lit. ‘to face, to turn towards + second’.

Xokleng’s numerals given by Gensch look very interesting, even if not wholly understandable (to me). First, they seem like a continuation in counting after two of the other source(s), and the set undoubtedly shares the word for “two” with them. Secondly, they seem to contain some additional material over pure numerals roots, as witnessed e.g. by *nuneng-láeglo+* ‘two’ vs. *lenglæ-mú+* ‘twice’. Table 2 highlights the sequence overlaps between Xokleng and Austronesian numerals for three, four, and five, accompanied by some information from Kaingang.

The highlighted Xokleng sequences, which are similar to those in Austronesian, seem to be supported by segmentation considerations. In all three words the initial *u-* seems the Xokleng (and Kaingang) pronominal *ũ*, and *-kɔ* is a predicating particle

(Greg Urban, personal communication). Thus, we get respectively: for “three”, *ũ – mari – kel – kɔ*, where *mari*, if guessed by its meaning in Kaingang, is an emphasis word meaning ‘also, too’; for “four”, *ũ – (m)pen – kɔ* (the Xokleng nasal *n* is changed to the homorganic stop *t* in this context, as described by Henry 1945), and besides apparently *ðai – pa* lit. ‘corner – four’; and, for “five”, *ũ – ndu – pélemo*, where *ndu* is a postposition meaning ‘after’. Given this, the comparisons are:

Three: X – *kel* = H *kolu*, M *toru*, Proto-Micronesian *\*telu*, Kisar *wo-kelu*, Kei *tel*, Yamdena, Selaru *tél* (all Maluku), Central Masela *wəkəl*, Emplawas *wokel*, Dawera Daweloor *ʔel* (all Babar).

Four: X *pa* or *pen* = H *hā*, M *whā*, Anuta *pā*, Buru (Maluku) *pā*.

Five: X *pelemo* = H *pālima* ‘five times, in fives, fivefold’, M *rima*, Tungag *palpalimana*, Tiang *patlima* (both New Ireland).

**Table 2.** Sequence overlaps (in bold) in the numerals for “three”, “four”, and “five”

	<i>Xokleng</i> ( <i>Gensch</i> )	<i>Xokleng</i> ( <i>Henry</i> )	<i>Kaingang</i>	<i>Austronesian</i>
THREE	<i>umarikélko</i>			POc <i>*tolu</i> , PCEMP <i>*talu</i>
FOUR	<i>umpétko</i>	<i>ðai</i> <i>pa</i> ‘four-cornered’	<i>Φir</i> ‘corner’ <i>penu</i> <i>gnu</i> ‘quadrangle’, <i>penu</i> ‘angle, corner’	POc, PCEMP <i>*[ə]pat</i> , <i>*pati</i> , <i>*pani</i>
FIVE	<i>undupélemo</i>			POc <i>*lima</i>

### 5.5. Long words

Similarities in longer words are less likely to be coincidental than similarities in shorter words as is well-known in historical linguistics. Below are some examples:

Be same or similar: X *halike*, K *hā ri ke* = M *whārite*, H *hālike*.

Smell, odour: X *(di?)kukræ+* ‘stink’, K *kəkrā-ŋ* ‘stink of rotten’ (cf. also K *kaʔi* ‘smell’, *kāhɔr/ɔ* ‘odourless’) = M *kakara*, H *ʔaʔala* ‘fragrant’, East Futuna (Horne Is.) *kakalu* ‘that which smells bad’, M *kekererū* ‘stinkroach’.

Snow: X *kuklule+*, K *kukrir/i* = M *hukarere*.

Thunder: X *t̃t̃ɔl*, K *(ta) t̃ t̃ā̃r (hɛ)* = M *(wha)titiri*, H *(he)kili*, Samoan *(fāi)titili*, Tuamoto *(fa)tutiri*, Tahiti (1773) *(pa)tiree* ‘it thunders’.

Fish: K *kākuΦər* ‘small fish’ = M *kō-kota* (shellfish), Mangarevan *kokota* ‘small shell-fish’.

### 5.6. Compound words

The comparison of “compound words” (in our context, words comprising more material than just a single stem) presents significant evidence when both the compounds themselves and their constituent parts match in the compared languages. Below I give several illustrations, including as component part a grammatical morpheme.

(1) Compare entries Nos. 1-3 from our list of similarity sets. These three entries illustrate similar compound words, e.g. Xokleng *halike*, Hawaiian *hālike*, etc., all

having an identical meaning, viz. ‘be same or similar’. These composite words comprise prefixes with identical form and function in present context, variously designated in the different languages: “emphatic” (Xokleng), “assertive” (Kaingang), and “causal” (Polynesian) (from *\*fā*), and stems (meaning ‘be same or similar’), which are also formally similar, e.g. Xokleng Prefix: *ha* + Stem: *like*, Hawaiian Prefix: *hā* + Stem: *like*, etc. Such a coincidence of three compared entities, viz. a compound word and its two constituents, is so highly unlikely, as to be practically impossible to occur by mere chance.

(2) Henry (1935, 1948) lists for Xokleng *maikaug* ‘fear, be frightened’, which comprises a prefix *mai-* (in other Xokleng sources written *wai-* or *wā-*; Kaingang *wāŋ-* or *wěŋ-*), a “reflexive” with general meaning, and a stem *kaug*. Henry (1935, 1948) draws attention to the fact that this prefix has a valency-decreasing function, writing that “Certain verbs that begin with *mai* omit it when they have direct objects” (Henry 1935: 204), giving, among others, examples with the verb ‘fear, be frightened’. Compare

Frighten: X *maikaug* = H *makaŋu*, M *mataku*, PAn *\*ma-takut*.

Now, the stems seem related (cf. also Yamdena and Selaru (southeast Maluku) having *taut*, Kédang (Timor) *taug* or Puyuma (Formosa) *ma-kauð* ‘fear, be frightened’, where the middle consonant *k* is elided). Additionally, Austronesian (Proto-Oceanic) *ma-* is known to have a valency-decreasing function (Evans and Ross 2001), in that prefixing it to a verbal stem reduces the number of arguments this verb may have. As we see, Xokleng’s prefix *mai-* behaves in exactly the same way, as actually does Kaingang’s correlative. (Curiously, this same verb seems to be the common illustrative example of the phenomenon in both language families.)

(3) Compare the “long word” for fish above. The Polynesian *kō-kota* ‘shellfish’, is a compound word, comprising the prefix *kō* ‘like, similar to’ and the stem *kota* ‘shell, scrapings’. The Kaingang *kākuΦar* ‘small fish’ also seems to be a compound, viz. *kā-kuΦar*, as seen from its meaning equivalent *kuvar* in one of Kaingang’s dialects (São Paulo) (Wiesemann 1978: 212). Its stem *kuΦar* then corresponds to Polynesian *kota* ‘shell, scrapings’ as evidenced by Kaingang *kuΦen* ‘to shell, to peel’, Xokleng *kɔða* ‘shell’. The Kaingang prefix *kā-* seems to be allomorphic to the preposed Kaingang particle *kɔm* ‘similar to, parallel to’, and hence also corresponding to the Polynesian prefix *kō* ‘like, similar to’.

### 5.7. A compound word and a synonymous set

The next example also describes an event which would not normally be expected in random comparisons, so is of some interest. The constituent parts of the compound Polynesian word *pō-fatu* ‘stone’ (M *pō(w)hatu*, Mangarevan *pōŋatu*), in which the sequence *fatu* ‘stone’, correspond to a synonymous set in the Kaingang family: Kaingang *pɔ* ‘stone’, and Xokleng *kaðu+* ‘stone’ (from older *kasu+* given by Gensch, in which *s* represents *ð*). Note that *kaðu* is “regular” in that it fully agrees with our sound correspondences in Table 1. It is interesting to note, whatever the exact implications, that the contemporary form for stone in Xokleng is *kɔði*, and it nicely matches Pre-Rotuman *\*hafu* ‘stone’ pronounced [*hɔθu*] (cf. also Xokleng *ðe*, Kaingang *Φe* ‘heart’, Pre-Rotuman *\*afe* ‘liver’, pronounced [*æθe*], Biggs 1965: 188).

## 6. Predictions

The usual way of testing a scientific theory is to draw logical deductions from the theory and check whether these predictions of the theory fit the data or not. The more of these predictions are true, the more corroborated the theory is. A similar approach, of course, can be used in historical linguistics. In the following, this general mode of reasoning takes a specific form. I take a sequence of two words in Kaingang <W1 + W2>, whose meaning as a whole, as well as the meaning of one of the constituent words, W1, is known, but that of the other, W2, is not, though W2 can be reasonably reliably predicted from context. This prediction, then, under the assumption that the Kaingang and Austronesian families are related – somewhat anticipating the hypothesis I shall put forward to explain the observed similarities – can be tested by seeing whether or not a correlative word in Austronesian exists with the appropriate predicted meaning. This reasoning mode mimics the real-life situation in which one tries to reconstruct the died-out meaning of a word in some language by reference to a related language that has, or might have, preserved this word meaning. A positive outcome of such a reconstruction constitutes positive evidence for the idea of the existence of a relationship among these languages. Additionally, it allows us to gain a better understanding of one of the languages by making the reconstruction.

(1) Kaingang *ka rigri* means ‘small mosquito’, *ka* in this context standing for ‘mosquito’. The word *rigri*, however, is with unknown meaning and according to Wiesemann (personal communication) does not occur outside this word complex. Assuming a connection between Kaingang and Austronesian/Polynesian, we can predict that if *ringri* designates ‘small’ – as it would follow from context – we could find a correlative in Austronesian. Indeed, the formally similar *riki* means ‘small’ in Austronesian.

(2) Kaingang *ka pūr* ‘black person, African’, *pūr* ‘burnt’ = Proto-Central Pacific \**pula* ‘burn’, Proto-Micronesian \**pwula* ‘burn’, Rotuman *pula* ‘burn’, Hawaiian *pula* ‘kindling’, Waya (western Fiji) *bula-n* ‘burn’. The unknown Kaingang meaning of *ka* in this context, probably ‘person’ as derived from context, is confirmed by Hawaiian *ka* meaning ‘the one who, the person in question’.

(3) In the early documentation of Xokleng by Gensch (1908), the form *kulu-* is prefixed in 7 words denoting colour, and we have the sequence *kulu* + <colour term> + *ma*, as exemplified in *kulukuprima*+ ‘white’, *kuluklama*+ ‘yellow’, etc. The form *ma* is known to be a predicating particle, but what does *kulu* mean in this context? It would be natural to suppose that *kulu* means ‘colour’ or something related with colour, but no such use of the word is known e.g. to the investigator of Kaingang and Xokleng Wiesemann (personal communication). Assuming a relationship between Xokleng and Austronesian, we could expect to infer the actually unknown meaning of *kulu* from some corresponding word in Austronesian. Indeed, in a language like Hawaiian (cf. also Paumotan *huru* ‘colour’) one finds *hulu*, meaning – among other things – ‘colour’ (‘species of colour’, Andr), i.e. we have the “regular” correspondence:

X *kulu* = H *hulu* (PAn \**bulu*); cf. also Nos. 15, 16.

As additional piece of evidence for this conclusion, consider the “unusual” coinciding polysemy of *kulu/hulu* in Kaingang/Austronesian families, cf. 5.2(2).

(4) Gensch (1908) lists as entry and sub-entry in Xokleng  
X *kulug-*+ ‘dark’ (German *dunkel*)

X *kuru-loa*+ lit. ‘darker stuff’ (German *dunkler Stoff*), which have the same root *ku(l/r)u* for ‘dark’ (*l* and *r* freely alternating in Xokleng). The meaning of Xokleng *loa* does not occur elsewhere in Gensch (1908) and is unknown. The Xokleng form *loa* does not seem to be associated with its substantive literal translation *staff*, for if it were the case, then, first, it should have preceded the adjectival *kuru* ‘dark’ (Xokleng’s word order being substantive + adj), and, secondly, it should, as an autonomous word, have been written separately from the adjectival form. Therefore, *loa* appears to be a sort of comparative degree, or intensifier, of the adjectival *kuru* ‘dark’. This prediction is fully substantiated by the Polynesian particle *loa*, having two meanings: (i) long, and (ii) ‘very, very much, exceedingly’, a post-posed intensifier probably used in our context. I note that there is a full match also of the other Xokleng word in the complex; thus, Hawaiian *kulu* ‘be late at night’ (Puk), ‘first night in which the moon is dark or can’t be seen’ (Andr); cf. also PAn *\*kudem*, Nggela *kuro*.

Further evidence that we are on the right track is the word *halikelɔ* ‘how long’, listed several times by Henry (1935), in which *halike* means ‘how’ (Kaingang *hēri ke* ‘how’), and *-lɔ*, apparently related to the older form *loa*+, has to mean ‘long’, the first meaning of the identical Polynesian word. It is not clear whether in Xokleng *-lɔ/-loa*+ are separate words or are only used in compounds (as it is the case e.g. in Kapingamarangi). Note that our argumentation here follows the idea of Section 5.2, viz. comparison of polysemous sets.

(5) For the word ‘hair’ in Xokleng, Gensch gives *kren-kula-ma*+ (lit. = ‘head’-*kula*-predicating particle), where the meaning of *kula* is unknown. Henry (1935) lists for ‘hair’ *klē kiki* lit. ‘head feather’. Given also that a formally similar word in Kaingang, *kule*, has a similar meaning, ‘internal fibres of taquara’, one could predict that the unknown meaning of *kula* is also feather or something similar. This prediction is corroborated by the complete match with Western Fijian (Navosa) *kula* ‘feathers’, as well as by the fact that a number of Austronesian languages (e.g. Sekar, Ujir, Yakan, Buru) form the words for ‘hair’ as the combination of ‘head+feathers’.

## 7. Extra-linguistic data

There are several pieces of evidence, besides the linguistic evidence, that seem to make less incredible the idea of the existence of some linguistic link between the geographically distant Austronesian-speaking and Kaingang-speaking populations. First, genetically South America is the most diverse part of the world, and Central America is more similar to North America than to South America (Cavalli-Sforza et al. 1994: 339).

Secondly, and more specifically, the Macro-Ge people, in drawing a phylogenetic tree of 23 American tribes, grouped according to linguistic criteria (Cavalli-Sforza et al. 1994: 323-4), were found to be the worst outliers (with Macro-Tucanoans).

Thirdly, and most importantly, apart from these more circumstantial, even if quite suggestive, pieces of genetic evidence that (at least some parts) of South America do not fit into the scenario of exclusively North-South population movement – which is the prevalent current belief today – there emerged recently genetic work giving sound evidence for the predominantly South-East Asian and Oceanic origin of South American native populations. E.g. Ribeiro et. al. 2003, analyzing the Macro-Ge-speaking Xikrin

and the Tupi-speaking Parakanã (note that Tupi is believed to be related to Macro-Ge), found them to be genetically similar to Indonesians and South-East Asian populations, concluding that “These results corroborate the existence of genetic affinities between Brazilian Indians and South-east Asian and Oceanic populations”, their investigation being intended to “further contribute to the theory of a predominantly Asiatic origin of the American natives” (p. 59).

And, finally, an argument from Xokleng’s beliefs. According to Henry (1945: 127) “The Kaingang [i.e. the Xokleng] have a clear idea of a period long ago when a number of events happened: *their ancestors came out of the sea* and over the mountains to the west...” [italics mine].

## 8. Conclusion

In this paper, I showed parallels between the Kaingang and the Austronesian language families in grammar and kinship semantics, as well as presented a network of similarities in lexicon. I cherish no illusion that my description is free from errors. Rather, I expect occasional inaccuracies to occur both in the data, and in my interpretation of some data, for it could hardly be otherwise, given the early stage of my investigation, the rather scarce knowledge we have today about the Brazilian languages, and especially my lack of first-hand knowledge of both examined language families. Nevertheless, the nature and scope of the presented parallels seem to enforce the conclusion that these similarities, taken collectively, cannot be just random, a conclusion I have also reached by direct computation of probabilities of matches in basic vocabulary comparisons. There are much too many coincidences, and this requires an explanation. One plausible explanation is a historical (probably genetic) relationship between the Kaingang and the Austronesian language families, and specifically its Oceanic branch, the exact nature of which is presently unknown. Further studies are required to get more definitive answers. The severe testing of this hypothesis is a worthwhile enterprise, because, if true, it will have far-reaching consequences not only for linguistics, but for the study of human pre-history as well. Such testing should be concerned with trying to undermine a significant part of the presented data, and trying to find a more plausible explanation of the (remaining) data. Regarding the current classification of the Kaingang languages as members of the Ge family, it will be clear that if my hypothesis is true, either this classification is not valid, or it is valid, and Ge is also somehow linked to Austronesian. At present I can only state these as two logical possibilities.

**Acknowledgments.** I wish to thank Robert Blust for making available to me his *Austronesian Comparative Dictionary*, and Ross Clark for POLLEX. Greg Urban and Ursula Wiesemann most kindly supplied answers to my questions regarding Xokleng and Kaingang noted in the paper. All errors are entirely mine. Partial support is also acknowledged from grant MI-1511 with the Bulgarian Ministry of Education and Science.

# Predicting innovative alternations in Korean verb paradigms\*

**Adam Albright**

## Abstract

In Korean verbal inflection, all forms in the paradigm (A-suffix, C-suffix, or i-suffix forms) suffer from neutralization of some lexical contrasts, and there is no single form of the paradigm from which one can correctly predict all the other forms in the paradigm. Nevertheless, a survey of child errors and historical change show that the attested reanalyses are overwhelmingly based on ambiguities in A-forms, rather than in other affixal contexts (Kang 2006). In this study we conducted a computational modeling of learning of inflected forms of 952 Korean verbs using the Minimal Generalization Learner algorithm (MGL; Albright and Hayes 2002, 2003) to account for this striking asymmetry. The simulation result shows that A-suffix form correctly predicts the other forms in the paradigm at a higher rate than C-suffix form or i-suffix form does, indicating that the A-suffix form is indeed the most informative form of the paradigm. This is in line with the previous studies showing that learners designate the most informative form as a privileged base form (Albright 2002, 2008). We compare the model's errors with attested child errors and historical changes.

**Keywords:** Korean, morpho-phonology, verb paradigm, analogy, acquisition, language change, computational modeling

## 1. Introduction

Children learning to inflect Korean verbs and adjectives faces a number of challenges simultaneously. Their primary task is to segment words in the input data into morphemes, and determine their meanings. This task is made more difficult, however, by the fact that morphemes undergo a wide variety of phonological alternations. These include fully predictable processes that satisfy general phonotactics of Korean, such as intervocalic voicing and post-obstruent tensification ([d] ~ [t'] in (1a)), allophonic [r] ~ [l] alternations ((1b)), neutralization of laryngeal and manner features in codas ((1c-e)), cluster simplification ((1f-g)), and elision of [i] ((1h-i)). There are also many cases of alternations caused by phonologically conditioned allomorphy, in which the

morpheme has multiple forms that are not fully predictable from one another based on regular phonological processes, but the distribution of the allomorphs is guided by phonotactic constraints ((2a)).

|     | d. | C' ~ C             | kyək'-ə 'experience'                 | kyək-t'a 'experience'                     | (*C'/_C)              |
|     | e. | s ~ t              | pəs-ə 'take off'                     | pət-t'a 'take off'                        | (*s/_C)               |
|     | f. | CC ~ C             | əps'-ə 'lack'                        | əp-t'a 'lack'                             | (*C/C_C)              |
|     | g. | CC ~ C             | nəlb-ə 'wide'                        | nəl-t'a 'wide'                            | (*C/C_C) <sup>1</sup> |
|     | h. | i ~ Ø              | c <sup>h</sup> ir-ə 'pay for'        | c <sup>h</sup> iri-da 'pay for'           | (*iV)                 |
|     | i. | i ~ Ø              | əps'- <b>imyən</b><br>'lack (cond.)' | nolla- <b>myən</b><br>'surprised (cond.)' | (*Vi)                 |
| (2) | a. | s'i ~ Ø            | ka- <b>mnida</b><br>'go (defer.)'    | ip-s' <b>imnida</b><br>'put on (defer.)'  | (*CCC)                |

In addition to phonotactically motivated alternations, Korean learners are also faced with numerous irregular alternations that do not find any apparent synchronic phonotactic motivation. For example, the declarative suffix /-ta/ is expected to surface with intersonorant voicing after verb stems that end in vowels and sonorants, but it surfaces instead with either an aspirated or tense stop after many verbs ending in vowels and liquids ((3a–c)), and after all verbs ending in nasals ((3d–e)).

- |     |    |                 |   |                            |                       |
|-----|----|-----------------|---|----------------------------|-----------------------|
| (3) | a. | co-a 'be good'  | ~ | co- <b>t<sup>h</sup>a</b>  | (V-da is expected)    |
|     | b. | ci-ə 'compose'  | ~ | ci- <b>t'a</b>             | (V-da is expected)    |
|     | c. | ʃir-ə 'dislike' | ~ | ʃil- <b>t<sup>h</sup>a</b> | (l-da is phon. legal) |
|     | d. | man-a 'be many' | ~ | man- <b>t<sup>h</sup>a</b> | (n-da is phon. legal) |
|     | e. | ʃin-ə 'put on'  | ~ | ʃin- <b>t'a</b>            | (n-da is phon. legal) |

Furthermore, roots may show other lexically restricted segmental alternations, such as those in (4).

- |     |    |               |   |                 |                        |
|-----|----|---------------|---|-----------------|------------------------|
| (4) | a. | tow-a 'help'  | ~ | top- <b>t'a</b> | (p ~ w: 'p'-irreg.)    |
|     |    | ʃir-ə 'load'  | ~ | ʃit- <b>t'a</b> | (r ~ t: 't'-irreg.)    |
|     |    | hill-ə 'flow' | ~ | hiri-da         | (ll ~ ri: 'li'-irreg.) |

A standard view of how learners encode alternations, assumed in most work in generative phonology, is that learners compare the surface variants of each morpheme, extracting all unpredictable values and (wherever possible) incorporating them into an underlying form (UR) that contains all unpredictable values (Kenstowicz and Kisseberth 1977, chap. 1; Tesar and Prince 2007). For example, comparing the forms of the verb 'lack' in [əps'-ə] and [əp-t'a], the learner would establish a UR /əps/, which encodes the unpredictable presence of the cluster. Similarly, comparing the forms [ʃir-ə] and [ʃil-t<sup>h</sup>a] 'dislike', the learner might encode the fact that the verb unpredictably triggers aspiration on the suffix by positing the UR /silh/, with a stem-final [+aspirated] segment. The task of the learner is to arrive at a UR that is compatible with the range of attested surface variants.

A prediction of this approach is that in cases where the learner has incomplete

data about the behavior of a particular morpheme, the UR will be determined solely on the basis of whatever surface forms happen to be available. This means that the UR may contain a subset of the information needed to produce the unseen target forms. For example, if a learner had heard only [ʃir-ə] but not [ʃil-t<sup>h</sup>a] ‘disliked’, then there is no need to posit an underlying /h/ for this verb: /sil/. This provisional assumption, based on incomplete information, could lead the learner to project the declarative form \*ʃil-da], which is innovative relative to the adult language. (We use here the notation ‘\*’ to mark innovations, which are incorrect in the adult language but correct or expected under the learner’s analysis.) Such errors would reveal that a reanalysis has taken place, in this case based on the form of the stem that appears before the suffix /-ə/.

In principle, many different types of reanalysis are possible in Korean, depending on which inflected forms happen to be known. In addition to reanalyses like \*/sil/ based on prevocalic form [ʃir-ə], it is conceivable that the learner might happen to have encountered a particular word in only preconsonantal forms: e.g., [əp-t’a] but not [əps’-ə] ‘lack’. In this case, the learner would have no reason to posit a /ps/ cluster in the UR (\*/əp/), leading to the possibility of innovations such as \*[əb-ə] instead of [əps’-ə]. More generally, learners operating with incomplete information are free to consider a much broader range of underlying forms than they would if all surface allomorphs were known, leading to a wide variety of possible reanalyses. These are illustrated for the irregular verb [ʃir-ə] ~ [ʃit-t’a] ‘load’ in (5b–c).

(5)	a. Actual forms	[ʃir-ə]	[ʃit-t’a] ‘load’
	b. Possible reanalysis based on [ʃirə]	/sil-ə/	→ *ʃil-da
		/silə-ə/	→ *ʃirə-da
		/sili-ə/	→ *ʃiri-da
		/silh-ə/	→ *ʃil-t <sup>h</sup> a
		/silʔ-ə/	→ *ʃil-t’a
	c. Possible reanalyses based on [ʃit-t’a]	→ *ʃid-ə	/sit-ta/
		→ *ʃit <sup>h</sup> -ə	/sit <sup>h</sup> -ta/
		→ *ʃis-ə	/sis-ta/
		→ *ʃic-ə	/sic-ta/
		→ *ʃic <sup>h</sup> -ə	/sic <sup>h</sup> -ta/
		→ *ʃi-ə	/siʔ-ta/

Given such massive surface ambiguity, it is not surprising that innovative forms are in fact widely attested in Korean. Kang (2006) surveys a variety of studies of historical change, dialect differences, and acquisition, and finds that virtually all types of irregular verbs show the effects of reanalysis. But strikingly, the attested innovations are overwhelmingly asymmetrical: they are nearly all based on the stem variant that occurs before vowel-initial suffixes (Kim 2001), and in particular, before suffixes that start with -ə/-a (Kang 2006) (“A-suffixes”, in which the vowel quality is determined by vowel harmony). Concretely, reanalyses like those in (5b) are well-attested, while reanalyses based on pre-consonantal forms, like those in (5c), are vanishingly rare in verbs and adjectives.<sup>2</sup> Such asymmetries are not unusual; in fact, they are common in historical change, and are also observed in studies of child errors in other languages (Spanish: Clahsen, Avelado, and Roca 2002; German: Clahsen, Prüfert, and Eisenbeiß 2002). At the same time, these asymmetries are puzzling under the view that learners

establish URs based on whatever surface allomorphs are available to them, since in the case of Korean, it appears that learners focus primarily on the form of the stem before A-suffixes when deciding the (morpho-)phonological properties of words, while systematically ignoring information from other forms. The challenge is to understand why these forms would play such a privileged role in driving reanalysis in Korean.

In response to such asymmetries in historical change and child errors, Albright (2002, 2008) proposes a more restrictive model of underlying form discovery, in which learners designate a single inflected form as a privileged base form. The base form is constrained to be the same for all lexical items of a given category, and serves as the input (or underlying form) to a grammar of morphological and phonological rules (or constraints), which are used to project the remaining forms. In this model, asymmetries in innovation reflect asymmetries in paradigm structure: the base form serves as the basis of (re)analysis, while the non-base forms are projected by the grammar and are thus open to restructuring. This is referred to as the *single surface base* hypothesis.

To see the implications of this hypothesis for a language like Korean, let us assume for present that the form with the informal suffix *-ə/-a* is the base. (This assumption will be justified below.) The grammar must then operate on this form to derive other inflected forms, for example by transforming [X ə] → [X ta] to yield the declarative form, and then performing any necessary phonological adjustments such as cluster simplification, liquid allophony, intersonorant voicing, post obstruent tensification, etc.

- |     |    |                     |   |         |                     |
|-----|----|---------------------|---|---------|---------------------|
| (6) | a. | cər-ə               | → | cəl-da  | ‘limp’              |
|     | b. | əps’-ə              | → | əp-t’a  | ‘lack’              |
|     | c. | əb-ə                | → | əp-t’a  | ‘carry on the back’ |
|     | d. | təp <sup>h</sup> -ə | → | təp-t’a | ‘cover’             |

A consequence of this direction of mapping is that if the *-ə/-a* base form is ambiguous, the grammar may be uncertain about how to project other forms. For example, given a form like [ʃirə] ‘load’, should the declarative *-ta* form be [ʃilda], [ʃilt<sup>h</sup>a], [ʃirida], [ʃirəda], (correct) [ʃi(t)t’a], or some other form? In many cases, it is impossible to know the answer based on regular grammatical mappings alone; the speaker must instead rely on memorized lexical knowledge to settle the matter. We assume that listed information about the behavior of a word supercedes whatever other output the grammar would have produced, by means of morphological blocking (Aronoff 1976). Blocking may fail, however, in cases where the learner does not have sufficient data about the correct form, or if lexical access happens to fail for some other reason. In such instances, an innovative overregularized form will be produced (Paul 1920, Marcus et al. 1992).

To summarize, the single surface base hypothesis predicts an asymmetry between base forms, which are taken as given by the grammar and must therefore remain constant, and non-basic forms, which are projected by the grammar and may therefore be overregularized if the adult form is not known or not accessed reliably. A question that must be answered is why an A-suffix such as the *-ə/-a* form would serve as the base of Korean verbal inflection. One potentially relevant factor is high token frequency. In fact, the informal *-ə/-a* form is very frequent in spoken language,

particularly in child-directed speech (Kim and Phillips 1998, Lee et al. 2003). This no doubt plays a role in making the *-ə/-a* a likely candidate for base status, but it cannot be the whole story since in many other documented cases, the base of reanalysis is not the most frequent form.<sup>3</sup>

Albright (2002) proposes instead that the decision depends on the relative informativeness of the forms in question. The premise of this hypothesis is the following: faced with the restriction that the grammar must be based on a single surface form, which may potentially suffer from neutralizations that remove information about lexical contrasts, learners seek the surface form that exhibits as many contrasts and suffers from as few neutralizations as possible. Ideally, the base form would reveal all contrastive phonological properties (the segments of the morpheme, its tonal pattern, etc.), as well as all morphological contrasts (gender, inflection class). Unfortunately, in most languages, there is no single perfectly revealing surface form, since different inflected forms are affected by different types of neutralizations. In such cases, the learner must choose the form that has least serious neutralizations, and allows accurate projection of the inflected forms of as many words as possible.

As noted, Korean provides an excellent example of the ubiquity of neutralizations, with no single inflected form revealing all contrasts. The question that we address in this study, therefore, is whether A-suffixes such as the *-ə/-a* form are nonetheless the most informative form in Korean. This idea has some a priori plausibility, since these suffixes are vowel-initial, and therefore do not trigger neutralizations in manner and laryngeal features of stem-final consonants, or reduction of stem-final clusters—that is, they provide a phonologically advantageous “pre-vocalic” environment for the preceding stem. At the same time, some of these neutralizations have quite limited practical impact; for example, there are relatively few verb roots ending in obstruent+obstruent clusters, so it is not difficult to guess that a verb should not end in a cluster. Furthermore, although vowel-initial suffixes reveal laryngeal features and clusters, Kang (2006) points out that they also trigger neutralizations such as elision or coalescence of preceding vowels, and they fail to reveal whether the preceding root exceptionally causes aspiration or tensification of a following obstruent (see (3) above). Thus, it is an empirical question which set of neutralizations causes greater difficulty in predicting inflected forms of words.

In the remaining sections, we show that although the A-suffixes trigger various types of neutralization, they are not as serious as one might think, since they affect comparatively few words, they can be predicted more often than not, and they are more than offset by neutralizations caused by consonant-initial and *i*-initial suffixes. The claim is that A-forms are indeed more informative about C-forms than vice versa, and that the direction of reanalysis in Korean is therefore correctly predicted by a theory that makes use of the most informative form as a base form. In order to show this, we first lay out a model for learning grammars that project morphologically related forms from one another. We then describe simulations employing this model to assess the relative accuracy of projections between various inflected forms in Korean, comparing the consequences of using A-suffixes vs. other types of affixes as the input to the grammar. The results reveal that the A-suffixes are indeed more predictive about other forms than vice versa. We discuss the predictions of a grammar that uses A-suffixed forms as the

base of morphological projection, including unproblematic or unambiguous mappings (for which no innovation is expected) as well as problematic or ambiguous mappings (open to innovation). We compare these predictions to the attested range of innovations, and find a fairly good qualitative match. A few discrepancies also emerge, however, for which we discuss possible resolutions.

## 2. A model for learning surface mappings between inflected forms

### 2.1. Predicting allomorphy based on phonological context

The model that we employ takes as its training data a set of pairs of morphologically related surface forms, and attempts to learn a grammar of morphological and phonological mappings that project one from the other. For example, suppose the learner has been given a set of pairs involving the *-ə/-a* informal suffix and the *-imyən/-myən* conditional suffix, as in (7).

- |     |    |       |   |           |              |
|-----|----|-------|---|-----------|--------------|
| (7) | a. | siə   | ~ | simyən    | ‘sour’       |
|     | b. | kiə   | ~ | kimyən    | ‘crawl’      |
|     | c. | cəgə  | ~ | cəgimyən  | ‘write down’ |
|     | d. | əps’ə | ~ | əps’imyən | ‘lack’       |
|     | e. | iruə  | ~ | irumyən   | ‘create’     |
|     | f. | nə ə  | ~ | nə myən   | ‘hand in’    |
|     | g. | cəlmə | ~ | cəlmimyən | ‘young’      |

The model learns grammars in both directions (informal → conditional and vice versa), using the Minimal Generalization Learner algorithm (MGL; Albright and Hayes 2002, 2003). The algorithm starts by parsing each pair to see what the related forms have in common, and what has changed between forms, as in (8).

- |     |    |   |   |       |          |
|-----|----|---|---|-------|----------|
| (8) | a. | ə | → | myən  | / si__   |
|     | b. | ə | → | myən  | / ki__   |
|     | c. | ə | → | imyən | / cəg__  |
|     | d. | ə | → | imyən | / əps’__ |
|     | e. | ə | → | myən  | / iru__  |
|     | f. | ə | → | myən  | / nə __  |
|     | g. | ə | → | imyən | / cəlm__ |

The parse reveals that some pairs share the same change (e.g., (8a,b,e,f) all map *ə* → *myən*), while others have different changes. The model attempts to learn a grammar that predicts which change each form will take, by comparing forms that share the same change and trying to discover what phonological features they have in common. For example, comparison of the *-myən* forms in (8) yields the generalizations in (9).

(9) Iterative comparison of  $\emptyset \rightarrow my\grave{a}n$  pairs

- a.  $\emptyset \rightarrow my\grave{a}n$  / si\_\_  
 b.  $\emptyset \rightarrow my\grave{a}n$  / ki\_\_  
 =  $\emptyset \rightarrow my\grave{a}n$  /  $\begin{bmatrix} -son \\ -lab \end{bmatrix}$  i\_\_ (after non-labial obstruents + i)  
 e.  $\emptyset \rightarrow my\grave{a}n$  / iru\_\_  
 =  $\emptyset \rightarrow my\grave{a}n$  /  $\begin{bmatrix} +syl \\ +high \end{bmatrix}$  \_\_ (after high vowels)  
 f.  $\emptyset \rightarrow my\grave{a}n$  / næ\_\_  
 =  $\emptyset \rightarrow my\grave{a}n$  / [+syl]\_\_ (after vowels)

Consideration of a broader range of forms (e.g., [yər-ə] ~ [yəl-myən] ‘open’) would show that *myən* occurs not just after vowels, but also after laterals. Likewise, comparison of the  $\emptyset \rightarrow \#my\grave{a}n$  pairs in (8c,d,g) yields the rule  $\emptyset \rightarrow \#my\grave{a}n$  / [-syl, -lat]\_\_. Thus, the learner is able to discover that *-myən* and *-#myən* occur in complementary phonological contexts.

The discovery of complementary contexts for competing affixes is useful in allowing the model to predict the conditional form of each word correctly, but in this case it is also incomplete as an analysis of Korean, since it treats the relation between *-myən* and *-#myən* as completely arbitrary. This misses the generalization that a unified analysis: the suffix is /#myən/, but the initial /#/ of the suffix is deleted after a stem-final vowel. In order to discover this, the model must be able to consider the possibility of adding *-#myən* after a vowel-final stem, even though it is never actually observed in this context. Albright and Hayes (2002) propose to accomplish this by letting the model “clone” mappings, so that  $\emptyset \rightarrow my\grave{a}n$  is tried in the contexts where  $\emptyset \rightarrow \#my\grave{a}n$  is known to apply, and vice versa. The resulting outputs are then checked to see whether they contain sequences that are known to be illegal in the language. For example, applying  $\emptyset \rightarrow \#my\grave{a}n$  after vowels yields incorrect predictions such as \*[ki#myən] and \*[ru#myən], while applying  $\emptyset \rightarrow my\grave{a}n$  after consonants yields incorrect forms like \*[əps'myən] and \*[cəlmmyən]. Comparison of the incorrect and correct forms leads the learner to consider the possibility of phonological rules of elision in suffixes ( $\# \rightarrow \emptyset$  / V+\_\_), or epenthesis in suffixes ( $\emptyset \rightarrow \#$  / CC+\_\_C). As it turns out, when the behavior of other affixes is considered, the elision rule receives broad support, while there are /CC+C/ contexts which are repaired by deletion rather than epenthesis. Finding support for the directionality of a phonological process often requires broad consideration of a wide range of sources of data, beyond the scope of what the model can determine in considering just a limited set of morphological relations. Therefore, as a simplification, in the simulations reported here we simply provide the model with a list of generally valid phonological mappings which can be used to explain the domain of morphological rules. In the present case, this means that the model is provided with an elision rule  $\# \rightarrow \emptyset$  / V+\_\_, which it may then use to generalize the mapping  $\emptyset \rightarrow \#my\grave{a}n$  to all contexts (including after vowels).

## 2.2. Unpredictable allomorphy

Although the procedure sketched above works well to learn the general distribution of the allomorphs *-myən* and *-#myən*, it is not possible to predict the distribution of other affixes perfectly in every single case on the basis of the *-ə/-a* form alone. One systematic source of ambiguity is elision of stem-final *ɨ*, which creates a neutralization between consonant-final and *ɨ*-final verbs ((10a) vs. (10b)). Another difference that is not evident from the A-form is whether a stem triggers aspiration of the following consonant or not ((11b) vs. (11a)). In addition, certain lexically restricted irregular patterns are neutralized in the *-ə/-a* form, but are distinct in other forms ((12)).

(10)	a.	/kip <sup>h</sup> /	kip <sup>h</sup> ə	~	kip <sup>h</sup> ɨmyən	~	kipt'a	‘deep’
	b.	/səkɨlp <sup>h</sup> ɨ/	səgɨlp <sup>h</sup> ə	~	səgɨlp <sup>h</sup> ɨmyən	~	səgɨlp <sup>h</sup> ɨda	‘sad’
(11)	a.	/sə/	sə	~	səmyən	~	səda	‘stand up’
	b.	/nəh/	nəə	~	nəɨmyən	~	nət <sup>h</sup> a	‘insert’
(12)	a.	/yəl/	yərə	~	yəlmyən	~	yəlda	‘open’
	b.	/sil/irreg	ʃirə	~	ʃirɨmyən	~	ʃitt'a	‘load’

In these cases, the general rules fail. For example, the mapping of *ə* → *#myən* coupled with the elision rule, *ɨ* → ∅ / V + \_\_, incorrectly predicts that the conditional of [nəə] ‘insert’ should be \*[nəmyən]. Similarly, the general rules incorrectly predicts that lateral-final verbs like (12a) should take [ɨmyən] in the conditional. For such cases, the mapping *ə* → *myən* is still needed as a minority pattern, existing alongside and competing with the more general (and more successful) *ə* → *#myən* rule. For irregular verbs like ‘load’, even more specific rules are needed

In order to assess the competition between different patterns, the model calculates the *accuracy* or *reliability* of each rule, defined as the ratio of forms for which the rule works divided by the number of forms where the rule could potentially apply. These reliability ratios are then adjusted downwards using lower confidence limit statistics, in order to capture the fact that rules based on just a few data points tend to inspire less confidence than rules based on many applicable forms (Mikheev 1997; for details see Albright and Hayes 2002). This allows the model to estimate a *confidence* value for each rule, which determines the probability with which the model will use the rule in deriving novel outputs.

The end result of learning in this system is a grammar of competing rules of varying degrees of generality, including very general rules (such as *ə* → *#myən* in any context) and very specific rules (such as *ə* → *myən* / *ɾ*\_\_, and rules for other) each associated with a confidence score. When the grammar is invoked to produce an inflected form, all applicable rules are tried, and for each change, the rule with the highest confidence is used. This results in a set of output candidates, each given a confidence score, as shown in (13) for the A-suffixed form [kara] ‘grind’. In many cases, the candidate output with the highest confidence also matches the form that is attested in the input data. In some cases, however (i.e., in the case of minority patterns) the grammar may prefer something other than the actual attested form. These cases are lexical exceptions, which must be listed and produced from memory, blocking the

grammatically preferred form. Such forms are open to innovative regularization, however, if blocking fails because the word is not known or is too low frequency to be retrieved reliably.

(13) Candidate declarative *-ta* forms for informal *-ə/-a* form [kara] ‘grind’

<i>-ə/a</i> form		Projected <i>-ta</i> form	Confidence
[kara]	→	√ [kalda]	0.589
		★ [kalt’a]	0.331
		★ [karada]	0.168
		★ [karida]	0.098
		★ [kalt <sup>h</sup> a]	0.065

### 2.3. Selecting a base form

The example in (13) shows that the grammars that the model learns are not fully deterministic. In any language that has exceptions due to irregularities and neutralization, it is inevitable that there will be a certain number of listed exceptions. Furthermore, in languages like Korean, this is true no matter which inflected form is chosen as the starting point for morphological mappings. For example, rules starting with an A-suffix like *-ə/-a* are bound to have difficulty predicting features like presence of stem-final *i* or aspiration of a suffix-initial obstruent, while rules starting with a C-initial suffix will have difficulty predicting the laryngeal quality of stem-final obstruents or the presence of clusters. A plausible goal of the learner is to minimize reliance on listing, not only in order to decrease the burden on memory, but also (and more importantly) to increase the chance of being correct when inflecting unknown words. By comparing grammars in various directions, it is possible to assess which mappings are on average more accurate or confident in producing the correct (attested) inflected forms. Specifically, we assume that for some small initial batch of data the learner attempts to learn grammars that use each form to project all remaining forms. For each mapping in each direction, the learner then calculates the confidence with which the resulting grammar produces the form that was attested in the training data. The *base* is the form that yields grammars which are able to reproduce the training data with highest possible confidence.

## 3. Testing the model on Korean verbal inflection

### 3.1. Training data

In order to test the model, we trained it on forms drawn from a database of 952 inflected predicates (verbs and adjective) compiled by the National Institute of the Korean Language<sup>4</sup> augmented with token frequency information from Sejong Corpus

(Kim and Kang 2000). The inflected forms were romanized using the Hcode 2.1 software package (Lee 1994). Predictable phonological processes such as cluster reduction and coda neutralizations, post-obstruent tensification, nasalization, lateralization, and aspiration by /h/ in clusters were then applied automatically by script,<sup>5</sup> yielding a database of inflected forms in broad phonetic transcription. The results were spot-checked by a native speaker (the second author) to ensure that neutralizing phonological processes had been applied consistently.

In selecting input data for the morphological learner, we focus on combinations of a verb or adjective stem plus the immediately following suffix.<sup>6</sup> In particular, we selected the set of affixes in (14), chosen from among the most frequent affixes (as determined by corpus counts based on written texts) to include a representative set of phonological shapes.

(14) Affixed forms fed to the model

- a. A-initial suffixes: -ə/-a, -ətə/-ato, -ətaka/ataka
- b. C-initial suffixes: -ta, -ko, -ke, -ci, -nin; -(sɪ)mnita
- c. ɪ-initial suffixes: -(ɪ)l, -(ɪ)n, -(ɪ)n, -(ɪ)myən

As described above, each affix is taken as the starting point for a grammar of rules to derive the remaining inflected forms. Since the neutralizations triggered by a particular affix are primarily a function of the initial segment of the affix, many of the affixes in (14) are equivalent from the point of view of informativeness. We therefore report here just the results for three representative affixes: informal -ə/-a (A-suffix), declarative -ta (C-initial suffix) and conditional -(ɪ)myən (ɪ-initial suffix).

### 3.2. Comparing severity of neutralizations

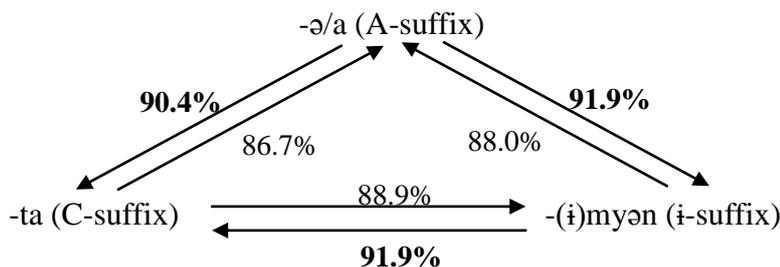

As Kang (2006) notes, all of the forms under consideration suffer from a certain degree of neutralization. The most widely-discussed neutralizations in Korean phonology are laryngeal and continuancy neutralizations among obstruents in coda position, which force all obstruents and obstruent clusters to reduce to a single unreleased stop before another obstruent. These processes are triggered by C-initial suffixes, and lead to a considerable number of neutralizations in forms like the declarative -ta form. In addition, consonant-initial suffixes mask several lexically irregular differences, including the difference between so-called *p*-irregular and regular /p/ verbs ((15a,c)), and the difference between *t*-irregular and regular /t/ verbs ((15d,h)). At the same time, A-suffixes such as -ə/-a also cause a number of neutralizations (see especially (15e-h, j-m)), as do /ɪ/-initial suffixes ((15f-m)). Thus, it is clear that all available forms suffer from numerous neutralizations.

(15)	a.	p	coba	~	copt'a	~	cobimyən	'narrow'
	b.	ps	əps'ə	~	əpt'a	~	əps'imyən	'lack'
	c.	p-irreg	towa	~	topt'a	~	toumyən	'help'
	d.	t	tada	~	ta(t)t'a	~	tadimyən	'close'
	e.	l	yərə	~	yəlda	~	yəlmyən	'open'
	f.	lh	ʃirə	~	ʃilt <sup>h</sup> a	~	ʃirimyən	'dislike'
	g.	li	t'ara	~	t'arida	~	t'arimyən	'follow'
	h.	t-irreg	ʃirə	~	ʃi(t)t'a	~	ʃirimyən	'load'
	i.	lə-irreg	irirə	~	irida	~	irimyən	'reach'
	j.	li-irreg	hillə	~	hirida	~	hirimyən	'flow'
	k.	n	ʃinə	~	ʃint'a	~	ʃinimyən	'put on'
	l.	nh-	mana	~	mant <sup>h</sup> a	~	manimyən	'many'
	m.	C	kip <sup>h</sup> ə	~	kipt'a	~	kip <sup>h</sup> imyən	'deep'
	n.	Ci	ap <sup>h</sup> ə	~	ap <sup>h</sup> ida	~	ap <sup>h</sup> imyən	'sick'
	o.	Cə, Cu	sə	~	səda	~	səmyən	'stop'
			p <sup>h</sup> ə	~	p <sup>h</sup> uda	~	p <sup>h</sup> umyən	'scoop'
	p.	V	kiə	~	kida	~	kimyən	'crawl'
	q.	h	c'iə	~	c'it <sup>h</sup> a	~	c'iimyən	'pound'
	r.	s-irreg	ciə	~	ci't'a	~	ciimyən	'compose'

For purposes of the present model, the question is how much ambiguity these neutralizations cause in practice, owing to the number of relevant words of different shapes. In order to test this, we ran the model on all pairwise mappings between the suffixes *-ə/-a*, *-ta* and *-(i)myən*, and used the resulting grammars to assess the accuracy of mappings in each direction. The first result is that in spite of the impressive degree of neutralization shown schematically in (15), it is possible to construct grammars that perform most morphological mappings very accurately in all directions. The most difficult (= least accurate) mapping is from the C-initial *-ta* form to the A-initial *-ə/-a* form, which can be predicted with only 86.7 accuracy. Most of the remaining mappings can be predicted with accuracy approaching or exceeding 90%, showing a high degree of “multiple predictability” between surface forms (Hayes 1999).

Turning to asymmetries between surface forms, we find that as one might expect, it is somewhat more accurate to project from a vowel-initial suffix (i or A) to a C-initial suffix than vice versa (lower left corner of (16)). Furthermore, in projecting C-initial forms, it is slightly more accurate to start with an i-initial suffix (91.9%) than with an A-suffix (90.4%). This difference is offset, however, by the fact that the A-form is significantly more predictive of the i-form than vice versa (91.9% vs. 88.0%). We conclude that on average, the A-initial suffix has greater accuracy in predicting the remaining forms (91.1%) than the i-initial form (90.0%) or the C-initial form (87.8%).

(16) Asymmetrical mappings among suffixed forms

The simulations described here are based on the entire available lexicon of 952 lexical items. It is plausible to think, however, that a learner would wish to establish the architecture of the grammar (which form is the base, which are derived) early in the acquisition process, before an entire lexicon of data is available. It is therefore interesting to note that the same asymmetry shown in (16) is seen to an even greater extent when the model is trained on smaller data sets consisting of just the most frequent verbs, which are presumably more representative of the learning data available to a typical child. The reason is that the irregularities that lead to ambiguity tend to affect a small number of the most frequent words, which are a larger proportion of the lexicon in a smaller training sets. It therefore appears that the advantage of the A-forms in predicting the remaining forms of the paradigm would be evident not only from the unrealistically large training set employed here, but also from smaller sets of data available to children learning Korean. This result corresponds well to the observation that A-forms are also the ones that typically act as the base of reanalysis in child errors and historical change.

### 3.3. Predictions for innovative phonological reanalysis

According to the single surface base hypothesis, the most informative form is selected as the base form in order to avoid ambiguities when producing inflected forms. We saw in the preceding section that the *-ə/-a* form is generally quite informative in predicting the remaining inflected forms. However, it is not perfect, yielding errors on approximately 8.8% of the forms tested. This naturally leads us to wonder whether cases in which the model is erroneous or uncertain correspond to cases where humans, too, produce innovative forms.

It turns out that many of the errors predicted by the model are also attested as innovations in acquisition and language change, as discussed by Kang (2006) in a sampling of the relevant literature.<sup>7</sup> One example of this is the distinction between /Cə/-, /Cu/-, and /Ci/-final stems (15m-o), all of which undergo elision before *-ə/-a*. For these, the model predicts reanalysis as /Ci/-final verbs: [sə] ~ [səda] ‘stop’ replaced by innovative \*[sida], and [p<sup>h</sup>ə] ~ [p<sup>h</sup>uda] ‘scoop’ replaced by \*[p<sup>h</sup>ida]. Such reanalyses are in fact attested.

Another example concerns the glide in forms like [k<sup>h</sup>jə] ‘crawl’, which in principle could correspond to either /k<sup>h</sup>i-ə/ or /k<sup>h</sup>jə-ə/. The attested/conservative *-ta* form of this verb is [k<sup>h</sup>jəda] (i.e., based on /k<sup>h</sup>jə/), but the model predicts the innovative form \*[k<sup>h</sup>ida], which is also attested as a human innovation. Finally, *-ə/-a* forms neutralize the distinction between stems that aspirate a following consonant and the model predicts that innovations should lack aspiration: [k<sup>h</sup>inə] ~ [k<sup>h</sup>int<sup>h</sup>a] ‘cut’ replaced by \*[k<sup>h</sup>inda], [irə] ~ [ilt<sup>h</sup>a] ‘lose’ replaced by \*[ilda], and so on. Such reanalyses are in fact marginally attested, particularly as child errors in American Korean (Choi 2003). However, as mentioned above, such changes are rarely seen elsewhere (Kang 2006, 194), while the more common change in such forms is in the other direction, i.e., to

extend the tense or aspirated allomorphs  $-t^{\prime}a$ ,  $-t^{\prime}a$ .<sup>8</sup> Further data is required on this point in order to determine whether the child errors in American Korean are representative of what any Korean learner would be tempted to do given reduced input data, or whether they are due to some additional difference in American Korean.

There is also ambiguity in the A-suffixed forms between /C/-final and eliding /CV/-final verbs. Among these, /C/-final verbs are more common in the lexicon, so the model predicts innovative reanalyses in the  $-ta$  form, particularly in replacing  $-C\grave{a}da$  with  $\star-Cta$ . Such reanalyses are attested, but to a limited extent: in particular, they affect /l/-final verbs ((15e)) such as [t'ara] ~ [t'arida] 'follow' ((15g)), replaced by innovative C-final  $\star[t'alda]$ . The model also predicts parallel changes for other /Ci/-final items, such as  $\star[kopt'a]$  instead of [kop<sup>h</sup>ida] 'hungry',  $\star[kipt'a]$  instead of [kip<sup>h</sup>ida] 'happy', and  $\star[camt'a]$  instead of [camgida] 'lock'. Interestingly, it appears that such changes are not attested after consonants other than the liquid.

There are several possible reasons why speakers may actually prefer to preserve /i/ between obstruents. First, it is possible that the /i/ is being employed to break up CC clusters. Usually, illegal /CC/ clusters are repaired by assimilation (normally, changing features of C<sub>1</sub>) in Korean. However, from the point of view of a learner, data concerning /CC/ clusters may be mixed, especially in verbal inflection, since the large number of /i/-initial suffixes give the appearance of epenthesis after /C/-final stems. This is mirrored by the fact that in loanword adaptation, epenthesis of [i] is actually the preferred repair for illegal /CC/ combinations—e.g., English *picnic* adapted as [p<sup>h</sup>ik<sup>h</sup>inik]. It is possible that the preference for preserving [i] in this context reflects a form of epenthesis, at least in child Korean. In this connection, it is relevant to note that children do epenthesize in contexts where adult Korean would have clusters, and that they do so less often in /IC/ clusters than in other /CC/ clusters (Lee and Im 2004). This difference may be due the fact that in their learning data, /l/-final stems pattern with vowel-final stems and take [i]-less form of some /i/-initial suffixes such as (i)myən, (i)lə etc. Alternatively, this asymmetry may be due to some articulatory difference, or perhaps it is an effort to avoid inserting vowels in contexts where they are relatively more perceptible (Fleischhacker 2001). Either way, the fact that our simulations assume perfect knowledge of cluster reduction may give it an unfair advantage in producing /CC/ reanalyses.

A second possible explanation of the discrepancy is that /i/ may be inserted specifically in order to maintain laryngeal properties of C<sub>1</sub>, by avoiding neutralization in pre-consonantal position. Consistent with this idea, Oh (2004) hypothesizes that the use of [i] is favored Output-Output faithfulness constraints which ban alternations in aspiration and tenseness. We might conjecture that [l] ~ [r] alternations are considered less serious than C ~ C<sup>h</sup> alternations (a difference that is also seen, to a limited extent, in loanword adaptation). Alternatively, it could be that preservation of the [i] is favored by Paradigm Contrast constraints (Kenstowicz and Sohn, to appear), since it helps to maintain lexical contrasts between verbs that end in lax, tense, and aspirated obstruents. Under this account, we might expect to find fewer /li/ ~ /l/ contrasts than other /Ci/ ~ /C/ contrasts in the lexicon, creating less pressure to maintain /i/ after /l/.

The third hypothesis is that this [i] insertion is indeed a reflection of the lexical pattern. As it turns out, in present day Korean a high proportion of /Ci/-final stems

actually involve laryngeally marked C's, making /Ci/ a very strong pattern when C is aspirated or tense. Although this trend is weak enough that the model did not pick up on and extend it, perhaps speakers notice it more reliably for some reason, and upon hearing [...C<sup>h</sup>ə] forms they infer /...C<sup>h</sup>i/. Unlike the previous two hypotheses, this account does not seek to explain why the existing lexicon has this pattern, but merely connects the current lexical statistics with the observed behavior of speakers. We currently have no basis for deciding among these competing hypotheses.

There is one final type of phonological error that the model predicts, but which is not reflected in human errors. As we saw above the model, like humans, occasionally reinterprets elided vowels as coming from a different source (★[p<sup>h</sup>ida] instead of [p<sup>h</sup>uda] ‘scoop’). In some cases, however, the result of elision is unambiguous due to vowel harmony of the suffix vowel (-a after [a], [o]). For instance, the form [p<sup>h</sup>a] ‘dig’ is unambiguously /p<sup>h</sup>a+ə/ with harmony of the suffix vowel, since underlying /p<sup>h</sup>i+ə/ would yield surface [p<sup>h</sup>ə] (no harmony). The model is extremely limited in its ability to encode vowel harmony, since it encodes rules that refer to the immediately adjacent phonological context and cannot encode long-distance conditioning environments. Therefore, it occasionally inflects forms like [p<sup>h</sup>a] as ★[p<sup>h</sup>ida], rather than as correct [p<sup>h</sup>ada]. It appears that speakers do not produce similar innovations. We anticipate that a better ability to encode and learn the relation between the stem vowel and the suffix vowel would eliminate such errors.

### 3.4. Predictions for innovative regularizations

The reanalysis based on A-suffix forms also lead to regularization of many irregular verbs. A good example can be found in p-irregular verbs such as [kiw-ə] ~ [kip-t’a] ‘sew’ ((15c) above), for the model predicts regularized C-initial forms, mirrored also in human innovations: ★[kiu-da]. Similarly, for verbs like [na:] ~ [nat’a] ‘get better’, which trigger tensification of a suffix obstruent, the model predicts reanalysis to the attested innovation ★[nat<sup>h</sup>a], or secondarily to [nada], which is also attested in American Korean (Choi 2003).

The model also predicts some changes to irregular verbs which imperfectly resemble attested innovations. For so-called t-irregular verbs ((15h) above) such as [murə] ~ [mu(t)t’a] ‘ask’, the model predicts reanalysis to a regular liquid-final verb: ★[mulda]. Such verbs are indeed partially rebuilt in their C-initial forms, but the innovative form typically preserves the tense stop in the suffix (★[mult’a]) rather than regularizing all the way to ★[mulda]. The innovative form ★[mult’a] innovation is particularly interesting because it creates a verb type that is not found in the pre-existing lexicon. One possibility is that retention of the tense [t’] reflects partial preservation of the older form [mu(t)t’a], perhaps through hypercorrection as suggested by Kang (2006). It is also worth noting, however, that tensification after sonorants is also seen quite regularly with nasal-final stems, where all verb stems cause a suffix-initial consonant to become either aspirated or tense (that is, no verbs like [an-a] ~ [an-da], only [an-t<sup>h</sup>a] ‘do not’ or [an-t’a] ‘hug’). Therefore, it seems possible that the tense stop in ★[mult’a] is part of a broader trend towards tense stops in post-sonorant position—reflecting either a

lexical trend that the model is not picking up on correctly, or motivated by a phonotactic constraint against sonorant+voiced stop sequences (Pater 1999, Hyman 2001).

Another example of a minor discrepancy concerns “lə-irregular” verbs like [irɪrə] ~ [irɪda] ‘reach for’ ((15i)). For these, the model predicts regularization to a liquid-final stem (★[irɪlda]), while human learners prefer to reanalyze them as regular li-final verbs (★[irɪrɪda]). In this case, the number of existing regular /li/ verbs is quite small, leading the model to prefer to treat ambiguous verbs as /l/-final. It is possible that human learners are motivated to retain the [ɪ] in order to avoid the [ld] sequence in hypothetical ★[irɪlda]. It may also be significant that the preferred pattern involves a perceptually minimal [ɪ] ~ □ alternation ([irɪr-ə] ~ [irɪrɪ-da]), rather than a [l] ~ [r] alternation ([irɪr-ə] ~ [irɪl-da]).

Another discrepancy between the attested innovation and the prediction of the model is found in li-irregular verbs. For example, the irregular verb [hɪllə] ~ [hɪrɪda] ‘flow’ show the extension of geminate [ll] from the A-suffix form throughout the paradigm: ★[hɪllɪda], ★[hɪllɪmyən]. As Jun (2007) points out, this innovation is particularly puzzling given the fact that the li-irregular verbs outnumber /li/-final verbs by 160 to 21, (according to Jun (2007) based on Kang and Kim (2004)), and by 49 to 1 in our learning data. One possibility is that the form ★[hɪllɪda] may be encouraged by a desire for elimination of irregular allomorphy or for non-alternating paradigms (Kim 1972, Huh 1985, Choi 1993, Park 2002, Oh 2006, Kenstowicz and Sohn in press, among others), which overrides the analogical pull to robust existing alternations. Another possibility, suggested by Jun (2007), is that the ★[hɪllɪda] is derived from [hɪllə] by a general mapping rule ə → da and the resulting illegal cluster [lld] is repaired by [ɪ] insertion (See section 3.3.).

#### 4. Base selection in the broader context of Korean inflection

The results of the preceding section support the idea that A-forms are, in fact, the most informative forms in predicting properties of other inflected forms. However, this result is based on a schematic comparison of just three affixes (-ə/-a, -ta, -(ɪ)myən), standing in for broader classes (A-suffixes, C-suffixes, i-suffixes). This is clearly an idealization, since in actuality, each class of affixes has many members, with its own segments and frequencies. The size and frequency of these classes is potentially an issue, since if some affix shapes are much more common and more widely used than others, the ubiquitous need to predict their form could make it preferable to choose a base form accordingly. To see how this could have an effect, consider the schematic example in (17), in which there is just a single A-suffix alongside three different C-suffixes. In this example (like in actual Korean), the -a suffix is better at predicting C-suffixes than vice versa. However, since the C-suffixes are perfectly mutually predictable, there is an overall advantage to selecting a C-suffix as base, since the larger number of C-forms makes them better on average.

(17) The role of affix class size, schematically

In/Out	-a	-ta	-ko	-ke	Average
-a	100%	<b>90%</b>	<b>90%</b>	<b>90%</b>	92.5%
-ta	<b>85%</b>	100%	100%	100%	<b>96.3%</b>
-ko	<b>85%</b>	100%	100%	100%	<b>96.3%</b>
-ke	<b>85%</b>	100%	100%	100%	<b>96.3%</b>

In fact, this situation is not unlike actual Korean. In (18) we provide frequency counts from the National Institute of the Korean Language<sup>9</sup>, showing that there are many frequent C-initial and i-initial suffixes. If comparisons are weighted to take into account the number of relevant inflected forms as well as their relative frequency, there is the danger that this could tip the balance (incorrectly) in favor of choosing a form other than an A-suffix as base.

(18) Inventory of most frequent verbal affixes

A-initial		C-initial		i-initial		Other	
ə/a	57894	ta	78116	(i)n	87410	(ni)nta	22141
əsə/asə	11613	nin	60551	(i)l	30545	(si)mnida	9524
ədə/adə	2142	ko	46689	(i)myən	9832	(n)inde	4118
ədaga/adaga	1898	ke	18406	(i)myənsə	4784		
		ci	12144	(i)m	4236		

Why does the large number of C-initial suffixes not influence base selection? One possibility is that learners abstract over broad classes of affixes, much as in the idealized simulation. That is, instead of seeking the most informative affix, perhaps learners seek the best affixal context, grouping sets of affixes that behave alike with respect to phonological and morphological context. We assume that ‘behaving alike’ involves a combination of taking the same stem allomorph in case of irregularity, and also inducing the same set of phonologically predictable alternations and neutralizations. If bases are selected in this more abstract fashion, then the learner may indeed conclude that A-suffixes are the most predictive, even though there happen to be many individual C-suffixes that are mutually predictable.

This idea of “affix grouping” has some intuitive appeal, but it also raises a mystery, since in other known cases the frequency of individual inflected forms does appear to matter.<sup>10</sup> We therefore consider a second possibility, which is that the corpus counts in (18) are simply not representative of spoken child-directed Korean. In fact, this seems quite likely, since the intimate or informal -ə/-a form is highly underrepresented in written texts, while the declarative -ta form is strongly overrepresented. Kim and Phillips (1998) show that in child-directed speech, informal -ə/-a is actually 6.6 times more frequent than declarative -ta.<sup>11</sup> We conclude that in colloquial speech (and especially in child-directed speech), -ə/-a forms are by far the most frequent. Therefore, it is not necessarily advantageous to select a C-initial form in order to be able to predict the large number of other C-initial forms correctly.

This conclusion now turns the question about the role of frequency on its head: could it be the case that the high frequency of -ə/-a alone that creates the observed asymmetry, and that there is no role for informativeness at all? We believe that this

conclusion is not warranted, for several reasons. First, it is important to bear in mind that although the *-ə/-a* form is very frequent, other, more neutralizing forms are also relatively frequent in spoken speech: *-ta* ‘declarative’, *-(nɨ)n* ‘progressive’, *-ko* ‘and’, and so on. It is not at all unlikely that a child might hear a particular verb for the first time used with one of these more neutralizing affixes. However, childrens’ own productions overwhelmingly (80%–100%) involve *-ə/-a* forms, especially in the earliest stages (Kim and Phillips 1998; Lee, Lee and Im 2003). Logically, this means that there should be words that have been heard only in the context of a C-initial suffix, for which the child wants to produce a *-ə/-a* form. This predicts the possibility of innovative reanalyses based on C-initial forms. However, as Kang (2006) shows, these tend not to occur. By imposing a paradigm structure in accordance with the single surface base restriction and by giving the model no means for ‘back-formation’ to infer unknown base forms, we correctly prevent the model from making such reanalyses.

A more subtle hypothesis is that frequency is not the sole explanation of the asymmetry in innovations, but that it is the reason why *-ə/-a* forms are selected as the base, without any need to compare the relative informativeness of different forms. This hypothesis is compatible with the Korean facts, if we take Kim and Phillips’ counts to be representative of the learning data. It also coincides with the more general observation that analogical change tends to favor more frequent base forms (Manczak 1958). This account is unlikely to be sufficient in the long run, however, since there are numerous other cases in which the direction of reanalysis is not predicted straightforwardly by frequency (Hock 1991; Albright 2002). Tellingly, both of the acquisition studies on child morphophonology cited above (Clahsen, Avelado, and Roca 2002; Clahsen, Prüfert, and Eisenbeiß 2002) involve errors based on less frequent forms, and innovations on more frequent 3SG forms. It appears that frequency alone is not sufficient, and that the relative informativeness of inflected forms is also a crucial factor in motivating the direction of reanalysis.

## 5. Conclusion

The model we have presented here attempts to explain a striking asymmetry in the reanalyses seen in Korean verbal inflection, both in child errors and in historical change. In particular, attested reanalyses are overwhelmingly based on ambiguities in A-forms, rather than in other affixal contexts (Kang 2006). This asymmetry is attributed to the structure of the morphological grammar that Korean speakers use to project inflected forms, which uses A-forms to project the remaining inflected forms. We hypothesize that this directionality is learned based on the fact that A-forms provide a better basis for predicting other forms than vice versa. Computational modeling confirms that this predictability relation is in fact true, making the analysis of Korean compatible with other cases investigated so far.

This study leaves a number of open questions. First, the role of frequency has been seen to cooperate with phonological predictiveness in guiding base selection, but the mechanism by which frequency is taken into account requires further clarification. One obstacle to investigating this issue is that the frequency counts of child-directed

spoken language available to us are at best rough estimates, and more comprehensive data is needed. Furthermore, we observed several cases in which the model predicted errors that are not mirrored by attested innovations. In some cases, these discrepancies may be explained by phonological considerations that are not incorporated into the model; others require further empirical investigation.

## Notes

\* We would like to thank the following people for helpful comments and discussion: Bruce Hayes, Jongho Jun, Michael Kenstowicz, Hyang-sook Sohn, and the CIL18 audience. All remaining errors are, of course, our own.

<sup>1</sup> As Cho (1999) documents, simplification of /IC/ clusters is not enforced categorically in inflected verbal forms.

<sup>2</sup> Such reanalyses are frequently seen in nouns: unaffixed [kap] ‘price’ corresponds to [kapsʰ-i] ~ \*[kab-i] ‘price-NOM’ (Kenstowicz 1996; Ko 2006).

<sup>3</sup> The Spanish and German examples cited above are a good example of this: highly frequent 3SG forms are reanalyzed on the basis of less frequent plural or non-third person forms; see Albright (2002) for additional examples.

<sup>4</sup> [www.korean.go.kr//08\\_new/include/Download.jsp?path=OpenPds&sub=1&idx=28](http://www.korean.go.kr//08_new/include/Download.jsp?path=OpenPds&sub=1&idx=28)

<sup>5</sup> An optional process of glide formation that may apply in some A-suffixed forms ([kiə] ~ [kjə:] ‘crawl’) was omitted. In actual learning data, the availability of such variants make for A-suffix forms likely make the A-suffix form less ambiguous and more informative than in the current simulation.

<sup>6</sup> That is, we abstract away from the fact that Korean verb forms may involve long sequences of suffixes, since the only thing that is relevant for determining stem allomorphy is the immediately following suffix, and the only thing that determines affix allomorphy is the immediately preceding context.

<sup>7</sup> Sources: The AKS (1990-1995), Bak (2004), H-W. Choi (2003, 2004), M.-O. Choi (1988, 1993), B.G. Kim (2003), H. Kim (2001, 2002), Park (2002, 2004), Um (1999), Yoo (2000).

<sup>8</sup> Jun (2007), in an acceptability judgement experiment, similarly finds that Korean speakers find the innovative tensification and aspiration to be quite acceptable (e.g. [i-ə] ~ \*[i-kʰo] (norm: [i-kʰo]) ‘to connect’, [sʰa-a] ~ \*[sʰa-kʰo] (norm: [sʰa-kʰo])). Interestingly, such innovation is found even for regular s-final verbs such innovation is unexpected based on an A-form based reanalysis.

<sup>9</sup> [www.korean.go.kr//08\\_new/include/Download.jsp?path=OpenPds&sub=1&idx=60](http://www.korean.go.kr//08_new/include/Download.jsp?path=OpenPds&sub=1&idx=60)

<sup>10</sup> For example, see Albright (2008) for discussion of how frequency influences the direction of leveling in Korean noun paradigms.

<sup>11</sup> Unfortunately, Kim and Phillips (1998) provide data only for mood markers, so it is not possible to determine the relative frequency of other common C-suffixes, or of other common A-suffixes such as the past tense marker *-as* ‘-as’.

### Abstract

French liaison is not to be considered as a unified phenomenon. We underline the interplay of three dynamics. The first is a phonological one aiming to drop final consonants. The second is morphological in nature as its main purpose is the preservation of number and person marks. The third one is orthographical. It promotes the visual form of written words. Contradiction between those three dynamics leads to state of equilibrium. Moreover, we assume that the notion of *liaison* does not apply to such environments as clitic pronouns, pseudo-lexemes put inside an idiom, determiners, or adjectives put in front of a noun, and conclude that the *categorical liaison* does not probably exist at all in French.

**Keywords:** liaison in French, phonological dynamic, morphological dynamic, orthographical dynamic, morpho-syntactic conditions, so-called categorical liaison.

## 1. La liaison en français

### 1.1. Approches et définitions

En règle générale, les mots français à consonne finale voient au cours du moyen-âge cette consonne progressivement cesser d'être prononcée, sauf parfois devant voyelle. C'est le cas de :

*chat, repas, bout, coup, beaucoup, roux*

Prononciation ancienne : ʃat, rəpas, but, kup, bokup, ru(k)s

Prononciation contemporaine : ʃa/, r(ə)pa/, bu/, ku/, boku/, ru/

Toutefois, quelques persistance régionale sont observées. Seguy 1950: 22 écrit ainsi, à propos du français tel qu'il est parlé à Toulouse, que « *dans le midi toutes les*

*lettres se prononcent* ». Il en veut pour preuve le fait que la consonne [k] des mots suivants se prononce encore à Toulouse au milieu du 20<sup>ème</sup> siècle en position finale :

*estomac, broc, escroc, joug, aspect, respect, marc, zinc*

Seguy 1950 parle à ce propos d'*hypercorrection* et l'explique par l'influence de l'usage graphique (l'orthographe) sur l'usage oral. Il est intéressant de relever, à propos de *zinc*, que l'usage « hypercorrect » a fini par triompher en français standard contemporain, où la consonne finale est dorénavant fixe.

Dans certains cas, plutôt que de chute (*amuïssement*) de la consonne finale, il vaut mieux parler de *vocalisation*. C'est ce qui passe, dans les exemples ci-dessus, pour *broc* et *escroc* qui, prononcés initialement [brɔk] et [eskɔk], sont aujourd'hui prononcés [bro] et [eskro].

La flexion du pluriel, consonantique, peut s'accompagner d'un phénomène de vocalisation. C'est ainsi qu'à propos des mots à finale consonantique en [l] au singulier, et vocalisée au pluriel, tels que :

*cheval/chevaux, travail/travaux, ciel/cieus*

*bal/baus, portail/portaus, col/cous, rossignol/rossignous, appel/appeaus*

*fol/fous, sol/sous, agnel/agneaus*

Léon Clédât 1917: 154 propose une approche, caractéristique de sa manière, marquée par un souci de l'usage et des fréquences. Il écrit :

*Les noms qui s'employaient souvent aux deux nombres ont conservé les deux formes ; [...] ceux qui s'employaient surtout ou exclusivement au singulier [...] ont maintenu la forme avec l non vocalisé; [...] ceux qui s'employaient surtout au pluriel [...] ont refait le singulier sur le pluriel.*<sup>1</sup>

---

1 On pourrait s'étonner de la notion de *vocalisation* à propos du passage, par exemple, de *fol* à *fous*. Pourquoi ne pas dire : « amuïssement de la consonne [l] accompagné d'une variation de la voyelle qui la précède immédiatement (passage de [ɔ] à [u]) » ? Ce serait sans compter sans le fait que *fous* se prononçait [fous]. Il en va de même avec *agneaux* et *travaux*, qui se sont prononcés [aɲəus] et [travaus]. Le souvenir des diphtongues [ɔu], [au] etc. s'est conservé dans l'orthographe.

Considérons à présent la phénoménologie de la *liaison*. Il s'agit également d'un phénomène d'*amuïssement* ou de *vocalisation* d'une consonne finale lorsqu' elle est suivie par une autre consonne. Dans le cas considéré, la consonne constitue le phonème initial du mot suivant. Clédat 1917: 163 écrit encore :

*La liaison des mots entre eux avait pour effet, au moyen-âge, d'amiïir ou de vocaliser la consonne finale, qui se maintenait naturellement devant voyelle comme à la pause. Elle a pour effet aujourd'hui de maintenir devant voyelle la consonne finale lorsqu'elle est tombée partout ailleurs, et c'est ce que nous nommons proprement une "liaison".*

Quelques phénomènes de *vocalisation* de la consonne finale se maintenant « *naturellement devant voyelle comme à la pause* » (pour reprendre les mots de Clédat) se sont conservés en français contemporain. Ainsi :

*Un bel enfant* la consonne finale de l'adjectif est conservée devant la voyelle du nom suivant

*Un beau château* la consonne finale [l] est vocalisée devant la consonne initiale [ʃ] du mot suivant<sup>2</sup>.

Considérons enfin un exemple d'*amuïssement* de la consonne finale se maintenant devant voyelle :

ze boku travaje (*J'ai beaucoup travaillé*)

ze bokupapri (*J'ai beaucoup appris*)

Nous faisons donc nôtre la définition synthétique de Clédat 1917, selon qui la *liaison* est un phénomène de « non-amuïssement » de la consonne finale d'un mot devant la voyelle initiale du mot suivant.

---

2 En réalité, l'évolution comporte trois étapes, la dernière étant une « dé-diphtongation » de [beo]. On a donc : [bel] → [beo] → [bo] (prononciation contemporaine). En adoptant un traitement strictement phonologique, nous nous écartons donc ici d'un traitement par supplétion morpholexicale, tel celui de Bonami, Boyé & Tseng 2005.

## 1.2. Cinq questions concernant la liaison

a) Certains mots ne permettent jamais la chute de leur consonne finale :

*but, troc, sac, trac, net, brut, sec, avec* (en français moderne standard)

Il ne s'ensuit pas qu'ils se lient devant voyelle ou qu'ils resyllabent avec la voyelle suivante : *sak-o-rãʒ* vs \**sa-ko-rãʒ* (*sac/orange*). De plus, certaines consonnes ne sont jamais liantes :

Les seules consonnes passibles de lier sont : *s, z, x, t, d, n, r, p, g*. Pour *p* et *g* la liaison est limitée aux mots *trop, beaucoup* et *long* (Grammont 1933: 42).

b) Certains mots ayant perdu la consonne finale, encore présente dans le paradigme, ne se lient jamais devant voyelle : *drap, galop, coup*. Clédat 1917 favorise à nouveau ici une explication fréquentielle : « L'emploi très fréquent d'un mot à la pause est aussi de nature à protéger la consonne finale (*brut, but, sec, las*) ».

c) Une liaison normalement autorisée peut être impossible dans certains environnements :

*J'ai travaillé beaucoup à Paris* : ʒe travaje boku/ a pari (\* ʒe **tr**avaje bokupa pari),

*Vous allez au zoo* (! vuzalezozo)

*Cela il l'a beaucoup été* (! s(ə)laillabokupete)

d) Une liaison autorisée peut n'être que facultative dans un contexte donné :

*J'ai beaucoup appris* : ʒe bokup **ap**ri ; ʒe boku/ **ap**ri

e) Dans certaines suites, la liaison semble présenter présente un caractère d'obligation :

*deux amis* (dø**z** ami) *très ému* (trɛ**z** emy)

\* dø/ ami

\* trɛ/emy

Les consonnes finales graphiques du français se laissent classer en 4 catégories :

- les consonnes finales qui ont définitivement chuté et qui, bien que présentes dans le paradigme, ne font jamais surface et ne lient donc pas

- les consonnes finales qui ne sont pas tombées et qui ne se lient jamais devant voyelle
- les consonnes finales qui peuvent se lier devant voyelle
- les consonnes finales qui doivent se lier devant voyelle

On ne s'intéressera ici qu'aux problèmes c), d) et e), et plus particulièrement au problème e).

### 1.3. Les effets de la liaison sur la syllabation

Soit l'expression *deux aimables enfants*. Les deux liaisons, obligatoires, sont signalées par des soulignements. Marquons la syllabation en scandant l'expression comme si elle faisait partie d'un vers classique. Cela donne *dø-ze-ma-blə-zã-fã* et non \**døz-e-ma-bləz-ã-fã*.

De la même façon, l'expression *on a le temps* est syllabée *õ-na-l(ə)-tã* et non *õn-a-l(ə)-tã*. En somme, la liaison fait fi de la séparation entre les mots. C'est ce qu'écrit Delattre 1951 :

*Le français enchaîne les mots, quitte à perdre de vue leurs limites. D'où l'impression unie, liée, que donne la chaîne parlée. Les syllabes ne cherchent aucunement à éviter de chevaucher les mots (...). La consonne d'enchaînement peut être une consonne qui se prononcerait de toute façon dans le mot isolé : petite amie ('enchaînement' proprement dit) ou une consonne qui serait muette dans le mot isolé: petit ami ('liaison'). Dans les deux cas, on s'efforcera d'ouvrir la dernière syllabe du premier mot comme si c'était la syllabe intérieure d'un mot: pe-ti-tesse, et de faire succéder les syllabes d'une manière aussi coulante, unie, liée, que si c'étaient les syllabes successives d'un mot.*

Cette tendance à la *syllabation ouverte est typique du français*. La diachronie de nombreuses langues romanes montre un mouvement constant et radical vers cette syllabation ouverte. La chute des consonnes finales n'en est que la conséquence (cf. Martinet 1955). Le sandhi externe qui caractérise la liaison enchaînée et resyllabée constitue la marque de cette dynamique profonde.

On sait que la fréquence de la liaison dépend pour partie du niveau stylistique

(Grammont 1933, Delattre 1955, 1966, Encrevé 1988). La conversation ordinaire est pauvre en liaison, la conversation soignée un peu plus riche. Quant à la parole publique (conférence, discours, théâtre etc.), elle présente une fréquence importante avec des phénomènes typiques tels que le non enchaînement (Encrevé 1988, Laks 2007). De façon générale, comme l'a montré Encrevé, la liaison se présente comme un processus sociolinguistique inversé dont la fréquence est liée au niveau d'hétérosurveillance sociale qui s'exerce sur le locuteur.

## **2. Les limites d'une conception strictement phonologique la liaison en français**

Dans la longue histoire des traitements de la liaison, qui commence dès l'institution du français au 16<sup>ème</sup> siècle (Palsgrave 1530), les descriptions phénoménologiques abondent, de même que les cacologies (Thurot 1881-1883). Au 19<sup>ème</sup> siècle et dans la première moitié du 20<sup>ème</sup> encore, l'analyse phonologique du phénomène est adossée à un corpus descriptif précis et détaillé. La liaison y apparaît comme un phénomène complexe, profondément hétérogène et variable, conditionné par des facteurs très divers relevant de niveaux linguistiques différents (phonétique et euphonie, rythmique et accent, fréquence lexicale et niveau stylistique, type de construction syntaxique, force du lien syntactico-sémantique, sémantique et pragmatique du composé). En proposant un traitement formel de niveau strictement phonologique, en considérant la liaison comme un phénomène stable et univoque et en restreignant les données considérées aux descriptions normatives de Fouché 1959, la phonologie générative introduit une rupture formelle, conceptuelle et empirique dans cette histoire.

### *2.1. La liaison en phonologie générative*

Première application de la phonologie générative au français et parmi les toutes premières mises en œuvre du système de SPE (Chomsky & Halle 1968), Schane 1967, 1968 définit la liaison comme un phénomène dont l'analyse serait strictement circonscriptible au niveau phonologique. Postulant au niveau lexical une représentation abstraite qui contient toujours la Consonne Liée (CL), il reprend sans le dire le concept de consonne latente (Damourette et Pichon) et suppose qu'elle est toujours réalisée dans un contexte d'initiale à Voyelle. La liaison est alors un **processus** par lequel la CL se trouve être prononcée, parce qu'elle ne chute pas, et ne pas chuter

parce que l'initiale Voyelle la protège de la chute. Cette conception, qui fait fi de toute la complexité phénoménologique décrite, met en œuvre un formalisme strictement phonologique. Sous une forme ou une autre, ce formalisme qui a perduré pendant vingt ans se lit comme une tautologie. En effet, quelles que soient les adaptations à des cadres théoriques génératifs et post-génératifs différents depuis la proposition initiale de Schane le traitement présuppose une Consonne Liée lexicalement présente qui se prononce devant initiale vocalique et qui chute partout ailleurs. Sous les diverses sophistications formelles, on ne retrouve rien d'autre que la définition normative et pédagogique des manuels « La liaison consiste à prononcer une consonne finale de mot, muette partout ailleurs, lorsque le mot suivant commence par une voyelle ». Ce type de stipulation repose sur une hypothèse lexicale elle-même circulaire (i.e. c'est la présence éventuelle d'une CL à l'oral qui fait postuler une CL) et n'atteint pas à l'adéquation descriptive et explicative requise. Reprenant cette approche, les traitements formels par représentation sous-jacente de CL et processus de chute, ou de non liage syllabique, doivent eux aussi être considérés comme de pures stipulations qui n'expliquent rien.

## 2.2. *En réaction contre Shane*

A l'opposé de cette conception, Morin & Kaye 1982 réintroduisaient en phonologie du français la très riche analyse descriptive des conditionnements morphologiques, syntaxiques et même sémantiques du sandhi et en proposaient une analyse qui cadrerait mal avec la vitrification empirique promue par la phonologie et la syntaxe génératives standards sous couvert d'algorithmique abstraite (Laks 2005). La question reste en effet celle des contraintes qui expliquent et motivent la non réalisation de la liaison dans des contextes où elle est phonologiquement possible, ce qui représente la très grande majorité des cas. Ceci constitue le problème de la liaison du point de vue épistémologique et phénoménologique. Dans des contextes phonologiques identiques (C-V), la liaison présente une tripartition : liaisons obligatoires, variables et impossibles. C'est cette tripartition qui doit être d'abord décrite et si possible motivée, à défaut d'être totalement explicitée.

Sensibles à cette problématique classique, au sein même de la grammaire générative, un certain nombre de travaux plus détaillés sur la liaison (Milner 1967, Selkirk, 1972, 1981, 1984) ont tenté de préciser les contraintes syntaxiques qui conditionnent la liaison en opérationnalisant notamment la force du lien syntaxique évalué en nombre de frontières majeures entre les mots. Ces analyses, fondées sur le

réajustement des limites de mots pour les rendre poreuses et accessibles à la liaison, ou étanches et bloquantes, n'ont donné que très peu de résultats, car ils partageaient une conception aprioriste et rigide de la morphologie (mots et limites) et de la syntaxe (catégories et rection) débouchant sur une conception *ad hoc* de la notion de cohésion ou de force du lien. Dans des analyses présentées ailleurs et reprises ici, nous défendons *a contrario* qu'il faut partir des phénoménologies de l'oral en français, car ce sont elles qui attestent de la cohésion ou la force du lien. Sont prononcés comme un groupe unique les éléments qui sont en relation forte. On en déduira alors une syntaxe et une morphologie adéquates, nécessairement plastiques, variables, hétérogènes et déformables.

### 2.3. *La leçon des analyses anciennes*

Les positions classiques, antérieures à Schane, avaient parfaitement saisi ce point. Grammont 1914, 1933, Fouché 1959, Martinon 1913 et Clédat 1917 tâchent d'expliquer non la prononciation d'une consonne, muette partout ailleurs que devant mot à initiale Voyelle, ce qui est trivial, mais les contraintes, conditions et motivations de la liaison ou de son absence. **Les notions de cohésion syntaxique, sémantique, voire pragmatique y jouent un rôle central.**

## 3. Deux approches explicatives du phénomène de liaison en français

### 3.1. *La spécificité de la prosodie du français et son corrélat, à savoir le caractère flou des limites de mot en français*

Comme on le sait, le français, ne connaît à l'oral que des groupes intonatifs, groupes accentuels, groupes de souffle (selon les auteurs) : toutes entités qui correspondent à une longue suite de morphèmes sans césure interne d'aucune sorte, suite que l'on a coutume de désigner sous le nom de *mot phonologique*.

On aura garde de confondre la notion de mot phonologique avec celle de mot grammatical ou lexical : c'en est la négation même. Dire que le français ne connaît à l'oral que des mots phonologiques, c'est précisément dire que la notion banale de mot n'y a aucun statut et que les tronçons auxquels nous sommes accoutumés l'écriture n'y apparaissent pas. Contrairement en effet aux langues dites *nexus* qui conservent une

identité phonétique aux éléments qu'elles agrègent à une unité principale, le français est une langue cursus qui fond les éléments composés en une unité unique indifférenciée (Pulgram 1970). Il s'ensuit des homophonies souvent relevées : *les petits pois sont verts/ les petits poissons verts, un port très joliment peint/ un portrait joliment peint, un nain valide/ un invalide* etc.

Martinet 1965 rend compte de façon définitive du phénomène : « Il y a longtemps qu'on a fait remarquer que, si le français n'avait pas de graphie traditionnelle, il y a beaucoup de chances pour que quelque explorateur linguiste venu d'un autre continent soit tenté d'écrire en un seul mot, *jlaluidonne*, ce qu'on orthographie en fait en quatre mots ».

Il existe en linguistique française un très riche corpus de travaux qui reprennent et analysent l'idée fondamentale selon laquelle, en français, le mot ne constitue pas une unité phonologique et ne possède aucun statut théorique ou formel défini (Blanche-Benveniste & Chervel 1969: 211, Damourette & Pichon 1911-1927: 182, Troubetzkoy 1939: 296, 313, Pulgram 1970, Bybee 2001: 30, Morin & Kaye 1982: 291 et sv, Selkirk 1972). Ce n'est que dans la forme graphique, la tradition orthographique et la norme académique qu'il reçoit une délimitation précise car, comme le rappelle Catach 1968, « l'orthographe commence avec la séparation des mots ».

### 3.2. *Le rôle de la graphie dans la conservation des consonnes*

La graphie a joué depuis le 13<sup>ème</sup> siècle un rôle de conservatoire de ces consonnes qui avaient chuté et ne transparaisaient plus éventuellement que dans le paradigme. Tout le travail dérivationnel de la langue s'est normativement appuyé sur ces consonnes graphiques (*long/longuement* etc.), renforçant leur statut de *consonnes latentes* selon la définition qu'en a donné Pichon 1938. On ne peut donc traiter cognitivement la liaison en faisant abstraction de la forme graphique qui constitue le réservoir interne (cognitif) et externe (dictionnaires orthographiques) des consonnes liées. Ainsi pour tout français, bien qu'il ne l'ait jamais prononcé en dehors de l'hymne national, *sang-impur* est une liaison possible (du moins non interdite ou impossible). Il en est de même de *salut-à-vous braves soldats du 17<sup>ème</sup>*, un *long-été* (mais *de long/ en large*), *pot-à-lait* (mais *pot/ à tabac*). *A contrario*, comme le souligne Martinon 1913, *pas-t-à moi* est une faute d'orthographe orale, un *pataquès* (c'est l'origine du mot d'ailleurs) !

C'est pourquoi, comme nous l'avons défendu ailleurs dans Laks 2005, « nous proposons d'inscrire *l'identité visuelle du mot* dans la représentation cognitive en posant comme entrées lexicales des constructions auto-segmentalisées comprenant, outre des lignes phonologiques, sémantiques et syntaxiques, *une ligne auto-segmentale de représentation graphique* comprenant au moins la consonne finale et la limite de mot graphique, car, pour maîtriser les liaisons, spécialement celles postposées à une catégorie principale qui sont facultatives et peu fréquentes, « il faut se représenter mentalement le mot écrit ».

Ceci permet de rendre compte notamment du marquage possible des liaisons optionnelles dans des registres de langue très formels : *les gens habitués à faire cela*, *un événement imprévu*, *le temps aux plus belles choses se plaît à faire un affront*.

#### 4. Trois types de pseudo-liaison obligatoire

Par définition, la liaison est un phénomène qui met en jeu la consonne finale d'un lexème et la voyelle initiale du lexème suivant. Il suit qu'on ne saurait parler de liaison quand des unités autres que les lexèmes, notamment des affixes ou des pseudo-morphèmes faisant partie d'une locution, perdent leur consonne finale devant voyelle. Comme nous le verrons, les unités concernées sont extrêmement nombreuses, et exhibent toutes la liaison prétendument obligatoire. Leur exclusion de la problématique de la liaison variable renforce ainsi la thèse selon laquelle les liaisons obligatoires *per se* sont rares, pour ne pas dire inexistantes.

##### 4.1 Premier type de pseudo-liaison : l'allomorphie de certains préfixes

Soient par exemple les deux variantes *bi-* et *bis-* du préfixe signifiant à peu près « deux » ou « deux fois ». La forme longue [biz] figure devant voyelle ; la forme brève [bi] figure devant consonne : *bisaïeul* vs *biréacteur*. Il s'agit incontestablement d'un phénomène de sandhi externe, mais comme il ne met pas en cause un couple de lexèmes, on parle à son propos non de *liaison*, mais d'*allomorphie* (s'il fallait parler de liaison dans un cas de ce genre, il faudrait alors aussi parler de liaison en cas d'allomorphie d'un radical devant un suffixe à initiale vocalique : *petit* /*petit-esse*). Citons quelques autres préfixes de ce type : *tri-/tris-*, *dé-/dés-*, *mé-/més-*. Un cas proche concerne un phénomène de dénasalisation de la voyelle finale devant la voyelle initiale du radical :

*non-* [nɔ̃] / *non-* [nɔn] (*non-actif, non-aligné, non-engagé*), *pan-* [pã] / *pan* [pan] (*panthéiste, panaméricain*). On peut encore citer les préfixes *sans-* et *sous-*. Dans leur cas, leur caractère de préfixe est indiscutable, du fait de la présence du trait d'union : *sans-abri, sans-emploi ; sous-alimenté, sous-homme, sous-officier*.

Quand le trait d'union est absent, l'appartenance à la catégorie des préfixes peut être mis en doute. Cependant, comme le montre Mathieu-Colas 1993, l'alternative *trait d'union/absence de trait d'union* est extrêmement fréquente. Il n'est que de prendre deux des exemples ci-dessus. Les mots *sans-abri, sans-emploi* ont un trait d'union quand ils sont employés comme noms et ils le perdent, sans raison, dans leur emploi adjectival :

*un travailleur sans emploi ; une famille sans abri*

Ces exemples illustrent deux cas de *pseudo-liaison obligatoire* : le segment *sans* n'y est pas une préposition mais un préfixe. Voici d'autres exemples d'expressions à préfixe *sans-* et *sous-*, qui exhibent le même comportement :

*sans apprêt, sans effort, sans égal, sans exception, sans excès, sans objet*  
*sous abri, sous aucun prétexte, sous anesthésie, sous influence, sous un faux nom*

#### 4.2. Deuxième type de pseudo-liaison : l'allomorphie de certains pronoms clitiques

Considérons les clitiques ayant une forme longue et une forme courte, tels les pronoms personnels : *nous* [nu/nuz], *vous* [vu/vuz], *ils* [il/ilz], *elles* [ɛl/ɛlz], *on* [ɔ̃/ɔ̃n], *en* [ã/ãn].

Si on suit l'analyse de Miller 1991, les pronoms clitiques sont assimilables à des affixes, et ce cas ne serait, du coup, pas distinct du précédent. Ce phénomène est bien extérieur à la problématique de la liaison en français. Les pronoms personnels clitiques s'unissent prosodiquement (et graphiquement, dans certaines langues, et même en français, pour *quelques-uns*) à un verbe, soit à gauche, soit à droite :

***Tu*** viendras (pronom *proclitique*)

Viendras-***tu*** ? (pronom *enclitique*)

Dans le deuxième exemple, le clitique porte un accent tonique évidemment non

intrinsèque : c'est l'accent de groupe. On en déduit que les pronoms *moi, toi, lui, nous, vous, leur* quand ils sont au cas datif immédiatement à droite d'un verbe sont des pronoms *enclitiques accentogènes*, dans les termes de Garde 1968 :

*Dis-moi la vérité ! Prête-nous 10 € !*

De plus, ces clitiques peuvent s'enchaîner les uns aux autres :

*Pierre a oublié son parapluie. Je le lui dirai* (chaîne de proclitiques)

*Ce livre m'intéresse. Prête-le moi* (chaîne d'enclitiques)

De façon obligatoire, dans les chaînes de proclitiques, les pronoms personnels à consonne finale (*on, nous, vous, ils*) réalisent cette consonne devant les clitiques à voyelle initiale (*en, y*) ainsi que devant un verbe à voyelle initiale : *Je vous en ai parlé.*

Au cas des pronoms personnels proclitiques à consonne finale, il faut associer celui du pronom relatif proclitique *dont* : *les gens dont on parle.*

De façon obligatoire également, dans une chaîne d'enclitiques, l'éventuelle consonne finale du verbe qui la précède est réalisée devant un enclitique à initiale Voyelle, et l'éventuelle consonne finale d'un clitique se réalise si le clitique suivant est à initiale vocalique : *Fais-y attention ; donne-nous en.*

Quand le verbe se termine par une voyelle, il se produit une sorte de pataquès grammatical obligatoire entériné par l'orthographe :

*Vas-y*

*Chante-t-il ? Viendra-t-il ?*

Parce que tous ces pronoms clitiques sont pour nous des flexions (à la fois personnelles et casuelles) et non des mots, nous les excluons théoriquement de la phénoménologie de la *liaison en français*. Cela réduit d'autant la part des liaisons dites obligatoires, comme nous l'avons déjà signalé.

La question peut être légitimement posée de savoir si les adverbes d'intensité ou

de degré *fort, très, bien, trop, tout, plus* et *moins* ne sont des proclitiques des adjectifs :

*C'est bien agréable*

En français classique, le trait d'union est usuel entre *très* et l'adjectif : *je suis votre très-obéissant serviteur*. Le caractère obligatoire de la liaison semble toutefois dans le cas des autres adverbes ne pas avoir un caractère absolu.

#### 4.3. Troisième type de pseudo-liaison : à l'intérieur des expressions locutionnelles

Parmi les expressions adverbiales locutionnelles colligées par Gross 1986, on en relève environ 60 qui comportent un phénomène de sandhi externe obligatoire, telles :

*de fond en comble, au pis aller, comme tout un chacun, à bras ouverts, du tout au tout, au cas où, en temps utile, avis aux amateurs, en tout et pour tout, bout à bout, c'est-à-dire, le cas échéant, comme par un fait exprès, mais enfin !, contre vents et marées, mieux encore, corps et âme, mot à mot, corps et biens, d'ores et déjà, petit à petit, d'un bout à l'autre, pour rien au monde, d'un instant à l'autre, de bout en bout, qui pis est, qui plus est, tant et plus ...*

Pour soutenir l'idée qu'il y a des liaisons au sein des locutions, il faudrait apporter la preuve que leurs composants, séparés par des espaces typographiques, sont des mots. Mais ce ne semble pas être le cas. Une expression comme le mot *pomme de terre* pourrait aussi bien s'écrire *pommedeterre* ; une évolution de la convention orthographique est encore possible, comme ç'a été le cas pour *lorsque* (< *lors que*), *quelquefois* (< *quelque fois*) et *puisque* (< *puis que*). Dans *pomme de terre*, les éléments *pomme* et *terre* ne contribuent pas au sens global du mot. Ce sont des signifiants qui ont été dépossédés de leur signifié. Ayant été déchus de leur signifié, ils ne sont plus des signifiants : ni lexèmes, ni morphèmes. Dans *lorsque* et *puisque*, ou encore dans *lierre, nombril, aujourd'hui, dinde, belle lurette, en nage*, les éléments constitutifs étymologiques ne sont pas reconnus par les locuteurs comme étant des morphèmes. Dans d'autres expressions, telles *de fond en comble, comme tout un chacun, d'ores et déjà*, certains éléments peuvent être reconnus isolément, mais on ne parvient pas à calculer le sens de l'ensemble à partir d'eux. Ce sont tout compte fait des suites de phonèmes, autrement dit des *mots simples*. On ne saurait donc y trouver des liaisons.

Voilà pourquoi il faut, si on se place du point de vue synchronique, éliminer de la problématique de la *liaison* les phénomènes de sandhi (interne) observables au sein des locutions. Nous les appelons *phénomènes de soudage*.

#### 4.4. Première conclusion

Dans la littérature sur la liaison, beaucoup d'exemples sont hors de propos, qui concernent des préfixes, des clitiques et des composants non significatifs à l'intérieur de locutions. Tous ces cas, qui mettent en cause des expressions extrêmement fréquentes, sont réputés à tort concerner le phénomène de la liaison obligatoire. Celui-ci se révèle donc être moins fréquent qu'on le croit. D'autres phénomènes particuliers, qui font l'objet de la partie suivante de cet article, vont nous conduire à remettre en question la notion même de *liaison obligatoire*.

### 5. Le soudage au sein du *bloc déterminant* du Syntagme Nominal doit être distingué de la liaison

Appelons *bloc déterminant dans le SN* l'ensemble formé par le ou les déterminants au sens strict du terme, suivi(s) d'un éventuel adjectif antéposé :

*quelques amis*

*plusieurs autres amis*

*les autres anciens amis*

#### 5.1. Le soudage de l'adjectif antéposé et du nom qu'il détermine

L'essentiel sur la composition soudée de l'adjectif antéposé et du nom qu'il détermine a été dit par Grammont 1933, mais dans des termes assez généraux :

*Il est de règle en français, d'une manière générale, que les liaisons consonantiques se font toujours dans l'intérieur d'un groupe rythmique et ne se font jamais d'un groupe rythmique au suivant (...). Ainsi l'adjectif qui précède le nom fait partie du même groupe rythmique que le substantif qu'il qualifie et sa consonne finale se lie; mais quand l'adjectif est placé après le nom dont il est attribut, il appartient à un autre groupe rythmique et la consonne finale du nom*

*ne se lie pas sur lui.*

Il est de fait frappant de constater que l'adjectif antéposé se lie, en général de façon obligatoire, avec le nom qu'il détermine, alors que l'adjectif postposé ne se lie pas au nom qu'il détermine :

*grand ami, sérieux échec* [grãtami], [serjøzeʃɛk] vs \*[grãami], ?[serjøʃɛk]  
*mort affreuse, maison agréable* \*[mɔʁtafrøz], \*[mezɔ̃nagreabl]

Le même phénomène s'observe quand c'est la flexion vocalique du pluriel de l'adjectif qui se lie au nom qu'il détermine :

*de beaux enfants* [dəbozãfã] vs \*[dəboãfã]  
*d'agréables amitiés* [dagreabləzamtje] vs \*[dagreablamtje]

Tous les adjectifs antéposables ont-ils cette propriété ? Une étude au cas par cas de cette catégorie devrait apporter une réponse. Les adjectifs antéposés les plus fréquents qui peuvent se lier le font obligatoirement (cf. Wilmet 2003: 239 et sqq.). Voici ceux qui s'antéposent à 96,72 % selon Wilmet : *grand, petit, bon, jeune, beau, vieux*. Par exemple, s'antéposent et se lient :

- les « caractérisants non stricts, numéraux et personnels » (Wilmet) : numéraux ordinaux, l'adjectif *propre* (*mes propres opinions*), les adjectifs préfixés en *in-* (*d'inutiles efforts*)
- les adjectifs à sens relatif (*de petits éléphants ; de gigantesques abeilles*)
- les couples d'adjectifs contradictoires qui « installent le nom au centre d'une filière » (Wilmet) : *nouveaux amis/anciens amis*
- les adjectifs à redondance ou affinité sémique (*regrettables agissements, rudes épreuves, chers amis*).

## 5.2. Le soudage du déterminant avec le nom qu'il détermine

Les déterminants monosyllabiques, quand ils précèdent immédiatement le nom qu'ils déterminent, se lient obligatoirement quand ils ont une finale consonantique. Sont concernés, entre autres :

- les articles : *les, des, un*
- les possessifs et apparentés : *mes, nos, mon, les propres N*
- les démonstratifs : *cet, ces*
- des quantifieurs de divers types : *aucun, plusieurs, quelques, tout ; deux, trois, cent ; différents, divers, certains ; les mêmes, les autres ; le premier, le second ; le dernier ; le prochain ; de fréquents, d'innombrables, de nombreux*

Le sandhi interne est de mise. Il existe toutefois des exceptions ponctuelles. S'agissant par exemple des déterminants numéraux cardinaux, on rencontre certes par exemple *deux euros* [døzøro] ou [døøro]. Il n'en reste pas moins que la liaison des numéraux cardinaux est en règle générale obligatoire :

*deux ans, deux enfants, trois amis, dix ans, cent ans ...*

Dans la logique morphosyntaxique que nous adoptons, ces cas ne correspondent donc pas à des liaisons, mais de composition soudée, ou partiellement soudée. Le(s) déterminant(s) se soude(nt) au nom qu'il(s) détermine(nt). On a vu précédemment que les adjectifs antéposés se soudent au nom qu'ils déterminent. Les différents éléments du bloc déterminant se soudent au nom qu'ils déterminent. « Soudure » signifie que :

- ils forment un bloc prosodique tel que c'est la dernière syllabe (ou l'éventuelle unique syllabe) du nom tête qui porte l'accent du SN tout entier
- aucune insertion n'est possible entre les éléments du groupe, mises à part certaines incisives.

Les éléments du bloc déterminant ont donc deux des trois principales propriétés reconnues aux clitiques. Il leur manque celle d'être des monosyllabes. Si les éléments du bloc pouvaient être assimilés à des clitiques, on pourrait alors faire la généralisation suivante :

*La liaison obligatoire n'existe pas. Elle ne correspond pas à un phénomène de l'oral, mais à un soudage morpho-lexical produit par l'usage.*

## **Conclusion**

Les principaux facteurs explicatifs de la liaison en français ont été identifiés par

la tradition grammaticale (Clédat, Grammont, Martinet notamment). Mais ces analyses sont trop générales : elles ne sont pas explicites, elles ont donc un pouvoir prédictif faible. Pour remédier à ces inconvénients, il faudrait construire une grammaire des environnements syntaxiques pertinents, connectée à un dictionnaire exhaustif des mots liaisonnants et non liaisonnants. Un tel dictionnaire serait composé de :

- un glossaire des mots à consonne finale (au singulier) qui peuvent se lier
- un glossaire des mots à consonne finale (au singulier) qui ne peuvent pas se lier

Le dictionnaire comporterait aussi des glossaires d'expressions parfois identifiées à tort comme liaisonnantes, mais relevant en fait des phénomènes de *pseudo-liaison* (§ 4) et de *soudage* (§ 5) : clitiques à consonne finale, éléments internes aux locutions, adjectifs antéposables. Une grammaire spécifierait en outre, par exemple :

- les environnements syntaxiques propices à la liaison optionnelle des flexions : par exemple, dans les verbes, la liaison entre l'auxiliaire et le participe passé ; dans les expressions à verbe support, la liaison entre le verbe support et le prédicats ; dans le SN, la liaison de la tête nominale avec un adjectif post-posé ; dans la relation Nom-Adjectif Relationnel (*les bières allemandes, les conflits armés*) ; dans les coordinations de constituants du même ordre (*belles et jolies ; parents et enfants*)
- les environnements syntaxiques qui interdisent toute liaison, par exemple entre les syntagmes déplacés à gauche et le reste de la phrase (ex. *à quels amis as-tu parlé* [\*amizaty] ; *quand arriveras-tu ?* [\*kâta]).

# Convergence and Divergence in Language Obsolescence

Charles B. Chang\*

cbchang@post.harvard.edu

## Abstract

Previous research on language attrition has distinguished between internally and externally motivated change and between convergent and divergent change, with most literature focusing on speech communities that have undergone either one or the other type of change. In this paper, I argue that these types of change may coexist within the same community or even the same speaker, with the result that the obsolescing language becomes simultaneously more similar to and more different from the contact language. The results of a cross-generational acoustic study of Southeastern Pomo (Northern Hokan, Pomoan) indicate that in the domain of phonetics and phonology, the speech of the last fluent generation has converged with English in some ways and diverged from it in other ways.

**Keywords:** language contact, obsolescence, sound change, convergence, divergence.

## 1. Introduction

The study of language attrition has generally focused on characterizing how and why changes come about in an obsolescing language vis-à-vis earlier, more robust stages of the language. Change may occur as a result of external influence from a dominant language in the community or language-internal dynamics having nothing to do with the dominant language. When change is externally motivated, the obsolescing language may come to approximate features of the dominant language; conversely, external influence may cause salient features of the obsolescing language not found in

---

\* This work was supported by a Jacob K. Javits Fellowship and fieldwork funding from the Department of Linguistics at the University of California, Berkeley. I am grateful to the Pomoists who generously made their notes and recordings available to other linguists; to all the Southeastern Pomo speakers who were willing to be recorded; to Mark Kaiser and Donna Fenton for help with accessing materials from the Berkeley Language Center and the Survey of California and Other Indian Languages; to Thera Crane and Shira Katseff for collecting useful language background data; to Andrew Garrett, Leanne Hinton, Keith Johnson, members of a field methods course on Southeastern Pomo, and audiences at ASA 154, SSILA 2008, and CIL 18 for their insightful comments and feedback; and to Loretta Kelsey and Robert Geary for all of their help and their endless patience. Any errors are my own.

the dominant language to be enhanced, thus further differentiating the obsolescing language from the dominant language. In short, externally motivated change may result in either convergence with or divergence from the dominant language. In a similar way, internally motivated change, by virtue of its independence from the influence of an outside language, introduces features into the obsolescing language that may happen to converge with the dominant language or to diverge from it. Whether or not the change is convergent or divergent, then, depends upon the nature of the languages involved.

Though externally motivated change and internally motivated change are often referred to in terms of a dichotomy of opposing categories, logically they are not mutually exclusive types of change. As Dorian (1993) cautions, it can be difficult to tell whether a particular change in an obsolescing language is due exclusively to external influence from a dominant language, exclusively to language-internal dynamics, or to some combination of external and internal pressures when they would both push the language in the same direction. Furthermore, it is likely for a language to be undergoing changes due to internal pressures at the same time that it is being affected separately by contact with another language.

Given that an obsolescing language may undergo externally motivated changes and internally motivated changes and that both types of change may be convergent or divergent, it stands to reason that it should be possible for an obsolescing language to show both convergent and divergent change with respect to the contact language. Nonetheless, the literature on language attrition has largely focused on cases of either one or the other, rather than on cases of both happening at the same time. In this paper, I draw on evidence from a cross-generational acoustic study of five speakers of Southeastern Pomo to argue that these types of change may indeed coexist within the same community or even the same speaker, with the result that the obsolescing language becomes simultaneously more similar to and more different from the contact language.

## **2. Phonological Change in Language Obsolescence**

Andersen (1982: 95) identifies three main patterns of phonological change in obsolescing languages. First, fewer phonological distinctions are made overall than at more viable stages of the language. Second, phonological distinctions common to the obsolescing language and the dominant contact language tend to be preserved. Finally, phonological distinctions with a high functional load are maintained longer than those with a low functional load. The first pattern, which constitutes a loss of structure, is

most often exemplified by changes convergent with the dominant contact language, since the structure lost is usually one not found in the contact language: through the loss of structure particular to the obsolescing language, the obsolescing language becomes more similar to the contact language. Thus, convergent change is the type of change most commonly cited in the literature on language obsolescence. Examples follow.

### *2.1. Convergent change*

Citing much of Campbell's previous work in this area, Campbell and Muntzel (1989: 186-187) describe many cases of convergent phonological change. One instance is the language Pipil (Southern Uto-Aztecan, Aztecan), whose speakers have for the most part neutralized a vowel length contrast not found in the dominant language, Spanish, leaving just short vowels. In Tuxtla Chico Mam (Mayan, Mamean), a contrast between velar and post-velar/uvular plosives, again not found in dominant Spanish, has also disappeared, leaving just velars. Goodfellow (2005: 134-138) documents several other examples of convergent phonological change in younger generations of Kwakwala speakers, who have lost several classes of Kwakwala sounds that are absent from English, either omitting them or replacing them with more familiar sounds from English. Glottalized consonants are replaced by plain pulmonic consonants; uvulars are replaced by velars; velar fricatives are omitted; and lateral affricates are replaced by /gl/ clusters.

Campbell and Muntzel (1989) describe these sorts of externally motivated changes as predictable or expected. What they have in common is the loss of structures in the obsolescing language that are not present in the dominant language. Campbell and Muntzel also enumerate several other categories of phonological change that they describe as "of uncertain predictability". These include the overgeneralization of marked features, which normally results in divergent change.

### *2.2. Divergent change*

Campbell and Muntzel (1989: 189) cite Jumaytepeque Xinca (isolate) as one case of a marked form being overgeneralized, with the result that the language diverges further from the dominant language that does not have the marked form. In this case, Jumaytepeque Xinca has a rule glottalizing consonants in specific environments, but some speakers have lost this rule and generalized the relatively marked glottalized consonants to all environments over the relatively unmarked plain consonants . Teotepeque Pipil is another example of this kind of overgeneralization . In this case ,

voiceless [l̥] used to be a word-final allophone of voiced [l], but speakers came to generalize this relatively marked segment to all environments. Campbell and Muntzel (ibid.) state that “[t]hese changes are internal to the structure of the obsolescent language in that they appear to have no direct analog in the dominant language,” but Woolard (1989) counters that these sorts of divergent changes may actually be externally motivated: a marked structure not present in the dominant language is exaggerated in the obsolescing language to differentiate it from the dominant language. In this way, the divergent change may serve as a symbolic act of distancing from the dominant language by speakers who want “to emphasize their differentness from the dominant group” (Thomason 2001: 230), a motivation reminiscent of the well-known case of vowel centralization in Martha’s Vineyard described by Labov (1963).

Thus, it is possible for divergent change to occur in language obsolescence. Nevertheless, convergent change remains the more commonly attested type of change, often resulting in the merger of phonemes that do not contrast in the dominant language. Given that these sorts of mergers are widely attested, it should come as no surprise that they do not form a homogeneous class. Instead, they have come to be differentiated from each other by the particular path to merger: transfer or approximation.

### 2.3. *Transfer, approximation, and expansion in phonological merger*

Trudgill and Foxcroft (1978) introduce the concepts of *transfer* and *approximation* in their analysis of vowel mergers in East Anglia. In the case of transfer, two phonemes merge via the first phoneme categorically changing to the second phoneme in more and more words containing the former phoneme; in this case, the merger is accomplished by the unidirectional transfer of one phoneme to another in a process that “involves...a form of lexical diffusion” (ibid.: 73), which is “not consistent with a result that shows an intermediate phonetic form” (Labov 1994: 321). In the case of approximation, however, two phonemes merge as their individual phonetic spaces approach (i.e. approximate) each other; here both phonemes typically shift, resulting in a merged category with a phonetic space intermediate between the original phonemes. In addition to these two merger types, Labov (1994: 321-323) adds a third type, *expansion*, in which the phonetic space of the merged category ends up spanning the phonetic spaces of both original categories.

These categories of merger figure prominently in an acoustic and articulatory study of Northern Paiute (Uto-Aztecan, Western Numic) carried out by Babel (to appear), who documents two kinds of sound change in the language. First, a three-way

laryngeal contrast is maintained in each of three generations of speakers; however, the phonetic realization of this contrast differs across generations, and in the youngest generation there is increased subphonemic variation. Second, the place of articulation of the language's sibilant shifts from a palatalized post-alveolar to a plain alveolar /s/, while a more palatalized allophone is replaced by the palato-alveolar /ʃ/ in the youngest generation. Based upon these results, Babel hypothesizes that contrasts based on timing relationships (e.g. laryngeal contrasts) are more likely to undergo sound change via approximation, while contrasts that are more categorical in nature (e.g. consonantal place contrasts) are more likely to undergo sound change via transfer. Labov (1994: 321) additionally asserts that transfer happens more often when "one form has acquired a social stigma or prestige", the less prestigious form typically transferring to the more prestigious form used in the dominant standard language.

#### *2.4. Change in the status of phonological rules*

Campbell and Muntzel (1989) review two other types of phonological change that can occur in obsolescing languages. First, variability may develop in the application of phonological rules: rules that used to be obligatory may apply optionally, show substitutions, or simply be lost. The case of optional rule application usually results in free variation between forms that have resulted from the rule and those that have escaped it. For example, consonant gradation rules in standard Finnish which voice stops in certain environments are not applied consistently in American Finnish, producing free variation between voiced and voiceless stops in environments where only voiced stops would occur in standard Finnish. Second, phonological rules may be undergeneralized or overgeneralized. In the case of Teotepique Pipil mentioned above, a rule devoicing final sonorants has been overgeneralized for /l/, but undergeneralized for /w, j/, resulting in voiceless [l̥] and voiced [w, j] in all environments.

#### *2.5. A case of convergent and divergent change?*

A possible case of convergent and divergent change is reported by Dorian (1993), who describes a multifaceted change having to do with gender assignment. In East Sutherland Gaelic, which has masculine and feminine gender categories, there has been a change towards extending the use of the masculine pronoun /a/ 'he' in substituting for a noun (thus decreasing the use of feminine /i/ 'she'). The increase in usage of /a/ to agree with nominal antecedents parallels the generality of English *it*, and so seems to be

an externally motivated change resulting from contact with English. However, it is not the case that nominal gender assignment has weakened overall. On the contrary, the form of English which has had the greatest influence on East Sutherland Gaelic, Northeast Scots, has non-standard features that have the effect of strengthening gender assignment. Though Northeast Scots lacks grammatical gender, it makes greater use of diminutive morphology like the suffix *-ie*, which can be freely added to virtually any monosyllabic noun. Correspondingly, East Sutherland Gaelic is also characterized by relatively frequent diminutive formation, which takes the form of a suffix that indexes gender information: /-an/ for masculine nouns and /-ag/ for feminine nouns. In this way, gendered diminutive formation has the effect of boosting nominal gender assignment, counterbalancing the gender weakening effect of the novel pronoun replacement pattern.

The case of East Sutherland Gaelic thus seems to be an example of convergent and divergent change happening at the same time: the weakening of gender assignment in pronominal replacement is convergent with English, while the strengthening of gender assignment in diminutive formation is divergent from English. However, this divergent change is unlike those cited above in that it is not externally motivated. Here it is not because grammatical gender is missing in English that it becomes more robust in East Sutherland Gaelic. In fact, grammatical gender is strengthened only because of another convergent change – the increase in diminutive formation paralleling the frequency of diminutives in the contact dialect of English. In this sense, it is simply a coincidence that this change has turned out to be divergent from English. What remains to be seen, then, is whether convergent and divergent change can co-occur under the same external influences, and moreover, whether they can co-occur in the phonological domain. Below I argue that both of these situations obtain in Southeastern Pomo.

### **3. Background on Southeastern Pomo**

#### *3.1. Geography and dialectology*

Southeastern Pomo (Northern Hokan, Pomoan), varieties of which are called Sulfur Bank Pomo, Elem Pomo, and Lower Lake Pomo, is a severely endangered language that was spoken primarily in the area around Clear Lake, East Lake, and Lower Lake in Lake County, California (Moshinsky 1974, Gordon 2005). Southeastern Pomo (hereafter, SEP) is not mutually intelligible with the other Pomo languages such as Eastern Pomo (Grekoff 1957: 5). The terms “Sulfur Bank Pomo” and “Elem Pomo”

most likely refer to one dialect spoken in the region of Sulfur Bank and Rattlesnake Island in East Lake, given that a current speaker (Speaker 2A, cf. §4.1.1) remembers this region used to be one connected land mass and refers to the dialect spoken by her father (Speaker 1B), which Moshinsky refers to as Sulfur Bank Pomo, as Elem Pomo. Sulfur Bank/Elem Pomo may differ to some extent from Lower Lake Pomo, which Speaker 2A recalls as a separate dialect. Moshinsky, however, states that “[d]ialect divergences between Sulfur Bank and Lower Lake seem to be minimal...possibly restricted to a small number of lexical differences” (ibid.: 1). It follows that any phonetic differences between these two varieties are probably subphonemic.

### 3.2. Inventories

Moshinsky (1974: 5) presents consonant and vowel inventories of the language as in Tables 1 and 2 (predictable and marginal segments have been placed in parentheses). The segment inventories found in independent fieldwork largely agree with the inventories posited by Moshinsky, but they also depart from them in a few significant ways. These divergences constitute some of the sound changes described below.

**Table 1.** Consonant inventory of Southeastern Pomo

	LABIAL	DENTAL	ALVEOLAR	PALATO(ALV.)	VELAR	POST-VELAR	GLOTTAL
STOPS	p p' b	t t'	t t' d		k k'	q q'	ʔ
AFFRICATES			ts ts'	(tʃ tʃ')			
FRICATIVES	f		s	ʃ	x	χ	h
NASALS	m		n		(ŋ)		
LIQUIDS			r l				
GLIDES	w			j			

**Table 2.** Vowel inventory of Southeastern Pomo

	FRONT	CENTRAL	BACK
HIGH	i		u
MID	e	(ə)	o
LOW		a	

As for suprasegmentals, Moshinsky (1974) includes stress as a contrastive feature, but others (e.g. Goodman 1992) have argued that stress is invariably stem-initial underlyingly, with late processes of epenthesis resulting in surface forms in which an initial syllable is unstressed. The Stress Placement and Pretonic Vowel Epenthesis rules that Moshinsky (1974: 19, 21) himself posits seem to indicate that he also adheres to the

non-contrastive analysis on some level. Thus, phonological stress may be regarded as a non-contrastive feature of SEP prosody.

## 4. Sound Change in Southeastern Pomo

### 4.1. Methods

#### 4.1.1. Speakers

This study is based on recordings of four male speakers from the previous generation (Generation 1: Speakers 1A, 1B, 1C, and 1D) and recordings of one current female speaker (Generation 2: Speaker 2A). As summarized in Table 3, Speaker 1B was from Sulfur Bank, and Speaker 1C was from Upper Lake near Sulfur Bank (Moshinsky 1974: v); presumably they both spoke Sulfur Bank/Elem Pomo. Speaker 1A was a Lake Miwok speaker and not a native speaker of SEP; coming from Middletown in Lake Miwok-speaking territory, he would have been geographically closest to Lower Lake, so the variety of SEP he spoke was probably closest to Lower Lake Pomo. Speaker 1D is described by Moshinsky (*ibid.*) as coming from Sulfur Bank, but his niece (Speaker 2A) reports that he was from Lower Lake (like his sister and her mother, Speaker 1F) and came to Sulfur Bank by way of marriage to Speaker 1G; thus, he most likely spoke Lower Lake Pomo, too. Like Speaker 2A, all Generation 1 speakers also spoke English.

**Table 3.** Linguistic backgrounds of Southeastern Pomo speakers

Speaker	Gender	Origin	SEP dialect	Other languages	Year of Recording
1A	male	Middletown	Lower Lake	Lake Miwok, English	1956
1B	male	Sulfur Bank	Sulfur Bank	English	1960s
1C	male	Upper Lake	Sulfur Bank	English	1960s
1D	male	Lower Lake	Lower Lake	English	1960s
1E	male	Sulfur Bank	Sulfur Bank	E. Pomo, English	N/A
1F	female	Lower Lake	Lower Lake	English	N/A
1G	female	Sulfur Bank	Sulfur Bank	English	N/A
2A	female	Sulfur Bank	S. Bank/L. Lake	English	2006-07

Speaker 2A is one of the last fluent speakers of SEP. She is dominant in English and learned SEP at home primarily from her mother, with whom she spoke almost exclusively in SEP. According to her, the variety of SEP her mother spoke was Lower Lake Pomo, which she regards as a variety of SEP differing slightly from Sulfur Bank/Elem Pomo (*cf.* §3.1). Unfortunately, there are no recordings of her mother's speech, although she did serve as a consultant to linguists who worked on the language

and is therefore recorded in the field notes of Grekoff (1957) and Moshinsky (1965-1968). Speaker 2A's father, Speaker 1B, usually spoke to her in English, although she remembers hearing him speak to other people in SEP while growing up. She describes her own idiolect of SEP as somewhere in between her father's and her mother's speech.

#### *4.1.2. Corpus construction*

A corpus was constructed from archival and original recordings of these speakers to compare word forms across the two generations. First, the Generation 1 word lists were searched for overlaps between speakers using the glosses audible after each word. In the case of Speaker 1D, whose recordings do not include any glosses, overlaps were postulated based upon the SEP word forms instead of the English glosses, a process facilitated by the arrangement of much of Speaker 1D's word list into minimal pairs. The Generation 2 word list was then searched for overlaps with Generation 1, and words that overlapped were included in the corpus. Words that were missing were elicited and included if they overlapped with a Generation 1 form; otherwise, they were removed. The final result was a cross-generational corpus containing approximately 200 words shared among Speaker 2A and at least two Generation 1 speakers.

#### *4.2. Convergent changes*

##### *4.2.1. Narrowing of the velar/post-velar distinction*

The velar/post-velar distinction is one example of an SEP distinction that is not found in English. Moshinsky (1974) observes that velar and post-velar stops may be distinguished not only by place of articulation, but also by quality of contact, the post-velar stop being more fortis in articulation and often affricated or wholly fricated. The velar and post-velar fricatives may be cued by secondary features as well, the velar having less noise and occurring with concomitant lip spreading.

The extent to which velars and post-velars are differentiated in Generation 1 vs. Generation 2 was examined through acoustic measures of place of articulation, degree of contact, and vowel quality. The minimal pair examined was /xa/ 'fish' and /χa/ 'water'. To gauge place of articulation, the second resonance (F2) of the fricative noise was measured over the whole fricative interval, as well as the onset of the first formant (F1) in the following vowel. Measures of fricative duration and intensity were also taken as correlates of the degree of contact. Finally, the quality of the following vowel was estimated via average measures of the F1 and F2 over the whole vowel interval.

The data are summarized in Table 4. Note that the data for Speaker 1B and

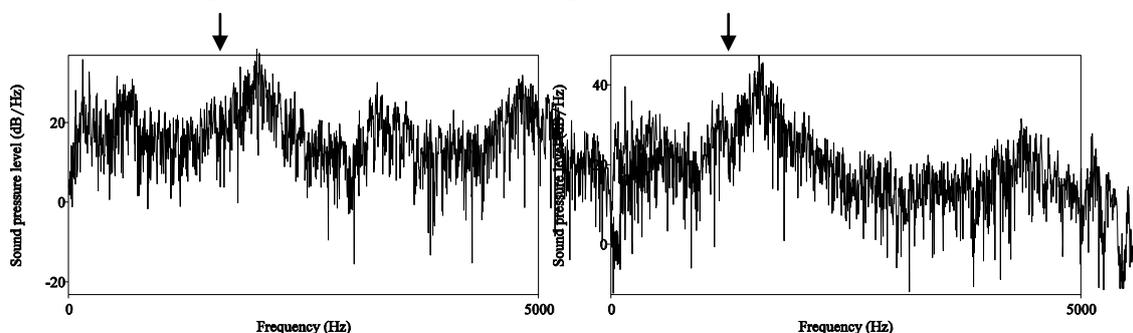

Speaker 1D represent single tokens, as only one token of each word was available. The data for Speaker 1A's /xa/ and /χa/ are averaged over 6 and 4 tokens, respectively, and the data for Speaker 2A's /xa/ and /χa/ are averaged over 14 and 10 tokens, respectively.

**Table 4.** Average acoustic data for /xa/ 'fish' vs. /χa/ 'water'

	Speaker 1A		Speaker 1B		Speaker 1D		Speaker 2A	
	/xa/	/χa/	/xa/	/χa/	/xa/	/χa/	/xa/	/χa/
Fricative F2 (Hz)	<b>1212</b>	<b>1128</b>	<b>1331</b>	<b>1066</b>	<b>1588</b>	<b>1272</b>	<b>1488</b>	<b>1417</b>
F1 onset (Hz)	501	519	491	597	572	560	397	378
Duration (ms)	296	253	324	244	326	381	224	258
Intensity (dB)	55.5	56.1	64.5	62.3	58.5	64.8	60.6	60.2
Average F1 (Hz)	791	813	745	816	825	891	569	548
Average F2 (Hz)	1358	1358	1351	1284	1612	1518	1547	1495

It turns out that the only significant and consistent difference between /xa/ and /χa/ lies in the F2 of the fricative noise, bolded in Table 4. For all speakers, F2 is lower in the post-velar fricative than in the velar fricative, indicating a more retracted place of articulation. This difference is statistically significant (Speaker 1A:  $t(7) = 1.864$ ,  $p = .049$ ; Speaker 2A:  $t(20) = 2.485$ ,  $p = .012$ ) and is illustrated in Figure 1, where it is clear in spectra of these fricatives that the F2 frequency in /χa/ is lower than that in /xa/.

**Figure 1.** Spectra of the initial fricatives in Speaker 1D's /xa/ 'fish' (L) and /χa/ 'water' (R)

Though the post-velar fricative's F2 is on average lower than the velar fricative's F2 for all speakers, the difference between the two is greater in magnitude for all three Generation 1 speakers as compared to Speaker 2A, who shows a difference of 71 Hz. In comparison, Speaker 1A shows a slightly greater difference of 84 Hz. For Speakers 1B and 1D, there are only single tokens of the velar and post-velar, so it is difficult to conclude how much overlap there is between these two categories. However, the single tokens lie much farther away from each other than 71 Hz: the difference is 265 Hz for Speaker 1B and 316 Hz for Speaker 1D. The acoustic distance between the velar and post-velar fricatives thus appears to have decreased significantly in Generation 2.

This narrowing of the velar/post-velar contrast can be most straightforwardly interpreted as an externally motivated change. There is no similar contrast between dorsals in English; consequently, this contrast is left more vulnerable to loss. It should be noted, however, that the contrast is in fact maintained in Generation 2. The distance between the categories simply decreases.

#### 4.2.2. Narrowing of the dental/alveolar distinction

The dental/alveolar distinction is a second example of an SEP contrast that is not found in English. Moshinsky (1974) describes this contrast as an opposition between an “apico-interdental to apico-dental stop” and an “apico-alveolar to retroflexed apical stop”. We can expect this sort of contrast to be realized acoustically in two main ways. First, the frequency of the most prominent peak in the stop burst will be higher for a dental than an alveolar/retroflex (Ladefoged 2005: 158-159). Second, the formants in adjacent vowels will differ due to coarticulation with consonants of different places; in particular, the frequency of the third formant (F3) will be lower next to a retroflex.

The extent to which dentals and alveolars are differentiated in Generation 1 vs. Generation 2 was thus examined through acoustic measures of the stop burst and of vowel quality. The minimal pair examined was [ʔə'tʰat] ‘touch’ and [ʔə't'at] ‘ruddy duck’. The frequency of the burst peak and the intensity of the burst were measured over the whole burst interval. Formant measurements of both vowels were also taken as averages over the whole vowel interval.

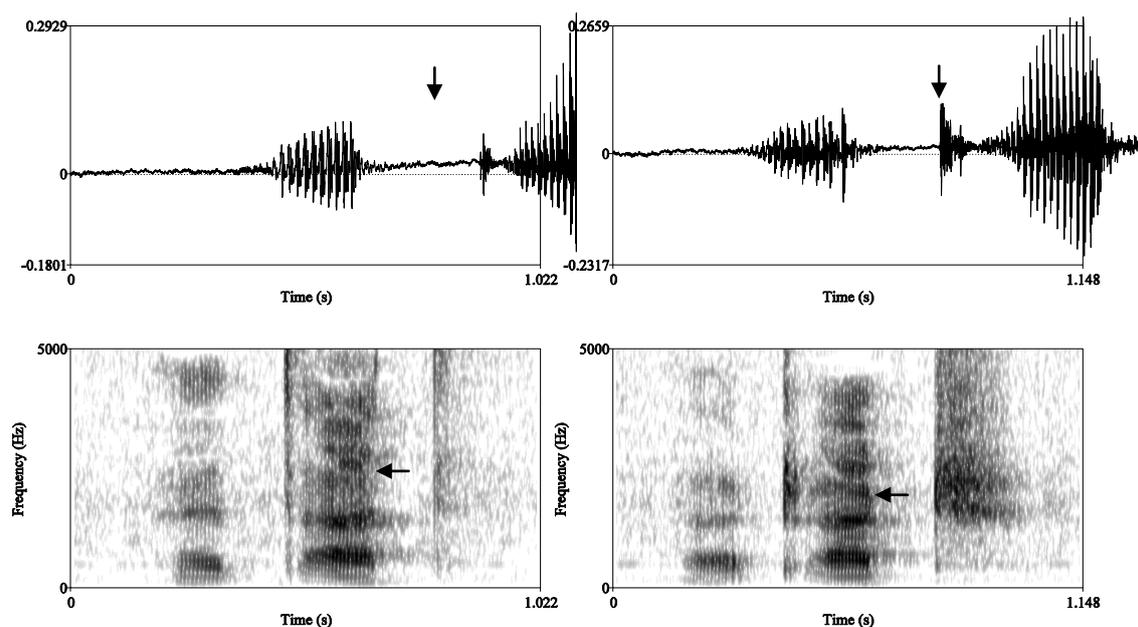

The data are summarized in Table 5. The data for Speaker 1C represent two tokens of each word; the data for Speaker 1D represent one token of each word; and the data for Speaker 2A represent three tokens of each word.

**Table 5.** Average acoustic data for [ʔə'tʰat] ‘touch’ vs. [ʔə't'at] ‘ruddy duck’

	Speaker 1C		Speaker 1D		Speaker 2A	
	[tʰ]	[t]	[tʰ]	[t]	[tʰ]	[t]
Intensity of ejective burst (dB)	53.6	58.5	67.3	67.1	50.6	44.6
Intensity of plosive burst (dB)	<b>49.9</b>	<b>58.8</b>	<b>66.4</b>	<b>71.2</b>	<b>40.0</b>	<b>42.2</b>
Frequency of ejective burst peak (Hz)	<b>4304</b>	<b>2113</b>	<b>4364</b>	<b>3422</b>	<b>4142</b>	<b>3603</b>
Frequency of plosive burst peak (Hz)	<b>4705</b>	<b>2213</b>	<b>4211</b>	<b>3831</b>	<b>4118</b>	<b>3868</b>
Average F1, first vowel (Hz)	540	568	755	653	603	648
Average F2, first vowel (Hz)	1587	1498	1943	1756	1623	1820
Average F3, first vowel (Hz)	2456	2331	3031	2898	2526	2833
F1 onset, second vowel (Hz)	606	586	594	549	758	784
Average F1, second vowel (Hz)	689	661	704	732	696	694
Average F2, second vowel (Hz)	1490	1527	1559	1671	1428	1654
Average F3, second vowel (Hz)	<b>2602</b>	<b>2401</b>	<b>2930</b>	<b>2480</b>	2669	2796

There are several consistent differences between [ʔə'tʰat̚] and [ʔə't'at]. First, the burst intensity of the alveolar plosive is greater than that of the dental plosive for all speakers, and the difference is significant for Speaker 1C ( $t(2) = -5.084$ ,  $p = .037$ ). Second, as expected, the frequency of the dental burst peak is higher than that of the alveolar burst peak for both the ejective (Speaker 1C:  $t(2) = 12.010$ ,  $p = .007$ ; Speaker 2A: difference approaching significance at  $t(4) = 2.395$ ,  $p = .075$ ) and the plosive (Speaker 1C:  $t(2) = 59.091$ ,  $p = .0003$ ; Speaker 2A: difference approaching significance at  $t(4) = 2.298$ ,  $p = .083$ ). Finally, F3 is lower in the vowel following the alveolar (Speaker 1C:  $t(2) = 6.787$ ,  $p = .021$ ), though not for Speaker 2A. These differences are illustrated in Figure 2. In the waveforms, it is clear that the alveolar bursts have greater intensity relative to the vowel than the dental bursts, while the spectrograms show that F3 is lower adjacent to the (retroflexed) alveolars than adjacent to the dentals.

**Figure 2.** Waveforms and spectrograms of Speaker 1C's [ʔə'tʰat̚] 'touch' (L) and [ʔə't'at] 'ruddy duck' (R)

As alluded to above, Speaker 2A patterns a bit differently from Speakers 1C and 1D. The intensity differences and burst peak frequency differences between her dental and alveolar stops are all substantially smaller than those achieved by Speakers 1C and 1D. For example, the burst peak frequency difference between the dental and alveolar ejectives is 539 Hz for Speaker 2A, as compared to 2191 Hz and 942 Hz for Speakers 1C and 1D, respectively. Furthermore, for F3 in the vowels, Speaker 2A's data goes in the opposite direction of Speakers 1C and 1D, the lower F3 occurring next to the dental.

Like the narrowing of the velar/post-velar contrast, the narrowing of the dental/alveolar contrast here is most likely the result of external influence: the absence of a similar contrast in English leaves the native contrast more susceptible to change. Again, however, the contrast is not actually lost, but merely reduced, both in terms of the number of cues to the contrast and the magnitude of the acoustic distance effected between the two categories.

### 4.3. Divergent changes

#### 4.3.1. The elimination of rhotics

Generation 2 differs from Generation 1 in that Speaker 2A's inventory contains no rhotics, whereas flaps, trills, and alveolar/retroflex approximants are not uncommon in the speech of Generation 1, as shown in Table 6 (phonetic forms are given in relatively narrow IPA transcription). Note that while some forms are clearly loanwords (e.g. [ˈperas] ‘pears’, cp. Sp. *peras* ‘pears’), others, judging from their semantics, segments, and phonotactics, seem to be native SEP words rather than borrowings (e.g. [ˈkʰɪxra] ‘leaf’; [ˈt̪ʰoʔrokɪn] ‘soft’). Though there are only 1-3 tokens available of each word, the appearance of rhotics is consistent across these tokens; therefore, we can be fairly certain that the forms in Table 6 contain some sort of rhotic phoneme.

**Table 6.** Generation 1 forms containing rhotic segments

Speaker	Phonetic form	Phonemic form	Gloss	Source <sup>1</sup> (file, time)
1A	kʰusneru	kusneru	‘cook’	7M4049A, 29:21
1B	ʔorkeθa	ʔorkeʔa	‘fork’	7M2054, 26:02
1B	qʰol.kʰras	qolkras	‘to jump’	7M2054, 20:32
1B	kʰsak.mʃʰɪrə	ksakmʃɪra	‘Sunday’	7M2054, 28:40
1B	ˈperas	peras	‘pears’	7M2054, 26:51
1B	kʰɪxra	kikra	‘leaf’	7M2054, 31:02
1C	kʰɪtkʰɪa	kitkra	‘leaf’	7M2055, 27:04
1C	pʰɪəˈmedik	prmedik	‘relative’	7M2055, 18:21
1C	tʰokʰrokɪn	tʰokrokɪn	‘soft’	7M2055, 28:01
1C	tʰokruʃkiʃ	tʰokruʃkiʃ	‘to choke’	7M2055, 28:05
1D	kʰuʃ	kʰuʃ	(unavailable)	7M2056A, 10:17
1D	qʰəɪa	qʰra	(unavailable)	7M2056A, 8:15
1D	sɛɪka	serka	‘fence’	7M2056A, 3:42
1D	t̪aɪapu	t̪arapu	‘cloth, flag’	7M2056A, 1:08
1D	tʰoʔrokɪn	tʰokrokɪn	‘soft’	7M2056A, 18:11
1D	wuru	wuru	‘donkey’	7M2056B, 1:03
1D	χqʰoɪaʃ	χqoraʃ	(unavailable)	7M2056A, 15:10

<sup>1</sup> The source information refers to the name of the relevant audio recording on file at the Berkeley Language Center.

The fact that Speaker 2A’s inventory lacks rhotics is clear from certain words she has in common with Generation 1 speakers. Table 7 lists examples of words for which a Generation 1 speaker’s form contains a rhotic, while the Generation 2 form contains no rhotic. In each case, the phonetic environment is similar, yet the rhotic is conspicuously absent from the Generation 2 form.

**Table 7.** Comparison of rhotic vs. non-rhotic forms in Generation 1 and Generation 2

Generation 1 form (speaker)	Generation 2 form	Gloss
<sup>1</sup> ʔorkeθa (1B)	<sup>1</sup> ʔoŋkeŋa	‘fork’
<sup>1</sup> seɹka (1D)	<sup>1</sup> seŋka	‘fence’
<sup>1</sup> k <sup>h</sup> ɪtk <sup>h</sup> ɹa (1C)	<sup>1</sup> k <sup>h</sup> ɪkt <sup>h</sup> a	‘leaf’

Thus, it appears that Speaker 2A’s phonological inventory differs in a significant way from that of Generation 1 in having virtually eliminated rhotic segments. With regard to how this change might have come about, we can entertain two main possibilities. First, it is possible to attribute this change to external influence from English, a language in which rhotics are abundant. This subtractive change would then be complementary to the additive exaggeration of non-English features that has been reported for other obsolescing languages; however, in this case, not only would rhotics in loanwords have been eliminated to make the language less similar to English, rhotics in apparently native SEP words would also have been eliminated. Second, it is possible to attribute this change to internal forces. Rhotics carry a low functional load in SEP – they occur in only a few native words and otherwise in loanwords and fail to distinguish any minimal pairs – making them vulnerable to loss over time.

The fact that rhotics are lost in an inconsistent manner (cf. Table 7, which shows that /r/ can be replaced by [ɹ], [tʰ], or [l]) suggests that the former analysis is probably right. This is not an ordinary conditioned sound change; instead, it appears that, whether consciously or unconsciously, rhotics have been replaced wholesale in the language by other segments that are not so saliently identified as English sounds.

#### 4.3.2. Generalization of /d/-deletion

According to Moshinsky (1974: 25-26), SEP has a rule of d-deletion whereby /d/ is deleted preceding another consonant (e.g. /lodt/ ‘my hair is falling out’ → [lot]; /btedlaj/ ‘women’ → [btelaj]). However, it is clear from the speech of Generation 1, particularly Speaker 1C, that this was an optional rule, not an obligatory one. Table 8

lists many examples of forms containing /d/ before another consonant, indicating that /d/ was not necessarily deleted in this environment.

**Table 8.** Generation 1 forms containing -dC- sequences

Speaker	Form	Gloss	Source (file, time)
1A	<sup>h</sup> id̩le	‘noon’	7M4049A, 14:29
1A	<sup>h</sup> id̩lejukin	‘before noon’	7M4049A, 14:00
1A	<sup>h</sup> id̩lebə̌,tonə̌wa	‘afternoon’	7M4049A, 13:49
1C	ʔə <sup>h</sup> k <sup>h</sup> ud̩l	‘ridge’	7M2055, 15:43
1C	k <sup>h</sup> ʔid̩l	‘meadowlark’	7M2055, 10:54
1C	<sup>h</sup> mk <sup>h</sup> ud̩l	‘log’	7M2055, 26:22
1C	<sup>h</sup> mxud̩lxa	‘to put out to dry’	7M2055, 23:14
1C	q <sup>h</sup> oʃid̩l	‘toad’	7M2055, 19:33
1C	q <sup>h</sup> ʃid̩lbu	‘little finger’	7M2055, 20:49
1D	q <sup>h</sup> oʃid̩l	‘toad’	7M2056A, 10:31

Furthermore, it appears that d-deletion could apply optionally within the same speaker, resulting in free variation between forms that maintained pre-consonantal /d/ and those that deleted it. Table 9 lists examples of this variation from Speaker 1C. In each case, one token of the word contains /d/, while the other does not, and the form with d-deletion occurs as either the first or second token.

**Table 9.** Free variation in Speaker 1C between forms with and without pre-consonantal /d/

Token 1	Token 2	Gloss	Source (file, time)
k <sup>h</sup> əʔid̩l	k <sup>h</sup> əʔil	‘yellow’	7M2055, 16:10
k <sup>h</sup> əʔod̩l	k <sup>h</sup> əʔol	‘honeybee’	7M2055, 26:58
<sup>h</sup> k <sup>h</sup> f̩id̩n	<sup>h</sup> k <sup>h</sup> f̩in	‘mistletoe’	7M2055, 17:19
q <sup>h</sup> t̩id̩l	q <sup>h</sup> t̩il	‘to lock’	7M2055, 27:30

What was once an optional rule has become obligatory for Speaker 2A. There are no instances of pre-consonantal /d/ in her speech, which can be seen most clearly in words she has in common with Generation 1 speakers. Table 10 shows that for words in which the Generation 1 form either has a pre-consonantal /d/ or alternates between having the /d/ and deleting it, Speaker 2A’s form invariably deletes the /d/.

**Table 10.** Comparison between Generations 1 and 2 with respect to pre-consonantal /d/

Generation 1 form (speaker)	Generation 2 form	Gloss
<sup>h</sup> id̩le (1A)	<sup>h</sup> il̩e	‘noon’
k <sup>h</sup> əʔid̩l ~ k <sup>h</sup> əʔil (1C)	k <sup>h</sup> əʔil̩t̩’o	‘yellow’
k <sup>h</sup> ʔid̩l (1C)	k <sup>h</sup> əʔil	‘meadowlark’
jʊd̩l (1F, 1G) <sup>2</sup>	jʊl	‘snow’
k <sup>h</sup> ʔod̩l (1C)	k <sup>h</sup> ʔol	‘honeybee’
k <sup>h</sup> t̩id̩l (1C)	k <sup>h</sup> t̩il	‘to lock’

<sup>2</sup> These data for Speakers 1F and 1G are from the field notes of Grekoff (1957: 19, 80).

k <sup>h</sup> fiɖl̩ (1C)	k <sup>h</sup> fiɭ	‘poison’
'mxud̩ɭxa (1C)	'mxulka	‘to put out to dry’

In short, Speaker 2A has generalized an optional rule, obligatorily deleting /d/ before another consonant – a change in the status of the rule that seems to be internally motivated. Influence from English is unlikely to be responsible for this change, as there is no comparable ban on pre-consonantal /d/ in English (cf. words such as *addle*, *paddle*, *madden*, *redden*, *ridden*, *fiddle*, *riddle*, *coddle*, *cuddle*, *idle*, *sidle*, etc.); moreover, there is no clear analog in English to the d-deletion rule that has been generalized.

## 5. Discussion

To summarize, data collected in four cross-generational case studies of SEP phonetics and phonology suggest that convergent change and divergent change can exist simultaneously within the same speaker. On the one hand, the narrowing of the velar/post-velar contrast and the narrowing of the dental/alveolar contrast are convergent with English and likely due to this external influence. On the other hand, the elimination of rhotics from the consonant inventory and the generalization of a SEP-specific d-deletion rule are divergent from English. The elimination of rhotics seems also to be a reaction to external influence from English, while the generalization of d-deletion is probably the result of language-internal factors.

Before discussing these results further, we should more firmly establish their validity. How sure can we be that the phonetic and phonological differences found are due to diachronic change rather than simply correlated with gender or dialect? First, we can be fairly certain that the patterns found cannot be attributed to dialectal differences, at least in large part. The Generation 1 speakers come from both major dialect groups, yet the differences found between Generation 1 and Generation 2 are not correlated with this variable. It is not the case, for instance, that the Lower Lake speaker, Speaker 1D, also happened to lack rhotics like Speaker 2A, or that the Sulfur Bank speakers all patterned together with or against Speaker 2A in a particular dimension.

We cannot be so sure about gender. It is an unfortunate fact that all of the recordings available of Generation 1 speakers are of males, while the only Generation 2 speaker is female. It is possible that Speaker 2A patterns differently from Generation 1 speakers because females and males say things differently in SEP. Nonetheless, gender differences cannot be responsible for the generalization of d-deletion. In this case, data from other female speakers (1F and 1G) pattern with the Generation 1 male speakers, not with the Generation 2 female speaker. Moreover, estimates of vocal tract size from

vowel formant measurements suggest that the much greater distances between categories achieved by the Generation 1 male speakers cannot be solely due to physiological differences between speakers. Thus, the data collected in this study cannot be written off entirely to gender effects, either.

More specifically, we might want to re-consider the divergent changes presented in §4.3. For example, there are two possible explanations for the presence of rhotics in Generation 1 and their absence in Generation 2. In the first scenario, (i) rhotics were not originally in the inventory, (ii) there was individual variation with respect to (innovative) rhotic realizations of certain words, and (iii) the Generation 1 speakers analyzed here all happened to have rhotic forms. In this case, the absence of rhotics in Generation 2 would be an “original” state rather than the result of sound change; the apparently consistent presence of rhotics in Generation 1 would then be an artifact of sample size. In the second scenario, (i) rhotics were originally in the inventory or entered it early on due to language contact, and (ii) they were then lost in Generation 2.

Two points favor the second, simpler analysis. First, whether or not rhotics were restricted to loanwords, they must have been fairly common for Moshinsky (1974) to include them in his consonant inventory, a fact that casts some doubt on the idea that there were many Generation 1 speakers who lacked rhotics entirely. Second, assuming that such speakers were common in Generation 1, it becomes highly improbable that of the four speakers on the recordings, not one would turn out to be one of these rhotic-less speakers, especially considering the fact that they were from different dialect regions.

One might return to the gender issue to counter that (i) rhotics might not have been a standard part of the inventory, (ii) female speakers tend to conform more to the standard variety of a language, and (iii) Speaker 2A is female. This is a possibility that we cannot fully discount due to the unavailability of recordings of other female SEP speakers. However, it is clear from the data that rhotics appear in native SEP words and not just in loanwords that have not been fully integrated into SEP phonology.

In fact, comparative evidence from other Pomo languages heightens the probability that there were indeed original rhotics in SEP. McLendon (1973) includes rhotics in the inventories of Northeastern Pomo as well as Eastern Pomo, the Pomo language most closely related to SEP, and one correspondence set she cites in particular suggests an alternation between /r/ and /l/ – the Pomo words for ‘leaf’. The forms in all seven Pomo languages as cited by McLendon are summarized in Table 11 below.

**Table 11.** Comparison of Pomo forms for ‘leaf’ (McLendon 1973: 79)

Proto Pomo	Kashaya Pomo	Northern Pomo	Central Pomo	Northeastern Pomo	Eastern Pomo	Southeastern Pomo
*siʔt’ál	siʔt’al	siʔ’ál	st’ál	túʔt’a	sit’ál	kiqt’a

McLendon (1973: 79) notes that the “lack of a reflex for \*-l in [Northeastern Pomo] and [Southeastern Pomo] perhaps indicates that this \*-l was a separate, segmentable morpheme in Proto Pomo”, but it appears \*-l might actually have had a reflex in SEP – namely, a rhotic. Compare the forms in Table 11 with the Generation 1 SEP forms for ‘leaf’: [kixra] (Speaker 1B) and [kitkɪa] (Speaker 1C). If this \*l ~ r correspondence is legitimate, it further strengthens the argument for original rhotics in SEP.

As for the other case of divergent change, the generalization of d-deletion raises interesting questions about the stability of truly free variation. Campbell and Muntzel (1989) mention examples of previously obligatory rules becoming optional in obsolescence and resulting in free variation, but they do not present any cases of optional rules becoming obligatory ones. The former situation fits well into the notion of an obsolescing language being imperfectly learned in that it is subtractive: a language structure is forgotten or omitted. The latter situation, on the other hand, is additive: a rule of ambiguous status is regularized such that it can be applied all the time.

Of course, the generalization of d-deletion is a perfect example of an optional rule becoming obligatory. It seems the factors leading to this change might not be internal to the language so much as universal across languages. In many ways, truly free variation is a difficult problem for learners predisposed to associating a difference in sound to a difference in meaning. How do they cope with a difference in sound when they cannot associate it with a difference in meaning? One solution is just to eliminate the difference in sound: take account of all the variants, pick one, and stick to it. Perhaps this sort of motivation underlies the generalization of the SEP rule.

The findings of Hudson Kam and Newport (2005) lend support to this hypothesis. In this study, adults and young children were compared with respect to how they acquired unpredictable grammatical variability in an artificial language. Hudson Kam and Newport found that adult learners of the artificial language reproduced the pattern of variability they were exposed to in the input. However, many of the child learners, rather than reproducing the variability of the input like the adults, instead regularized the language. Thus, children’s predisposition to constructing a grammar of regular patterns – often cited as a driving force behind the formation of creole languages – may account for the generalization of d-deletion seen in Generation 2.

With regard to the convergent changes discussed above, it remains a question what route to merger the narrowing of SEP contrasts is following. Babel (to appear)

presents a case of place contrasts undergoing merger via complete and rather rapid transfer in Northern Paiute, but in the case of SEP, the change appears to be slower and more gradient. Both the velar/post-velar and dental/alveolar contrasts are actually maintained despite being lessened in degree. What seems clear is that the road to merger in the case of SEP is not one of transfer as claimed by Babel for Northern Paiute, but rather one of approximation, since there indeed seems to be an intermediate phonetic form in this case. The dental/alveolar contrast, for instance, is diminished by way of the retroflexed alveolars of Generation 1 approaching the dentals by becoming non-retroflex in Generation 2. On the other hand, the dentals themselves maintain robust dental contact and do not move back in place of articulation, so it seems that if the two categories were to fully merge in the future, the result would be a merged category with approximately the same phonetic space as the dentals.

## 6. Conclusion

In contrast to previous linguistic studies focusing on the occurrence of either convergent or divergent change in obsolescing languages, this paper has argued, using phonetic and phonological evidence from Southeastern Pomo, that it is possible for these different types of change to occur simultaneously within the same speaker, resulting in the obsolescing language both converging with and diverging from the contact language under the same sort of external influence. Though these findings are based on data from one language, they suggest that the case of simultaneous convergent and divergent change is likely to be more common than the literature reflects.

## Abstract

The distribution of geminate obstruents in Japanese loanwords appears very complex. Some consonants are more prone to gemination than others, on the one hand, and one and the same consonant is more likely to geminate in some phonological contexts than in others, on the other hand. This paper tackles these problems by considering the relationship between consonant gemination in native words and that of loanwords. It proposes a principled prosodic analysis by which gemination is allowed to occur if and only if it improves prosodic structure. This analysis reveals that gemination in loanwords is essentially an output-oriented phenomenon and that loanword phonology is closely related with and severely constrained by native phonology.

**Keywords:** Japanese loanwords, consonant gemination, prosodic structure, loanword phonology

## 1. Introduction

The distribution of geminate obstruents, or *sokuon*, in Japanese loanwords is notoriously complex. For example, /p/ is geminated in /kyap.pu/ ‘cap’, but not in /kya.pu.ten/ ‘captain’ (dots indicate syllable boundaries). ‘bat’ undergoes gemination, while ‘butter’ fails to do so: /bat.to/ vs. /ba.taa/. There are many pairs of words like these. Representative examples are given in (1).

(1)

		Gemination		No Gemination
<i>p</i>	<i>cap</i>	kyap.pu	<i>captain</i>	kya.pu.ten
<i>t</i>	<i>bat</i>	bat.to	<i>butter</i>	ba.taa
<i>s</i>	<i>listen</i>	ris.sun	<i>listener</i>	ri.su.naa
<i>k</i>	<i>tax</i>	tak.ku.su	<i>tact</i>	ta.ku.to
<i>g</i>	<i>frog</i>	fu.rog.gu	<i>log</i>	ro.gu

This paper discusses how the distribution of geminate obstruents as opposed to single obstruents (e.g., /pp/, /tt/, /kk/ vs. /p/, /t/, /k/) is determined in loanword adaptations in Japanese, whose native system employs consonant length contrastively. The main focus will be placed on an analysis of loanwords from English. We will propose a phonological analysis to account for both new and previously-established generalizations regarding consonant gemination in Japanese loanwords and demonstrate how severely loanword phonology is constrained by native phonology.<sup>1</sup>

This paper is organized as follows. The next section describes basic constraints holding in the native phonology of Japanese. Section 3 proposes a principled output-oriented analysis of major gemination and non-gemination patterns in loanwords. The final section (Section 4) summarizes main points as well as questions that remain for future work.

## 2. Relevant Constraints in Native Phonology

### 2.1. Voiced geminate

As is well known, consonant length as well as vowel length is distinctive in Japanese phonology. Thus, there are many minimal pairs including those in (2) that contrast between a single consonant (singleton) and a geminate consonant (geminate). Geminate consonants appear only word-medially.

(2)

<i>Singleton</i>	<i>Geminate</i>
ki.ta ‘came’	kit.ta ‘cut (past)’
syu.tyoo [ʃu.tʃo:] ‘assertion’	syut.tyoo [ʃut.tʃo:] ‘business trip’
sa.ki ‘point, edge’	sak.ki ‘a short time ago’
ka.sya [kaʃa] ‘freight car’	kas.sya [kaʃʃa] ‘pulley’

Phonetic studies have shown that, other things being equal, consonant length is signaled primarily by consonant duration (Fujisaki & Sugito 1977, Han 1994). Thus, the closure duration of [t] is much longer in /kit.ta/ ‘cut (past)’ than in /ki.ta/ ‘came’. Geminate fricatives have a much longer frication duration than singletons: e.g., [s] is considerably longer in /kas.sen/ ‘battle’ than in /ka.sen/ ‘underline’.

While consonant length is contrastive in Japanese, not all consonants have a geminate counterpart. First, no voiced consonant, whether obstruent or sonorant, can be geminated in native phonology: /b, d, g, m, n, y, r, w/ do not have their geminated counterparts. This is symbolized by the fact that /ta.da/ ‘only’ turned into /tat.ta/, not /tad.da/, when geminated for emphasis in the course of the history. It follows from this and other facts that the native phonology of Japanese is subject to the constraint in (3), a constraint that is observed across languages.

(3) \*Voiced Geminate (\*VoiGem)

Voiced geminate consonants are prohibited.

Second, voiceless fricatives fall into two types, those that can be geminated ([s] and [ʃ]) as shown in (4), and those that cannot ([h]).

(4) ka.sen ‘underline’—kas.sen ‘battle’

ka.sya [kaʃa] ‘freight car’—kas.sya [kaʃʃa] ‘pulley’

Note that /h/ can be geminated in several independent contexts in native phonology, but when geminated, it alternates with [pp] rather than [hh] for historical reasons.<sup>2</sup> This is true irrespective of the following vowel, which determines the phonetic quality of /h/ ([ç], [ϕ] or [h]) in native and SJ words.<sup>3</sup> Some examples are given in (5).<sup>4</sup>

(5) a. ha ‘leaf’ + ha ‘leaf’ → hap.pa ‘leaves’

b. ni.hon ‘Japan’ → nip.pon ‘Japan’

c. a.ho ‘fool’ → ap.po ‘fool (colloquial)’

d. it ‘one’ + hu ‘husband’ → ip.pu ‘one husband’

e. it ‘one’ + hi ‘day’ → ip.pi ‘first day of the month’

## 2.2. Syllable weight

Geminate consonants cannot occur after a long vowel or diphthong in native phonology. Thus, /to.ki/, /tok.ki/, and /too.ki/ are all legal forms, but /took.ki/ is not.

(6)

	<i>Singleton</i>	<i>Geminate</i>
<i>Short V__</i>	to.ki ‘time’	tok.ki ‘projection’
<i>Long V__</i>	too.ki ‘pottery’	*took.ki

Kubozono (1999) attributed this distributional restriction to a constraint on the optimal size of the syllable, which permits light (monomoraic) and heavy (bimoraic) syllables, but not superheavy (trimoraic) ones.

(7) \*superheavy (\* $\sigma_{\mu\mu\mu}$ )

Trimoraic syllables are banned.

The same constraint accounts for the seemingly peculiar loanword adaptation process known as ‘pre-nasal vowel shortening’ (Lovins 1975). This process, as illustrated in (8), shortens long vowels and diphthongs before a moraic nasal, thus creating bimoraic syllables out of a string that would otherwise result in trimoraic syllables (see Kubozono 1999 for more evidence for the trimoraic syllable ban in Japanese).

(8) Pre-nasal vowel shortening

<i>Cambridge</i>	<u>ken</u> .bu.riz.zi, *kein.bu.riz.zi
<i>corned beef</i>	<u>kon</u> .bii.fu, *koon.bii.fu

### 2.3. Prosodic form

Native phonology exhibits a striking tendency to favor Heavy-Light (HL) and Heavy-Heavy (HH) sequences and to disfavor Light-Heavy (LH) in word-final position. This tendency is observed in various independent phenomena in Japanese, one of which is the *zuzya-go* formation discussed in depth by Itô et al. (1996).

*Zuzya-go* is a jazz musicians’ secret language involving metathesis: e.g., /ma.nee.zyaa/ → /zyaa.ma.ne/ ‘manager’. The input to this process can be any word with any prosodic structure, but its output is severely constrained in prosodic terms. This is illustrated with monosyllabic and disyllabic input forms in (9) below.

(9)

Input		Output		Gloss
Prosodic form	Word	Prosodic form	Word	
L	me	HL	ee.me	eye
H	kii	HL	ii.ki	key
LL	me.si	HL	sii.me	rice
LH	go.han	HL	han.go	meal, rice
HL	tan.go	HL	gon.ta	tango
HH	too.kyoo	HH	kyoo.too	Tokyo
	ron.don		don.ron	London

In these examples, the input forms vary from a monomoraic monosyllable (L) to a disyllabic word consisting of two heavy syllables (HH). This variability in the input is quite contrastive with the uniformity in the output, where only HL or HH structures are permitted. For example, the input /me/ (L) gives rise to /ee.me/ (HL). More striking is the fact that both HL and LH inputs yield HL outputs: /go.han/ and /tan.go/ turn into /han.go/ and /gon.ta/, respectively. This output neutralization in prosodic structure results from the irregular process that HL inputs undergo, namely, the process by which input mora strings are entirely reversed: /ta-n-go/ → /go-n-ta/, \*/go.tan/. All in all, *zuzya-go* formation exhibits a strong tendency towards HL and HH outputs and against LH outputs.

*Zuzya-go* is not the only process that exhibits such a tendency. Baby words display a more remarkable tendency towards HL and HH in preference to LH and other prosodic forms. In (10), words to the left of the arrows are adult forms from which baby forms are derived.

(10) Baby words

a. LL → HL

ba.ba → baa.ba, \*ba.baa ‘grandma’

zi.zi → zii.zi, \*zi.zii ‘grandpa’

ku.tu → kuk.ku ‘shoes’

da.ku → dak.ko ‘to hold up’

ne.ru → nen.ne ‘to sleep’

o.bu.u → on.bu ‘to carry a baby piggyback’

b. LL → HH

ha.u → hai.hai ‘to crawl’

buu.buu ‘car, pig’

The interesting asymmetry between HL and LH in the output is also observed in the process of loanword truncation. Crucially, HL forms are perfectly acceptable in the output, whereas LH forms are strictly prohibited (Itô 1990, Kubozono 2003).

(11) a. HL

roo.tee.syon → roo.te ‘rotation’

pan.hu.ret.to → pan.hu ‘pamphlet’

sin.po.zi.u.mu → sin.po ‘symposium’

b. LH → LL

ro.kee.syon → ro.ke, \*ro.kee ‘location’

de.mon.su.to.ree.syon → de.mo, \*de.mon ‘demonstration’

There are several other independent processes that display a bias towards HL and HH outputs in Japanese (see Kubozono 2003 for more evidence). Considering all these processes with respect to the wellformedness of output forms, it can be said that Japanese favors HL and HH sequences and disfavors LH sequences in word-final position. This leads us to propose the following prosodic constraint. As we will see in section 3, this constraint is primarily responsible for consonant gemination in loanwords.

(12) Prosodic Form (ProsForm)<sup>5</sup>

Words must end in Heavy-Heavy or Heavy-Light sequences.

#### 2.4. Accent structure

(Tokyo) Japanese exhibits a certain bias with respect to accent structure, too. It permits two major accent patterns: accented and unaccented (McCawley 1968, Kubozono 1988/1993). Putting aside the unaccented pattern, Japanese displays a striking tendency to put an accent on the third or fourth mora from the end of the word if the word is a noun. Seen conversely, it avoids placing an accent on the penultimate or final mora of the word.

In native and SJ words, words with an accent on the antepenultimate mora, e.g., /i.no.ti/ ‘life’, overwhelm those with an accent on the penultimate or final mora, e.g. /ko.kó.ro/ ‘heart’, /o.to.kó/ ‘man’ (Kubozono 2006, 2008). This is true of loanwords, too. For example, most three-mora loanwords bear an accent on the antepenultimate mora irrespective of the location of the accent in the source words, as shown in (13).

(13) source: *banána potato Cánada cámara cláss*

loan: bá.na.na pó.te.to ká.na.da ká.me.ra kú.ra.su

This is suggestive of the constraint in (14) (Kubozono 2006) .

(14) Penultimate accent restriction ( $*\mu\mu'\mu]_{PrWd}$ )

In (Tokyo) Japanese, accent on the penultimate mora is prohibited in trimoraic or longer words.

Note in this connection that penultimate accent is perfectly well-formed in bimoraic nouns. Many bimoraic native nouns have an accent on the penultimate mora: e.g., /né.ko/ ‘cat’. Moreover, this penultimate pattern is by far the most common in bimoraic SJ nouns (e.g., /é.ki/ ‘station’, /tó.syo/ ‘book’), and accounts for virtually all bimoraic loanwords, as exemplified in (15).

(15) source: *bus*      *location*    *pill*      *cab*      *demonstration*  
loan:      bá.su    ró.ke      pí.ru    kyá.bu    dé.mo

### 2.5. Loss of syllabicity

It is worth referring here to the peculiar behavior of /ru/, /su/ and /fu/ (= [ϕu]) in Japanese phonology.<sup>6</sup> These CV sequences seem to lose their syllabicity in several independent phenomena so that /CV+ru/, /CV+su/ and /CV+fu/ behave as if they were a heavy syllable. In other words, /ru/, /su/ and /fu/ count as one mora, but not as one syllable, with the vowel /u/ behaving like an extraprosodic element.

Consider the deaccenting rule in loanwords, for example. While loanwords generally show a remarkable bias towards the accented (vs. unaccented) pattern in Tokyo Japanese (Sibata 1994, Kubozono 2006), they tend to become unaccented if they are four moras long and involve a sequence of light syllables word-finally: /a.me.ri.ka/ ‘America’ and /mon.ba.sa/ ‘Mombasa (placename)’. However, /ru/, /su/ and /fu/ behave as if they were not syllabic in loanwords. Thus, while /a.me.ri.ka/ and /mon.ba.sa/ take the unaccented pattern as predicted by the deaccenting rule, /kón.do.ru/ ‘condor’, /ín.da.su/ ‘the Indus River’ and /mó.ro.zo.fu/ ‘Morozoff’ pattern with /rón.don/ ‘London’, /sái.daa/ ‘cider’, /bú.ru.zon/ ‘blouson’, respectively. In other words, /ru/, /su/ and /fu/ in word-final position behave like the moraic nasal and other non-syllabic moras in accent assignment (Kubozono 1996, Giriko 2008).

## 3. Phonological Account of Consonant Gemination in Loanwords

### 3.1. Segmental and contextual conditions

Japanese has three lexical strata—native, Sino-Japanese (SJ) and foreign (loanwords). Geminate consonants are relatively rare in native words but are quite common in the other two types of vocabulary. They are extremely common in the foreign stratum, as we will see shortly, but their distribution is quite severely constrained by linguistic factors. These factors fall into two kinds, those that relate to the consonant itself (segmental conditions) and those that concern the phonological environment in which gemination occurs or does not occur (contextual conditions). In this section, we will look at each of these conditions in detail and propose an output-oriented analysis to account for both old and new generalizations regarding gemination and non-gemination in loanwords.

The essential points of our analysis are as follows. First, we claim that geminate obstruents are universally more marked than singletons (\*Gem >> \*Single). Second, despite this markedness, obstruents can be geminated in order to improve prosodic well-formedness. Specifically, gemination is triggered by a force to create a HL or HH string in word-final position. In our analysis, this constraint dominates \*Gem, which militates against geminate obstruents. Third, gemination does not occur when it is not motivated: that is, it is blocked either if it will not improve prosodic well-formedness or if it would produce a structure that is banned in native phonology.

### 3.2. Voicing condition

The first segmental condition concerns the voice/voiceless distinction in the consonant to be geminated. In loanwords, voiceless obstruents can be geminated, whereas voiced ones are seldom geminated. This condition is exemplified in (16).

(16)

Source	Loan	Source	Loan
Voiceless C	Gemination	Voiced C	No Gemination
<i>tap</i>	tap.pu	<i>tab</i>	ta.bu
<i>lock, rock</i>	rok.ku	<i>log</i>	ro.gu
<i>lack, rack</i>	rak.ku	<i>lag, rug</i>	ra.gu

The voiced/voiceless distinction in (16) follows directly from the constraint in (3), \*VoiGem, which constrains native and SJ words very severely, as we saw in section 2.1 above. (17) describes how relevant constraints interact with each other to produce the

correct outputs.

(17) a.

lock, rock	*VoiGem	ProsForm <sup>7</sup>	*Gem
☞ .rok.ku.			*
.ro.ku.		*!	

b.

log	*VoiGem	ProsForm	*Gem
.rog.gu.	*!		*
☞ .ro.gu.		*	

In (17a), the geminated form is chosen as the optimal output since it satisfies the prosodic constraint demanding HL or HH in word-final position. In this case, gemination improves the prosodic structure without violating any higher constraint. In (17b), in contrast, the ungeminated form becomes the winner since the geminated form violates \*VoiGem, which dominates the prosodic constraint in the constraint hierarchy.

It must be noted here that voiced obstruents are geminated in some loanwords such as /dog.gu/ ‘dog’, /bag.gu/ ‘bag’, /bed.do/ ‘bed’ and /hed.do/ ‘head’ (Itô & Mester 1999). While it remains an open question why voiced geminates are tolerated in these instances, it is worth emphasizing two related facts here. First, many of these ‘exceptions’ are known to undergo devoicing, showing a free variation between a voiced geminate and a voiceless one: e.g., /bag.gu/~bak.ku/, /bed.do~/bet.to/.

A second fact that bears on the voiced geminate issue is that loanwords can and often do exhibit patterns that deviate from native patterns (Itô & Mester 1999). For example, [ti] and [di] are not permitted in native phonotactics but are permissible in loanwords—in such words as ‘team’ and ‘Disney’. Similarly, [p] cannot occur word initially in native words, but it can do so in loanwords, e.g., /pen/ ‘pen’. The native vocabulary cannot have more than one voiced obstruent within a morpheme due to an OCP effect, but loanwords are exempt from such a restriction (e.g., /ze.bu.ra/ ‘zebra’). In all these phenomena, loanwords are more faithful to the input than are native words and are free from markedness constraints to which native words are sensitive. The voiced geminate obstruents in loanwords can be seen as another instance showing this type of deviation from the native restriction.

### 3.3. [s] vs. [ʃ]

A second segmental condition on loanword gemination concerns the distinction between [ʃ] and [x], on the one hand, and [s] and [f], on the other. All of these are voiceless fricatives in the source words, but [ʃ] and [x] undergo gemination in

loanwords, while [s] and [f] generally do not. Some examples are given in (18).

(18)

Source	Loan	Source	Loan
ʃ/x	Gemination	s/f	No Gemination
<i>bush</i>	buʃ.ʃu	<i>kiss</i>	ki.su
<i>cash</i>	kyaʃ.ʃu	<i>bus</i>	ba.su
<i>Bach</i> (German [x])	bah.ha	<i>tough</i>	ta.fu
<i>Gogh</i>	goh.ho	<i>rough</i>	ra.fu

(18) involves a puzzling fact. [s] and [ʃ] belong to one and the same phoneme /s/ in the native phonology of Japanese ([ʃ] appears before [i], and [s] elsewhere), but only [ʃ] undergoes gemination in loanwords. Likewise, [x] but not [f] is geminated in loanwords despite the fact that their adapted forms—[h] and [ϕ]—are in complementary distribution in native phonology: [ϕ] before [u], [ç] before [i], and [h] elsewhere. We attribute this asymmetrical behavior between [s] and [ʃ] (or between [ϕ] and [h]) to the fact mentioned in section 2.5, namely, that /su/ and /fu/ (= [ϕu]) lose their syllabicity in word-final position in Japanese. Our output-oriented analysis accounts for the facts in (18) as in (19), where [f] and [x] are compared for illustration. (<u> means that this vowel is extraprosodic and does not contribute to syllabicity).

(19) a.

tough	*σ <sub>μμμ</sub>	ProsForm	*Gem
.taff.<u>	*!	*	*
☞ .taf.<u>		*	

b.

Bach	*σ <sub>μμμ</sub>	ProsForm	*Gem
☞ .bah.ha.			*
.ba.ha		*!	

The essential part of our analysis is that /fu/ and /su/ are counted as an independent mora but not as an independent syllable. Under this analysis, /tafu/ in (19a) forms one heavy syllable, [.taf.<u>], whereas its geminated counterpart, /taffu/, constitutes a superheavy syllable, [.taff.<u>]. The latter structure is rejected by the general constraint prohibiting trimoraic syllables, which dominates the prosodic constraint triggering consonant gemination. Because of this constraint interaction, the candidate with a single consonant becomes optimal in (19a).

In contrast, the output form with a geminate consonant is chosen as the optimal candidate in (19b) since it violates neither the syllable structure constraint nor the

prosodic structure constraint. In this case, gemination leads to the improvement of prosodic structure. This is true of the case of [ʃ], too: [buʃ.ʃu] wins over [bu.ʃu] as it has a Heavy-Light structure in word-final position.

Yet, the analysis in (19) raises one question regarding the gap between native and loanword phonology. As mentioned in section 2, native phonology permits [ss] and [ʃʃ] as well as their singleton counterparts (see (4) above), but does not permit [ʃʃ] or [hh]. In loanword phonology, however, [ʃ] and [h] can be geminated, while [s] and [f] (= [f]) generally cannot. The non-gemination of [s] and [f] has already been accounted for in (19). What remains to be answered is why [h] is geminated in loanwords although its geminated form is not allowed in native words.

In OT terms, this can be accounted for by ranking a constraint prohibiting [hh] (\*[hh]) below ProsForm, thus assuring that the geminated form is more harmonic than the ungeminated form. However, this account is merely descriptive and not explanatory. The question still remains why loanwords permit [hh] although it is prohibited by native words. This will require phonetic as well phonological considerations. At the descriptive level, the gemination of [x] into [hh] in loanwords is just another instance showing that loanwords are sensitive to phonological (markedness) constraints to a lesser extent than native words.

### 3.4. Vowel length condition

There are quite a few contextual conditions to which loanword gemination is sensitive. In this and the next four sections we will consider five major contextual conditions all of which define the phonological contexts in which gemination is (un)likely to occur.

The first contextual condition on consonant gemination is a ‘vowel length condition’, by which gemination is invariably blocked if the consonant is preceded by a long vowel or diphthong (as opposed to a short vowel) in the output:

(20)

Source	Loan	Source	Loan
short V __	Gemination	longV ____	No Gemination
<i>mitt</i>	mit.to	<i>meat</i>	mii.to
<i>pick</i>	pik.ku	<i>peak</i>	pii.ku
<i>pack</i>	pak.ku	<i>park</i>	paa.ku

The vowel length condition illustrated in (20) can be accounted for by the

constraint against trimoraic syllables in a straightforward manner. This is shown in (21), where we have the same constraints and constraint ranking as in (19). In (21a), the output form with a geminate consonant is more harmonic than its ungeminated counterpart due to the force to have a Heavy-light or Heavy-heavy structure word-finally. In (21b), however, the form with a geminate consonant is less harmonic than the ungeminated form since it violates the higher ranking syllable structure constraint.<sup>8</sup>

(21) a.

mitt [mit]	*σ <sub>μμμ</sub>	ProsForm	*Gem
☞.mit.to.			*
.mi.to.		*!	

b.

meat	*σ <sub>μμμ</sub>	ProsForm	*Gem
.miit.to.	*!	*	*
☞.mii.to.			

### 3.5. Positional effect

A second case where gemination is sensitive to phonological context concerns what we call a ‘positional effect’. Namely, coda consonants in word-final syllables in the source language can be geminated but those in word-medial syllables cannot (Kawagoe & Arai 2002). This effect is exemplified in (22).

(22)

Source	Loan	Source	Loan
word-final C	Gemination	word-medial C	No Gemination
<i>cap</i>	kyap.pu	<i>captain</i>	kya.pu.ten
<i>dock</i>	dok.ku	<i>doctor</i>	do.ku.taa
<i>mix</i>	mik.ku.su	<i>mixer</i>	mi.ki.saa
<i>sax</i>	sak.ku.su	<i>saxophone</i>	sa.ki.so.fon
<i>box</i>	bok.ku.su	<i>boxer</i>	bo.ku.saa
<i>tax</i>	tak.ku.su	<i>taxi</i>	ta.ku.sii
<i>picnic</i>	pi.ku.nik.ku	<i>picnic</i>	pi.ku.nik.ku

To take one example, the English word ‘picnic’ consists of two syllables, /pik/ and /nik/, of which only the coda consonant of the second syllable undergoes gemination when adapted into Japanese: /pi.ku.nik.ku/, \*/pik.ku.nik.ku/, \*/pik.ku.ni.ku/. The same generalization holds in all other cases given in (22).

Our analysis of this positional effect is illustrated with the *dock*—*doctor* pair in (23). The lack of gemination in *doctor* can be accounted for in a straightforward manner by the prosodic structure constraint, ProsForm. Recall that this constraint requires that the output should end in a Heavy-Light or Heavy-Heavy syllable string in word-final position. The first candidate in (23a), /dok.ku/, satisfies this requirement. On the other hand, the first candidate in (23b), i.e., /dok.ku.taa/, does not fulfill it as gemination creates a HL string in *non-final* position. In other words, gemination of [k] in this word does not improve the prosodic structure and, hence, lacks prosodic motivation. The same analysis explains all other cases in (22) (see the next section for the motivation of coda gemination in *mix*, *sax*, *box* and *tax*).

(23) a.

dock	ProsForm	*Gem
☞ .dok.ku.		*
.do.ku.	*!	

b.

doctor	ProsForm	*Gem
.dok.ku.taa.	*	*!
☞ .doku.taa.	*	

The next tableau explains how /pi.ku.nik.ku/ is chosen for ‘picnic’.

(24)

picnic	ProsForm	*Gem
.pik.ku.nik.ku		**!
.pik.ku.ni.ku	*!	*
☞ .pi.ku.nik.ku		*
.pi.ku.ni.ku	*!	

### 3.6. /-ks/ vs. /-kt/, /-sk/

In word-final position, gemination readily occurs in /-ks/ but almost never in /-sk/, /-kt/, /-sp/ or /-st/ (Kawagoe & Arai 2002). This is illustrated in (25).

(25)

Source	Loan	Source	Loan
word-final -ks	Gemination	word-final -sp/-sk/-st/-kt	No Gemination
<i>tax</i>	tak.ku.su	<i>task</i>	ta.su.ku
<i>max</i>	mak.ku.su	<i>mask</i>	ma.su.ku
<i>sax</i>	sak.ku.su	<i>tact</i>	ta.ku.to
		<i>duct</i>	da.ku.to
		<i>wasp</i>	wa.su.pu
		<i>list</i>	ri.su.to

Our analysis provides a principled account for the gemination of [k] in /-ks/, as shown in (26a). The geminated pattern, /takkusu/, has /su/ in word-final position, which is non-syllabic according to our discussion in section 2.5. Accordingly, this output form consists of two heavy syllables: [tak.kus.<u>]. The ungeminated form, [ta.kus.<u>], is also disyllabic but consists of a light syllable followed by a heavy one. This prosodic form thus fails to satisfy ProsForm and, hence, cannot win over the geminated form.

(26) a.

tax	* $\sigma_{\mu\mu\mu}$	ProsForm	*Gem
☞ .tak.kus.<u>			*
.ta.kus.<u>		*!	

b.

task	* $\sigma_{\mu\mu\mu}$	ProsForm	*Gem
.tas.su.ku.		*	*!
☞ .ta.su.ku		*	

c.

tact	* $\sigma_{\mu\mu\mu}$	ProsForm	*Gem
.tak.ku.to.		*	*!
☞ .ta.ku.to.		*	

The *task* case in (26b) involves /su/ in the output but only in word-medial position. The geminated pattern in (26b), /tassuku/, is syllabified as /tas.su.ku/, which does not satisfy ProsForm despite gemination. Since gemination does not improve the prosodic structure, the ungeminated form will be chosen. Here \*Gem plays a decisive role in selecting the most harmonic candidate.

A similar situation can be found in (26c), where gemination of [k] does not improve the prosodic structure, either. Since the prosodic form constraint, ProsForm, cannot be satisfied in any case, the ungeminated pattern turns out to be the winner.

### 3.7. *listen* vs. *listener*

Let us now consider the *listen*—*listener* pair. We saw in section 3.3 that [s] and [f] generally fail to undergo gemination due to the non-syllabic status of word-final /su/ and /fu/ in Japanese phonology. In certain phonological contexts, however, even [s] and [f] can be geminated. One such context is where they are followed by a syllabic sonorant ([ŋ] or [l]) in the source words. Thus, [s] is geminated in such words as *lesson*, *listen*, *hustle*. [f] is geminated in *shuffle* and *waffle*.

(27)

Source	Loan	Source	Loan
followed by syllabic sonorant [ŋ], [l]	Gemination	not followed by syllabic sonorant	No Gemination
<i>lesson</i>	res.sun	<i>less</i>	re.su
<i>hustle</i>	has.su.ru	<i>huss</i>	ha.su
<i>listen</i>	ris.sun	<i>listener</i>	ri.su.naa
<i>shuffle</i>	syaf.fu.ru	<i>shaft</i>	sya.fu.to
<i>tackle</i>	tak.ku.ru	<i>tact</i>	ta.ku.to

Our analysis is summarized in (28) with *listen*, *listener* and *hustle*.

(28) a.

listener	*σ <sub>μμ</sub>	ProsForm	*Gem
.ris.su.naa.		*	*!
☞.ri.su.naa.		*	

b.

listen	*σ <sub>μμ</sub>	ProsForm	*Gem
☞.ris.sun.			*
.ri.sun.		*!	

c.

hustle	*σ <sub>μμ</sub>	ProsForm	*Gem
☞.has.sur.<u>			*
.ha.sur.<u>		*!	

First, [s] is not allowed to geminate in *listener* in (28a) since gemination does not improve the prosodic structure: the geminated output violates both ProsForm and \*Gem. Its ungeminated form, /ri.su.naa/, does not satisfy ProsForm but it fulfills \*Gem. Here again, \*Gem plays a decisive role in selecting the most optimal candidate.

In the case of *listen* and *hustle* in (28b/c), on the other hand, gemination does improve the prosodic structure by producing HH outputs. In (28c), in particular, the

geminated output involves a HH output due to the extraprosodicity of the word-final /u/ in /ru/.

### 3.8. *tough* vs. *staff*

We saw in sections 3.2 and 3.3 that voiced stops as well as [f] and [s] generally resist gemination. However, they become less resistant to it if an extra consonant is added to the beginning of the word. This is exemplified in (29).

(29)

Source	Loan	Source	Loan
Complex onset	Gemination	Simple onset	No Gemination
<i>frog</i>	fu.róg.gu	<i>log</i>	ró.gu
<i>flag</i>	fu.rág.gu	<i>lag</i>	rá.gu
<i>drug</i>	do.rág.gu	<i>rug</i>	rá.gu
<i>snob</i>	su.nób.bu	<i>knob</i>	nó.bu
<i>stab</i>	su.táb.bu	<i>tab</i>	tá.bu
<i>staff/stuff</i>	su.táf.fu	<i>tough</i>	tá.fu

Gemination of [g] is generally blocked since it would produce a voiced geminate. What is it then that motivates its gemination in *flag* and *frog*? The answer to this question lies in the accent structure of /fu.rá.gu/ and /fu.ró.gu/. As noted in section 2.4, Japanese has a constraint against accenting the penultimate mora in trimoraic or longer words. Non-gemination of [g] in *flag* and *frog* produces a phonological structure violating this constraint. In contrast, gemination in these words helps to avoid this marked accent structure since it serves to shift the accent from the penultimate to the antepenultimate mora while keeping the accent on the same vowel/syllable: /fu.rág.gu/ and /fu.róg.gu/.

Non-gemination of [g] in *lag* and *log* does produce an output form with a penultimate accent, too, but this bimoraic output does not violate the prosodic constraint in question. We can account for this interesting interaction between accent structure and consonant gemination by positing the penultimate accent restriction in (14) higher than \*VoiGem. This is illustrated in (30).

(30) a.

log	*μμ'μ] <sub>PrWd</sub>	*VoiGem	ProsForm	*Gem
róg.gu.		*!		*
☞ ró.gu.			*	

b.

frog	* $\mu\mu'\mu$ ]PrWd	*VoiGem	ProsForm	*Gem
$\varphi$ .fu.róg.gu.		*		*
.fu.ró.gu.	*!		*	

Similarly, we can account for the difference between *tough* and *staff* by positing the penultimate accent restriction higher than \* $\sigma_{\mu\mu\mu}$ , as shown in (31).

(31) a.

tough	* $\mu\mu'\mu$ ]PrWd	* $\sigma_{\mu\mu\mu}$	ProsForm	*Gem
.táff.<u>		*!	*	*
$\varphi$ .táf.<u>			*	

b.

staff	* $\mu\mu'\mu$ ]PrWd	* $\sigma_{\mu\mu\mu}$	ProsForm	*Gem
$\varphi$ .su.táff.<u>		*	*	*
.su.táf.<u>	*!		*	

It must be noted here that gemination is not the only solution to avoid the marked accent structure. An alternative solution is to change the accent structure of the output either by deleting the accent or by moving it onto a different syllable. These solutions are actually used in many words including those in (32): superscribed /<sup>o</sup>/ denotes that the word is unaccented. Not surprisingly, accent change and consonant gemination are complementary to each other so that they do not co-occur in one and the same output form. The English word *flag*, for example, results either in /fu.rág.gu/ (geminated, but with no change in accent position) or in /fu.ra.gu<sup>o</sup>/ (unaccented, but with no gemination). The geminated, unaccented form /fu.rag.gu<sup>o</sup>/ never surfaces in the output.

(32) a. deaccenting: *flág* → fu.ra.gu<sup>o</sup>, *plúg* → pu.ra.gu<sup>o</sup>, *blóg* → bu.ro.gu<sup>o</sup>

b. accent shift: *plúg* → pú.ra.gu, *cláss* → kú.ra.su, *clúb* → kú.ra.bu

It is possible to account for this interesting interaction between accent change and consonant gemination by positing the faithfulness constraint in (33) and ranking it as relative to \*VoiGem or \* $\sigma_{\mu\mu\mu}$ . The variation between /fu.rág.gu/ and /fu.ra.gu<sup>o</sup>/, for example, can be dealt with as in (34), where Faith-acc >> \*VoiGem will select the geminated and accented form as in (34a) and the reverse ranking will choose the ungeminated, deaccented (or accent-shifted) form as in (34b).

(33) Faith-accent

The accented vowel in the input must be accented in the output.

(34) a.

flág	*μμ'μ]PrWd	Faith-acc	*VoiGem	ProsForm	*Gem
☞.fu.rág.gu.			*		*
.fu.rá.gu.	*!			*	
.fu.ra.gu.°		*!		*	
.fú.ra.gu.		*!		*	

b.

flág	*μμ'μ]PrWd	*VoiGem	Faith-acc	ProsForm	*Gem
.fu.rág.gu.		*!			*
.fu.rá.gu.	*!			*	
☞.fu.ra.gu.°			*	*	
☞.fú.ra.gu.			*	*	

## 4. Conclusion

### 4.1. Summary

In this paper, we looked at various facts regarding gemination in Japanese phonology, especially in loanwords. The distribution of geminate obstruents in Japanese loanwords appears very complex at first glance, but it can be accounted for in a principled manner if one considers various conditions on the occurrence of geminate obstruents in native phonology (in native and SJ words). The basic claim underlying our analysis is that gemination in loanwords is essentially an output-oriented phenomenon. While gemination itself creates a marked structure, it is permitted when and only when it improves output structure. Specifically, it occurs in contexts where it creates Heavy-Light or Heavy-Heavy syllable strings in word-final position. On the other hand, it is blocked in contexts where it would not improve prosodic structure or it would produce a more marked structure in one way or another.

With these ideas in mind, we proposed an Optimality-theoretic analysis that can provide a simple and principled account for all major gemination and non-gemination patterns in loanwords. The relevant constraints in our analysis are ranked as follows:

(35) \*μμ'μ]PrWd >> \*VoiGem, \*σμμμ >> ProsForm >> \*Gem

The output-oriented account proposed here is compatible with the idea that loanword phonology is severely constrained by native phonology (Kubozono 2006) or, in phonetic terms, that speech perception is highly constrained by the phonological structure of the listener's native language (Best et al. 1988).

## 4.2. Future agenda

This study has uncovered several interesting questions for our future work. Two questions emerge regarding the gap between native and loanword phonology. One of them concerns the gemination of (German and Dutch) [x] into [hh] in Japanese loanwords. As mentioned above, [h] turns into [pp] and not into [hh] when geminated in native phonology. It remains unclear why [hh] is tolerated only in loanwords. Equally interesting is the fact that voiced obstruents (especially [g] and [d]) are geminated in some loanwords, e.g., /bag.gu/ ‘bag’, /bed.do/ ‘bed’, despite that they are not allowed to geminate in native words (recall the gemination of [d] into [tt] in /ta.da/ → /ta.tta/ ‘only’). It is interesting to ask why voiced geminates are allowed to occur in some loanwords.

A third question that remains unanswered concerns the fact that [t] in [tʰ] in English is not geminated in Japanese, e.g., /bo.to.ru/, \*/bot.to.ru/ ‘bottle’; /sya.to.ru/, \*/syat.to.ru/ ‘shuttle’. Given that other voiceless obstruents are geminated in the same phonological context, e.g., /kyas.su.ru/ ‘castle’, /ap.pu.ru/ ‘apple’, /tak.ku.ru/ ‘tackle’, /waf.fu.ru/ ‘waffle’, it is strange to find that only [t] is not allowed to geminate in this particular context. This looks particularly peculiar since [t] is at least as prone to gemination as other voiceless obstruents in other phonological contexts.

Another puzzling fact about gemination can be found in loanwords from other languages. Although our analysis in this paper was mainly restricted to loanwords from English and German, loanwords from Korean seem to display somewhat different patterns from those that derive from English. One notable case is that voiceless coda stops generally do not geminate. /pak/ ‘Park (Korean surname)’, for example, has basically the same syllable structure as the English word ‘pack’, but its coda consonant nevertheless fails to undergo gemination when adapted into Japanese: /pak/ → [pa.ku], \*[pak.ku]. We need to ask why the same phonological string is adapted into Japanese in different ways and, for that matter, what phonetic details contribute to this adaptation difference. This question leads us to a new aspect of loanword phonology as it points to the necessity of comparing loanwords from English with those from other languages (e.g., Korean, French) and explaining their differences and similarities.

Finally, it is necessary to ask about the universality of the constraints used in our analysis, all of which hold in the native phonology of Japanese. It is equally important to explore the empirical basis of the phonological constraints. The former question will require a detailed cross-linguistic survey, while the latter will require phonetic, physiological and/or cognitive experimentation and considerations.

## Notes

<sup>1</sup> In this paper, the term ‘native phonology’ is used contrastively with ‘loanword phonology’, referring to the phonology of native and Sino-Japanese words.

<sup>2</sup> Modern Japanese /h/ derives from old Japanese [p] and is believed to be underlyingly /p/ in modern Japanese (Itô & Mester 1996).

<sup>3</sup> /h/ has three allophones in Japanese: [ç] and [ϕ] appear before /i/ and /u/, respectively, while [h] appears other vowels.

<sup>4</sup> [pp] occurs in reduplication in (5a), in emphatic forms in (5b-c), and in compound-medial positions via regressive place assimilation in (5d-e).

<sup>5</sup> This constraint is here stated descriptively, and can perhaps be formally understood as resulting from the interaction of several constraints, including NonFinality and FootForm, as well as accentual constraints (see Itô et al. 1996 for a proposal in this direction). In this paper we retain this preliminary formulation, leaving its formal investigation for future work.

<sup>6</sup> In what follows, [ϕu] is represented as /fu/ rather than /hu/ to show the correspondence between [ϕ] in loans and [f] in source words.

<sup>7</sup> A violation mark is assigned if the form does not end in HH or HL.

<sup>8</sup> It may be worth adding here that \*σ<sub>μμμ</sub> can be violated in some languages. In Finnish, for example, geminate consonants can appear before long vowels both in native words and loanwords: e.g., /piik.ki/ ‘peak’, /paak.ki/ ‘park’.

# **A Phonetic Analysis of the Prosody of Hebrew-Speaking Children with High-Functioning Autism**

**Hila Green and Yishai Tobin**

Ben-Gurion University of the Negev  
greenh@bgu.ac.il yishai@bgu.ac.il

## **Abstract**

Atypical prosody is a core feature in the language of many individuals with autism spectrum disorders. We analyzed and compared the intonation of two children diagnosed with high-functioning autism and two matched children without developmental disorders as an initial part of our research. Pitch accents and edge tones were examined in two elicitation tasks (semi-spontaneous speech and reading-aloud). The data were transcribed using the PRAAT system according to Autosegmental-Metrical theory with the Israeli Hebrew adaptation of the ToBI transcription framework. The results were analyzed and explained according to the theory of Phonology as Human Behavior of the Columbia School of Linguistics.

**Keywords:** Phonology, Prosody, Autism.

## **1. Introduction**

This paper presents a preliminary study applying the Autosegmental Metrical (AM) theory (Pierrehumbert 1980, Ladd 1996) and the ToBI (Tones and Break Indices; Beckman and Hirshberg 1994, Beckman and Ayers-Elam 1997) framework being adapted for Israeli Hebrew (IH) for this study, in order to describe, compare and contrast prosodic features of intonation of Hebrew-speaking children diagnosed with Autism Spectrum Disorders-High Functioning (ASD-HF) with matched peers without developmental disorders, using a phonetic analysis of pitch accents and edge tones.

ASDs are neuro-developmental disorders that emerge early in life, prior to 30 months (Short and Schopler 1988, Volkmar 1997, Volkmar *et al.* 2005). It is a behaviourally defined disorder. The three essential criteria for diagnosing autism include: (a) qualitative impairments in social reciprocity and engagement, (b) delays and deficits in language and communication, and (c) the presence of restricted repetitive and stereotyped behaviours, activities, or interests (Wing and Gould 1979, APA 1994). The severity of these impairments varies from individuals to individual (e.g. Sigman and McGovern 2005). The autistic continuum ranges from the most severe mentally retarded individuals with social impairment as one of several other severe impairments, to highly intelligent and capable persons with social impairments (Wing 1991). Researchers began using the term High Functioning Autism (HFA) (together with low-functioning autism) as a quasi-diagnostic label to distinguish the relative levels of adaptation and development. The research community recognizes that HFA does not occur in people with an IQ of less than 70.

Despite the abundant evidence that prosody is a feature of impaired communication in ASD (Kanner 1946, 1971, Baltaxe and Simmons 1985, 1992, Paul *et al.* 2005, Tager-Flusberg 1981), there has only been limited research in the prosody of

autism. However, there is general agreement that when atypical prosody is present, it tends to be persistent and shows little change over time, even when other aspects of language improve (e.g. Kanner 1971, Simmons and Baltaxe 1975). For those with HFA, prosody can be one of the main barriers to social acceptance (Shriberg *et al.* 2001, McCann and Peppé 2003). The research into the prosody of autism has concentrated on disordered stress patterns that have been described as being excessive, unvarying or misplaced (e.g. Baltaxe and Simmons 1985, McCaleb and Prizant 1985, Baltaxe and Guthrie 1987, Fine *et al.* 1991, Shriberg *et al.* 2001). Others (Fine *et al.* 1991, Thurber and Tager-Flusberg 1993), point out that autistic children use grammatical pausing in a way similar to typically developing children. Peppé (2007) investigated the prosodic boundary in children with ASD-HF and Asperger syndrome (AS) and found that children with ASD (HF and AS) can use prosodic boundaries in speech for linguistic distinctions and assumed that it is possible that factors other than prosody contributed to the perception of atypicality. Baltaxe (1984) found that the children with autism do not have a significantly different frequency range from typically developing children but produced either very narrow or very wide frequency ranges. These findings suggest that the mean of these frequency ranges does not adequately capture the atypical nature of intonation in children with autism (McCann and Peppé 2003). At present, research into prosody neither provides a full description nor an explanation for the atypical prosody produced by many individuals with autism.

Prosody has been conceptualized as the melody of language. Fujisaki (1997:28) defined prosody as: “a systematic organization of various linguistic units into an utterance or a coherent group of utterances in the process of speech production. Its realization involves both segmental and suprasegmental features of speech, and serves to convey, not only linguistic information, but also paralinguistic and non-linguistic information”. Prosody plays an important role in a range of communicative functions that enable speakers to construct discourse through expressive language. Based on the AM model of intonational phonology, the ToBI transcription method was developed for use in labelling of intonation and prosody of spoken Mainstream American English (MAE\_ToBI). In time it has come to refer to a general framework for the development of prosodic annotation systems of different typological languages (Jun 2005). The prosodic model assumed in ToBI is a phonological model (rather than a phonetic one) and the ToBI system of one language is not appropriate for describing the prosodic system of other languages (Jun 2005). Therefore, the specification of IH and the distinctive prosodic events of the IH-ToBI (for the age group of the current research) serve as an important background to our research.

At the turn of the 19<sup>th</sup> century Hebrew was "revived" as an everyday vernacular or spoken language and became the national language of the Jewish majority of the State of Israel. The genetic affiliation of IH is the Northwest sub-branch of the general Afro-Asiatic Semitic language family. IH has a synthetic morphology and basic lexicon which are drawn from Biblical Hebrew (BH). The phonology of IH, as well as certain syntactic phenomena such as word order, no longer exclusively reflect the characteristics of BH, but have been strongly influenced by European languages (Tobin

1997). The preferred word order in IH is Subject–Verb–Object, but IH word order is relatively free and all possible alternations can appear in specific contexts. Differences in word order also influence the use of prosodic patterns. IH may be referred to as an “intonational language” because it employs prosodic means to provide meaningful communication distinctions on the lexical and utterance levels. There has not been much research on the intonational phonology of IH in general; on the phrase level (e.g. Laufer 1987, 1996, Izre’el *et al.* 2001, Becker 2003, Mixdorff and Amir 2002, Amir *et al.* 2004), and even less research in developmental prosody on the word level (e.g. Ben David 2001) and for developmental clinical prosody (e.g. Frank *et al.* 1987, 1989, Adi-Bensaid and Bat-El 2004, Adi-Bensaid 2006). However, the stress pattern of IH has been relatively well studied (e.g. Rosen, 1977, Bolozky, 1978, Berman 1978, Melčuk and Podolsky 1996, Falk 1996, Bat-El 1993, Graf and Ussishkin 2001, Becker 2003) and demonstrate that primary stress usually occurs on the final syllable, with secondary stress occurring on alternating syllables to the left. Stress in IH nouns is mostly ultimate or penultimate.

We will now present our initial description of IH prosodic and intonation events through the investigation of pitch realization. As in other ToBI systems, this IH-ToBI transcription is a method for transcribing the distinctive prosodic events of a spoken utterance. It is based on the MAE\_ToBI, but it has been adapted so as to take into account the main goal of the current study. The distinctive prosodic events of spoken IH fall into two main categories; (a) *Phrasing*, which creates a grouping of words, and (b) *Accents*, which contribute to a word's relative prominence in an utterance.

IH-ToBI differentiates three levels of phrasing: the *intermediate phrase* (ip), the *intonation (phrase) unit* (IU) and the *utterance* (U). An U may include more than one IU which might include more than one ip. The degree of perceived disjuncture between sequential words across IU boundaries is larger than that between words within and across the ip and it is coded in the Break indices tier. Two types of phrase accents (PhA) defined: high (Hp) and low (Lp). Hp has roughly the same fundamental frequency (FO) value as the peak corresponding to the most recent H tone, which creates a plateau until the end of the phrase or an upstep from the recent H tone before a very high boundary tone (BT). Lp constitutes either an FO minimum low in the range or tone but can also be downstepped in relation to a previous tone. The PhA in IH also functions as “blocking” a downstep (Lp) and upstep (Hp) of the intonation contour patterns. For the BT we determine three types of boundaries: one initial (%) BT and two final BTs: high (H%) and low (L%). These two BTs combine with the PhAs in four different configurations that appear to have specific pragmatic functions. In this paper we will focus on the various prosodic patterns of IH using a partial presentation of the IH-ToBI developed for this research.

Every IU unit contains at least one Pitch Accent (PA). PAs are the events which are associated with the stressed syllable but may be in contrast to stress (which is lexically determined). In the domain of tone it is not expected that every stressed syllable will be accented. A detailed narrow transcription of the data of our speech samples revealed five pitch accents: two mono-tonal PAs: H\* and L\*, and three bi-tonal

PAs: L+H\*, H\*+L and L\*+H. As in the description of other languages, the H and L tones for IH are described as high or low relative to each speaker's pitch range. The basic PA's may additionally be scaled within a modified pitch range: lowering ('!' symbol), sequence of pitch accents where each accent involves a step up in pitch or a step up to a boundary tone ('^' symbol) and peak delay ('<' symbol) after the associate syllables.

For the present paper we combined the results of H\*, L+H\* and the H\*+L transcription into one H\* group even though the most common PA in IH is the L+H\* (cf. Table 2 for a detailed summary of IH-ToBI transcription and coding).

## **2. Methodology**

### *2.1. Subjects*

The data of this preliminary study are drawn from the speech samples of four children: two children diagnosed with ASD as HF (ASD-HF) and two matched children without developmental disorders (WDD) selected by the special education teacher who was not aware of the research aims. The children were recruited from two classes from a mainstream primary school with special education classes for children with ASD. The ASD children receive their regular academic program together with their peers and remedial assistance for both academic and social issues in the special education classes. Subjects for this study were matched peers. The children fulfilled the following criteria: two children WDD (9:08, 12:09) and two children diagnosed with ASD-HF (9:11, 12:10). All participants were male, monolingual speakers of IH; their parents were born in Israel and are monolingual speakers of IH. None of the members of the immediate families of the subjects have learning or other known disabilities. All four mothers have at least 15 years of education, which is indicative for socioeconomic status, since maternal educational level is a significant predictor of language functioning in children (Dollaghan *et al.* 1999). The recruitment of the ASD-HF subjects was made using inclusion criteria of: (a) a diagnosis of DSM-IV Autistic disorder or Asperger disorder on the basis of clinical interview by the child psychiatrist, (b) IQ test results. The ASD children were found to be within the norm for their chronological age, both in their performance and verbal IQ (WISC-R), and (c) typical, within the average, school performance in the mainstream class in language and reading. The recruitment of the control group was made using inclusion criteria of: (a) children WDD, i.e. they have not been referred to a specialist for any developmental reasons, (b) they belong to the same home classes as the HFA subjects, and (c) as reported by the teachers, their academic achievements are similar to the ASD-HF subjects. Details are presented in Table 1.

Table 1: Subject's characteristics

Subject and Research Group	School Year	IQ			Age
		VIQ	PIQ	FIQ	
N-ASD-HF	5	90	99	94	9:11
T-ASD-HF	7	108	99	104	12:10
D-WDD	5				9:08
A-WDD	7				12:09

## 2.2. *Speech Material*

It has often been pointed out that reading tasks can be very useful for research dealing with controlled data, but reading aloud fails to account for several linguistic phenomena that are crucially important when one is making assumptions about spoken language (Beckman 1997). This is particularly relevant when researching the complex domain of prosodic intonation which is the natural context of prosody. This study will concentrate on both Read Aloud (RA) and Semi-Spontaneous Speech (S) data. The S sample will provide the naturally occurring conversational prosodic behaviour and will be compared with an elicited RA language sample. However, the definition of what characterizes S is controversial. Speech is usually labelled as being either spontaneous or read, without taking into account that there is a continuum that lies between the two (Fujisaki 1997). Therefore, we have adopted a more gradual holistic view of S, defined by the main characteristic of spontaneity: i.e. that it must occur “by its own internal force, motivation, etc., rather than by external ones” (Fujisaki 1997:38).

## 3. Procedures

The speech material was gathered from RA and S elicitation tasks. Each child participated in an introductory meeting with the first author, followed by a session where language samples were collected: (a) RA: each subject read a short story considered by the teacher to be appropriate for the age and grade of the subjects. We analyzed ten sentences of the story: seven complex declarative sentences (181 words) and three simple WH questions (12 words). (b) S: natural language samples were collected during interaction between the children and the researcher in response to the question: “I want to get to know you better. Is that OK with you?” After receiving a positive reply, directed, open questions were asked about the subject's school environment and hobbies. The goal was to produce a fluent narrative, preferably a monologue or a series of monologues, from the child. We analyzed the first ~100 IU of each subject's S. Meetings took place in the child's room.

### 3.1. *Preparation of the Material*

Two procedures were followed before the actual analyses of the data:

1. Digitalization of the acoustic material: All the language samples were recorded directly onto a laptop computer using Audacity, a software package for recording and editing sound files. The recording was done at a sample rate of 44.1 KHz and at a bit depth of 16 bits.
2. Transcriptions and coding procedure were separated into: (a) Division of the data into IUs following the commonly used procedure of parsing an utterance into IUs delimited

by their boundaries (Cruttenden 1986). All utterances/sentences were saved in .wav format for further coding and analyzes. (b) Using PRAAT software (Boersma and Weenink 2005) and the adaptation of ToBI framework to IH-ToBI our research procedure generates a sound file and a textgrid for each utterance or sentence. This textgrid has five different tiers: tones, words, breaks, phonetic and comments. In this paper we will not consider all the important issues of each tier, rather we will concentrate on the initial analysis of the intonation features of pitch accents and edge tones in the language of ASD-HF subject and control WDD in two elicitation tasks. In table 2 we summarize the IH-ToBI transcription and coding procedures we have just described.

Table 2: Summary of IH-ToBI transcription and coding

IH-ToBI Tiers		Description
Tone	PAs	L+H* - This is a rising PA. It is by far the most frequently used PA in IH. The accented syllable is perceived as high. This PA is preceded by a syllable with a low pitch target which leads to a rise in the accented syllable (In this PA the peak might be late in the accented syllable).
		H* - FO peak which is preceded by a small rise.
		H*+L - This is a falling pitch accent.
		L* - Low pitch accent.
		L*+H - The L*+H differs from the L* primarily by a rising pitch movement that follows the L* target. This PA is in contrast with the L+H* PA. In the L+H* PA the H tone appears roughly in the middle of the accented vowel and even if the peak is late (L+H*<), this PA perceptually perceived as high. In contrast, The L*+H PA always show a late alignment of the H tone and perceptually perceived as low.
	PhA	Lp - FO minimum low in the range / downstepped in relation to a previous tone. Hp - The same FO value as the peak corresponding to the most recent H tone / upstep in relation to previous H tone.
BT	%	- Initial boundary tone.
	L%	- Final low boundary tone.
	H%	- Final high boundary tone.
Words: It is an orthographic tier and contains a straightforward transcription of all of the words in the utterance, written in Latin alphabet to transliterate IH words (following Berman 1978). The word transcriptions are aligned with their locations in the speech waveform.		
Break indices	B	Marking the beginning of an IU
	1	Marking typical word boundaries in a fluent sequence of words within a phrase
	1p	Marking a short disfluent break
	0	Marking when two words are produced as one
	2	Marking mismatch between tones and perceived juncture
	3	Marking of ip
	3p	Marking a disfluent break long enough for an ip boundary
	4	Marking the end of an IU
4u	Marking the end of an U	
Phonetic: Provides an IPA transcription of a word with addition of PA placement (/) before the accented syllable.		
Comments: Information is only encoded if it cannot be derived from labels from other tiers or from the speech signal. This tier includes nonverbal noise produced in the vocal tracts of speech event participants as well as other related details.		

## 4. Results

The results describe, compare and contrast the intonation components of PAs and ETs of the ASD-HF and WDD groups in each elicitation task.

### 4.1. PAs in the RA task

The ASD-HF subjects produced more PAs than the WDD control group. Differences were also found in the kinds of PAs. All subjects produced high PAs (L+H\*,

H\*, H\*+L) more frequently, but the ASD-HF subjects showed a greater use of high PAs, as well as a dissimilarity in their use within the ASD-HF group. The use of high PAs by the two ASD-HF participants was 70.0% and 81.2% of the total, while the WDD subjects produced 64.2% and 66.1% of high PAs respectively (see Table 3).

Table 3: PAs in the RA task

Component	ASD-HF		WDD	
	N-ASD	T-ASD	D-WDD	A-WDD
PAs per total number of words	1.29	1.15	1.05	0.94
	1.22		0.99	
% of H* PAs	70	81.3	64.2	66.1
	75.65		65.15	

#### 4.2. ETs in the RA task

The sample contained 169 IUs of which 162 were analyzed. 7 IUs were excluded because the visibility of the ETs (on the PRAAT software) was unclear or absent. The results indicate that for all subjects the most frequent use of ETs is a contour pattern of L% final. For declarative sentences, the ASD-HF and the WDD use almost the same patterns in sentence-final position (H\*LpL%, L\*LpL%): i.e. 79% of the ETs were similar, except that they showed a preponderance of high PA (similar to the PA component). The HFA subjects have more L% final than their WDD peers. With regard to the ETs patterns in the RA task, the WDD subjects exhibit more similar contour patterns (58.2% and 62.7%) of L% final while the ASD-HF subjects exhibit dissimilar patterns. One ASD-HF participant produced 53.9% of L% final which is more similar to the contour patterns of the control WDD subjects and the other ASD-HF participant used an L% final in 83.7% of his IUs boundaries, far more than all the others. These differences in the falling pattern are even more prevalent when we compare the two groups. The HFA subjects used more final lowering patterns than the WDD controls but with less diversity (see Table 4).

Table 4: Distribution of ETs in the RA and S tasks

ETs	N-ASD		T-ASD		D-WDD		A-WDD	
	RA	S	RA	S	RA	S	RA	S
H*HpH	7.6	14.1	2.3	2.1	11.4	9	19.4	16.7
H*LpH	23.2	17.4	9.4	7.2	5.8	7	8.4	10
L*HpH	9.6	2.2	2.3	3.1	8.6	7	8.4	15.6
L*LpH	5.7	0	2.3	2.1	11.5	10	5.6	1.1
Total of high- BT	46.1	33.7	16.3	14.5	37.3	33	41.8	43.4
H*HpL	7.7	17.3	20.9	22.6	17.1	14	19.4	10
H*LpL	28.8	39.2	51.1	49.4	20.0	29	22.2	22.1
L*HpL	0	2.2	4.7	3.1	8.5	5	0	10
L*LpL	17.4	7.6	7.0	10.4	17.1	19	16.6	14.5
Total of low-BT	53.9	66.3	83.7	85.5	62.7	67	58.2	56.6

#### 4.3. PAs in the S task

The sample contained 405 IUs (about 100IU of each subject). The ASD-HF subjects produced *more* PAs than the WDD controls with a greater use of the high PAs. The S analysis of high PAs by the two ASD-HF subjects was 75.6% and 79.5% of the total number. Differences between the two ASD-HF subjects were smaller, when

compared with the RA task. The PAs of the WDD subjects show that the use of high PAs is 64.4% and 64.3% and hence similar to the RA task (see Table 5).

Table 5: IUs and PAs in the S task

Component	N-ASD	T-ASD	D-WDD	A-WDD
Number of IUs	96	103	108	98
PAs per IU	3.84	3.69	3.12	3.2
		3.765		3.16
% of high PAs	75.6	79.5	64.4	64.3
		77.55		64.35

#### 4.4. ETs in the S task

The most frequent use of boundary tones at the edge is a contour pattern of L% final for both groups. Comparing the WDD controls with the ASD-HF subjects, the WDD controls are more similar (58.2% and 62.7%) for L% final while the ASD-HF subjects exhibit dissimilarity. While one ASD-HF subject has 53.9% of L% final and is more similar to the WDD controls, the other uses an L% final in 83.7% of his IUs tone boundaries. Comparing the matched HFA-WDD peers, the differences are more pronounced. While one WDD subject has 62.7% of final lowering, his ASD-HF peer has 53.9% the other WDD subject produces 58.2% of final lowering and his ASD-HF peer produces 83.7%. When considering the ETs in the contour pattern at the end of the IU, we observed again that the ASD-HF subjects use the final lowering pattern more than the WDD controls with less diversify in their use. For both groups the contour pattern of H\*LpL% at the edge of prosodic domain was the most frequent one (see Table 4).

## 5. Discussion

The present study reflects the advances made in the linguistic study of intonational phonology, the technological progress in the computer description and analysis of prosodic intonation as well as the further refinements in the assessment and definition of autism. In doing so, we have examined new ways to describe the particular intonation of children who meet the criteria for ASD-HF who are mainstreamed in the regular school environment. There were two fundamental research questions in this initial study which could serve as a basis for further research. First, is it possible to distinguish the phonological representations of the intonation contours of children with ASD-HF versus children WDD according to the procedure presented above? The second question focused on the influence of the elicitation task on the intonation of ASD-HF and WDD children.

As to the first question, the analysis of the pitch contour using the methodology presented above does in fact clearly show differences between subjects with ASD-HF and the WDD control group even though we concentrate only on two components of the intonation contour (PAs and ETs). Our chosen methodology allows the representation of intonation in a script form of the linear sequence of speech. We have observed that the intonation script, based on acoustic measurements, facilitates a phonological representation of the differences in intonation between the research and control groups.

The following pitch contour differences were found. The ASD-HF subjects produced more high PAs (L+H\*, H\* and H\*+L) and within the ASD-HF group there is a greater variation than in the WDD control group. This may indicate that if the causes of the variation in intonation are differences in the kinds of PAs and transitions between the prominent components, then when (a) the prominence exists in more frequent high PAs and (b) there are consequently fewer transitions, a monotonous accent is created. The other intonation feature we examined was the edge of the IU, i.e. the last PA, the PhA and the BT of an IU. ASD-HF children exhibited a limited repertoire of prosodic ET patterns within the norm of the language. These patterns are repeatedly used both in the RA and in the S elicitation tasks. Therefore both the *monotonous accent* and the *repetitiveness of ETs* produced by the ASD-HF subjects create a stiff sounding prosody. Conversely, the prosodic patterns found in the WDD control group, showed a greater number and a larger degree of variations for the same tasks creating a more diverse and flexible sounding prosody.

The second question focused on the influence of the elicitation tasks on the intonation features of ASD-HF and WDD children. The results in both tasks showed a similar tendency. However in S the characteristics were more pronounced than in the RA elicitation task. In the WDD control group no differences between the RA and S were found. However, differences were observed between the two ASD-HF subjects in the research group. One subject (N-ASD) exhibited a similar distribution of the prosodic events that were examined in both tasks. The second subject (T-ASD) exhibited: (1) more high PAs in the S than in RA, and (2) the predominant ET in RA (H\*LpL%) occurred even more frequently in S, an increase to a more patterned speech by the T-ASD-HF subject in the S. The variation that was found between the ASD-HF subjects and the lack of variation in the WDD control group seem to indicate that the differences are not age related. We suggest that this variation reflects the specific differences between individuals who are diagnosed with ASD that was previously mentioned (e.g. Wing 1991, Sigman and McGovern 2005), a topic worthy of further research. The present study has laid the way for future research examining the prosodic differences between ASD-HF and matched children WDD in these and in additional elicitation tasks.

## Abstract

Stops and strident fricatives show a similar pattern of voicing neutralization. Voicing contrast is preserved more often (i) in between sonorants than in word boundaries; (ii) word-initial than word-final position. In case of stops, the asymmetry between word-initial and word-final position is due to the availability of VOT cues. However, it has been less investigated what cues are responsible for fricative voicing neutralization. The present study has identified the important cues to voicing distinction of fricatives in the intervocalic position. It turned out that the cues in surrounding vowels as well as frication duration are important. This explains the asymmetry between intervocalic position versus word boundaries, though it does not explain the asymmetry between word-initial and word-final positions.

**Keywords:** fricatives, voicing contrast, neutralization, Licensing by Cue, perception

## 1. Introduction

Speech perception and speech production condition the phonological distribution of sounds and play an important role in determining whether the contrast between two classes of sounds is implemented or whether it is neutralized (Liljencrants and Lindblom 1972, Ohala 1981, Steriade 1997). Crucial to the interaction of perception and phonological processes is the concept of “cue,” defined following Wright (2001) as the information in the acoustic signal, which allows the listener to apprehend the existence of phonological contrast. The absence of an important cue to the perception of a contrast

---

<sup>1</sup> We thank Edward Flemming, Donca Steriade, and Adam Albright for their precious help. We are also grateful to the audience of CIL 18 for their comments. All errors are ours. The research was funded by the MIT Linguistics department.

\* The names are in alphabetical order. Both authors contributed equally to this paper.

in a given phonological context has as a major consequence the triggering of neutralization.

Steriade (1999:4) hypothesizes that “the likelihood that distinctive values of the feature F will occur in a given context is a function of the relative perceptibility of the F-contrast in that context” (Licensing by Cue Hypothesis). Given that different phonological contrasts rely on different cues, different contrasts show specific and individual patterns of distribution. Also, the availability and the nature of the cues to a given contrast type vary systematically with the context in which the segments occur: different phonological contrasts are therefore ‘licensed’ in different positions. An extensive recent literature has shown that perceptual considerations shape the typology of contrast neutralization: more perceptible contrasts are preferred to less distinct contrast, and contrasts are usually neutralized first in environments where they would be less distinct (cf. Dispersion Theory of Contrast, Flemming 1995, 2002).

Not all cues to a contrast are the same: a distinction has to be drawn between internal and external cues (Steriade 1997: 9). Whereas internal cues are realized during the segment itself, e.g. vowel formants and fricative noise, external cues are realized on adjacent segments, e.g. formant transitions, or they rely on the presence of adjacent segments, e.g. VOT (Flemming 2007). The availability of external cues depends on the environment of the target segment; the presence of external cues is thus highly variable across contexts. On the other hand, internal cues are less context-dependent as they are intrinsic acoustic properties of the segment itself.

The paper is organized as follows: In Section 2, we report the pattern of voicing contrast neutralization of stops and that of fricatives. In Section 3, we will present our experiment and the results. In Section 4, we will discuss how the unavailability of important cues in certain conditions would result in the typological asymmetries in the patterns of voicing contrast neutralization. Section 5 is the conclusion.

## **2. Voicing contrast in stops and in fricatives**

### *2.1 Voicing contrast in stops*

The distribution of voicing contrast in stops is strongly conditioned by the availability of acoustic cues to voicing in different contexts (Kingston and Diehl 1994, Steriade 1997). Contexts in which more cues are available are those in which the voicing contrast is more likely to be preserved cross-linguistically.

Among the acoustic correlates of stop voicing, cues in the transition following the release of the stop are more important to the perception of the contrast, than cues in the closure (Raphael 1981). VOT is a more perceptually salient cue than closure duration (Lisker 1957). Other cues to the presence of voicing are amplitude and duration of the release burst (Repp 1979) and the amplitude of F1 at release (Lisker 1986) and F1/F0 adjacent to the closure (Haggard, Ambler and Callow 1970). Cross-linguistic patterns of [±voice] neutralization provide evidence for the link between contrast preservation in a certain position and availability of perceptible cues in that context: no language neutralizes the voicing contrast in a more informative context, unless it also does so in a less informative context. The patterns across languages are shown in (1).

(1) Patterns of voicing neutralization in stops (Steriade 1997)

Context Language	#_O, O_#	R_O	R_#	_R	R_R
Totontepec Mixe	no contrast	no contrast	no contrast	no contrast	<b>contrast</b>
Lithuanian	no contrast	no contrast	no contrast	<b>contrast</b>	<b>contrast</b>
French	no contrast	no contrast	<b>contrast</b>	<b>contrast</b>	<b>contrast</b>
Shilha	no contrast	<b>contrast</b>	<b>contrast</b>	<b>contrast</b>	<b>contrast</b>
Khasi	<b>contrast</b>	<b>contrast</b>	<b>contrast</b>	<b>contrast</b>	<b>contrast</b>

O = obstruent, R = sonorant

Contrast is very rarely attested in stop clusters: in both positions of the cluster, C<sub>1</sub> and C<sub>2</sub>, important cues to contrast are missing. VOT information is not available to discriminate voicing in C<sub>1</sub>, and information about cues in the preceding vowel (such as duration) is not available in C<sub>2</sub>. The voicing contrast is even less frequent in obstruent clusters at the edges of a word: in a word-initial cluster both cues in the preceding vowel and VOT cues in C<sub>1</sub> are missing, the same is true for C<sub>2</sub> in a word-final cluster. Only cues in the closure (duration and voicing) are preserved. As the contexts become more informative (moving rightwards in (1)): voicing identification becomes more reliable and thus more languages exhibit voicing contrast in those contexts. Examples from Russian are shown in (2).

(2) Russian (data from Padgett 2002), arranged by descending cue availability.

	Contrast R_R	sled-a 'track (GEN.SG.)'	sviet-a	'light (NOM.SG.)'
	Contrast _R	teatr 'theater'	kadr	'film sequence'
	No Contrast R_#	slet 'track (NOM.SG.)'	sviet	'light (GEN.PL.)'
	No Contrast #_O	gde 'where'	*kde, gte	
		kto 'who'	*kdo, gto	

A crucial part of the Licensing by Cue hypothesis is that different phonological contrasts are licensed by different cues and therefore can present different distribution. There are no specific syllabic positions where contrast is in *general* less attested, different contrasts are neutralized in positions which are *specific* to the cues signaling the contrast. Steriade (1997:30) shows that this hypothesis not only accounts for the distribution of voicing contrasts, but also for the distribution of other contrasts, e.g., pre- and post aspiration and glottalization contrast. There are languages which maintain voicing contrast before all consonants (e.g., bt, pt, bn, pn (initial clusters)) but they only maintain aspiration contrast before sonorants ( $t^h m$ ,  $p^h n$  \* $t^h p$ , \* $p^h d$ ) (e.g., Khasi (Henderson 1976)). Although voicing and post-aspiration contrasts are licensed by almost the same set of cues, the non-perfect overlap of cues results in a different cross-linguistic distribution.

## 2. 2 Voicing contrast in fricatives

### 2.2.1 Acoustic and articulatory properties of voiced and voiceless fricatives

Little attention has been devoted until now to the perceptual cues to voicing in fricatives, but purely acoustic properties of voiced and voiceless fricatives have been described at length in the literature.

Voicing during the frication, as well as voicing during stops is subject to the aerodynamic voicing constraint (Ohala 1983, Stevens 2000). In order for voicing to occur, two basic requirements have to be met. First, the vocal chords must have the appropriate degree of tension and the appropriate degree of adduction. Second, there must be air flowing through the glottis (Ohala 1983). In stops, voicing is hard to maintain because the air flowing through the vocal folds accumulates in the oral cavity raising the oral pressure to the point where voicing ends (i.e. when oral pressure equals to subglottal pressure). In fricatives, the difficulty to maintain voicing could theoretically be smaller, given that some of the air accumulated in the oral cavity escapes, lowering the oral pressure. However this is not the case. The difficulty comes about from the conflict between the production of voicing and the generation of turbulence that is required for the identification of a fricative and its place of articulation. For the generation of strong frication turbulence, high oral air pressure is necessary and, as in stops, if the oral air pressure is raised too much, it becomes too close in magnitude to subglottal air pressure and the production of voicing will cease. In the production of strident fricatives such as /z/ this issue is even more relevant (Beckman et al. 2006): in

order to distinguish strident from non-strident fricatives, strident fricatives need to be produced with a large amplitude of frication turbulence. Ohala (1997) observes that there is statistically greater tendency for fricatives to favor voicelessness than for stops: 24% of the world's languages have only voiceless stops and about 38% have only voiceless fricatives.

A rough comparison of the acoustic properties of voiced and voiceless fricatives is given in (3).

(3) Acoustic properties of voiceless and voiced fricatives in a V1-C-V2 sequence

	Acoustic properties	Voiceless fricative	Voiced fricative
<b>C</b>	Frication duration	Longer	Shorter
	Voicing during frication	No	Yes
<b>V1, V2</b>	V1 duration	Shorter	Longer
	F0/ V1, V2	Higher	Lower
	F1/ V1, V2	Higher	Lower

(Adapted from Steven's (2000, *passim*) description of fricatives)

2.2.2 *Phonological patterns: distribution of the contrast and contrast neutralization.*

The distribution of voicing contrast in strident fricatives is to a certain extent similar to the distribution of voicing contrast in stops. The preservation of contrast in stops is dependent on the presence of a following sonorant segment since important cues such as VOT are available in those contexts. Many languages neutralize voicing contrast in word-final strident fricatives as well as in fricatives preceding a stop, similarly to the pattern of stops. In this section we describe a few cases of fricative voicing neutralization that show strong similarities with the previously described stop cases.

(4) illustrates the distribution of voicing contrast in strident fricatives with a sample of languages.

(4) Patterns of voicing neutralization in fricatives

Context Language	V_V	#_V	V_#
Italian (e.g. Tuscan dialect)	no contrast	no contrast	no contrast
German, Italian (e.g. Milanese dialect)	<b>Contrast</b>	no contrast	no contrast
Russian, Polish, Czech	<b>Contrast</b>	<b>contrast</b>	no contrast
Hungarian, Turkish, Romanian, French	<b>Contrast</b>	<b>contrast</b>	<b>contrast</b>

*German*

	niz-a	‘bottom (GEN.SG.)’
Contrast #_[+son]	ḡad-	‘orchard (NOM.SG.)’
	zad-	‘back (NOM.SG.)’

b. Voicing contrast is neutralized everywhere else

No Contrast [+son]_#	leḡ-	‘forest (NOM.SG.)’
	niḡ-	‘bottom (NOM.SG.)’

### *Turkish*

In Turkish, word-finally, stops neutralize but fricatives do not. The distribution of voicing in fricatives has the same pattern as in English, where phonological voicing contrast is preserved everywhere (inter-vocalically, word-initially, and word-finally)<sup>2</sup>.

(8) a. Voicing contrast is preserved before sonorants

Contrast [+son]_[+son]	aḡa ‘stick’	aḡa ‘member’
Contrast #_[+son]	su ‘water’	zor ‘trouble’

b. Voicing contrast is preserved word-finally

Contrast [+son]_#	kaḡ ‘goose’	kaḡ ‘muscle’
-------------------	-------------	--------------

In spite of the fact that a comprehensive survey of the cross-linguistic distribution of fricative voicing neutralization has not been done, the small sample of languages illustrates a pattern which can be summarized by the implicational hierarchy below.

(9) No Contrast V\_V → No Contrast #\_V → No Contrast V\_#, No Contrast V\_O

The sample of languages presented in table 3 suggests that, as is the case for stop voicing neutralization, word-final neutralization in fricatives is more common than word-initial neutralization. More precisely, word-initial neutralization seems to imply word-final neutralization but not vice versa.

### **3. Experiment: Identifying important cues to voicing in fricatives**

---

<sup>2</sup> In spite of the absence of phonological contrast neutralization, both stops and strident fricatives are phonetically devoiced word-finally, i.e. spectrograms reveal that most of the times voicing is not produced throughout the closure/frication but only in the vicinity of the preceding sonorant.

The similar contrast neutralization patterns in stops and fricatives (§2) suggests that the perception of fricative voicing would also depend on cues that rely on the presence of a following sonorant segment, just as the VOT cue for stops does. Until now, however, perceptual cues to voicing in alveolar fricatives have not been thoroughly analyzed, and therefore there is no evidence of any sonorant-dependent property as a cue. The experiment reported here was designed to assess the saliency of individual acoustic cues to the perception of voiced and voiceless alveolar fricatives in the intervocalic environment.

### *3.1. Experimental Procedure*

Our perceptual study was a forced-choice identification task. Individual cues were edited one at a time, a method similar to Raphael's (1981) work on the acoustic cues to stop voicing in American English.

In order to investigate the contribution of individual cues to the perception of voicing in alveolar fricatives, we hypothesized that when a listener is presented with a stimulus which is overall ambiguous but contains one *salient* cue pointing him to one voicing category, e.g., [+voice], he will be prone to systematically categorize the stimulus as being [+voice] because of the high perceptibility of that cue. In contrast, when the listener is presented with a stimulus which is overall ambiguous but contains a *marginal* cue pointing him to one voicing category, e.g., [-voice], he will categorize the stimulus as being sometimes [+voice] and sometime [-voice], because the marginal cue is not salient enough to override the overall ambiguity.

The experiment was therefore designed to investigate the strength of each cue in moving the stimulus away from the categorical boundary (chance level [s] and [z] responses), into one of the voicing categories (more than chance level [s] or [z] responses). To do so, we first created the ambiguous base, using the measurements from five speakers. We moved this ambiguous stimulus into two directions of [s] or [z] by editing one cue at a time.

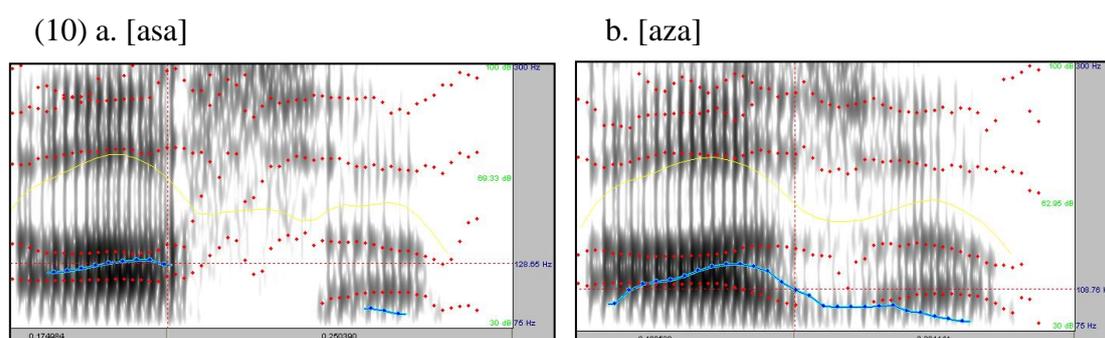

#### *3.1.1 Source material*

Five American English speakers (males, age 25-35) were recorded while reading [asa] and [aza] in a sound attenuated booth. Each item was repeated three times and embedded in a carrier sentence ("Say x please") to eliminate the effect of the boundary tone on the final vowel when they were read isolated. The recording was made to obtain

an average estimation of the acoustic properties of intervocalic /s/ and /z/. The speakers did not report any history of speaking or hearing disorder. The sound files were recorded at a sampling rate of 44.1 kHz. The following acoustic properties were measured using Praat: duration and intensity of the frication; duration of the surrounding vowels; F0, F1 and F2 at the offset of V1 and at the onset of V2.

The measurements were averaged across speakers and the standard deviation (SD) was calculated. The speaker whose values best fit within one SD from the average was chosen to be the representative speaker. In order to make the two tokens more representative, they were edited for the parameters which departed more than within 1 SD, based on the values across speakers. The resulting two tokens ([asa] and [aza]) were used as the source material to create the base stimulus for the editing.

The acoustic properties of the two tokens were in line with the descriptions of intervocalic fricatives in (3) in Section 2. Below are the spectrograms of the two tokens.

The frication duration was longer in the voiceless fricative [s]. Voicing bars were present during the frication of [z] but not [s]. The preceding vowel (V1) was longer with [s] than with [z]. F0 and F1 on the preceding and succeeding vowels (V1, V2) were higher with voiceless [s] than with voiced [z].

### 3.1.2 Preparing stimuli

Starting from the two tokens described above, an ambiguous stimulus was created through editing; its acoustic properties were exactly in the middle between those of the voiced and those of the voiceless fricative. Pretesting revealed that in order for the token to be perceptually ambiguous, there should be no voicing at all; therefore the frication of the ambiguous stimulus, the Base, was the frication of voiceless [asa], with edited duration. Moreover, we could not manipulate formant values of the vowels to the middle values since Praat does not allow manipulating formants without synthesis. We

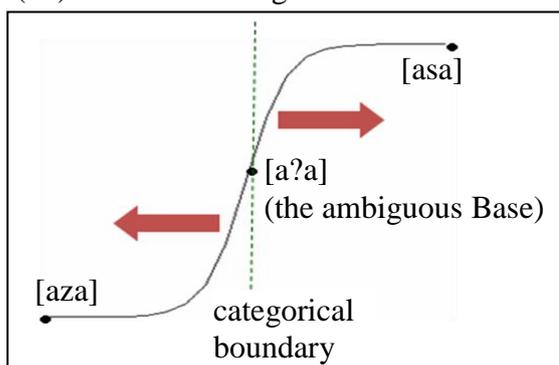

started with the vowels of [asa] to create the [Base], setting all the values to the averaged values of [asa] and [aza], except for the formant values which remained the same as those of [asa]. Despite this apparent [s] bias, in the pretesting phase of the experiment, subjects reported that the Base stimulus was very ambiguous: half of the listeners categorized it as [s], and half as [z]. The values of the acoustic variables of the tokens [asa], [aza] and the Base are shown in (11).

(11) Values of the acoustic variables

	V1 dur.	V2 dur.	Fric. dur.	F0/V1	F0/V2	F1, F2/V1	F1, F2/V2
[asa]	122	77	94	129	153	812 1248	525 1472
[aza]	152	88	52	106	95	447 1293	480 1371
Base	137	82	73	118	121	837 1247	495 1424

The perceptual effect of each cue was tested by subjecting the Base to a number of editing operations which consisted of manipulating *single* variables into the direction of [s] and of [z]. The stimuli for the perceptual experiment therefore differed from the Base only in one single cue. Assuming that the ambiguous Base lies near the categorical boundary between [s] and [z], the editing of each cue towards their values for [s] and [z] made the stimuli closer to [s] and [z] respectively. The directions and the effects of the editing are schematized in (12):

(12) Stimulus editing

(13) presents the values of the variables for each single-variable edited stimulus type. All the cues were manipulated one at a time into two directions, except for the formants. Formant cues were edited only to the [z] direction because the formants of the base were the same as the formants of the vowels in [asa], for the reason described above.

## (13) Single-variable editing

Cue Direction	V1 Dur	V2 Dur	Fric Dur	F0/V1	F0/V2	F1, F2/ V1		F1, F2/V2	
Unedited [asa]	122	77	94	129	153	812	1248	525	1472
Unedited [aza]	152	88	52	106	95	447	1293	480	1371
[Base]	<b>137</b>	<b>82</b>	<b>73</b>	<b>118</b>	<b>121</b>	<b>837</b>	<b>1247</b>	<b>495</b>	<b>1424</b>
V1 dur [s]	<b>122</b>	82	73	118	121	837	1247	495	1424
V1 dur [z]	<b>152</b>	82	73	118	121	837	1247	495	1424
V2 dur [s]	137	<b>77</b>	73	118	121	837	1247	495	1424
V2 dur [z]	137	<b>88</b>	73	118	121	837	1247	495	1424
Fric dur [s]	137	82	<b>94</b>	118	121	837	1247	495	1424
Fric dur [z]	137	82	<b>52</b>	118	121	837	1247	495	1424
F0/V1 [s]	137	82	73	<b>129</b>	121	837	1247	495	1424
F0/V1 [z]	137	82	73	<b>106</b>	121	837	1247	495	1424
F0/V2 [s]	137	82	73	118	<b>153</b>	837	1247	495	1424
F0/V2 [z]	137	82	73	118	<b>95</b>	837	1247	495	1424
F1, F2/ V1 [z]	137	82	73	118	121	<b>447</b>	<b>1293</b>	495	1424
F1, F2/ V2 [z]	137	82	73	118	121	837	1247	<b>480</b>	<b>1371</b>

In addition, a second set of stimuli was created from the Base by manipulating more than one variable at the time: the cumulative perceptual effect of vowel cues was tested by replacing (splicing) both vowels of the Base with vowels of [asa] and [aza] respectively. Although the frication was ambiguous, formant transitions and vowel durations pointed towards one of the two voicing categories. Acoustic properties of these two stimuli are listed in (14).

## (14) Vowel replacement

Cue Direction	V1 Dur	V2 Dur	Fric Dur	F0/V1	F0/V2	F1, F2/ V1		F1, F2/V2	
Unedited [asa]	122	77	94	129	153	812	1248	525	1472
Unedited [aza]	152	88	52	106	95	447	1293	480	1371
[Base]	<b>137</b>	<b>82</b>	<b>73</b>	<b>118</b>	<b>121</b>	<b>837</b>	<b>1247</b>	<b>495</b>	<b>1424</b>
V1 and V2 [asa]	<b>122</b>	<b>77</b>	73	<b>129</b>	<b>153</b>	<b>812</b>	<b>1248</b>	<b>525</b>	<b>1472</b>
V1 and V2 [aza]	<b>152</b>	<b>88</b>	73	<b>106</b>	<b>95</b>	<b>447</b>	<b>1293</b>	<b>480</b>	<b>1371</b>

Finally, a third set of stimuli was created with the aim of identifying the effect of voicing during the frication on the perception of voicing distinction in fricatives, all

cues other than frication voicing were kept as in the Base, as shown in (15). Voicing was added to the voiceless frication of the Base on a continuum from 10 to 50%.

(15) Frication voicing addition

Cue Direction	V1 Dur	V2 Dur	Fric. Dur	Voicing	F0/V1	F0/V2	F1, F2/ V1		F1, F2/V2	
Unedited [asa]	122	77	94	None	129	153	812	1248	525	1472
Unedited [aza]	152	88	52	None	106	95	447	1293	480	1371
[Base]	<b>137</b>	<b>82</b>	<b>73</b>	<b>None</b>	<b>118</b>	<b>121</b>	<b>837</b>	<b>1247</b>	<b>495</b>	<b>1424</b>
10% [z] voicing	137	82	73	10%	118	121	837	1247	495	1424
20% [z] voicing	137	82	73	20%	118	121	837	1247	495	1424
30% [z] voicing	137	82	73	30%	118	121	837	1247	495	1424
40% [z] voicing	137	82	73	40%	118	121	837	1247	495	1424
50% [z] voicing	137	82	73	50%	118	121	837	1247	495	1424

Fillers were added to the twenty-two target stimuli: these were sixteen stimuli of the form [VsV] and [VzV], where V= e, i, o, u. The entire stimulus set was RMS equalized using Becker's (2002) Praat script.

3.1.3 *The perceptual experiment*

The subjects who participated in this study were nineteen native English speakers (age 25- 55). None of them reported history of hearing or speaking impairment. The experiment was a two-alternative forced-choice identification task. Stimuli were randomized and presented in three blocks (((22+16) stimuli \* 6 repetitions) \* 3 blocks = 684 tokens total) using Psyscope X B5 1D. Each stimulus was thus repeated 18 times. The listeners were asked to do a speeded categorization task, by pressing one of the two keys, labeled [S] and [Z], as fast as they could. Each trial was timed out 2000 ms. after the sound was played, and then a screen told subjects to respond faster. There was an interval of 200ms between the key press and the beginning of the following stimulus.

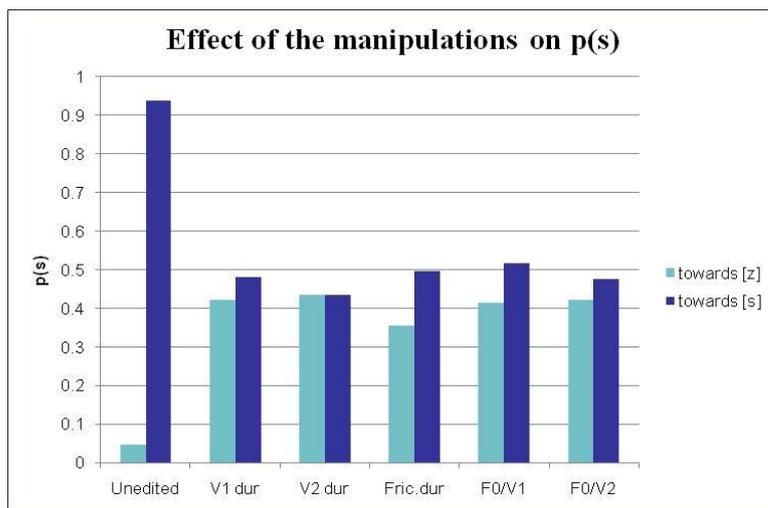

3.2. *Results*

3.2.1 *Effect of the single-variable manipulations on the subjects' responses*

The analysis of the subjects' responses revealed that listeners are sensitive to most of the edited acoustic properties. The chart in (16) plots the probability of categorizing

the stimulus as containing [s], p(s), for the stimuli for which one cue is edited at a time into both directions. Responses to the stimuli are plotted by comparing the effect of symmetric manipulations (editing the same cue in the two directions): the adjacent bars show that when the cue was edited towards the [s] value, p(s) rose, and when the cue was edited towards the [z] value, p(s) decreased. These results reveal thus that the direction of the manipulations is perceptually salient.

(16) Responses to single-variable edited stimuli (average across subjects)

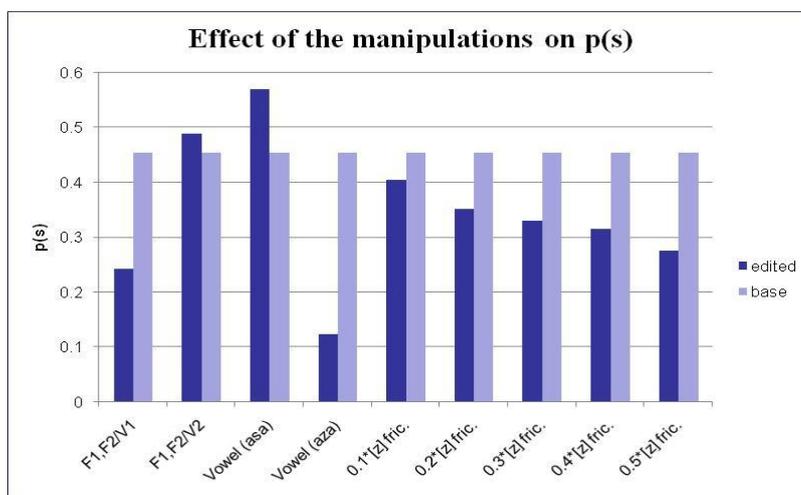

Unedited instances of [asa] and [aza] were almost always correctly identified by the subjects. Among the stimuli edited by a single variable, frication duration has the biggest effect on the response type. Cues in V1 are also salient to the subjects. Cues in V2 (duration and F0) had a smaller effect on the perception of voicing. However, this should not be interpreted to mean that cues in V1 are generally more important than those in V2. This asymmetry between V1 and V2 may have come from the fact that our speaker put stress on V1 and substantially reduced and shortened V2 in both [asa] and [aza]. Thus, V1's were distinct enough from each other in [asa] and [aza] whereas V2's in both utterances were similar to each other. It is therefore not surprising that cues in V1 had a greater discriminating effect than cues in V2. It is plausible that cues in V2 appear less perceptually salient because the segment was less salient overall, and not because of its intrinsic marginality.

Nevertheless, the results may also reflect the fact that the duration of the preceding vowel can often be a more crucial cue to voicing in both stops and fricatives than the following vowel, especially in a language like English where final phonological voicing neutralization does not occur, but where phonetic final devoicing is attested.

### 3.2.2 Effect of vowel replacement and frication voicing on the subjects' responses

The chart below plots pairwise comparisons between the probability that the Base is categorized as voiceless, and the probability that the edited stimuli are perceived as voiceless. Importantly, the results from the pretesting phase are confirmed during the experiment: although there is a slight bias to categorize the Base as [asa], the stimulus turned out to be ambiguous with  $p(s)$  almost 0.5.

(17) Comparing the Base stimulus to the edited stimuli

The effects of the single-cue manipulations are discussed below.

#### *Vowel formants:*

Formant editing had a big effect on the response type. It should be noted that F1 and F2 cannot be manipulated separately from the entire spectrum, and so our method of formant editing was rather indirect: Instead of changing formant values in the Base stimulus, we had to splice the entire [asa] or [aza] vowels onto the Base and subsequently edited other values (duration and F0) back to those of the Base except for the formant values. Because of this, we cannot guarantee that acoustic properties other than just formants were not transported to the Base beyond our control. Although for this reason we may have to underestimate the size of the effects of F1 and F2 cues than the results presented here, the formant cue should still be considered as one of the strongest. As for the formants on V2, the same caveat applies as in the previous section.

#### *Vowel replacement:*

The replacement of both vowels had a great effect on the categorization: Cues contained in the vowels are therefore very perceptually salient. This result is not

surprising given that the replacement involves giving the listener at least three types of information regarding voicing distinction: vowel duration, formant transitions into the frication, formant transitions out of the frication. All of these cues were found to be individually salient, and therefore the additive effect was expected.

The fact that replacement of the Base vowels with the vowels from [asa] has a much smaller perceptual effect than the replacement with the vowels from [aza] arises from the acoustic properties of the Base itself (§ 3.1.2): The smaller perceptual effect can be attributed to the slight bias of the Base, towards [s], as mentioned above.

#### *Frication voicing:*

The addition of frication voicing along a continuum interestingly had a linear effect on the subjects' responses: as the frication of the [Base] becomes more voiced, subjects are less likely to categorize the stimulus as being voiceless. More precisely, a linear decrease of p(s) corresponds to a linear increase of frication voicing. This finding suggests not only that even a small percentage of voicing is very perceptually salient, but also that perception of voicing during the frication is linear.

#### *3.2.3 Perceptual effect of the cues to frication voicing*

A more telling method to quantify the importance of a cue to the perception of a phonological contrast is to quantify the perceptual distance between the individual editings and the categorical boundary. The greater the distance between the ambiguous stimulus and the target stimulus edited for one acoustic dimension, the greater the perceptual saliency of that dimension for the listener. More precisely, if the editing of one single cue shifts the distribution of the responses to the stimulus by a large amount with respect to the responses to the ambiguous [Base], that cue is salient to the perception of the contrast under investigation.

There is an open debate in the literature as to which is the distance function for computing distance relationships between stimuli in the perceptual space. In our study, distance measures were obtained according to MacMillan and Creelman's Detection Theory (2005). The stimuli were classified as one-dimensional on the assumption that the single edit of perceptual cues will only produce a one-dimensional change in the perception of the stimulus. We are nevertheless aware of the fact that a one-dimensional change in the acoustic property of a stimulus may sometimes result in a multi-dimensional change on a perceptual scale. "[...] the question of the *perceptual* dimensionality of a stimulus set is distinct from that of physical structure. Stimuli

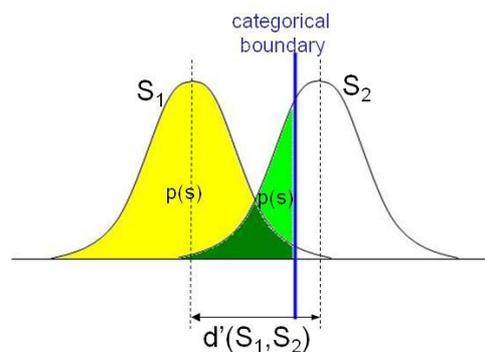

differing in one dimension can produce multi-dimensional perceptual changes.” (MacMillan and Creelman, 2004: 114). In the event that some of the editings had this unwanted result, our analysis will not capture the multi-dimensionality of the change, by treating them as one-dimensional.

Perceptual distance was calculated between the Base stimulus and each edited target stimulus in order to find out whether the editing of any cue resulted in bigger perceptual distance compared to the editing of other cues. Distance is measured by the sensitivity statistics  $d'$ , defined in terms of  $z$ , the inverse of the normal distribution function:

$$(19) d' = z(S_1) - z(S_2)$$

where the  $z$  transformation converts the probability of a response into standard deviation units. A probability of 0.5 is converted into a  $z$  score of 0, small probabilities into negative, and large probabilities into positive  $z$  scores. Probabilities of exactly 1 or exactly 0 have infinite  $d'$ . For this reason, we converted probabilities of 1 and 0 to 0.95 and 0.05.  $S_1$  was consistently chosen to be the stimulus with the highest  $p(s)$  between the two stimuli to be compared, regardless of whether it was the Base, or the edited stimulus.

(20) Converting  $p(s)$  into  $d'$ -values

$$d' = z(S_1) - z(S_2)$$

$S_1$ : Stimulus with higher  $p(s)$

$S_2$ : Stimulus with lower  $p(s)$

where  $S_1$  or  $S_2$  is the “base”

Starting from the ambiguous base, most cues were edited in two directions: towards [s] and towards [z], yielding two symmetric stimuli. Since the manipulation was done along a single dimension,  $d'$  values of the same cue in the two directions could be added. For each symmetric cue, the cumulative  $d'$  was calculated as in (21):

$$(21) d'(s, z) = d'(s, Base) + d'(Base, z)$$

For those stimuli which do not have a symmetric counterpart,  $d'$  could not be added and instead the individual  $d'$  values will be reported. The table in (22) shows the  $d'$  values of the different cues, arranged in descending order.

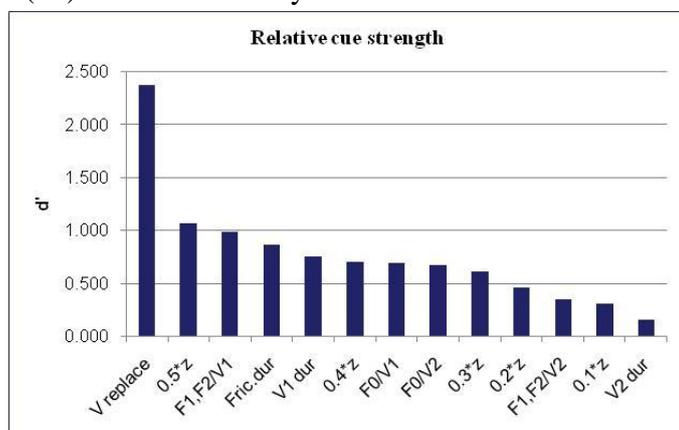

(22) Effect of the manipulations on  $d'$

Cues	$d'$
V1 and V2 replacement	2.368
50% [z] voicing	1.059
F1, F2/V1	0.985
Frication duration	0.859
V1 duration	0.749
40% [z] voicing	0.702
F0/V1	0.690
F0/V2	0.667
30% [z] voicing	0.603
20% [z] voicing	0.454
F1, F2/V2	0.340
10% [z] voicing	0.308
V2 duration	0.151

A repeated measures analysis of variance (ANOVA) was performed for the obtained  $d'$  values. The analysis indicated an effect of the factor cue manipulation on the  $d'$  value which was significant [F(11, 198),  $p < 0.001$ ].

As it emerged from the p(s) results, the  $d'$  analysis reveals that vowel replacement and frication voicing are the most informative cues to voicing categorization of the alveolar fricatives under analysis. Among the single-edited dimensions, durational cues in the frication and in the preceding vowel are most salient to listeners.

(23) Relative saliency of the edited cues

It should be noted that this experiment has investigated the relative importance of

different cues to the perception of voicing in alveolar fricatives. It does not address the question of whether the same weighting system is applicable to non-strident fricatives; we do not have the relevant evidence to extend our findings to all fricatives.

#### 4. Discussion

The present experiment has revealed that there are two categories of cues which are important in the discrimination of voicing of alveolar fricatives in intervocalic position in English. Two types of cues proved to be most salient to the listeners: these are cues in the adjacent vowels (duration and formant transitions), and cues in the frication (duration and voicing).

The Licensing by Cue hypothesis predicts that contrast will be preferably preserved in intervocalic position, and likely neutralized word-initially and word-finally. Contrary to the distribution of voicing contrast in stops, no perceptual cues were found for fricatives. When present, such cues, like VOT, cause the word-initial position to be a better environment for the discrimination of contrast than the word-final position. Even though the stronger influence of V1 was due to the fact that V1 was stressed and V2 was heavily reduced so that there was no discernable difference between V2s in [asa] and [aza], if the differences between V1 and V2 found in this paper are reliable at all, the asymmetry predicts a complementary pattern of contrast neutralization with respect to stops, i.e., postvocalic (V\_ #) better than prevocalic (#\_V).

Contrary to this prediction, a typological study showed that the distribution of voicing contrast in strident fricatives is remarkably similar to the one observed among stops. In the case of stop voicing contrast, the asymmetry is predicted by the nature of the strongest cue to the contrast, VOT, which depends on the *following* sonorant. In spite of the fact that only half of the formant cues are available at either edge of the word, the two edges are very different in terms of how informative they are. Whereas VOT cues are preserved in a word-initial stop, no VOT cue is available in the case of a word-final stop. The initial- vs. final- asymmetry is therefore accounted for by the Licensing by Cue hypothesis (Steriade 1997). The lack of VOT cue in word final position causes the identification of voicing to be less reliable, and therefore the contrast is more likely to undergo neutralization.

While the neutralization pattern of stops can be attributed to lack of VOT cue, it has been less clear what cues are missing in the case of fricatives. The current study showed that cues in surrounding vowels are as important as those in the fricative itself,

which explains the asymmetry between intervocalic and word initial/final positions. However, our results do not explain the word –initial and –final asymmetry: why word-initial position is a better place to keep the contrast than word-final position. We have shown in Section 2 the implicational hierarchy of positional neutralization of voicing contrast: Many languages neutralize the voicing contrast in word-final position (e.g., Russian); some neutralize the contrast both in word-final and in word-initial position (e.g., German). However, there is no language which preserves the distinction word-finally but neutralizes word-initially. Our results do not justify any differences of cues in V1 and V2, and thus the asymmetry between word-initial (prevocalic) and word-final (post-vocalic) positions. Therefore, they neither support nor disprove the Licensing by Cue hypothesis.

We have shown that the duration of frication is one of the most important single cues. We can hypothesize that the duration of frication is hard to perceive in word-final position, because acoustic signals gradually die out at the end of utterance, which may make the end point of frication in word final position less clear than the beginning of frication in word initial position. This may render frication duration harder to measure in word final position than in word initial position. Giavazzi (2008) is to investigate this hypothesis.

In a nutshell, our result showed that cues in the surrounding sonorant and cues that are more salient in the presence of surrounding sonorants are crucial for distinction of fricative voicing contrast. However, our results do not explain the asymmetry between word-final and word-initial position. The Licensing by Cue hypothesis is neither supported nor disproved by our results, in explaining the positional (word initial and final) asymmetry of voicing contrast neutralization of fricatives.

## **5. Conclusion**

The present study has identified the important cues to voicing distinction of fricatives, by looking at the intervocalic position. It turned out that sonorant-dependent properties such as the cues in surrounding vowels as well as frication duration were important. This explains why contrast is preserved more often in intervocalic position than in word boundaries. However, our results do not provide any evidence that a following sonorant should be more important than a preceding sonorant, as was the case for VOT for stops. We hypothesize that frication duration is less perceptible in word-final position; a further study is necessary to justify this speculation. According to our

results, the Licensing by Cue hypothesis is supported in explaining intervocalic and word-boundaries asymmetry, but it is neither supported nor disproved in explaining word-final/initial asymmetry of voicing contrast neutralization of fricatives.

## Abstract

The present study investigated Lyman's Law effect (OCP) in Japanese sequential voicing by two questionnaire-based experiments using nonexistent compounds. Experiment 1 explored the positional effect of the voiced obstruent contained in the second element. Experiment 2 investigated the influence of etymological type of lexical stratification of the first element. The change in results of these experiments for a period of twenty-one years was also examined. It may be concluded from this research that (1) Lyman's Law is a general tendency rather than a categorical prohibition, (2) the etymological type of the first element affects Japanese sequential voicing, and (3) the 'X-basigo' exception, where X represents any first element, has closely conformed to the tenets of Lyman's Law over twenty-one years.

**Keywords:** sequential voicing Lyman's Law OCP questionnaire decision tree analysis

## 0. Introduction

Sequential voicing in Japanese, or *rendaku*, refers to voicing of the initial voiceless obstruent of a second element in a compound. Lyman's Law is a well-known condition inhibiting *rendaku* when the second element of the compound already contains a voiced obstruent. Lyman's Law is one particular case of Obligatory Contour Principle (OCP) by which an identical element or feature is prohibited from repeating within a certain domain. In order to explore *rendaku* ruled by Lyman's Law, two experiments were conducted in the present study. Experiment 1 explored how the position and distance of the voiced obstruent contained in the second element affect

*rendaku*. Experiment 2 investigated how the etymological type of the lexical stratification of the first element influences *rendaku* in exceptional cases to Lyman's Law. Etymological types of lexical stratification of Japanese are generally classified into native Japanese, Sino-Japanese (Chinese Borrowing), and foreign loanwords. It has been well-documented and is uncontroversial that the etymological type of second elements affects *rendaku*. *Rendaku* occurs more frequently in cases that the second element is native Japanese, whereas it less frequently or hardly ever occurs where the second element is Sino-Japanese or foreign loanwords. In previous studies (Vance 1979, Ito and Meter 2003: 147), it is concluded that the etymological type of the second element affects *rendaku*, but that the first element has no effect on *rendaku* voicing of the second element. Another aim of this study is to investigate the change in results of these experiments over a period of twenty-one years. These experiments were conducted in 1984 by Murata and in 2005 by Ihara with an interval of twenty-one years based on the questions used in (Murata 1984) by simply asking for a single choice out of each pair of voiceless and voiced nonexistent compound words. These experiments were questionnaire-based. Vance (1979) originally applied a questionnaire-based approach to the research of *rendaku*. His experiment was run with too small sample size (14 participants) for a statistical investigation and too many test items for participants to process (645 items.) The test items used were hybrid compounds consisted of a modern Japanese word and an old Japanese word. (Murata 1984) and (Murata and Ihara 2006) expanded the sample size and employed carefully selected and elaborated test items for the specific phenomena of *rendaku*. The present study focuses on the experimental findings rather than theoretical considerations.

### 1. Sequential Voicing (*Rendaku*)

In the Japanese language, when two words are compounded, the initial voiceless consonant of the second element is voiced, which does not always occur consistently.

- (1) a. ko 'small' + taiko 'drum' → ko-daiko / \*ko-taiko 'small drum'  
 b. oo 'big' + hako 'box' → oo-bako / \*oo-hako 'big box'

For example, in (1a), where the first element /ko/ 'small' and the second element /taiko/ 'drum' are compounded, the initial voiceless obstruent /t/ of the second element /taiko/ is voiced as /d/ as in /ko-daiko/ 'small drum.' This is the phenomenon called *rendaku*.

In Japanese, /h/ behaves like an obstruent whose voiced counterpart is /b/. In (1b), /oo/ ‘big’ and /hako/ ‘box’ are compounded to be /oo-bako/ ‘big box.’ The voiceless /h/ alternates with the voiced /b/, because the modern Japanese /h/ was derived from /p/ via a voiceless bilabial fricative through historical change (Hashimoto 1950, Komatsu 1981, Vance 1979).

## 2. Lyman’s Law

Lyman’s Law is a well-known condition on *rendaku* that the existence of a voiced obstruent in a second element prohibits *rendaku*.

- (2) a. tori ‘bird’ + kago ‘cage’ → tori-kago/ \*tori-gago ‘birdcage’  
 b. naga ‘long’ + sode ‘sleeve’ → naga-sode/ \*naga-zode  
     ‘long sleeve’  
 c. oo ‘big’ + tokage ‘lizard’ → oo-tokage/ \*oo-dokage ‘big lizard’  
 d. nawa ‘rope’ + hasigo ‘ladder’ → \*nawa-hasigo/ nawa-basigo  
     ‘rope ladder’

In (2a), the second element /kago/, which contains a voiced obstruent, does not undergo voicing. The compounded word is not /\*tori-gago/ but /tori-cago/. *Rendaku* is prohibited.

- |  |  |
|--|--|
| (3) a. 2 <sup>nd</sup> element of (2a) | b. 2 <sup>nd</sup> element of (2b)                 |
| k a   g o                              | t o   k a   g e                                    |
| C <sub>1</sub> V C <sub>2</sub> V      | C <sub>1</sub> V C <sub>2</sub> V C <sub>3</sub> V |

Lyman’s Law is one particular case of Obligatory Contour Principle (OCP) by which an identical element or feature is prohibited from repeating within a certain domain (Ito & Mester 1986, 2003; Kubozono 1999, 2005). The relevant feature here is laryngeal [+voice, -sonorant] and the domain is the second element of a compound. In (2a-b), C<sub>2</sub> in the two-mora CVCV-structured second element is a voiced obstruent, and in (2c-d), C<sub>3</sub> contained in the three-mora CVCVCV-structured second element is a voiced obstruent. C<sub>1</sub> is a potential *rendaku* site. In (2a-b), C<sub>2</sub> is adjacent to the potential *rendaku* site C<sub>1</sub>. In (2c-d), C<sub>3</sub> is at a distance from C<sub>1</sub> by the intervention of C<sub>2</sub>. The intervening V is irrelevant here. (2d) /nawa-basigo/ is one of the few exceptions to

Lyman's Law found in the existing vocabulary. The second element /hasigo/ contains a voiced obstruent C<sub>3</sub>. Nevertheless, it undergoes *rendaku*.

### 3. Experiment 1

Experiment 1 explored how the position and distance of the voiced obstruent contained in the second element affect *rendaku*.

#### 3.1. Method

The experiments were conducted with a total of 256 undergraduate students of St. Marianna University School of Medicine, Tokyo Institute of Technology, and Nihon University in 2005, and 194 students of Kyushu Institute of Technology and Yamaguchi University in 1984. All participants were native speakers of Japanese. However, analyses were carried out depending on the number of participants who responded to each item due to missing values.

The second elements of two-element compounds were controlled by varying the positions of the voiced obstruent. The position of the voiced obstruent was varied from the second mora position to the fourth mora position (C<sub>2</sub>, C<sub>3</sub>, C<sub>4</sub>). The participants were asked to judge whether or not the first obstruent of these second elements is voiced in each question as exemplified in (4). These voiced-and-voiceless paired questions were randomly presented to participants in a single questionnaire.

(4) Voiced-and-voiceless paired question

- 長(ナガ)・タギ (/naga-tagi/)
- 長(ナガ)・ダギ (/naga-dagi/)

#### 3.2. Stimulus Items and Item-by-Item Analyses

As shown in Table 1, two real words /naga/ 'long' and /oo/ 'big' were chosen as the first elements. The two-mora CVCV-structured nonword /tagi/, the three-mora CVCVCV-structured nonword /harage/, and the four morae CVCVCVCV-structured nonword /haranige/ were chosen as second elements to measure *rendaku*. C<sub>2</sub> was a voiced obstruent in /tagi/, C<sub>3</sub>, in /harage/, and C<sub>4</sub>, in /haranige/. This manipulation was intended to keep the second element semantically neutral or avoid analogy and to make

the experiments easier to control.

Table 1. Experiment 1 in 1984

1st element + 2nd element	1984			Chi-square test of goodness-of-fit
	Voiced	Voiceless	Rate	
(1) CVCV-structured 2nd element				
naga-tagi / naga-dagi	16	177	0.08	$\chi^2(1)=134.31, p<.001$
oo-tagi / oo-dagi	30	164	0.15	$\chi^2(1)=92.56, p<.001$
(2) CVCVCV-structured 2nd element				
naga-haragi / naga-baragi	88	110	0.44	$\chi^2(1)=2.44, p=.12, n.s.$
oo-haragi / oo-baragi	75	122	0.38	$\chi^2(1)=11.21, p<.001$
(3) CVCVCVCV-structured 2nd element				
naga-haranige / naga-baranige	55	80	0.41	$\chi^2(1)=4.63, p<.05$
oo-haranige / oo-baranige	52	83	0.39	$\chi^2(1)=7.12, p<.01$

Table 2. Experiment 1 in 2005

1st element + 2nd element	2005			Chi-square test of goodness-of-fit
	Voiced	Voiceless	Rate	
(1) CVCV-structured 2nd element				
naga-tagi / naga-dagi	43	214	0.17	$\chi^2(1)=113.78, p<.001$
oo-tagi / oo-dagi	48	208	0.19	$\chi^2(1)=100.00, p<.001$
(2) CVCVCV-structured 2nd element				
naga-haragi / naga-baragi	71	182	0.28	$\chi^2(1)=48.70, p<.001$
oo-haragi / oo-baragi	71	184	0.28	$\chi^2(1)=50.07, p<.001$
(3) CVCVCVCV-structured 2nd element				
naga-haranige / naga-baranige	74	182	0.29	$\chi^2(1)=45.56, p<.001$
oo-haranige / oo-baranige	57	111	0.34	$\chi^2(1)=17.36, p<.001$

In Table 1 and 2, compound words are examined by a series of chi-square tests of goodness-of-fit setting an expected value of equal frequency (50% random chance) for choice of a voiceless or voiced initial consonant in the second element. Table 1 and Table 2 show that a significantly larger proportion of participants selected the voiceless case for almost all stimulus items.

Table 3. Comparison of 1984 and 2005 in Experiment 1

1st element + 2nd element	<i>Rendaku</i> rate		Chi-square test of independence
	1984	2005	
(1) CVCV-structured 2nd element			
naga-tagi / naga-dagi	0.08	0.17	$\chi^2(1)=6.894, p<.01$
oo-tagi / oo-dagi	0.15	0.19	$\chi^2(1)=0.832, p=.362, n.s.$
(2) CVCVCV-structured 2nd element			
naga-haragi / naga-baragi	0.44	0.28	$\chi^2(1)=13.058, p<.001$
oo-haragi / oo-baragi	0.38	0.28	$\chi^2(1)=5.317, p<.05$
(3) CVCVCVCV-structured 2nd element			
naga-haranige / naga-baranige	0.41	0.29	$\chi^2(1)=3.829, p<.05$
oo-haranige / oo-baranige	0.39	0.34	$\chi^2(1)=6.85, p=.408, n.s.$

In Table 3, a series of chi-square tests of independence are carried out for each item to compare voiced frequency between 1984 and 2005. Table 3 shows that the frequency of *rendaku* significantly increased in twenty-one years in the case of second elements with a voiced obstruent in the second mora (C<sub>2</sub>) and that the frequency of *rendaku* significantly decreased in the case of second elements with the third-/fourth-positioned voiced obstruent (C<sub>3</sub>, C<sub>4</sub>) as illustrated in (5).

(5) Positional blocking effects in 1984 and 2005

1984		2005
C <sub>2</sub>	>	C <sub>2</sub>
C <sub>3</sub>	<	C <sub>3</sub>
C <sub>4</sub>	<	C <sub>4</sub>

### 3.3 Results

Decision tree analysis CHAID (Chi-Squared Automatic Interaction Detection) was used setting a dependent variable of a voiced or voiceless decision predicting by the three independent variables of (1) two types of first element, (2) voiced mora position of the second element, and (3) years of research of 1984 and 2005. The decision tree analysis, as shown in Figure 1, revealed the following significant trends: (1) *rendaku* with a voiced obstruent in the second mora of the second element (15.2%) occurred less frequently than in the third and the fourth mora (34.0%) [ $\chi^2(1)=102.435, p<.001$ ]; (2) in the case of second elements with a voiced obstruent in the second mora, the frequency of *rendaku* significantly increased in twenty-one years from 1984 to 2005 (11.9% in

1984, 17.7% in 2005) [ $\chi^2(1)=5.855, p<.05$ ]; and (3) the frequency of *rendaku* significantly decreased in the case of second elements with the third-/forth-positioned voiced obstruent over twenty-one years from 1984 to 2005 (40.6% in 1984 and 29.3% in 2005) [ $\chi^2(1)=22.121, p<.001$ ].

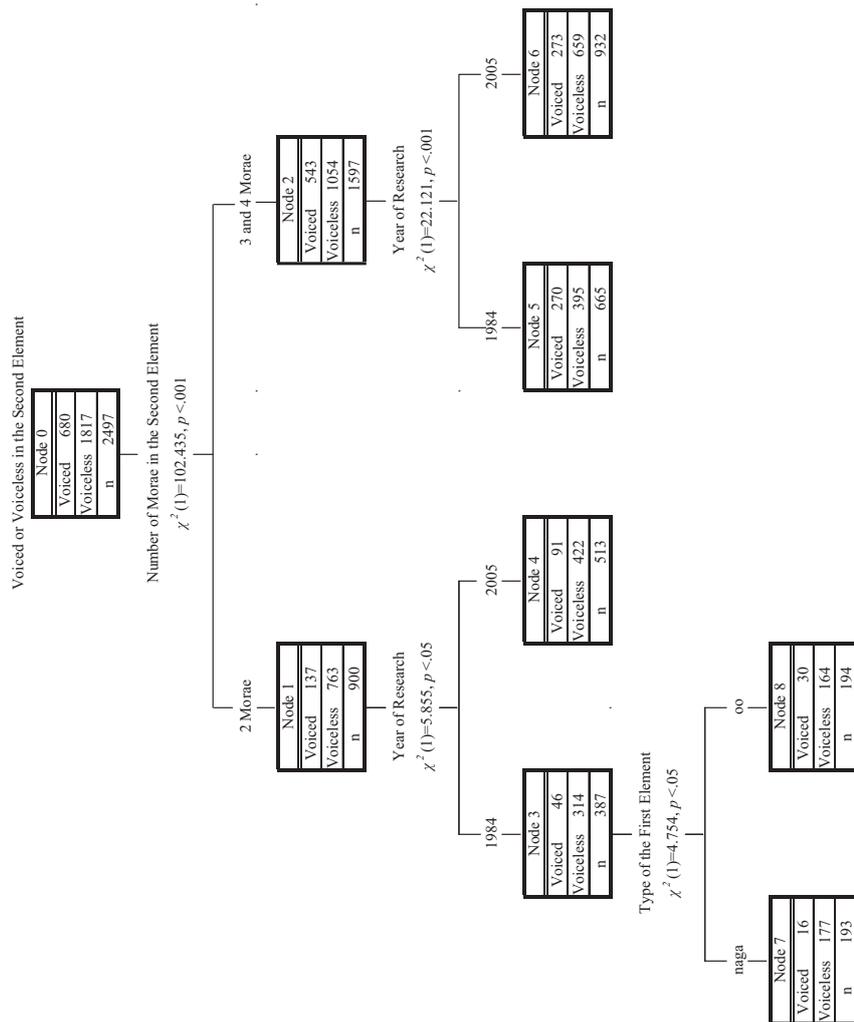

Figure 1. Decision tree analysis of Experiment 1

## 4. Experiment 2

Experiment 2 examined how the etymological type of lexical stratification of the first element influences *rendaku* in cases deviating from Lyman's Law. /Nawa-basigo/ 'rope ladder' is one of a few exceptions to Lyman's Law found in the existing vocabulary. Nonexistent pairs of X-hasigo and X-basigo, where X referred to any first element, were used.

### 4.1. Method

The participants are the same as in Experiment 1. The first elements were controlled by varying the etymological type of Japanese such as native Japanese, Sino-Japanese, and foreign loanwords. Again, the same participants were asked to judge whether or not the first mora of the second element is voiced in each question. These voiced-and-voiceless paired questions were randomly presented to participants in a single questionnaire.

### 4.2. Stimulus Items and Item-by-Item Analyses

As shown in Table 4 and Table 5, first elements were chosen according to three different etymological types of lexical stratification: native Japanese, Sino-Japanese (Chinese Borrowing), and foreign loan words. The first elements were native Japanese /naga/ 'long,' Sino-Japanese /tetusei/ 'iron-made,' and a foreign loan word /sutenresu/ 'stainless-steel-made.' These first elements were compounded to a pair of second elements, the voiceless /hasigo/ and the voiced /basigo/, respectively, to constitute a pair of nonwords.<sup>1</sup>

Table 4. Experiment 2 in 1984

1st element + 2nd element	1984			Chi-square test of goodness-of-fit
	Voiceless	Voiced	Rate	
(1) Native Japanese 1st element				
naga-hasigo /naga-basigo	7	190	0.96	$\chi^2(1)=169.99, p<.001$
(2) Sino-Japanese 1st element				
tetusei-hasigo / tetusei-basigo	127	71	0.36	$\chi^2(1)=15.84, p<.001$
(3) Foreign loan word 1st element				
sutenresu-hasigo /sutenresu-basigo	132	66	0.33	$\chi^2(1)=22.00, p<.001$

Table 5. Experiment 2 in 2005

1st element + 2nd element	2005			Chi-square test of goodness-of-fit
	Voiceless	Voiced	Rate	
(1) Native Japanese 1st element naga-hasigo /naga-basigo	82	175	0.68	$\chi^2(1)=33.65, p<.001$
(2) Sino-Japanese 1st element tetusei-hasigo / tetusei-basigo	188	70	0.27	$\chi^2(1)=53.97, p<.001$
(3) Foreign loan word 1st element sutenresu-hasigo /sutenresu-basigo	231	27	0.10	$\chi^2(1)=161.30, p<.001$

Table 4 and 5 shows that for native Japanese first elements, a significantly larger proportion of participants selected the voiced case, while for Sino-Japanese and foreign loanword first elements, a significantly larger proportion of participants selected the voiceless case.

Table 6. Comparison of 1984 and 2005 in Experiment 2

1st element + 2nd element	<i>Rendaku</i> rate		Chi-square test of independence
	1984	2005	
(1) Native Japanese 1st element naga-hasigo /naga-basigo	0.96	0.68	$\chi^2(1)=56.88, p<.001$
(2) Sino-Japanese 1st element tetusei-hasigo / tetusei-basigo	0.36	0.27	$\chi^2(1)=3.99, p<.05$
(3) Foreign loan word 1st element sutenresu-hasigo /sutenresu-basigo	0.33	0.10	$\chi^2(1)=36.09, p<.001$

Table 6 shows that for every etymological type, the frequency of *rendaku* decreased over twenty-one years.

#### 4.3. Results

As shown in Figure 2, the decision tree analysis revealed the following significant trends: (1) the frequency of *rendaku* is marked by notable differences among etymological types from the highest — native Japanese, Sino-Japanese, and foreign loanwords [ $\chi^2(2)=373.124, p<.001$ ] — and (2) for every etymological type, the frequency of *rendaku* has consistently decreased over the twenty-one-year period [ $\chi^2(1)=56.883, p<.001$  for native Japanese,  $\chi^2(1)=3.994, p<.05$  for Sino-Japanese, and  $\chi^2(1)=36.085, p<.001$  for foreign loan words].

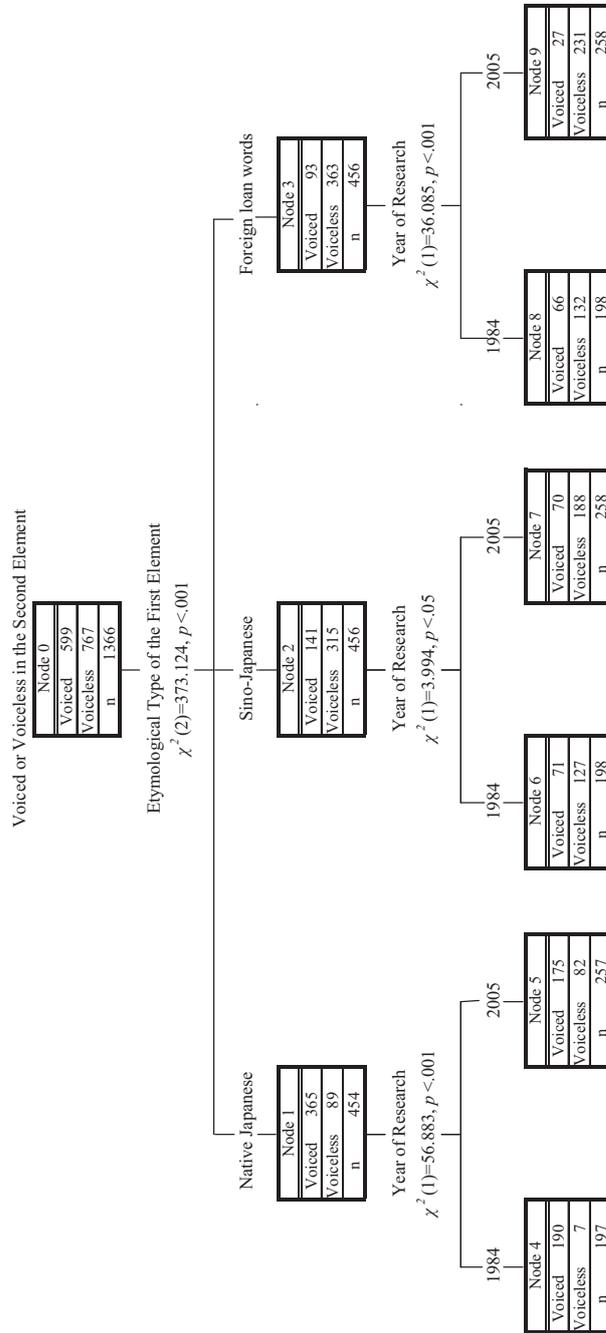

Figure 2. Decision tree analysis of Experiment 2

## 5. Discussion

The present study investigated Lyman's Law effect on *rendaku*. Experiment 1 demonstrated that the blocking effect of voiced obstruency was higher with voiced obstruents in the second mora position than in the third/fourth mora position. There was no significant difference in *rendaku* frequency between cases in the third mora and the fourth mora. This indicates that the blocking effect by Lyman's Law differs in strength depending on the position of the voiced obstruent contained, and what is more, there exists a gap between the second mora position adjacent to *rendaku*-targeted mora and the third/fourth mora position distant from the *rendaku*-targeted mora. The blocking effect decreases toward the end of the domain of *rendaku*. The strong effect of proximity is thus observed. Comparing the results in 2005 with those in 1984, in the case of the voiced obstruent in the second mora, Lyman's Law effect has weakened, whereas it has intensified in the case of the voiced obstruent contained in the third and fourth mora. These are opposing tendencies. This indicates that the difference in Lyman's Law effect between the second mora position and the third/fourth mora position has decreased over 21 years. Therefore, Lyman's Law differs in blocking effect depending on the position of the voiced obstruent already contained, although these differences tend to decrease. This implies that Lyman's Law is a general tendency rather than a categorical prohibition.

Experiment 2 revealed that the frequency of *rendaku* is marked by notable differences among the etymological type of the first elements.<sup>2</sup> The frequency of *rendaku* among native Japanese, Sino-Japanese, and foreign loanwords was observed in descending order. Comparing the results in 2005 with those in 1984, for every etymological type, the frequency of *rendaku* has consistently decreased in twenty-one years. In other words, the exceptionality of the *hasigo* exceptions to Lyman's Law tends to decrease. This reveals a tendency that in close conformance with the tenets of Lyman's Law.

Based on the two experiments and their close examinations with statistical analysis using decision tree analyses above, it may be concluded that (1) Lyman's Law, which is one case of OCP, is a general tendency rather than a categorical prohibition; (2) etymological types of the first element affect *rendaku*; and (3) the 'X-basigo' exception has closely conformed to the tenets of Lyman's Law in twenty-one years.

## Notes

\* The work reported in this paper was partly supported by the Grant-in-Aid for Scientific Research (C) from Japan Society for the Promotion of Science (No.19520352).

# Is marked less frequent? Polish word-final consonantal sequences in a dictionary

**Paula Orzechowska**

Adam Mickiewicz University, Poznań  
al. Niepodległości 4,  
61-874 Poznań, Poland  
paulao@poczta.wp.pl

## **Abstract**

The main objective of the paper is to determine the relation between the degrees of cluster markedness and their frequency. We base our analysis on Polish word-final dictionary clusters. The paper is a contribution to the ongoing debate on whether complexity goes hand in hand with statistical estimates. In addressing this issue, on the one hand, we establish the degrees of phonological preferability, and, on the other hand, we introduce the distinction between phonologically- and morphologically-motivated clusters.

**Keywords:** frequency, markedness, (mor)phonotactics, Natural Phonology.

## **1. General issues in Polish (mor)phonotactics**

### *1.1. Introduction*

It has long been acknowledged that the phonological description of a language should be concerned not only with phonemes in isolation but with “the combinations into which phonemes enter in forming morphemes and words” (Trnka 1966: 36). This postulate was asserted by other linguists who claimed that scarce attention had been given to “the sequential relations between sounds” (Saussure 1998 [1974]: 50) and that “what is now required is nothing less than a syntax of phonological expressions” (Kaye et al. 1990: 193). Phonotactics has thus become one of the principal areas of phonological investigation. Central to this contribution is the linear arrangement of consonants in Polish which emerge word-finally within a morpheme and across morphemic boundaries. In light of the facts that the majority of world languages does not permit consonantal clusters (Maddieson 1999), and that they tend to be avoided,

especially in the word-final position, the study of sequences in a phonotactically elaborate language such as Polish becomes particularly interesting.

### *1.2. Previous accounts of Polish (mor)phonotactics*

Previous research on Polish phonotactics has primarily focused on the classification, frequency and ranking of clusters in written (e.g., Dobrogowska 1984, 1990, 1992; Śledziński 2005) and spoken text (e.g., Bargielówna 1950, Dunaj 1985, Madejowa 1990). With the advances in phonological theories, theory-oriented analyses of phonotactics occurred (e.g., Cyran and Gussmann 1999, Dziubalska-Kołaczyk 2002, Rochoń 2000, Rubach and Booij 1990). These accounts, however, did not point explicitly to the role that morphology plays in cluster formation. The first systematic description of the Polish cluster inventory which accounted for the distinction between clusters emerging within a morpheme and across morphemic boundaries was Bargielówna's (1950). Recently Dressler and Dziubalska-Kołaczyk (2006) brought up the issue of morphologically-motivated phonotactics by proposing the study of morphonotactics. The authors provided the cross-linguistic description of selected intra- and intermorphemic clusters and discerned between sequences which emerge due to concatenative and non-concatenative morphological operations.

### *1.3. The study and domain of morphonotactics*

Dressler and Dziubalska-Kołaczyk (2006) define morphonotactics as a distinct area of morphophonology which is based on the semiotic model of morphonology proposed by Dressler (1985), on the one hand, and the Beats-and-Binding model of phonotactics propounded by Dziubalska-Kołaczyk (2002). The study of morphonotactics focuses on the interrelationship between phonotactic constraints and morphological rules in a given language. The authors distinguish between phonologically- and morphologically-motivated clusters, which are here referred to as intramorphemic and intermorphemic respectively. For instance, in Polish the cluster /-rt/ occurs only within a morpheme, (e.g., *żart* 'joke', *rekord* 'record', *miliard* 'billion'), in contrast to /-jɛ+tɕ/ which is unexceptionally intermorphemic (e.g., *pójs+ć* 'go', *wyjś+ć* 'come out', *wzejś+ć* 'rise'),. Next to the two groups of clusters, Dressler and Dziubalska-Kołaczyk (2006) mention sequences which occur in both contexts, i.e. intra- and intermorphemically. /-ɛ(+ )tɕ/ can serve as an example. The cluster is intramorphemic in *kość* 'bone', *złość* 'anger', *radość* 'happiness' and intermorphemic in *jeś+ć* 'eat', *kraś+ć* 'steal'

and *upaś+ć* 'fall'.

The issue which should be clarified from the outset of our considerations concerns the target domain within which morphonotactics operates. A word, on a par with its constituent morphemes, are regarded as domains relevant for the description of consonantal clustering. Firstly, a word, as a relatively independent linguistic unit, aspires to being the least problematic and controversial domain for formulating phonotactic generalizations (see Booij 1999, Ewen and Hulst 2001). Secondly, the discussion on the morpheme boundaries within clusters requires that the morphological domain be consulted. Therefore, constraints in morphonotactics are stated for the following: the lexical domain, to determine the possible strings in a given word position, and the morphological domain, to specify the structure of morphemes.

#### *1.4. Polish (mor)phonotactics*

Polish, as a phonotactically elaborate language, tolerates complex consonant clusters. It allows 4 consonants word-initially (e.g., *pstrąg* /pstrɔŋk/ 'trout'), and 5 consonants in the word medial and final position (e.g., *następstwo* /nastɛmpstfɔ/ 'consequence' and *skapstw* /skɔmpstf/ 'stinginess' [gen. pl.] respectively). Moreover, there are clusters which emerge as the realizations of the nasal vowels <a, ɛ> before obstruents (e.g., *okręt* /okrɛnt/ 'ship', *wąs* /vɔ̃wɔs/ 'moustache'). It must be noted that the most complex clusters emerge in subtractive morphology. For instance, the aforementioned final cluster /-mpstf/ in *skapstw*, *zastępstw* 'substitution' [gen. pl.] and *ustępstw* 'concession' [gen. pl.] results from the truncation of the plural marker {-a} from the nominative forms *skapstw+a*, *zastępstw+a* and *ustępstw+a*.

In a dictionary, which presents a very restricted morphological context, all the intermorphemic clusters emerge in concatenation. The vast majority of the clusters is found in verbal infinitives at the boundary of a verbal stem and the infinitival desinence {-ć}, e.g., in *podnieś+ć* 'lift' or *przyjś+ć* 'come'. The collected data also contains one pronoun *czyj+ś* 'somebody's' with an intermorphemic cluster.

## **2. Theoretical framework of Natural Phonology**

### *2.1. Beats-and-Binding phonotactics*

Natural Phonology is an explanatory theory based on universal preferences and

language-specific constraints. The model of phonotactics proposed within the theory is Dziubalska-Kołodziej's (2002) *Beats-and-Binding phonotactics* (henceforth BBP). The principle underlying the model is the preference for the canonical CV structure, which is considered the most optimal sequence universally. In the case of languages which allow consonant clusters, the model helps establish the phonotactic scale, whose extreme ends are represented by the most and the least preferred sequences with gradual transition between the two. Well-formedness conditions which specify cluster preferability are formulated on the basis of three parameters: sonority distances between consonants forming a cluster (measured in terms of the manner of articulation), cluster complexity (i.e. the number of consonants forming a cluster), and the position of a cluster within a word (i.e. initial, medial or final). Similar continua of cluster preferability can be established with the help of the revised version of the BBP model.

## 2.2. Net Auditory Distance (NAD)

Similarly to BBP, Net Auditory Distance (Dziubalska-Kołodziej and Krynicki 2008) serves to determine auditory distances between sounds neighbouring on one another. Well-formedness conditions which specify the word-final -CC and -CCC clusters are drawn from Dziubalska-Kołodziej (2002):

- (1)  $NAD(V-C_1) \leq NAD(C_1-C_2)$  for doubles, and
- (2)  $NAD(V-C_1) \leq NAD(C_1-C_2) > NAD(C_2-C_3)$  for triples.

What differentiates NAD from BBP is the way in which distances are calculated. In contrast to the original model, NAD calculates auditory distances not only for the manner of articulation (MOA) according to the sonority scale, but also on the basis of the place of articulation (POA) and voice specification ( $Lx$ ). According to (Dziubalska-Kołodziej and Krynicki 2008), the three coordinates (i.e. MOA, POA,  $Lx$ ) established for two adjacent sounds, say  $S_1$  and  $S_2$ , help specify the NAD between the sounds. The NAD for  $S_1$  and  $S_2$ , with the three defining coordinates  $S_1 = (MOA_1, POA_1, Lx_1)$  and  $S_2 = (MOA_2, POA_2, Lx_2)$ , is calculated along the following metric:  $NAD(S_1-S_2) = |MOA_1 - MOA_2| + |POA_1 - POA_2| + |Lx_1 - Lx_2|$ . MOA and POA distances for the Polish consonantal inventory are provided below.

Table 1. Auditory distances for Polish (based on Dziubalska-Kołaczyk and Krynicki 2008).

5	4	3	2	1	0
obstruent		sonorant			
stop	fricative	nasal	liquid	glide	vowel
	affricate		lateral	rhotic	
p b	f v	m		w	labial 1
t d	tʃ dʒ ts dz	s z ʃ ʒ	n	l r	coronal 2
k g	tʃ dʒ x	ɲ ɲ		j	dorsal 3
					radical 4
					glottal 5

As shown above, the auditory distance of 1 point holds between labial – coronal, coronal – dorsal, dorsal – radical, and finally radical – glottal consonants on the POA scale, which results in the  $NAD_{(POA)}$  equal to 0, 1 and 2 for /mp/, /jt/, and /xw/ respectively. As regards the MOA scale, the distance 1 holds between vowels – glides, glides – liquids, liquids – nasals, nasals – fricatives and fricatives – plosives. The distance of 1 point does not apply to two classes of consonants, namely affricates and liquids.

Firstly, affricates are assumed 0.5 distance from fricatives and plosives neighbouring on them, which results in the following  $NAD_{(MOA)}$  distances: /t-tʃ/ = 0.5, /x-tʃ/ = 0.5, /w-tʃ/ = 3.5, /l-dʒ/ = 2.5 and /n-dʒ/ = 1.5. Secondly, Dziubalska-Kołaczyk and Krynicki (2008) subsume /l/ and /r/ under one category. However, in line with the proposition of Selkirk (1982) and Vennemann (1988), we suggest to subdivide the liquids into the rhotic and the lateral. Therefore we acknowledge the distance of half a point between the sequences of glide – rhotic, rhotic – lateral, and lateral – nasal. This is how we arrive at the following  $NAD_{(MOA)}$  distances: /wɹ/ = 0.5, /jɹ/ = 1, /ml/ = 0.5, /nr/ = 1 and /rl/ = 0.5. Apart from the POA and MOA scales, NAD accounts for the voice characteristic of adjacent sounds. The distance equal 1 holds between two consonants which differ in terms of voice, in contrast to consonants with the same voice specification, which are assigned the distance 0.

Let us illustrate the working of the phonotactic model on the example of the final doubles /-jp/ and /-tl/. Given the metric for a word-final double:

$$(3) NAD(V-C_1) = |MOA(V) - MOA(C_1)|$$

$$(4) NAD(C_1-C_2) =$$

$$|MOA(C_1) - MOA(C_2)| + |POA(C_1) - POA(C_2)| + |Lx(C_1) - Lx(C_2)|,$$

the defining coordinates for /-jp/ and /-tl/ are the following:

(5)  $NAD (V-C_1) = |0 - 1| = 1$  for /-jp/,

(6)  $NAD (V-C_1) = |0 - 5| = 5$  for /-tl/,

(7)  $NAD (C_1-C_2) = |1 - 5| + |3 - 1| + |1 - 0| = 4 + 2 + 1 = 7$  for /-jp/ and

(8)  $NAD (C_1-C_2) = |2.5 - 5| + |2 - 2| + |0 - 1| = 2.5 + 0 + 1 = 3.5$  for /-tl/.

The cluster /-jp/, whose  $NAD (V-C_1) = 1$  is smaller than its  $NAD (C_1-C_2) = 7$ , meets the phonotactic condition and is therefore preferred. To the contrary, /-tl/, with the  $NAD (V-C_1) = 5$  and the  $NAD (C_1-C_2) = 3.5$ , is a dispreferred final double. The calculation of the auditory distances for triples proceeds along the lines given above but additionally involves the POA, MOA and Lx distances for the second pair of consonants  $C_2-C_3$ . Below we summarise the NAD distances for four selected doubles and triples.

Table 2. The Net Auditory Distances for word-final CC clusters (P = preferred, D = dispreferred).

	NAD (VC <sub>1</sub> )	NAD (C <sub>1</sub> C <sub>2</sub> )				Is the pref. condition met?
	MOA	MOA	POA	Lx	NAD	
jp	1	4	2	1	7	P. $1 < 7$
rɕ	2	2.5	0	0	2.5	P. $2 < 2.5$
ns	3	1	0	1	2	D. $3 > 2$
tl	5	2.5	0	1	3.5	D. $5 > 3.5$

Table 3. The Net Auditory Distances for word-final CCC clusters (P = preferred, D = dispreferred).

	NAD (VC <sub>1</sub> )	NAD (C <sub>1</sub> C <sub>2</sub> )				NAD (C <sub>2</sub> C <sub>3</sub> )				Is the pref. condition met?
	MOA	MOA	POA	Lx	NAD	MOA	POA	Lx	NAD	
wɕɕd	1	3.5	1	0	4.5	0.5	0	0	0.5	P. $1 < 4.5 > 0.5$
mpt	3	2	0	1	3	0	1	0	1	P. $3 \leq 3 > 1$
rnz	1.5	1	0	0	1	1	0	0	1	D. $1.5 > 1 \geq 1$
pst	5	1	1	0	2	1	0	0	1	D. $5 > 2 > 1$

Given the NAD distances in Tables 2 and 3, it can be stated that the doubles /-jp/ and /-rɕ/ occupy the preferred end of the scale, in contrast to /-ns/ and /-tl/ which are dispreferred. Out of the four triples, /-mpt/ and /-wɕɕd/ are preferred since their NAD (C<sub>1</sub>-C<sub>2</sub>) is greater than or equal to the NAD (V-C<sub>1</sub>) and greater than the NAD (C<sub>2</sub>-C<sub>3</sub>). To the contrary, /-rnz/ and /-pst/ do not meet the well-formedness condition. Since their NAD (V-C<sub>1</sub>) is greater than the NAD (C<sub>1</sub>-C<sub>2</sub>) and NAD (C<sub>2</sub>-C<sub>3</sub>), they are classified as dispreferred.

The approach to (mor)phonotactics put forward by Dziubalska-Kołodziejczyk (2002) and later refined by Dziubalska-Kołodziejczyk and Krynicky (2008) allows to establish the preferability degrees of clusters on the basis of several phonological features marshaled into NAD. The criterion not only accounts for a greater phonetic detail than the traditional accounts but also provides phonotactic continua with gradual transitions between preferred and dispreferred clusters. In such a way, the approach points to the pitfalls inherent in any phonotactic analysis which, firstly, relies on a single criterion (such as sonority), and, secondly, classifies clusters in simplistic terms into well- and ill-formed.

### 2.3. NAD and the Polish clusters

Having calculated NAD for all doubles and triples in the Polish dictionary, we arrive at two broad groups of clusters: preferred and dispreferred. Sequences in the two groups are further subcategorized depending on their structural complexity into (a) preferred -CC, (b) preferred -CCC, (c) dispreferred -CC and (d) dispreferred -CCC. Bearing in mind that the phonotactic model (Dziubalska-Kołodziejczyk 2002) is based on the universal preference for the CV structure, cluster size is assumed to be a stronger indicator of preferability than auditory distances between adjacent sounds. In practice this means that any -CC is universally more preferred than the most preferred -CCC. The distribution of exclusively phonologically-motivated clusters at each preferability degree is shown below.

Table 4. The distribution of exclusively intramorphemic clusters in the 4 preference groups.

Preferability for exclusively phonologically-motivated clusters		
Preferability	Cluster size	Cluster types
Preferred	-CC	fr, jf, jk, jl, jm, jn, jr, js, jt, jf, jts, jx, kl, kr, lf, lf, lk, lp, ls, lt, lts, lx, mf, mp, ms, nf, nt, nk, pn, pr, rē, rf, rk, rm, rn, rp, rs, rt, rf, rē, rts, rx, sw, tw, wf, wf, wk, wl, wm, wn, wp, wr, ws, wt, wē, wx
Dispreferred	-CC	cl, cn, fp, fj, ft, fx, fk, fl, fn, ft, fts, ks, kt, kx, lm, mf, mn, nr, nf, nts, jts, pl, ps, pt, rl, rn, sk, sm, sp, st, tf, tl, tm, tr, ts, xj, xt
Preferred	-CCC	jsk, jst, lēn, lft, lsk, mpf, mpt, nf, nks, nkt, rēē, rfj, rjt, wjt, wst
Dispreferred	-CCC	jnt, kst, ltr, mpl, mpr, ntr, nkr, psk, stj, str, wnt, xtr

The established degrees of preferentiality are translated into 4 markedness degrees (henceforth MDs), which are here presented in the form of a pyramid. The least marked clusters, i.e. the preferred doubles, are subsumed under the MD = 1, whereas the most marked clusters, here represented by the dispreferred triples, are grouped under the MD = 4 (see Figure 1). The bottom and top of the pyramid correspond with the MD = 1 and 4 respectively.

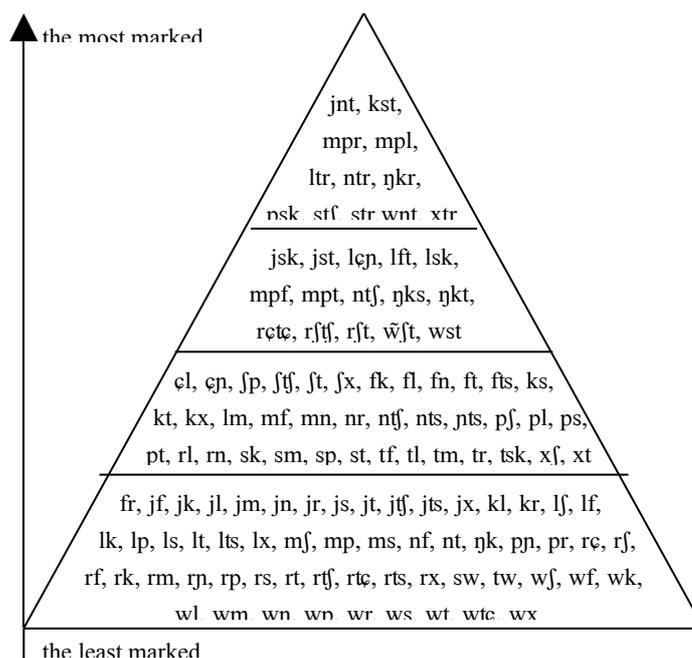

Figure 1. The markedness degrees for exclusively intramorphemic clusters in the Polish dictionary.

As far as exclusively morphologically-motivated sequences are concerned, they are represented by 2 types  $/j+\text{ɕ}/$  and  $/j\text{ɕ}+\text{ɕ}/$ . This means that only 2 degrees of preferability and the resulting 2 degrees of markedness can be established, where the MD = 1 is represented by the preferred double  $/j+\text{ɕ}/$ , and the MD = 2 by the preferred triple  $/j\text{ɕ}+\text{ɕ}/$ . No markedness continuum can be established for  $/ɲ(+)\text{ɕ}/$  and  $/\text{ɕ}(+)\text{ɕ}/$  which occur both intra- and intermorphemically as the 2 types are preferred doubles.

Summing up, we proposed a 4-degree continuum for the intramorphemic clusters and a 2-degree scale for the intermorphemic ones. Our objective now is to test the hypothesis that markedness corresponds to frequency (see Bybee 2001). We predict that there is a strong tendency for the unmarked to be more frequent. We expect the established markedness degrees to correlate particularly with type frequency. In the subsequent section of the paper, we discuss the frequency of the phonologically- and morphologically-motivated clusters assigned to each markedness degree.

### 3. The study

#### 3.1. Data

The data used in this study was compiled on the basis of the electronic version of a 200.000-entry *Uniwersalny Słownik Języka Polskiego* (Dubisz 2006). The complete set of words with final consonantal clusters was extracted manually with the help of the index *a tergo*. The collected data contains instances of obsolete words, proper nouns, acronyms, borrowings and rare vocabulary. The longest clusters found in the dictionary are triples, which occur intra- and inter-morphemically. The total of the lexical entries containing word-final clusters amounts to 6916, including 6806 doubles and 110 triples. We subcategorized all words into 126 types, among which there are 98 -CC and 28 -CCC clusters. As regards the morphologically-motivated sequences, the data contains only four final clusters. With the exception of the pronoun *czyj+ś* 'somebody's' ending in /-jɕ/, the remaining intermorphemic clusters /-jɲɕ/, -ɕɲɕ/, -jɕɲɕ/ are found in verbs. The clusters /-jɕ/, -jɕɲɕ/ are exclusively morphologically-motivated, whereas /-jɲɕ/, -ɕɲɕ/ are mixed and motivated both phonologically and morphologically.

Table 5. The frequency of cluster types and words containing a cluster in the Polish dictionary.

Cluster size	Cluster types	Different words containing a cluster	
	all types	words with phonological clusters	words with morphological clusters
-CC	77.8 %	82.1 %	16.3 %
-CCC	22.2 %	1.4 %	0.2 %
Total	100 %	83.5 %	16.5 %

We observe a correlation between cluster motivation, its structural complexity and frequency. As regards word frequency, the phonologically-motivated clusters, which constitute 83.5% of words containing a final sequence, are more frequent than the morphologically-motivated clusters, whose word frequency equals 16.5%. As far as cluster complexity is concerned, 98% of the intramorphemic and 99% of the intermorphemic sequences are doubles. Triples do occur, however, their total frequency in the dictionary does not exceed 1.4% for types and 0.2% for words.

Our objective is to address the issue regarding type and word frequency of the intra- and intermorphemic clusters. In line with the markedness continua established earlier (see 2.3.), we calculate frequency for clusters which are exclusively

phonological, exclusively morphological and for clusters with dual motivation. Let us start the analysis of the first group of clusters.

### 3.2. Exclusively intramorphemic clusters

The group of exclusively phonologically-motivated clusters is well-represented in the dictionary. In the collected data, we find 122 intramorphemic clusters (see Table 4), among which there are 95 -CC and 27 -CCC types. This means that nearly 78% of the intramorphemic sequences are doubles. Type and word frequency of the clusters found at each markedness degree is provided in Table 6. The graphical representation of the data is given in Figure 2.

Table 6. The number and frequency of exclusively intramorphemic clusters for the 4 markedness degrees.

Exclusively phonologically-motivated clusters						
MDs	dictionary types			dictionary words		
	no. of types	dictionary total	% of types	no. of words	dictionary total	% of words
1	57	126	45.2 %	1350	6916	19.5 %
2	38	126	30.2 %	1679	6916	24.3 %
3	15	126	11.9 %	31	6916	0.4 %
4	12	126	9.5 %	63	6916	0.9 %

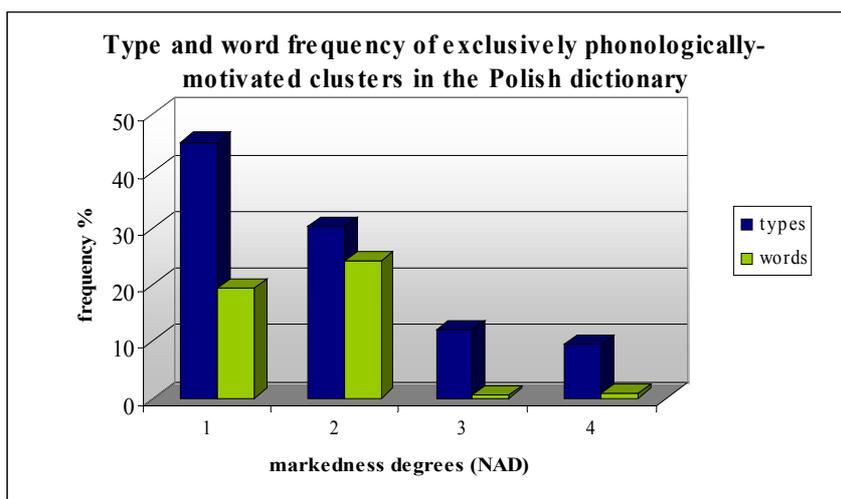

Figure 2. Type and word frequency of exclusively intramorphemic clusters for the 4 markedness degrees.

As shown above, type frequency reflects the established markedness degrees.

I.e. the frequency of types gradually decreases from 45.2% to 9.5% as the markedness degrees increase from the preferred -CC to the dispreferred -CCC clusters. To the contrary, the frequency pattern observed for words does not correspond with that of types. The classes of the dispreferred and preferred doubles subsumed under the MD = 2 and the MD = 1 have the highest word frequency, which amount to 24.3% and 19.5% respectively. Word frequency for all the triples gathered under the MDs = 3 and 4 is extremely low and does not exceed 1% in either case.

These observations lend support to the claim that phonology produces a wide range of unmarked types, i.e. preferred doubles, and incomparably fewer marked clusters, namely dispreferred triples. The tendency holds to a large extent for word frequency, which is much higher for -CC than -CCC clusters. Additionally, there is a greater percentage difference between the types subsumed under the MDs = 1 and 2 than the MDs = 3 and 4. More specifically, we observe a 15 percentage point difference between the groups of the preferred and dispreferred doubles. To the contrary the groups of the preferred and dispreferred triples differ from one another only by 2 percentage points. This may suggest that preferentiality in terms of phonological characteristics is a relevant indicator of markedness only for -CC. Clusters longer than doubles are too complex for phonology to apply efficiently. This claim, however, can only serve as a tentative hypothesis which should be verified in larger-scale research. No verification of the claim can be provided on the basis of the intermorphemic dictionary clusters, due to their paucity.

### 3.3. Exclusively intermorphemic and mixed clusters

The dictionary data contains two clusters which are exclusively morphologically motivated and two clusters which can emerge both intra- and intermorphemically. The first pair of clusters is represented by /-jɕ/ and /-jɕɕ/, which occur in the pronoun *czyj+ś* and verbal infinitives such as *odejś+ć* 'leave' and *wejś+ć* 'come in'. Similarly, /ɕ(+ )ɕ/ and /ɲ(+ )ɕ/, found in the mixed group, are phonologically-motivated in examples such as *liś* /liɕɕ/ 'leaf' and *pamięć* /pamiɕɕ/ 'memory', and morphologically-motivated in *nieś+ć* /niɕɕ/ 'carry' and *rosnąć+ć* /rosnoɲɕ/ 'grow'. Type and word frequency for the exclusively intermorphemic and mixed clusters are provided in Tables 7 and 8 respectively.

Table 7. The number and frequency of exclusively intermorphemic clusters for the 2 markedness degrees.

Exclusively morphologically-motivated clusters						
MDs	dictionary types			dictionary words		
	no. of types	dictionary total	% of types	no. of words	dictionary total	% of words
1	1	126	0.8 %	1	6916	0 %
2	1	126	0.8 %	17	6916	0.2 %

Table 8. The number and frequency of intra- and inter-morphemic clusters in the mixed group.

Phonologically-and morphologically-motivated mixed clusters						
MDs	dictionary types			dictionary words		
	no. of types	dictionary total	% of types	no. of words	dictionary total	% of words
Intramorphemic clusters						
1	2	126	1.6 %	2651	6916	38.3 %
Intermorphemic clusters						
1	2	126	1.6 %	1125	6916	16.3 %

Due to the fact that the group of exclusively intermorphemic clusters is represented by  $/-j\text{ç}/$  and  $/-j\text{çt}\text{ç}/$ , only two markedness degrees can be established. Type frequency for the MDs = 1 and 2 are equal, whereas word frequency is generally very low and amounts to 0% and 0.2% respectively. As far as the mixed group is concerned,  $/-j(+)\text{t}\text{ç}/$  and  $/-\text{ç}(+)\text{t}\text{ç}/$  are both preferred doubles subsumed under the MD = 1, from which it transpires that no markedness continuum can be proposed. What we can see, however, is that  $/-j\text{t}\text{ç}, -\text{çt}\text{ç}/$  are twice more frequent in the phonological than morphological context, which can be attributed to the fact that phonologically-motivated clusters are generally favoured in the dictionary.

Moreover, it should be noted that the intermorphemic and mixed clusters are marked by a specific phonological property.  $/-j\text{ç}, -j\text{çt}\text{ç}, -\text{çt}\text{ç}, -j\text{t}\text{ç}/$  are all native and contain at least one soft consonant. All the verbs end in the alveolo-palatal voiceless affricate  $/-t\text{ç}/$ , which is the infinitival desinence, whereas the pronoun ends in the soft voiceless fricative  $/-\text{ç}/$ , which marks indefiniteness on the pronoun. This observation ties well with the discussion on cluster markedness. It can be the case that the native status of the clusters, i.e. their phonological familiarity, is likely to neutralize the markedness effects that morphology has on phonotactics.

#### 4. Conclusions

Our analysis confirms the markedness-related effects in Polish phonotactics. Phonology was shown to produce primarily unmarked intramorphemic types (MD = 1) which are much more frequent than their marked counterparts (MD = 4). That is, we observed a gradual decline in type frequency for the increasing markedness degrees. This tendency, although largely preserved, is weaker for words containing types. As far as the morphologically-motivated and mixed clusters are concerned, they are heavily underrepresented in the dictionary. This results in only two markedness degrees for the exclusively intermorphemic clusters and no degrees for the sequences with dual motivation. Therefore, substantial generalizations on Polish dictionary phonotactics can be formulated only on the basis of the intramorphemic sequences.

The interesting by-product of our analysis is the observation that morphology is oblivious to phonological well-formedness and therefore only doubles seem to rely on the preferability degrees established by NAD. The tentative conclusion thus is that the phonological well-formedness is too weak a tool for determining the preferentiality degrees for clusters more complex than -CC, which strengthens the universal preference for the CV structure. Whether structural complexity is really a filter for the application of phonological features (such as the place and manner of articulation and voicing) should be verified on the basis of, e.g. corpora, whose intermorphemic clusters present a variety of morphological contexts. This remark is an implication for our future research. Since the dictionary data provides us with limited insights into word-final Polish morphonotactics, we stress the necessity of a corpus-based research. It is our contention that only such an exhaustive and a systematic study lays the foundations for the formulation of solid generalizations on morphonotactics.

{d93142002; jfon}@ntu.edu.tw

## Abstract

This paper investigated how consonant-/i/ syllable pairs initiated with L1 (Mandarin) and L2 (English) consonants varying to different degrees of similarity are perceived by Mandarin speakers of English. In the first experiment, 25 participants were tested with six such pairs varying in degrees of similarity in the initial consonant. In Experiment 2, another 26 participants were tested with the same syllables with the vowel /i/ either juxtaposed from a different production of the same stimuli (the same language) or from the corresponding syllable (the other language). Two competing models, the speech learning model (Flege, 1995) and the perceptual assimilation model (Best, 1995), were examined. The former proposed that the greater the perceived dissimilarity between an L2 sound and its closest L1 counterpart, the easier it is for L2 speakers to discern the difference, while the latter proposed that L2-to-L1 assimilation corresponds to their articulatory distance. For L2 sounds corresponding to the same L1 target, perceptual performance may still differ depending on how similar the L2 sounds are to the target. Results supported the SLM in that the accuracy for discerning individual consonants of the “dissimilar” pairs was higher than that of the “similar” pairs, which in turn was higher than that of the “identical” pairs. However, the fact that the accuracy for discerning the “similar” pairs was higher than that of discerning the “identical” ones indicated that L2 speakers were still able to distinguish different levels of similarity contrast between the two. To this, the PAM provides a better explanation. In addition, through these two experiments, vocalic information was found crucial in facilitating participants’ differentiation.

**Keywords:** L2 perception, consonantal similarity.

## 1. Introduction

Compared with children, adults are believed to be less sensitive to nonnative phonetic differences (Goto, 1971; Werker *et al.*, 1981; Werker & Tees, 1984). The relationship between second-language (L2 hereafter) sound differentiation ability and native (L1 hereafter) versus nonnative sound differences has been an important topic in

the field of L2 sound acquisition (Aoyama *et al.*, 2004). By now, most studies have been conducted on either lexical representation examination or minimal pair comparison (Hayes-Harb, 2007). In order to examine the degree of success among listeners in perceiving nonnative sounds, the speech learning model (SLM hereafter, Flege, 1995) and the perceptual assimilation model (PAM hereafter, Best *et al.*, 1988; Best, 1995), among others, provide the prediction based on the perceived phonetic distance between native and nonnative sounds. The two models differ in that the former focuses on the aspect of L2 learning, while the latter is established on the fact that some foreign language sounds are harder than others to distinguish (Guion *et al.*, 2000).

Regarding language contrasts, the SLM proposes that the coexistence of L1 and L2 phonetic systems in the same phonological space results in their mutual influence. If a new category is not formed for an L2 sound because of its similarity to the closest L1 counterpart, the L1 and L2 categories tend to assimilate, which will in turn result in the L2 sound being merged with an inter-category. On the contrary, if a new category is successfully established, this L2 sound may dissimilate from its neighboring L1 sound, thus preserving the phonetic contrast. Specifically, Flege (1995) believes that the greater the perceived dissimilarity of an L2 sound from its closest L1 sound, the more likely a new category will be formed. He is also convinced that adults can detect cross-language phonetic differences, and store the information into their long-term memory representations.

Modeling language contrast from a different perspective, the PAM proposes that sounds in a foreign language are perceived in accordance with their similarities to or differences from those that are articulatorily closest in one's L1 (Guion *et al.*, 2000). Following the assimilation pattern of the PAM, when two sounds are assimilated to two categories, the perceptual performance is expected to be good, whereas when they are assimilated to a single category, the performance is not (Sebastian-Galles & Soto-Faraco, 1999). One thing worth noticing is that when two sounds are assimilated to the same category, participants' performance may still differ according to their category goodness: If one of the two candidates is considered a better exemplar of the corresponding L1 target, the performance will be fairly good; if they are regarded as comparable candidates for the L1 target, the performance will be worse (Guion *et al.*, 2000).

To investigate which of the SLM and the PAM offers a better explanation in the case of Mandarin and English, the first experiment in the following session focused on how ESL speakers with Taiwan Mandarin as their L1 discern Mandarin and English consonant-/i/ syllables initiated with consonants of different levels of similarity from

both languages. Both the SLM and the PAM were investigated to see which one offers a better explanation.

## **2. Experiment 1**

### *2.1. Participants*

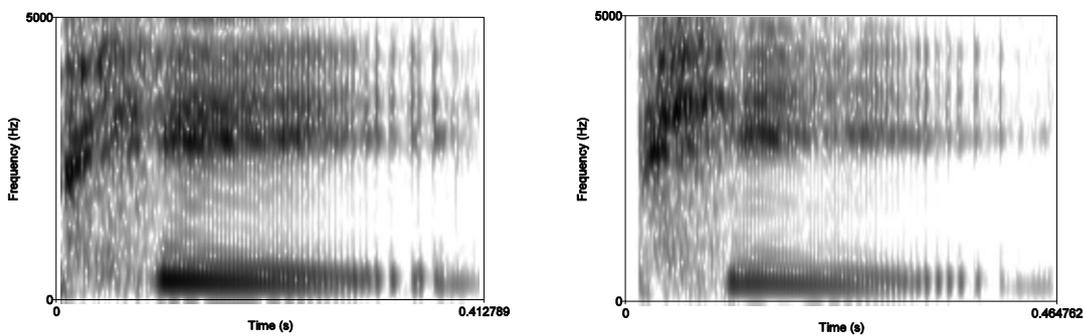

Participants of this experiment were 25 undergraduate students recruited from National Taiwan University. They received a compensation fee for their voluntary participation. Since L2 proficiency did not have any effect in our pilot study (N=15), participants of different English proficiency levels were collaborated in this experiment to explore whether consonantal similarity is robust.

### *2.2. Material*

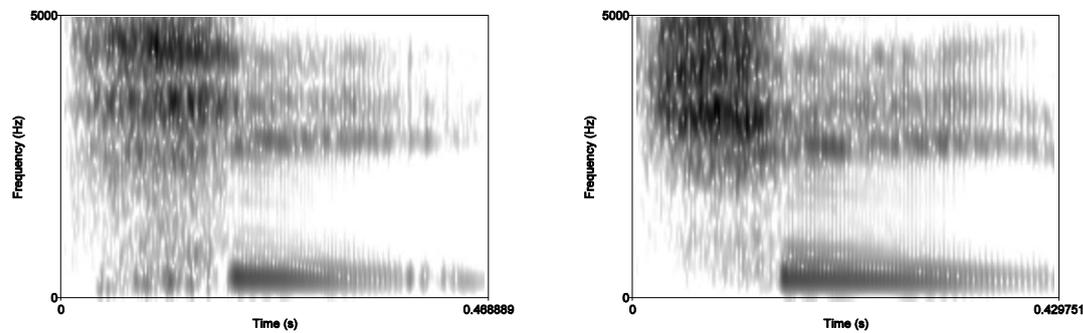

As shown in Table 1, six pairs of consonant-/i/ (C-/i/ hereafter) syllables were used as the stimuli of this experiment. The initial consonants of these Mandarin and English syllables differed in places of articulation to various extents, evident from their accompanying auditory and acoustic cues: First, bilabial /p/ and /m/ sounds are of the same place and manner of articulation in both languages, thus these C-/i/ syllables were categorized as “identical” pairs (See Figure 1a for acoustical evidence). Second, /t/ and /l/ are dental sounds in Mandarin but alveolar in English, and these two C-/i/ pairs were categorized as “similar” due to this closeness in place of articulation. Last, for [çi]-[ji] and [tç<sup>hi</sup>]-[tji] pairs, as shown in the spectrogram (Figure 1b), the two sounds of the same pair differ from each other to a great extent, as exhibited in their distribution of friction. In addition, the two English syllables, [ji] and [tji], also sound very differently from their Mandarin counterparts due to the auditory effect of lip protrusion. They were thus termed as “dissimilar” pairs.

**Table 1.** C-/i/ pairs used in Experiment 1

Mandarin			English	
關 ‘explore’	[p <sup>h</sup> i]	Identical	[p <sup>h</sup> i]	<i>pea</i>
密 ‘dense’	[mi]		[mi]	<i>me</i>
替 ‘help’	[t <sup>h</sup> i]	Similar	[t <sup>h</sup> i]	<i>tea</i>
力 ‘power’	[li]		[li]	<i>Lee</i>
系 ‘department’	[çi]	Dissimilar	[ʃi]	<i>she</i>
氣 ‘air’	[tɕ <sup>h</sup> i]		[tʃi]	<i>chee(se)</i>

**Figure 1a.** Acoustical contrast of the identical pair Mandarin [p<sup>h</sup>i] (left) vs. English [p<sup>h</sup>i] (right)

**Figure 1b.** Acoustical contrast of the dissimilar pair Mandarin [tɕ<sup>h</sup>i] (left) vs. English [tʃi] (right)

A female native speaker of Mandarin with near-native English proficiency was recorded for all stimulus words. The selected production of each item had been tested on native speakers of Mandarin (N=7) and English (N=5) and obtained an average of 6 on a 7-point (7 = 100% native) scale.

### 2.3. Procedure

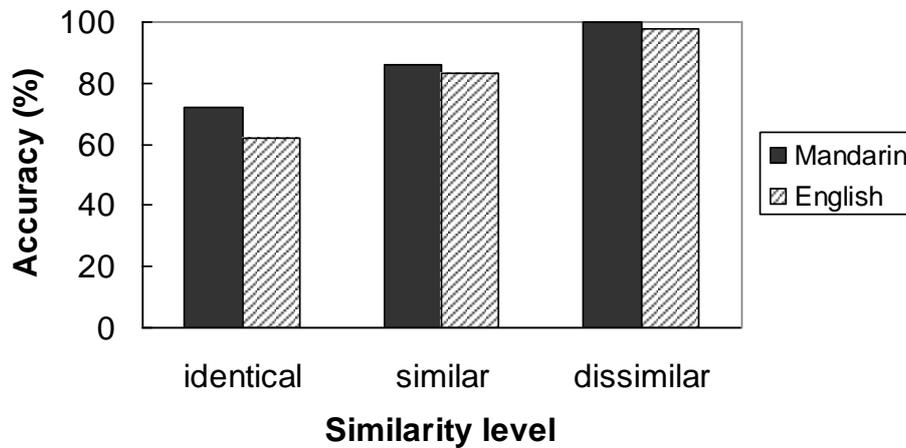

The experiment was conducted using a desktop computer with E-Prime 1.0 installed and a SR Box (model 200A) connected. All stimuli were repeated once. For each trial, participants were first given the orthographical spelling of syllable pairs of both languages on the screen in front of them. After 1000 ms, a sound was played via the headphone, and participants were told to press the corresponding button (left or right) based on their percept of this incoming sound—whether it was the Mandarin or an English syllable on the screen. The response window was 3000 ms. The direction of the orthographical spelling of both languages was counterbalanced.

### 2.4. Results

A 2 (language, Mandarin or English)  $\times$  3 (similarity level of the initial consonants of the C-/i/ syllables) repeated measure ANOVA was used to analyze the two factors manipulated in this experiment.

Results showed that both effects were significant, and no interaction was found. As shown in Figure 2, the overall accuracy was high (over 80%) for differentiating these C-/i/ syllables of the two languages [ $F(1, 99) = 4.98, p < .05$ ]. Specifically, Mandarin syllables were perceived with a higher accuracy than their English counterparts.

Similarity levels of the initial consonants were also found significantly influential to participants' performance [ $F(2, 198) = 34.20, p < .001$ ]. As shown in the figure, the accuracy was nearly perfect for differentiating syllables initiated by consonants of the “dissimilar” pairs, followed by the 80% accuracy for those of the “similar” pairs, which in turn was followed by the 70% accuracy for those of the “identical” pairs. Pairwise comparisons showed that differences between each two of the three similarity levels were all significant. The contrast was robust.

*Figure 2. Language and similarity effects of Experiment 1*

Results of this experiment conformed the native language advantage, and supported the SLM in that consonants took from the “dissimilar” pairs were perceived with higher accuracy than those from the other two similarity levels. However, the SLM made no clear prediction on how L2 learners would react on sounds of different similarity levels, *i.e.* similar and identical pairs in this experiment. It seems to treat similarity more as a dichotomous (instead of gradient) concept. On the other hand, equipped with the category goodness concept, the PAM seemed to provide a better explanation for the fact that the accuracy of /t/ and /l/ (“similar” pairs) differentiation was significantly higher than that of /p/ and /m/ (“identical” pairs), which in turn was significantly higher than the chance level.

With this unexpected overall high accuracy in the previous experiment, we suspected that supplementary information may be provided from the following vowel /i/ and facilitated participants’ perception. Thus we designed the following experiment in order to investigate the weighting of vocalic information in influencing participants’ decision on the differentiation of these C-/i/ syllables.

### 3. Experiment 2

#### 3.1 Participants

Participants were another 26 undergraduate students recruited from the same university. They also received a compensation fee for their voluntary participation. Following the previous experiment, English proficiency was not held as an independent factor in this experiment.

#### 3.2 Material

As vocalic information was the main factor in this experiment, the vowels of each C-/i/ item underwent manipulation to some degrees. As shown in Table 2, we had a two-by-two combinations between language (Mandarin or English) and vowel manipulation (of the same language as the consonant or not). For example, a newly combined syllable with a Mandarin consonant followed by the /i/ of its corresponding English syllable would be termed “ME”; if it’s the other way around, “EM”. One thing worth noticing was that even for those with consonants and vowels from the same language, *i.e.* MM and EE pairs, the /i/ sound was spliced from another production of the same syllable (illustrated as in Table 2). In this way we could assure that each stimulus was of equal extent of unnaturalness by the manipulation.

**Table 2.** *Manipulated C-/i/ pairs used in Experiment 2*

		Vowel <sup>1</sup>	
		<i>Mandarin</i>	<i>English</i>
Consonant	<i>Mandarin</i>	<b>M<sub>1</sub> + M<sub>2</sub></b>	<b>M<sub>1</sub> + E<sub>2</sub></b>
	<i>English</i>	<b>E<sub>1</sub> + M<sub>2</sub></b>	<b>E<sub>1</sub> + E<sub>2</sub></b>

The same speaker was again recruited for the recording of these stimulus items for this experiment.

---

<sup>1</sup> Segments extracted from different productions of the same syllable were marked with the lower-cased Arabic numbers 1 and 2.

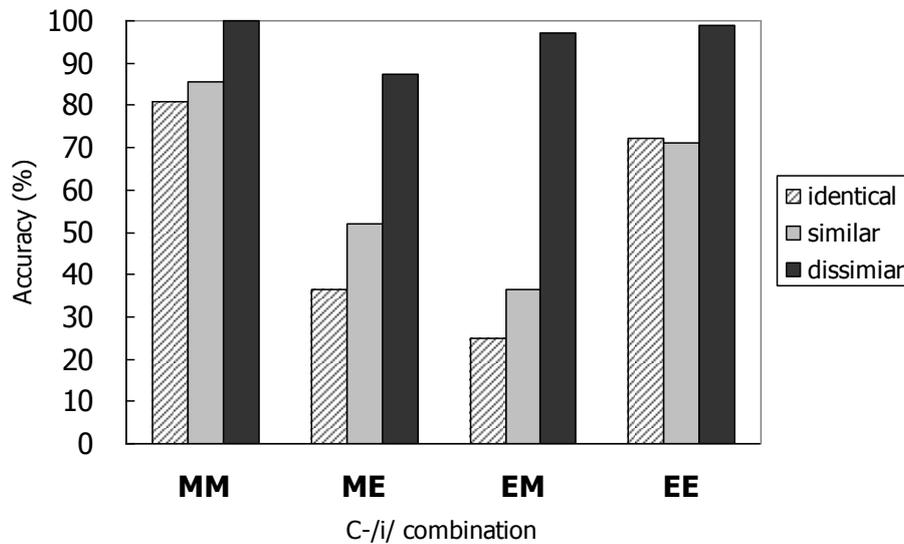

### 3.3 Procedure

Same as Experiment 1.

### 3.4 Results

In total, three factors were investigated in this experiment: In addition to language and similarity levels, vowel manipulation (/i/ from the same language as the preceding consonant or not) was also included as a within-group factor. Therefore, a 2 (language)  $\times$  3 (similarity level)  $\times$  2 (vowel manipulation) repeated measure ANOVA was conducted on the data collected.

Three main effects and two interactions were obtained in the analyses: Language effect was found significant, which indicated that for MM and EE pairs, though with the vowel /i/ juxtaposed from a different production, syllables initiated with Mandarin consonants were still perceived with a higher accuracy [ $F(1, 103) = 9.68, p < .01$ ]. In addition, the similarity effect replicated the results of the previous experiment in that syllables initiated with consonants of the “dissimilar” pairs were again perceived with a higher accuracy than those of the “similar” and “identical” pairs [ $F(1, 103) = 289.00, p < .001$ ]. However, compared with those natural (unedited) syllables in Experiment 1, the average accuracy for the “similar” and “identical” pairs of MM and EE conditions in this experiment decreased due to the replacement of /i/ from a different production. Post-hoc analysis on the interaction between language and similarity level showed that for Mandarin pairs, the three similarity levels significantly differed from each other [ $F(2, 414) = 52.30, p < .001$ ] while for English syllables, significance was only observed between the “dissimilar” pairs and the other two types [ $F(2, 414) = 103.97, p < .001$ ]. The difference between the “similar” and “identical” pairs was not significant.

*Figure 3. Language and similarity effects of Experiment 2*

The remaining main effect came from the manipulation of the vowel /i/. As shown in Figure 3, syllables with consonants and vowels extracted from the same language (MM & EE combinations) were consistently perceived with a higher accuracy than those with their /i/ sounds spliced from the other language (ME & EM combinations) [ $F(1, 103) = 159.06, p < .001$ ]. An interaction was also found between the similarity level of the syllable-initial consonants and vowel manipulation. The two correlated with each other, and post-hoc analysis showed that for syllables with /i/ and the preceding consonant from the same language, significance was only observed between the “dissimilar” pairs and the other two types [ $F(2, 414) = 30.80, p < .001$ ], whereas for those with /i/ juxtaposed from the other language, significance was found between each of any two similarity levels [ $F(2, 414) = 142.76, p < .001$ ].

Results of this experiment indicated that dichotomous differentiation seemed to be enough (at least for synthesized stimuli underwent the same level of C-/i/ manipulation) since the subtle difference between the “similar” and “identical” pairs might have been eliminated during the process of juxtaposition.

#### 4. Discussion and Conclusion

Results obtained from the first experiment supported that Mandarin speakers of English make use of their native language advantage when asked to differentiate L1 and L2 syllables. In addition, regarding the research questions mentioned earlier, the results also supported the SLM to a certain extent in that syllables belonging to the “dissimilar” Mandarin-English pairs were much easier to differentiate. However, the PAM offers a more detailed explanation on the relatively better performance on syllables of the “similar” pairs: Category goodness to Mandarin was believed to provide our participants ideal /t/ or /l/ exemplars. Bearing the ideal exemplars in mind, when asked to differentiate Mandarin and English /ti/ or /li/ pairs, all these L2 listeners had to do was to use this ideal phoneme as an “anchor”—anything close to it should be Mandarin, else should be English (since they were forced to determine between two choices).

Following this, results of the second experiment further confirmed the nativeness effect by showing that with the /i/ substituted from another production (of syllables of the same language), participants could still tell the difference between syllables of the “similar” and the “identical” pairs with an accuracy higher than the chance level. Vocalic information was found essential in facilitating those L2 listeners’ performance in accomplishing thus high accuracy. The correlation between vowel manipulation and the similarity level of the syllable-initial consonants showed that it is helpful in facilitating L2 listeners’ distinction when consonantal information alone is relatively weak.

In fact, making use of extra cues for speech perception has been studied on special populations for different purposes. For example, Revoile *et al.* (1987) found that by enhancing acoustical cues of consonants, speech perception of the hearing-impaired people improved. Vocalic information was also found crucial among native speakers of English in differentiating whether the following stop was voiced or voiceless (Crowther and Mann, 1992). With the results obtained from this study, we may further extend the influence of vocalic information to the differentiation between syllables initiated with native or nonnative sounds: In the conditions where consonantal cues are relatively weak (as in the case of the “similar” and “identical” pairs of this study), vocalic information is indispensable for L2 learners to maximize their accuracy in the differentiation of syllables initiated with L1 and L2 consonants varying in different degrees of similarity.

## Abstract

This study investigated the error patterns of Japanese second language (L2) learners in the perception and production of Korean phonemic contrasts and assessed how their phonetic realizations differ from native Korean speakers. 31 Japanese subjects took identification and pronunciation tests. The following are the salient findings: (1) the Japanese subjects often failed to produce vowel target /u/ acoustically distinct from /ɨ/; (2) in the word-initial position, the Japanese subjects often misperceived three-way contrasts as similar sounds and showed a tendency to mispronounce fortis consonants as lenis or aspirated ones; and (3) in the word-final position, the Japanese subjects demonstrated a tendency to mispronounce both alveolar and velar consonants as velar ones.

**Keywords:** perception, production, Korean phonemic contrasts, Japanese L2 learners

## 1. Introduction

Cross-language studies have shown that adult learners of a second language (L2) have difficulty in both the perception and production of non-native phonological segments (Flege 2003). Focused on Korean language education, Kim and Song (2006a, 2006b) analyzed journal articles and dissertations related to Korean language education and reported increased researches related to Korean as a second language since the 1980s. However, it is still necessary to study Korean language education in the quantitative and qualitative aspects.

This study is an extension of a previous work (Park et al. 2007) that reported the degrees of difficulty faced by Japanese L2 learners while learning Korean phonemic contrasts that are not distinct in Japanese. In this study, we investigated the error patterns of Japanese L2 learners in the perception and production of Korean phonemic contrasts and assessed how the phonetic realization of their patterns is different from

native Korean speakers.

The Korean target phonemes investigated in this study were selected based on the commonly mentioned issues with regard to the Japanese L2 learners in previous researches (Umeda 1985; Hasegawa 1997; Woo 1998; Jung 2003). As for vowels, Korean vowel contrasts of /o, ʌ/ and /u, ɯ/ from standard Korean ten vowels /i, e, ε, a, o, ø, u, y, ʌ, ɯ/ were investigated. For the vowel contrasts of /o, ʌ/ and /u, ɯ/, Japanese L2 learners were predicted to perceive and produce these vowel contrasts imperfectly since they are not distinct in the five-vowel Japanese system: /i, e, a, o, u/. For word-initial contrasts, we examined three-way and two-way contrasts in Korean obstruent consonants. Korean stops, affricates and fricatives are different from Japanese in that they are opposed in the word-initial position as lenis, fortis and aspirated consonants (i.e., /p/, /p<sup>\*</sup>/ and /p<sup>h</sup>/ for bilabial stops, the diacritic “\*” is used to mark fortis consonants) and are all realized as voiceless while Japanese shows voiced versus voiceless opposition (i.e., /p/ and /b/ for bilabial stops). For word-final contrasts, we investigated Korean stops and nasals that show articulatory-positional contrast with bilabial, alveolar and velar sounds in the word-final position. Japanese has special phonemes, *sokuon* and *hatsuon*, which are often compared to Korean word-final consonants. However, *sokuon* and *hatsuon* are different from Korean word-final consonants. *Sokuon* and *hatsuon* are realized as labial, alveolar and velar sounds in accordance with phonetic circumstances (Dantsuji 1996).

## 2. Methods

### 2.1. Subjects

The 31 subjects were comprised of 19 and nine Japanese university students who participated in primary and intermediate Korean classes (JP and JI subject groups), respectively. The members of the JP and JI subject groups attended classes three hours a week. The three remaining subjects were classified as the JL subject group who had been learning Korean for over nine years. The subjects of all three groups started to learn Korean after entering university, had Japanese parents, and had not stayed in Korea for more than one month. We also collected data from eight Seoul dialect speakers (four males and four females, mean age 28) who spoke Korean as their first language. The characteristics of the three groups of subjects are shown in Table 1.

Table 1. Characteristics of three subject groups

Group	N	Mean age	L2 leaning experience
JP	(10m/9f)†	21	first year of class
JI	6m/3f	21	second year of class
JL	3m	31	over 9 years

†m and f stand for male and female subjects

## 2.2. Stimuli/Test words

Two sets of word lists were given to the subjects for identification and pronunciation tests. Each word list consisted of 132 minimally different Korean words containing the following phonemic contrasts: (1) vowel contrasts of /o, ʌ/ and /u, ɨ/; (2) word-initial consonant contrasts of /p, p\*, p<sup>h</sup>/, /t, t\*, t<sup>h</sup>/, /k, k\*, k<sup>h</sup>/, /tɕ, tɕ\*, tɕ<sup>h</sup>/ and /s, s\*/; and (3) word-final consonant contrasts of /p, t, k/ and /m, n, ŋ/. Examples of the minimal contrasts are shown in Table 2.

Table 2. Minimal contrasts

Minimal contrast	Example			N†			
/o, ʌ/	/tɕo/	“millet”	/tɕʌ/	“I”	10		
/u, ɨ/	/ku/	“nine”	/kɨ/	“he”	10		
/p, p*, p <sup>h</sup> /	/pul/	“fire”	/p*ul/	“horn”	/p <sup>h</sup> ul/	“grass”	4
/t, t*, t <sup>h</sup> /	/tam/	“fence”	/t*am/	“sweat”	/t <sup>h</sup> am/	“avarice”	4
/k, k*, k <sup>h</sup> /	/ki/	“energy”	/k*i/	“meal”	/k <sup>h</sup> i/	“height”	4
/tɕ, tɕ*, tɕ <sup>h</sup> /	/tɕim/	“baggage”	/tɕ*im/	“steamed dish”	/tɕ <sup>h</sup> im/	“needle”	4
/s, s*/	/sal/	“skin”	/s*al/	“rice”			4
/p, t, k/	/kap/	“tiny case”	/kas/‡	“leaf mustard”	/kak/	“each”	6
/m, n, ŋ/	/sam/	“three”	/san/	“mountain”	/sarŋ/	“prize”	6

†The number of contrasts in one word list set.

‡We included words with word-final /s/ as well as word-final /t/ in the word list since /s/ is realized as alveolar stop [t̚] in the word-final position.

## 2.3. Procedure

Data collection was conducted from December 2006 to February 2007 when the two semesters that started in April 2006 were about to end.

During the identification test, words spoken by a native Korean speaker (male, age 34, Seoul dialect speaker) were randomly presented and the subjects responded with forced-choice identification of the stimulus.

For the pronunciation test, randomized test words were presented in Korean

orthography, and the subjects were instructed to read words in isolation. Three repetitions of each word were recorded, and the total number of elicited tokens was 12,276 (132 words x 3 repetitions x 31 subjects). The recording was made in a sound-attenuated booth at Kyoto University at a sampling rate of 48,000 Hz using a TASCAM DA-P1 DAT recorder and an AKG TPS D3800 microphone.

#### *2.4. Data analysis*

We calculated the identification scores from the identification test. The identification score was the mean percentage of subject correct answers in the identification of each word.

For the pronunciation test, three native Korean speakers (one male and two females, mean age 25, Seoul dialect speakers) majoring in Teaching Korean as a Foreign Language evaluated the subjects' pronunciations, followed by the intelligibility score, which was the mean percentage of times that the pronunciation was identified correctly as intended.

We performed an acoustic analysis for the subject tokens. For the acoustic measurements, the recording was downsampled to 16,000 Hz, and a KayPENTAX Multi-Speech 3700 was used to measure the acoustic properties. For the vowels, we measured the first three formant (F1, F2 and F3) frequencies at the midpoint of each vowel by a linear predictive coding (LPC) analysis. A 20 ms Hamming window was centered at the acoustic midpoint of each vowel. 16 LPC coefficients were calculated for most tokens. Where they failed to produce reliable formant frequency values, the number of LPC coefficients was adjusted accordingly. Also, a fast Fourier transform (FFT) spectrum was used as a supplementary check. For the word-initial consonants, first, voice onset time (VOT) for stops and affricates was taken from the position of the stop release to the voice onset of the following vowel. Second, the durations of both frication noise and aspiration were measured for fricatives. The VOT and the fricative durations were measured from the spectrograms of each token. Third, we measured the fundamental frequency ( $F_0$ ) for stops, affricates and fricatives at the position of voicing onset. In addition, we normalized the measured raw  $F_0$  values as per Kang and Guion (2006). The way of normalization includes the calculation of the average raw  $F_0$  values of all the two-way or three-way consonants pronounced by individual subjects. Then we divided the individual raw  $F_0$  values by the average  $F_0$  values. For the word-final consonants, we checked the formant transition patterns on the spectrogram.

### 3. Results

#### 3.1. Vowel contrasts

We summarized the vowel's mean identification and intelligibility scores in Table 3. The overall results show that the JP and JI subject groups showed no substantial difference in their abilities, despite the year's gap between their learning experiences. Meanwhile, it is notable that the native Korean speakers often identified the JP and JI subjects' pronunciations of both /u/ and /ɨ/ as /ɨ/.

Table 3. Mean identification and intelligibility scores for JP, JI and JL subject groups

	Mean identification score (%)			Mean intelligibility score (%)		
	JP (n = 19)	JJ (n = 9)	JL (n = 3)	JP (n = 19)	JJ (n = 9)	JL (n = 3)
/o/	76	71	87	68	64	77
/ɔ/	75	63	87	71	67	78
/u/	69	67	83	42	36	86
/ɨ/	72	72	97	87	86	88

Regarding the pronunciation test, we performed a LPC analysis to measure the first three formant frequencies. For the acoustic analysis, we selected the words / $\text{t}\text{e}\Delta$ ,  $\text{t}\text{e}\text{O}$ / and /ku, kɨ/ from the word list since we could obtain the steady-state parts of the vowels from these words. Figure 1 shows the plots of the first and second vowel formant (F1 and F2) frequencies. The overall results shown in Figure 1 indicate that native Korean speakers produced acoustically distinct vowel targets, whereas the subjects failed to do that. Focusing on the intelligibility scores of /u/ in Table 3, the JP and JI subject groups have F2 values of /u/ much closer to /ɨ/. Though F2 is related to the advancement of the tongue, F2 values can also be lowered by lengthening the oral cavity with rounded lips. Thus, it can be concluded that the Japanese learners had insufficient lip rounding in pronouncing rounded vowel /u/.

To explore what acoustic properties the native Korean speakers paid attention to when they evaluated the subject pronunciations, we carried out statistical analysis. Through a multiple regression analysis, we can learn the influence of independent variables on dependent variables. With formant frequency values as independent variables and intelligibility scores as dependent variables, we carried out a multiple regression analysis. The results shown in Table 4 suggest that the intelligibility scores were significantly influenced by F1 for vowels / $\text{t}\text{e}\text{O}$ ,  $\text{t}\text{e}\Delta$ / and F2 for vowels /ku, kɨ/.

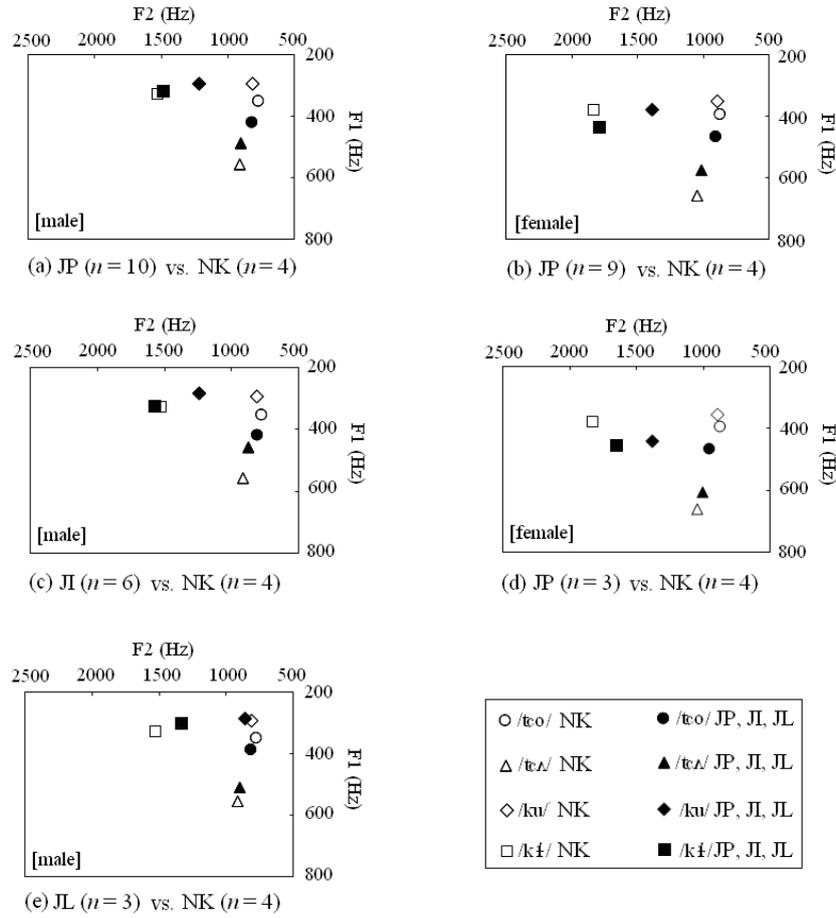

Figure 1. Mean F1 and F2 frequencies for JP, JI and JL subject groups and native Korean (NK) speaker group

Table 4. Multiple regression analysis results

Independent variable	/tɕo/		/tɕʌ/	
	Beta	<i>P</i>	Beta	<i>P</i>
F1	-.830	< .01	.846	< .01
F2	.215	.279	-.113	.626
F3	.099	.535	.040	.774
	/ku/		/kʰ/	
	Beta	<i>P</i>	Beta	<i>P</i>
F1	.268	.191	-.070	.811
F2	-.909	< .01	.647	< .01
F3	-.032	.852	-.100	.713

### 3.2. Word-initial consonant contrasts

#### 3.2.1. Three-way contrasts in stops and affricates

For three-way contrasts, we totaled the mean identification scores (underlined)

with a confusion matrix for the three groups of subjects in Table 5. The JI subject group's identification score for bilabial lenis stops was 83%. At the same time, however, the JI subject group's identification of bilabial fortis stops as lenis stops was 47% while their identification rate of bilabial aspirated stops as lenis stops was 31%. This result suggests that it is problematic to claim that the JI subject group does not have any problem identifying bilabial lenis stops based on the fact that the identification score for bilabial lenis stops was over 80%. Accordingly, we subjected the distribution of the identification scores and the error rates of each error type in Table 5 to an ALSCAL multidimensional scaling (MDS) analysis to map each group's perceptual space for the three-way obstruent contrasts.

Table 5. Perception confusion matrices: target consonants in rows and mean percentage values of subject identifications in columns (Percentages may not add up to 100% due to rounding)

	Mean identification score (%)

Figure 2 shows the MDS analysis results for the three subject groups and the native Korean speakers. The latter attained 100% identification scores for each phoneme. The results shown in Figure 2 indicate that the subjects often misperceived the three-way obstruent contrasts as they are similar to one another.

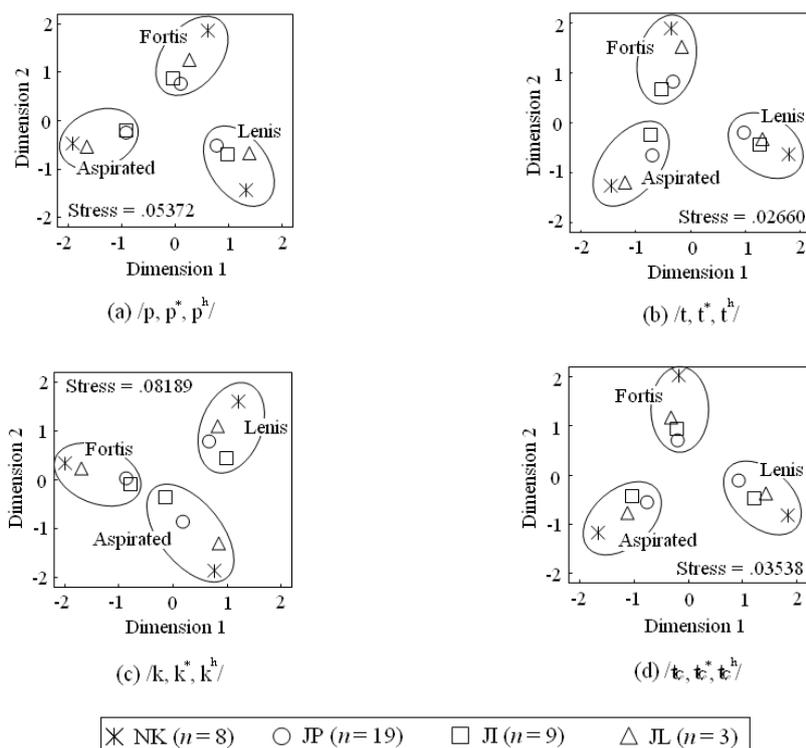

Figure 2. MDS analysis results for JP, JI and JL subject groups and native Korean (NK) speaker group

For the pronunciation test, Table 6 summarizes the mean intelligibility scores (underlined) with a confusion matrix for the three groups of subjects. The overall results show that the JP and JI subject groups had considerably lower intelligibility scores with respect to the fortis consonants compared to the others. This means that the JP and JI subjects had difficulty controlling the laryngeal tension necessary for pronouncing the fortis consonants. However, as seen in the results for the JL subject group, the tension control problem might be solved as the learning process continues. As for error types, the native Korean speakers demonstrated a strong tendency to judge the subject pronunciations of the fortis consonants as the lenis or aspirated ones.

We measured the VOT and F<sub>0</sub> values of all the tokens collected from the pronunciation test to further analyze the subject pronunciations. Figure 3 shows the mean values of VOT and normalized F<sub>0</sub> for the three subject groups and the native Korean speaker group. From the results shown in Figure 3, the JP and JI subject groups produced the three-way consonants as similar sounds compared to the native Korean speakers.

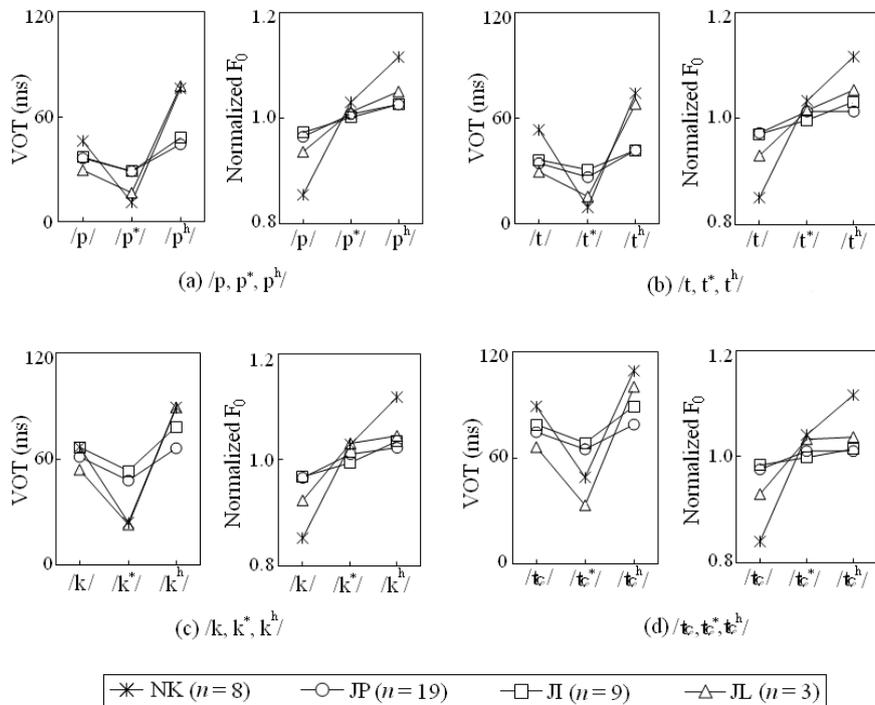

Figure 3. Mean values of VOT and normalized F<sub>0</sub> for JP, JI and JL subject groups and native Korean (NK) speaker group

We carried out a multiple regression analysis to assess the relation the acoustic analysis results have with those of the native Korean speaker evaluations of the subject pronunciations. The independent variables were the VOT and normalized F<sub>0</sub> values, and the dependent variables were the intelligibility scores. As seen in Table 7, the F<sub>0</sub> value of lenis, the VOT value of fortis, and both the VOT and F<sub>0</sub> values of aspirated consonants meaningfully influence the native Korean speaker evaluations of the subject pronunciations.

Table 7. Multiple regression analysis results

Independent variable	/p/		/p <sup>*</sup> /		/p <sup>h</sup> /	
	Beta	P	Beta	P	Beta	P
VOT	.332	.093	-.795	< .01	.453	< .01
Normalized F <sub>0</sub>	-.214	.273	-.145	.270	.415	< .01
	/t/		/t <sup>*</sup> /		/t <sup>h</sup> /	
	Beta	P	Beta	P	Beta	P
VOT	.109	.527	-.781	< .01	.604	< .01
Normalized F <sub>0</sub>	-.419	< .05	-.078	.510	.174	.246
	/k/		/k <sup>*</sup> /		/k <sup>h</sup> /	
	Beta	P	Beta	P	Beta	P
VOT	-.042	.819	-.833	< .01	.358	< .05

	/tɕ/		/tɕ <sup>*</sup> /		/tɕ <sup>h</sup> /	
	Beta	P	Beta	P	Beta	P
VOT	.303	.066	-.744	< .01	.141	.411
Normalized F <sub>0</sub>	-.575	< .01	-.017	.900	.435	< .05

### 3.2.2. Two-way contrast in fricatives

Table 8 shows each consonant's mean identification and intelligibility scores for the two-way contrast. The identification scores are high with the fortis consonants, while their intelligibility scores are high with the lenis consonants in all three groups of subjects. It seems that the subjects tended to perceive and pronounce as fortis consonants what native Korean speakers perceived and pronounced as lenis consonants.

Table 8. Mean identification and intelligibility scores for JP, JI and JL groups

	Mean identification score (%)			Mean intelligibility score (%)		
	JP (n = 19)	JI (n = 9)	JL (n = 3)	JP (n = 19)	JI (n = 9)	JL (n = 3)
/s/	53	61	50	73	65	81
/s <sup>*</sup> /	63	64	92	54	56	72

For the pronunciation test, we carried out an acoustic analysis. /sal, s<sup>\*</sup>al/ and /sada, s<sup>\*</sup>ada/ were selected from the word list on the ground that their acoustic characteristics

were observed clearly. From the native Korean speaker results in Figure 4, it is frication noises and aspirations that distinguish between lenis and fortis. Though certain differences exist in the normalized  $F_0$  values between the lenis and fortis consonants, they were not prominent compared with the three-way contrasts (see Figure 3). On the other hand, it was notable that the productions of every subject group realized the lenis consonants as sounds with little aspiration and the fortis consonants as sounds with much aspiration compared to the native Korean speakers.

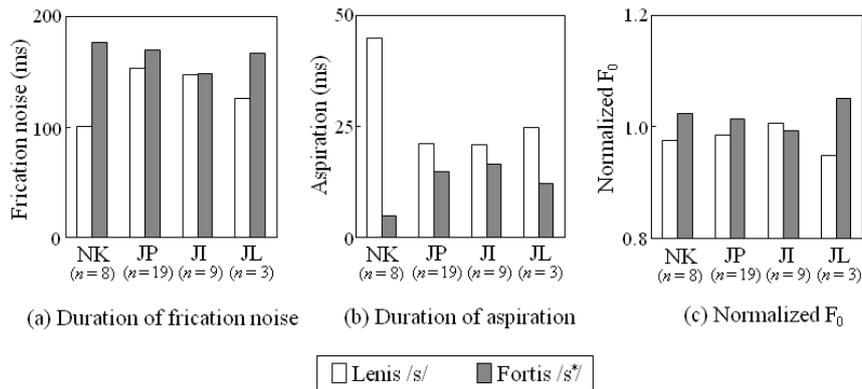

Figure 4. Mean values of durations and normalized  $F_0$  for JP, JI and JL subject groups and native Korean (NK) speaker group

To explore what acoustic properties the native Korean speakers paid attention to when they evaluated the subject pronunciations, we carried out a multiple regression analysis. The independent variables were the durations of the frication noise, the durations of the aspiration and the normalized  $F_0$  values; the dependent variables were the intelligibility scores. As seen in Table 9, the extent of aspiration included in subject production had the greatest influence on the native Korean speaker evaluations of the subject pronunciations.

Table 9. Multiple regression analysis results

Independent variable	/s/		/s*/	
	Beta	P	Beta	P
Duration of frication noise	-.309	< .01	.123	.128
Duration of aspiration	.731	< .01	-.881	< .01
Normalized $F_0$	.127	.164	.026	.739

### 3.3. Word-final consonant contrasts

In Table 10, we summarized the mean identification scores (underlined) with a confusion matrix for the three subject groups. To understand what perceptual spaces each group had for each paradigm, we carried out an ALSCAL MDS analysis for the distribution of the identification scores and the error rates of each error type in Table 10.

Table 10. Perception confusion matrices: target consonants in rows and mean percentage values of subject identifications in columns (Percentages may not add up to 100% due to rounding)

	Mean identification score (%)								
	JP ( <i>n</i> = 19)			JI ( <i>n</i> = 9)			JL ( <i>n</i> = 3)		
	/p/	/t/	/k/	/p/	/t/	/k/	/p/	/t/	/k/
/p/	<u>76</u>	15	9	<u>72</u>	11	17	<u>83</u>	6	11
/t/	11	<u>64</u>	25	17	<u>52</u>	31		<u>94</u>	6
/k/	7	24	<u>69</u>	9	20	<u>70</u>	6	33	<u>61</u>
	/m/	/n/	/ŋ/	/m/	/n/	/ŋ/	/m/	/n/	/ŋ/
/m/	<u>58</u>	25	17	<u>65</u>	28	7	<u>72</u>	28	
/n/	6	<u>61</u>	33	2	<u>81</u>	17		<u>94</u>	6
/ŋ/	4	39	<u>56</u>	7	44	<u>48</u>		22	<u>78</u>

The MDS analysis results are shown in Figure 5. The native Korean speakers achieved 100% identification scores for each phoneme. The results obtained by the MDS analysis indicate that the perceptual spaces for the alveolar and velar stops/nasals are shaped in positions far from the positions of the bilabial sounds both in the JP and JI subject groups.

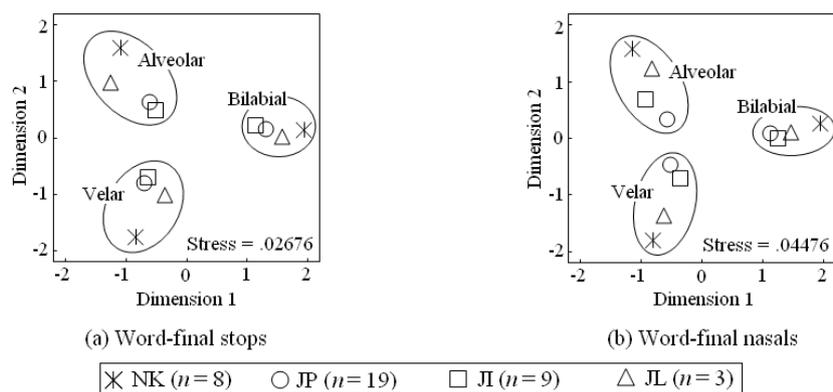

Figure 5. MDS analysis results for JP, JI and JL subject groups and native Korean (NK) speaker group

Table 11 summarizes the mean intelligibility scores (underlined) with a confusion matrix for the three groups of subjects. In Table 11, the results of the intelligibility

scores are characteristic in that the JP and JI subject group scores of alveolar sounds were significantly low. On the other hand, a strong tendency was found among the native Korean speakers to judge the JP and JI subject pronunciations of /n/ and /ŋ/ as /ŋ/. With regard to error types, what is interesting here is that there was a higher frequency of vowel insertion and consonant deletion errors in stops.

Table 11. Production confusion matrices: target consonants in rows and mean percentage values of native Korean speakers' identification on subject pronunciations in columns (Percentages may not add up to 100% due to rounding)

	Mean intelligibility score (%)															
	JP (n = 19)						JI (n = 9)					JL (n = 3)				
	/p/	/t/	/k/	VI†	CD‡	Others	/p/	/t/	/k/	VI	CD	Others	/p/	/t/	/k/	CD
/p/	<u>81</u>	6	4	6		3	<u>64</u>	14	5	11	5	1	<u>93</u>	7	1	
/t/	15	<u>37</u>	32	1	14	1	13	<u>41</u>	24	1	21		8	<u>85</u>	4	3
/k/	10	15	<u>65</u>	9	2		13	17	<u>49</u>	15	6		3	7	<u>90</u>	
	<u>/m/ /n/ /ŋ/</u>						<u>/m/ /n/ /ŋ/ VI</u>					<u>/m/ /n/ /ŋ/</u>				
/m/	<u>87</u>	4	9				<u>84</u>	6	8	2			<u>95</u>	4	1	
/n/	8	<u>38</u>	54				8	<u>49</u>	43				5	<u>89</u>	6	
/ŋ/	4	10	<u>85</u>				8	15	<u>77</u>				2	<u>98</u>		

†Vowel insertion

‡Consonant deletion

For the pronunciation test results, we examined what acoustic characteristics were observed among the subjects. Figure 6 (b) shows an example of frequently occurring pronunciation errors in the word-final consonants. The target sound of subject pronunciation (b) is an alveolar stop, which the native Korean speakers evaluated as a velar stop. The formant transition patterns reveal that subject pronunciation (b) resembles the velar stop in a native Korean speaker's result (a).

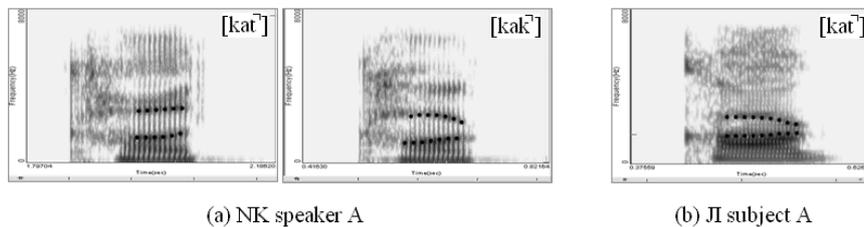

Figure 6. Formant transition patterns on spectrograms of a native Korean (NK) speaker and a JI subject

#### 4. Summary

In the present study, we investigated what error patterns Japanese L2 learners revealed both in the perception and production of Korean phonemic contrasts and observed the differences in their phonetic realizations from native Korean speakers. The following are the salient findings. First, for the vowels, Japanese subjects often failed to produce the vowel target /u/ acoustically distinct from /ɯ/. Second, Japanese subjects often misperceived the three-way contrasts in the word-initial position as similar sounds and demonstrated a strong tendency to mispronounce the fortis consonants as lenis or aspirated ones. Third, Japanese subjects often misperceived the alveolar and velar consonants in the word-final position as similar to each other and tended to mispronounce both the alveolar and velar consonants as velar ones. In general, the Japanese L2 learners whose first language is Japanese perceive and produce Korean phonemic contrasts on the basis of imperfect perceptual and productive criteria since they need to perceive and pronounce more diverse phonemes than those in their own language.

## Abstract

In Korean loanword adaptation, Japanese voiceless plosives are adapted as lenis in the word initial position but as aspirated or fortis in the word medial position, regardless of the input pitch patterns. We carried out perception tests of Japanese, French, English and Korean laryngeal categories by Korean listeners with stimuli manipulated in F0 and temporal characteristics. The results show that Korean laryngeal categorization relies heavily on F0 and VOT. Japanese initial voiceless stops were categorized as ‘aspirated’ when F0 was high. We argue that perceptive factors are not all directly reflected in loanword adaptation.

**Keywords:** Korean loanword, Japanese plosive, English plosive, French plosive, laryngeal category.

## 1. Introduction

Relationships between loanword forms and L2 sound perception have been an issue in recent phonological studies. This paper argues that perceptive factors are not all directly reflected in loanword adaptation. The basic question lies in whether the adaptation process has access to L2 contrast (i.e. phonological categorization of raw L2 sounds through L2 grammar before being mapped to L1 categories; cf. Paradis and Lacharité 1997, Rose and Demuth 2006), or whether L1 grammar filters all L2 sounds to obscure the L2 categories (i.e. phonetic mapping between L2 sounds and L1 categories; Peperkamp and Dupoux 2003). Our study focuses on adaptations between Japanese and Korean plosives, which are interesting for testing the above theses.

---

<sup>1</sup> This study was supported by the Sophia University Open Research Center. We are indebted to Yoshiaki Murakami for technical help, and to San-Cheol Ahn and Ju-Hee Lee at Kyung Hee University and to the members of the Phonetics Laboratory of Sophia University for logistic support.

Japanese has only a typical laryngeal contrast [ $\pm$ voice] while Korean has a well known three-way laryngeal distinction (lenis, fortis and aspirated); these two languages also use partially overlapping phonetic cues. In this study we shall report our findings on the role of perceptive factors in loanwords. The results show that only selected information has an active role in loanword grammar. This may contradict the pure phonetic mapping hypothesis.

The paper is structured as follows. After a brief description concerning the Korean and Japanese laryngeal systems in Section 2, attested phonological mapping patterns between Japanese, French and English and Korean sounds are examined in Section 3. Section 4 reports our perception studies of laryngeal contrasts in plosives by Korean native speakers. Comparisons of Korean adaptations of English and French plosives with our perception study results are also reported. The paper closes with a conclusion and a list of remaining issues.

## **2. Korean and Japanese laryngeal categories and acoustic cues**

Korean has phonation contrasts in obstruents. Of the many analyses proposed for Korean three-way laryngeal contrast (see M-R. Kim and Duanmu 2004), we adopt the distinction lenis [-tense, -spread glottis (s.g.)], fortis [+tense, -s.g.], and aspirated [+tense, +s.g.] proposed by H-S. Kim (2005), as it is relevant to the loanword patterns discussed in Section 3. The lenis, fortis, and aspirated consonant series are represented as C, C' and C<sup>h</sup>, respectively. Japanese only has voicing contrast, [ $\pm$ voice], in obstruents.

The laryngeal contrasts in Korean are realized with multiple phonetic cues. Higher F<sub>0</sub> values in the following vowel signal [+tense] sounds (M-R. Kim *et al.* 2002). VOT, closure duration and spectral tilt differences are involved in distinctions within the [+tense] category: VOT is longer for C<sup>h</sup>, (it is the shortest for C' among the three categories); closure duration is longer for C', and the low spectral tilt also signals a C' consonant (M-R. Kim *et al.* 2002). A further complication is that temporal characteristics such as VOT and closure duration values vary considerably depending on the type of consonants and their position in a phrase (Baker 2002; Cho and Keating 2001). In contrast, Japanese seems to involve radically different phonetic contrasts for laryngeal distinction. The VOT is known to be in proportion with the voiced-voiceless continuum: voiced ones are accompanied with vocal fold vibration; voiceless plosives are lightly aspirated. A perception study by Shimizu (1996) shows that categorical discrimination of voiced/voiceless distinction is made between around -30 ms and around +15 ms of VOT (see also our measurements in Section 4.3.).

The roles of prosody on the segmental distinction also seem to differ. Japanese F0 value has a distinctive role in the lexical pitch accent. Durational cues might not vary as much as in Korean in function of position. This timing difference between the two languages is documented also in the following experimental studies (Sagisaka and Tohkura 1984; Cho and Keating 2001). A more constant segmental duration in different positions in Japanese is also understood by the fact that it is constrained by moraic timing (Sagisaka and Tohkura 1984; Kondo and Shinohara 2003).

### 3. Phonological patterns of Korean loanword adaptation

We shall first observe two different sources of loanword data for Japanese to Korean loanword forms. Data include Korean adaptations of French and English stops. These are interpreted through feature attributions.

#### 3.1. Positional asymmetry in Japanese loans

In Korean loanwords from Japanese, the original [ $\pm$ voice] is neutralized in the phrase initial position and distinguished in the phrase medial position. The Japanese phrase initial voiceless and voiced plosives and phrase medial voiced plosives are uniformly adapted as lenis plosives across available data (Ito *et al.* 2006; H-S. Kim and Shinohara 2006). Below is the Korean adaptation of Japanese voicing contrast from Kim and Shinohara (2006) based on the common usage. Pitch patterns are added by the authors. H stands for high tone; L: low tone (see Table 7 & Figure 3b for sample F0 values of H and L). Transcriptions are quasi-phonemic. The input phonemic sequences of any language are indicated by | |; the output Korean adaptation forms are written in phonemic sequences in //.

Japanese initial voiceless plosive adapted to Korean lenis:

(1)

|tojota| HLL → /tojot'a/ ~ /tojot<sup>h</sup>a/ 'Toyota'  
 |karate| LHH → /karat'e/ ~ /karat<sup>h</sup>e/ 'Japanese martial art'

Initial or medial voiced plosive to lenis:

(2)

|buçi| HL → /pusi/ 'soldier'  
|daci| LH → /tasi/ 'soup stock'  
|soba| HL → /sopa/ 'Japanese buckwheat noodle'  
|nagoja| HLL → /nakoja/ 'Nagoya'

The following patterns were reported for adapting medial voiceless plosives to fortis and aspirated (Kim and Shinohara 2006). Hence, word medial plosives in loans keep the Japanese [ $\pm$ voice] opposition.

Medial voiceless plosive to fortis or aspirated:

(3)

|narita| HLL → /narit<sup>ʔ</sup>a/ ~ /narit<sup>h</sup>a/ 'Narita (Airport)'  
|oosaka| HHHH → /osak<sup>ʔ</sup>a/ ~ /osak<sup>h</sup>a/ 'Osaka'

However, there is inconsistency in the adaptation data: another study showed that word medial voiceless velar plosives are adapted only as fortis stop and alveolar plosive to lenis (Ito *et al.* 2006). These data were based on the Korean Etymological Dictionary and assumed to be the actual pronunciation. Given that loanword adaptation might involve factors other than perception of acoustic properties, our first task is to verify whether the perception is reflected in the Korean loanword adaptation of Japanese.

### 3.2. *Distinct categories for English and French*

The second issue is to assess the reasons for the initial neutralization of Japanese voicing contrast. An interesting puzzle arises when we observe Korean adaptations of English and French words, which maintain the original voicing distinction in every position. As in Japanese, French and English have a two-way laryngeal distinction. Only English has aspirated allophones of the voiceless plosives in stressed position, and devoiced allophones of the voiced plosives at the phrase boundaries. Below is data drawn from H-S. Kim (2005).<sup>2</sup>

---

<sup>2</sup> Transcriptions are adapted to ours.

Korean adaptation of French voicing contrast:

(4)

paRi	→ /p <sup>h</sup> ari ~ p'ari/	'Paris'
napɔleɔ̃	→ /nap <sup>h</sup> oreoŋ ~ nap'oreoŋ/	'Napoleon'
bɔRdɔ	→ /poruto/	'Bordeaux'

Here, French voiceless plosives are rendered as both fortis and aspirated. On the other hand, adaptations of English words show an alternation between lenis and fortis (the latter in an emphatic expression) of voiced plosives; while voiceless plosives are adapted to aspirated in every position.

English into Korean:

(5)

paɪp	→ /p <sup>h</sup> aɪp <sup>h</sup> u/	<i>pipe</i>
spi:kə	→ /suɪp <sup>h</sup> ik <sup>h</sup> ʌ/	<i>speaker</i>
ba:	→ /pa ~ p'a/	<i>bar</i> (the latter with emphasis)

These patterns suggest feature mapping during the adaptation process: [ $\pm$ tense] to [ $\pm$ voice] in French, and [ $\pm$ s.g.] to [ $\pm$ voice] in English (H-S. Kim 2005). Ito *et al.* (2006) report no variations in such cases: French voiceless stops are adapted as Korean fortis; English voiced ones as lenis. Therefore, the question is why Japanese initial voiceless plosives are adapted as lenis while French initial voiceless plosives are adapted as fortis, when both languages have only lightly aspirated voiceless plosives. Korean loanword data from different languages indicate that multiple factors are involved in identification of laryngeal contrast of L2. To find the acoustic factors, we have recorded laryngeal contrasts of these languages and carried out perception experiments with Korean listeners.

## 4. Perception Experiments

### 4.1. Recording

Three male speakers for each of Tokyo Japanese, General American, Parisian French, Seoul Korean and Mandarin Chinese uttered the two-syllabic nonsense words /papa/ and /bapa/ (/p<sup>h</sup>a-p<sup>h</sup>a/, /p'a-p'a/ and /pa-p<sup>h</sup>a/ for Korean) with HL/LH tone patterns

five times in carrier sentences.<sup>3</sup> For Japanese, French and Korean HL and LH tone patterns were demonstrated by the experimenter for imitation. For English, the experimenter presented to each speaker a board on which is written ‘papa’/‘bapa’ and ‘papah’/‘bapah’ to elicit HL and LH patterns, respectively. For Mandarin Chinese, ‘Tone 1’ (high level pitch) was employed for H tone pattern, and ‘Tone 3’ (low level pitch) was for L tone (for the Mandarin tones, see, e.g., Lin 2007).

The utterances were recorded in a sound-proof room onto a digital recorder (Marantz solid state recorder PMD671) with a microphone (Sony ECM-959DT) and digitized at the sampling rate of 48 kHz with 16 bit resolution. Three out of five tokens were retained for the listening tests. The target syllables were excised from the carrier sentences.

#### 4.2. Stimuli

We created 7 types of stimuli shown in Table 1, in order to discern the influence of each of the following parameters: 1) temporal characteristics in the first syllable (S1) and the second (S2); 2) F0 patterns. In our previous studies (Amino *et al.* 2007), it was found that the amplitude plays little role in identification of laryngeal categories; thus, except Type 2 and Type 4 which are normalized both in F0 and amplitude, we omitted the comparison of amplitudes this time.

**Table 1.** Stimulus Variations (7 conditions)

ID	Description	F0 contour	Syllable order
Type 1	Original	HL	As uttered (S1S2)
Type 2	Normalized F0 & Amp.	MM	
Type 3	Original	LH	Reversed (S2S1)
Type 4	Normalized F0 & Amp.	MM	
Type 5	Normalized F0	MM	As uttered (S1S2)
Type 6	Reversed F0	LH	
Type 7	Original	LH	

<sup>3</sup> Chinese stimuli were employed in a broader study on correlations between perception and acoustic patterns. Acoustic data and results for Chinese are omitted for the purpose of this study.

Purposes of the experiments with regard to the stimulus variation are summarized as follows:

1. To verify whether the perception is reflected in the Korean loanword adaptation of Japanese (French and English) – Type 1.
2. To assess the reasons for the initial neutralization of Japanese voicing contrast – Type 2 vs. Type 4.
3. To assess the effect of F0 on [ $\pm$ tense] categorization – Type 1-5-6.

The stimuli were created by the methods described in Table 2. We used a computer software Praat Ver.4.4.07 (Boersma and Weenink 2006) for the pitch manipulation.

**Table 2.** Stimulus Creation

ID	Methods
Type 1	Originally recorded sound files
Type 2	F0 and rms amplitude were normalized in Type 1 stimuli (See the text below.)
Type 3	Created by transposing S1 and S2 of Type 1 stimuli
Type 4	Created by transposing S1 and S2 of Type 2 stimuli
Type 5	F0 of Type 1 stimuli was normalized among syllables using Praat pitch manipulation
Type 6	F0 of Type 1 stimuli was transposed between S1 and S2 using Praat pitch manipulation
Type 7	Originally recorded sound files

In order to create Type 2 stimuli, we calculated the rms amplitude for each syllable by using the computer program MATLAB. Then, coefficients  $m$  and  $n$  were calculated to give an average for both  $A_1$  and  $A_2$ ,  $A_{ave}$ . Thus,

$$(6) \quad n * A_1 = m * A_2 = A_{ave}.$$

where  $n$  and  $m$  are coefficients;  $A_1$  is the rms amplitude of S1;  $A_2$  is the rms amplitude of S2; and  $A_{ave}$  is the average of  $A_1$  and  $A_2$ .

Finally, each element in S1 and S2 was multiplied by the coefficients  $n$  and  $m$ , respectively.

For Type 3 and 4 stimuli, transposition between the two syllables was conducted as follows: first, the intervals (the start and the end) for S1 and S2 were determined based on the waveforms, and the duration of S2 closure was measured. The S2 interval

was extracted and put before S1; a silence was then added between S2 and S1 that had the same duration as the closure of S2.

#### 4.3. Acoustic measurements

The VOT and F0 values of the relevant segments in S1 and S2 were measured using Praat (Boersma and Weenink 2006). The VOT was measured based on the waveforms and the spectrograms, and the average values of F0 were calculated from each vowel part.

The data were then averaged over the tokens of the different speakers. The results of Type 1 stimuli are shown in Tables 5-8.

**Table 5.** VOT average values [ms] of the relevant segments in English (En), French (Fr) and Japanese (Jp) (first and second bilabial stops)

VOT [ms]	En		Fr		Jp	
	S1	S2	S1	S2	S1	S2
pa-pa	53.6	17.0	13.2	14.7	32.3	6.0
ba-pa	14.5	/	5.4	/	8.7	/

**Table 6.** VOT average values [ms] of the relevant segments in Korean (Kr)

VOT [ms]	Kr	
	S1	S2
p <sup>h</sup> a-p <sup>h</sup> a	110.0	42.6
p <sup>ʼ</sup> a-p <sup>ʼ</sup> a	10.8	10.9
pa-p <sup>h</sup> a	23.4	/

**Table 7.** F0 average values [Hz] of the first vowels in three languages

F0 [Hz]	En	Fr	Jp
<b>pa</b> -pa (Type 1)	128.1	141.4	166.5
<b>pa</b> -pa (Type 5)	107.1	123.3	139.8
<b>pa</b> -pa (Type 6)	89.7	107.6	125.0

**Table 8.** F0 average values [Hz] of the first vowels followed by three types of Korean laryngeal categories

F0 [Hz]	<b>pa- p<sup>h</sup>a</b>	<b>p<sup>h</sup>a-p<sup>h</sup>a</b>	<b>p<sup>h</sup>a-p<sup>h</sup>a</b>
Type 1	121.0	129.6	136.5
Type 5	110.2	118.7	121.4
Type 6	95.6	103.0	104.6

#### 4.4. *Listeners and procedure*

Twenty-five Korean monolingual listeners with normal hearing participated in the perception test. The listeners are university students of an average age of 22.4 years old, residing in Seoul and Kyunggi areas (Seoul dialect areas) for 17.3 years on average. Most of them had English lessons in Korean schools, and they self-reported that they are not fluent in any foreign languages.

The stimuli were presented to the listeners diotically through headphones (Sony MDR-CD900ST). The stimuli were originally created for three places [labial, alveolar, velar] and presented to the listeners, although here we only report the results relating to the bilabial plosives. Seven sets of manipulated stimuli (Types 1-7 in Table 2) were prepared: they were grouped into five language combinations shown in Table 9, and presented randomly to the listeners. No language information was provided to them beforehand. The experiment was divided into two parts: each part had 1134 (three languages other than Korean) or 1323 (including Korean) stimuli (corresponding to three tokens for three speakers for three of the five languages, seven conditions, and six consonants for each language except nine consonants for Korean) presented in a pseudo-random order. The listeners concentrated on the categorization of the first (S1) consonant in part 1 and the second (S2) consonant in part 2. Each language was evaluated by fifteen listeners.

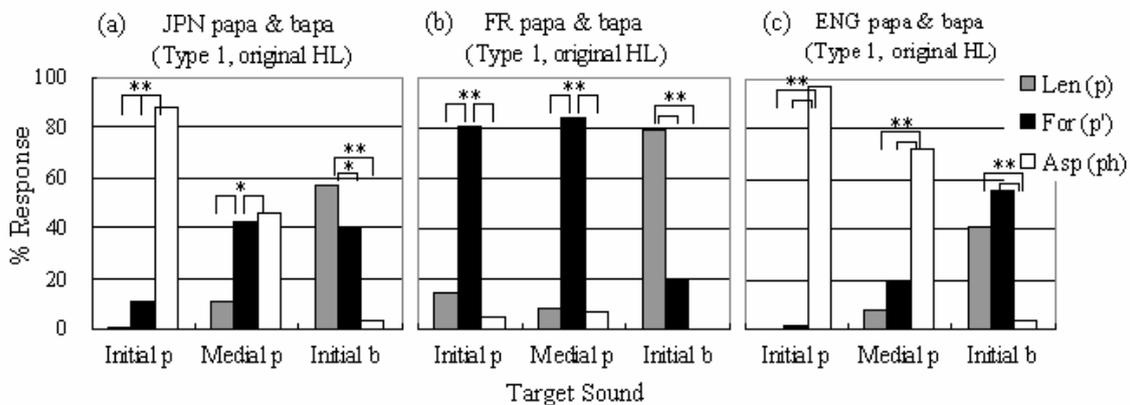

**Table 9.** Presented stimulus sets (Below Ch stands for Chinese)

Mixture of Languages	Number of Stimuli <sup>4</sup>	Number of Listeners
Ch- En- Jp	1134 (378 each language)	5
Ch- Fr- Jp	1134 (378 each language)	5
Ch- Fr- Kr	1323 (378 in Ch.& Fr. 567 of Kr.)	5
En- Fr- Kr	1323 (378 in En.& Fr. 567 of Kr.)	5
En- Jp- Kr	1323 (378 in En.& Jp. 567 of Kr.)	5

#### 4.5. Results

##### 4.5.1. Responses of the perception test of the first syllable of the original stimuli (Type 1)

The results for the original stimuli (Type 1) are shown as to Japanese, French and English in Figure 1(a), 1(b) and 1(c), respectively. The data were analyzed by one-way ANOVA, and the significantly different pairs are shown in the figures by asterisks.

**Figure 1:** Percentages of responses for the Type 1 stimuli: (a) for Japanese, (b) for French and (c) for English stimuli

Japanese voiceless |p| is perceived aspirated in the initial position (cf. loanword initial voiceless plosives are rendered as lenis). Voiceless |p| in medial position varies within [+tense] category. Voiced [b] is perceived with [-s.g] variation (cf. loanword |b| goes to lenis in every position.). Thus, initial neutralization between |p| and |b| does not

<sup>4</sup> Stimulus calculation

- Language sets without Korean: 2 laryngeal categories × 3 speakers × 3 repetitions × 3 places of articulation × 7 stimulus types = 378.
- Language sets including Korean: 3 laryngeal categories × 3 speakers × 3 repetitions × 3 places of articulation × 7 stimulus types = 567.

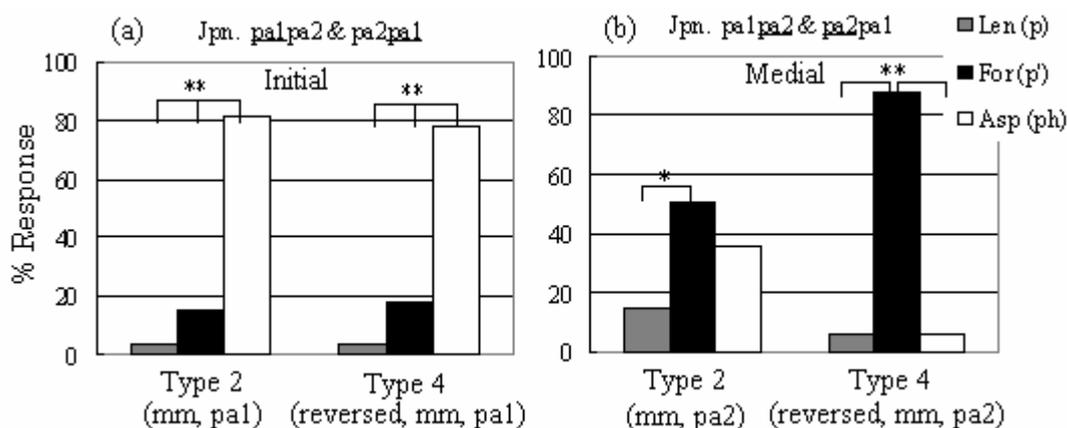

appear here. Recall that the voiced [b] was in initial position, hence H-toned; this might be reflected in 40% of fortis response.

French voiceless [p] is perceived overwhelmingly as fortis [+tense]; French voiced one overwhelmingly as lenis [-tense]. Clearly both voiceless and voiced ones are treated as [-s.g]. These results must be due to the short VOT in the stimuli. The responses to French stimuli correspond to the loanword patterns of H-S. Kim (2005). As her phonological analysis suggested, French voiceless and voiced distinction seem to differ in [ $\pm$ tense] values in the Korean laryngeal categories in this acoustic perception as well.

For English stimuli, voiceless [p] in initial and medial positions are mostly perceived as aspirated, hence [+s.g.]. Thus, clearly, VOT is the guiding factor. For English stimuli, voiceless [p] in initial and medial positions are mostly perceived as aspirated, hence [+s.g.]. Voiced one varies between fortis and lenis, hence within [-s.g] category, as in H-S. Kim's loanword data.

#### 4.5.2. Responses of the perception test of the syllable reversing of the equalized stimuli (Types 2-4)

We report in this sub-section the results of the second experiment. The purpose of this experiment was to observe whether Japanese plosives in different positions in a word are perceived distinctly by Korean listeners. For this second experiment, we reversed the first and second syllables with the normalized F0 (Mid-tone, hereafter, M-tone) and amplitude.

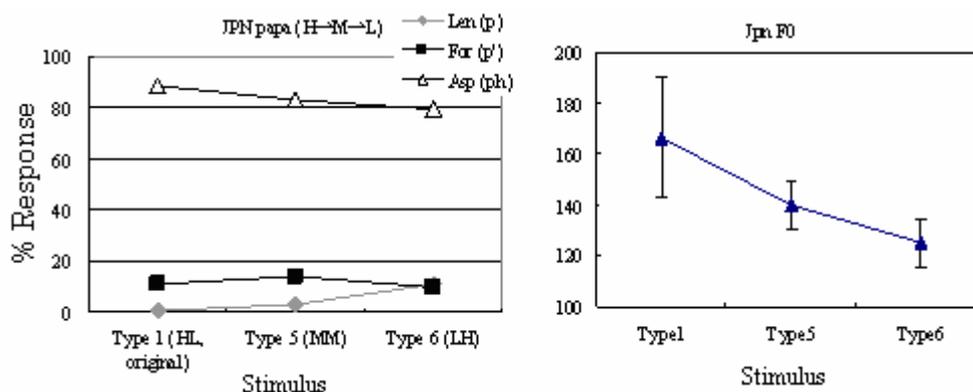

**Figure 2:** Percentages of responses for pa1 (a) and pa2 (b) of Japanese Types 2 and 4

Figure 2(a) shows that the [p] that originated from the first syllable is almost always identified as aspirated when moved to the second syllable. Figure 2(b) shows that the [p] that originated from the second syllable is perceived less often as aspirated and more often as fortis when moved to the initial position. This is an expected result, since, in Korean, aspirated plosives in the initial position have much longer VOT than ones in the medial position (cf. Table 6) We observe here that the categorization is guided by VOT variation.

Together with the results in 4.5.1, we can draw a conclusion from the results of this experiment that the Japanese [ $\pm$ voi] neutralization in initial position in loanwords is not due to the acoustic properties of the inputs since in this experiment there was no lenis percept of the initial [p].

#### 4.5.3. Responses to influence of F0 variation

We investigated in the influence of F0 because F0 is an important cue for [ $\pm$ tense] categorization in Korean, and because Japanese words have pitch specification. Figure 3(a) shows the responses given to the first syllables of Type 1 (the original H-toned stimuli), Type 5 (M-toned) and Type 6 (L-toned) stimuli. Figure 3(b) shows the corresponding F0 values of the stimuli.

**Figure 3:** Percentages of responses for Types 1, 5 and 6 (a) and the average F0s and their *S.D.* (b) of Japanese data

The results indicate that [+tense] response decreases and [-tense] increases as the F0 decreases. This tendency was consistent in the results of French and English voiceless [p] and the three Korean stop series in the initial positions. Other relevant graphs are omitted due to the space limitation.

#### 4.6. *Summary of the experiment*

Our experimental results indicate the following:

1. VOT determines the [ $\pm$ s.g] percept (English |p| as [+s.g]; French |p| as [-s.g]; Japanese |p| depends on the position).
2. F0 is an important cue for [ $\pm$ tense] categorization in Korean which is reflected in perception experiments across languages.

### 5. **Conclusion**

The general conclusion of this paper is that perception is only partially reflected in Korean loanword adaptation of Japanese plosives. Loanword patterns reported in H-S. Kim (2005) and Kim and Shinohara (2006) were overall closer to our acoustic perception results except that Japanese initial |p| was perceived as /p<sup>h</sup>/ (not as lenis as in the loanwords from Japanese). Given the perception results, reasons for the initial neutralization of Japanese voicing contrast may not be due to the acoustic properties investigated (VOT, amplitude and F0). The VOT information in the Japanese initial voiceless plosives is somehow neutralized in the loanword adaptation process.<sup>5</sup> F0 information from Japanese pitch accent is also completely cancelled in loanword adaptation of Japanese. Later research should see if there are any principles for the selection of acoustic cues for loanword rendition, where the factors other than acoustic perception are originating from and, ultimately, what the adequate model of loanword phonology is.

# Compensatory Lengthening is not Specific to Syllabic Positions

Te-hsin Liu

Department of Linguistics  
Paris 8 University  
2 rue de la Liberté  
93526 Saint-Denis  
Cedex 02 France

[liu.tehsin@gmail.com](mailto:liu.tehsin@gmail.com)

## Abstract

Compensatory lengthening has become a favorite topic for phonological analysis since De Chene & Anderson's work based on the history of French (1979). The main purpose of this paper is to shed light on a special case of CL, tonal compensatory lengthening, provoked primarily by the loss of a diminutive suffix in Yue dialects. It will be shown that compensatory lengthening is not specific to syllabic positions. Tones can lengthen after the elision of a diminutive morpheme, showing that they cannot be treated as pure melodies in Chinese.

**Keywords:** compensatory lengthening, tone, Cantonese

## 1. Introduction

Compensatory lengthening (henceforth, CL) has become a favorite topic for phonological analysis since De Chene & Anderson's work based on the history of French (1979). It is assumed that CL, as a process of structure preservation, exists only in a language where there is a pre-existing vowel duration contrast. On the contrary, Hock (1986), Hayes (1989) and Lin (1997) show that a pre-existing vowel length contrast is not a necessary condition for CL, a distinction between heavy and light syllables being sufficient in the moraic framework. In this sense, the mora, rather than the pre-existing long vowel, is preserved, with the essential idea that the loss of one segment is compensated by the lengthening of another one. Kavitskaya (2002) and Morin (2007) recently suggest that CL results from the phonologization of phonetically long vowel duration, which concerns neither transfer of duration nor transfer of weight. Although considerable research has been devoted to CL, rather less attention has been paid to the role of tones during this process.

This article addresses the phenomenon of the Changed Tone in Yue dialects, primarily

provoked by the loss of a diminutive suffix. It has been reported that this Changed Tone, carrying a rising contour 35, has a slightly longer duration than the lexical rising tone (Wang 1931, Whitaker 1956, Chao 1959, Bauer & Benedict 1997). Chao (1959) uses *mora* to describe this relative long duration associated with the Changed Tone, suggesting that *mora* is, in Cantonese, a suffix taking the form of a high tone, rather than corresponding to a segmental melody. This conjecture, capable of explaining the additional duration, is contrary to current theories according to which tones, being suprasegmental objects, do not have temporal basis of their own.

The goal of this paper is two-fold. Through a phonetic study validating the post-1940 data in §2.2, we shall account for the origin of this additional duration compared with the lexical rising tone (Section 3). We claim that it is the tone that lengthens after the elision of a diminutive morpheme. Taking the Cantonese Changed Tone as a jumping off point, we shall show that CL is not specific to syllabic positions. Tones can lengthen after the elision of a diminutive morpheme, demonstrating that they cannot be treated as pure melodies in Chinese. Discussion and concluding remarks appear in Section 4.

## 2. Preliminaries

Yue dialects are spoken in the province of Guangdong, at the east of Guangxi, and in the south-east of Asia. There are six lexical tones in Cantonese, i.e. 33, 22, 35, 23, 53 (55)<sup>1</sup>, and 21. Three entering tones are observed in closed syllables, i.e. 5, 3, 2.

Apart from the rising tone 35, there exists also rising tones derived from morphological alternations, referred to as *Pinjam* (Changed Tone) in the literature. Unlike tone sandhi in most Chinese dialects, *Pinjam* is not caused by the contact with neighboring tones. In Cantonese, the function of *Pinjam* is to derive, among others, nouns and diminutives, the derived elements bearing always a rising contour tone. In (1), nouns are derived from semantically related verbs. The same thing goes for (2), where diminutives are purely indicated by a change in tone. Data are drawn from Yu (2007) et Chen (2000):

### (1) Verb nominalization

Level tone		Rising tone	
sou33	“to sweep”	sou35	“a broom”
pɔŋ22	“to weigh”	pɔŋ35	“a scale”
wɑ22	“to listen”	wɑ35	“an utterance”
tan22	“to pluck”	tan35	“a missile”

<sup>1</sup> There was a contrast between high level and high falling, however, this distinction has collapsed for most speakers nowadays.

(2) Derivation of diminutives

t <sup>h</sup> oi21	“terrace”		t <sup>h</sup> oi35	“table”
k <sup>wh</sup> ən21	“skirt”		wəi21 k <sup>wh</sup> ən35	“apron”
kɛŋ33	“mirror”		ŋan23 kɛŋ35	“eyeglasses”
t <sup>h</sup> ɔŋ21	“sugar”		t <sup>h</sup> ɔŋ35	“candy”
nøy23	“women”		nøy35	“girl”
ɔp3	“duck”	~	ɔp35	
kɔt2 tsɔt2	“cockroach”	~	kɔt2 tsɔt 35	
kɔp3	“pigeon”	~	kɔp35	

Several aspectual markers in Cantonese which have either an underlying high or rising tone often elide in colloquial speech, causing the tone of the preceding syllable to change to rising, as in (3a) and (3b). Cantonese allows moreover the ellipsis of certain morphemes in certain constructions. Thus *iat 5* “one” is optionally skipped in examples such as in (3c). The elided entering tone is realized as 35:

(3) a. Omission of the perfective marker *tsɔ35*

pɔŋ22 tsɔ35	→	pɔŋ35	“to weigh (PERFECTIVE)”
fan22 tsɔ35	→	fan35	“to transgress (PERFECTIVE)”
ki:n33 tsɔ35	→	ki:n35	“to meet (PERFECTIVE)”

b. Omission of the potential marker *tək5*

pɔŋ22 tək5	→	pɔŋ35	“to weigh (POTENTIAL)”
fan22 tək5	→	fan35	“to transgress (POTENTIAL)”
ki:n33 tək5	→	ki:n35	“to meet (POTENTIAL)”

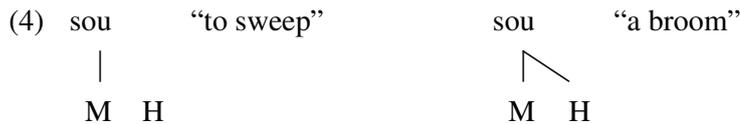

c. Omission of *iat 5* “one”

iat t <sup>h</sup> am iat t <sup>h</sup> am	→	iat t <sup>h</sup> am t <sup>h</sup> am	“puddle by puddle”
5 23 5 23		5 35 23	
iat hɔŋ iat hɔŋ	→	iat hɔŋ hɔŋ	“line by line”
5 21 5 21		5 35 21	
iat tip iat tip	→	iat tip tip	“plate by plate”
5 2 5 2		5 35 2	

According to Bai (1989), two conditions are required so that *Pinjam* could occur in (3). On the one hand, tones which give rise to the derived rising contour should be low tones such as 21, 23, 33, 22, 3 and 2, high tones (53/55, 35, 5) being not influenced by the process. On the other hand, the omitted syllable should carry 35 or 5.

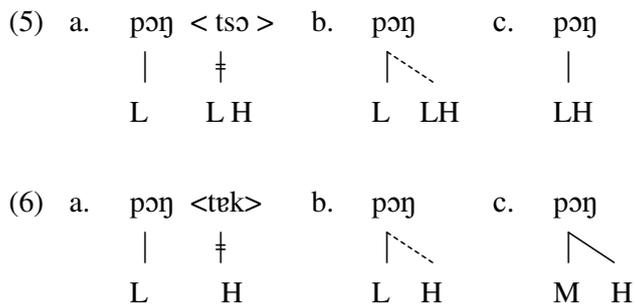

## 2.1 Traditional representations of the rising tone derived from *Pinjam*

In order to represent the derived rising tones in (1) and (2), Yip (1980) and Chen (2000) postulate a floating high tone associating to the end of the relevant syllable, creating thus a new rising tone.

When the stem has a falling contour tone such as 21 or 53, a rule of tonal simplification is added so that the floating high tone does not create complex contours, forbidden in Cantonese. However, when the stem has a rising contour tone such as 23, another rule is necessary. Based on tonal geometry, Yip (1980) assumes that \*25 is not allowed in the surface form since “cross-register” contours are banned in Cantonese. Chen (2000) suggests that Cantonese distinguishes only two rising contour tones, i.e. 23 and 35. As a result, \*25 is reduced to one of the two possible rising tones, and Cantonese chooses 35 as the final output. Nevertheless, the reason why 35 is preferred over 23 remains unexplained.

To derive the rising contour in (3a), Yip (1989) proposes the reassociation of the rising contour tone with the preceding host syllable. A set of tonal readjustment rules bans a succession of two adjacent low level tones, causing the loss of the first low tone of the verb, as is shown in (5). Concerning (3b), Yip (1980) and Chen (2000) hypothesize a floating high tone attaching to the previous syllable after the elision of the aspectual marker. A rule of register readjustment gives rise to the appropriate MH cluster in the surface form, as in (6).

The above treatments are problematic for two reasons. A floating high tone is postulated, in (4) and (6), in order to derive *Pinjam*. However, when the potential marker bears already a rising contour tone, as in (5), this hypothetical floating high tone disappears from the representation, and appears *ad hoc*. If *Pinjam* always carries the same rising contour tone,

why to explain it by two distinct hypotheses?

Moreover, these analyses predict that the derived rising tone is homophonous to the lexical rising tone. However, Chao (1959) notes that in Cantonese, when a word is pronounced with *Pinjam*, its duration is slightly longer than that of a word having a lexical rising tone. Chao uses *mora* to describe this relative long duration associated with *Pinjam*, suggesting that *mora* is, in Cantonese, a high tone taking the form of a suffix, rather than corresponding to a segmental melody. This conjecture, capable of explaining the additional duration associated with *Pinjam*, is contrary to current theories according to which tones, being suprasegmental objects, do not have temporal basis of their own. How to explain this paradox?

## 2.2 A phonetic experiment on Cantonese Pinjam

In order to verify the duration difference between the lexical rising tone and the derived rising tone, we conducted a phonetic experiment with a Cantonese native speaker of 77 years old, born in the Province of Guangdong. Five words were read with five repetitions. The duration of the tone was measured from the spectrogram window.

(7)

	Duration of lexical rising tone		Duration of derived rising tone
sister[ze]	0.29	girl [nø̃y]	0.51
bitter [fu]	0.21	candy [t <sup>h</sup> ɔ̃ŋ]	0.54
white [se]	0.25	apron [wø̃i k <sup>wh</sup> ɛ̃n]	0.4
speak [kõŋ]	0.29	call girl [mu nø̃y]	0.6
cause [saj]	0.24	table [t <sup>h</sup> oi]	0.54
Average duration	0.256	Average duration	0.518
Standard deviation	0.03	Standard deviation	0.08
Ratio lexical : derived	1 : 2.02		

The average duration of the lexical rising tone is 0.256 seconds, whereas the average duration of the derived rising tone is 0.518 seconds. Even the longest lexical rising tone averages shorter in duration than the shortest derived rising tone. Here are some spectrogramms of the lexical rising tone and the derived rising tone :

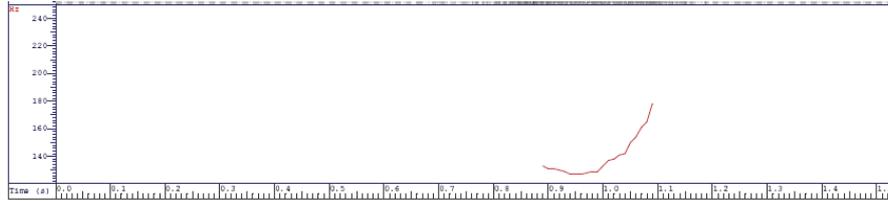

Figure 1 : [fu 35] "bitter" : lexical rising tone

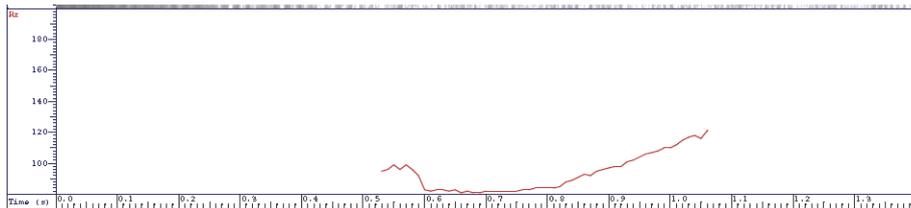

Figure 2 : [tʰɔŋ 35] "candy" : derived rising tone

The phonetic experiment confirms Chao's observation that the derived rising tone has a longer duration than the lexical rising tone.

### 2.3 Origin of *Pinjam*

From the phenomena observed in Yue dialects, a basic question follows: why does the derived rising tone always have a superior duration to that of the lexical tone?

Chao (1948) and Wong (1982) suggest that Cantonese *Pinjam* originates from the elision of certain morphemes which are no longer productif synchronically. Establishing a parallel between the function of *Pinjam* in Cantonese and the retroflex suffix [-ɿ] in Mandarin through a comparison of a hundred of lexical elements, Chao (1947, 1959) remarks that around sixty nominal morphemes with the suffix [-ɿ] in Mandarin correspond to *Pinjam* morphemes in Cantonese. Given this correspondance, Chao (1959) proposes to treat Cantonese *Pinjam* as a suffix. Diminutive suffixation is a very frequent morphophonological phenomenon in Chinese dialects. In Beijing Mandarin for exemple, the suffix takes a retroflex feature which is realised in the rime (Chao 1968, Cheng 1973). In other dialects, as a result of different historical developments, this suffix surfaces sometimes as an independent syllable, sometimes as a nasal integrated to the coda of the lexical stem.

Whitaker (1956) establishes a more explicit relation between Cantonese *Pinjam* and the suffix [-ɿ] 兒 in Mandarin, claiming that the latter is the ultimate source of *Pinjam*. She postulates that, at an earlier historical stage, Cantonese might have used the suffix 兒, pronounced as [-jī:]. At a later stage, the suffix disappeared, leaving a trace under the form of *Pinjam*. Her theory is based on a comparison with Bobai, a Yue dialect spoken at the southeast of Guangxi, where the process of suffixation might shed light on the origin of Cantonese *Pinjam*. Citing the study of Wang Li (1931) entitled *Une prononciation chinoise*

*de Po-pai*, Whitaker remarks that at the time when Wang Li described the dialect, there were two varieties. The more conservative variety used the diminutive suffix [ɲin] carrying a rising contour tone, as in (8a). When words ended in an occlusive coda, the final stop would change to its homorganic nasal counterpart and the word would acquire a long rising tone associated previously with [ɲin], as in (8b):

- (8) a.    kae32 ɲin25        “little chick”  
           iaŋ21 ɲin25        “little sheep”  
           ma21 ɲin25        “little horse”
- b.    œk54    “house” → oŋ25        “little house”  
           mat32    “thing” → man25        “little thing”  
           hɔp4    “box”    → hɔm25        “little box”  
           pak1    “uncle” → a33-paŋ25    “my little uncle”

In addition to suffixation with [ɲin25] and the homorganic nasalization of final stops, diminutivization in Bobai involved as well the change of the original tone to long rising *Pinjam* without suffixation, a pattern which closely resembles the Cantonese *Pinjam*. Whitaker sees these three synchronic processes as three diachronic stages in the development of the long rising tone: in the first stage, the suffix [ɲin] with a rising tone is used; by the second stage, the suffix has been lost, but left tonal (long rising contour) and segmental (nasalization of final stops) traces; in the third stage, the nasalization has disappeared, leaving only the long rising *Pinjam*.

Citing a study of Ye & Tang (1982), Bauer & Benedict (1997) remark that Xinyi, another Yue dialect, attests also similar *Pinjam* behaviors. There are two processes of nasal suffixation to indicate diminutivisation. In the first case, the nasal coda [-n] is suffixed to the lexical stem and the original tone of the stem becomes a rising contour, as in (10a). In the second case, the same type of nasalization as in Bobai is found, final stops becoming their homorganic nasal counterpart, as in (10b). Ye & Tang emphasize that the peak of this derived rising contour is so high that the traditional scale of five degrees proposed by Chao (1930) would not be capable of representing it. They use thus the symbol  $\uparrow$  for notation. Words already ending in a nasal consonant, or in a diphthong, do not take the nasal suffix, their lexical tone simply transforming to a rising contour, as in (9c).

- (10) a.    tɕy 53        “pig”            → tɕyn  $\uparrow$         “little pig”  
           lou 23 sy 35    “mouse”        → lou 23 syn  $\uparrow$     “little mouse”  
           sam 53 fu 33    “clothes”      → sam 53 fun  $\uparrow$     “clothes for kids”  
           hɔ 23        “river”        → hɔn  $\uparrow$         “little river”

b.	ʔap 22	“duck”	→	ʔam ʊ	“little duck”
	fət 22	“Buddha”	→	fən ʊ	“little Buddha”
	kək 33	“foot”	→	kɛŋ ʊ	“little foot”
c.	kɛi 53	“chicken”	→	kɛi ʊ	“little chick”
	k <sup>h</sup> ɛu 23	“ball”	→	k <sup>h</sup> ɛu ʊ	“little ball”
	sɛu 35 kən 53	“towel”	→	sɛu 35 kən ʊ	“handkerchief”
	kɔŋ 53	“jar”	→	kɔŋ ʊ	“little jar”

Unlike Cantonese *Pinjam* where 35(5) and 53(55) cannot be replaced, in Xinyi, the derived rising contour can substitute any lexical tone, even 53 and 35. Moreover, according to Ye & Tang (1982), in Xinyi, the rising *Pinjam* can distinguish easily from the lexical contour tone 35 in perception. This phenomenon is different from Cantonese where speakers have difficulties distinguishing them in perception (Yu 2007).

Given the data of Bobai and Xinyi, Bauer & Benedict (1997) consider that Cantonese *Pinjam* might be derived from a monosyllable which had carried a rising contour and was suffixed to words of different classes to represent diverse morphological functions. At an intermediate stage, this suffix might have been reduced to a nasal coda and to a rising contour tone which had replaced the lexical tone of the stem. The nasal coda lost later on, and the rising contour has become the only trace of the morphological process. We share Bauer & Benedict’s hypothesis on the origin of *Pinjam* and are skeptical about the postulate of a floating high tone, as is suggested by Yip (1980), Bao (1990, 1999) and Chen (2000). The analysis of a floating high tone needs several treatments depending on the lexical tone of the stem, and does not give a whole picture of *Pinjam* in Yue dialects. Furthermore, this hypothesis fails to explain why the rising contour derived from *Pinjam* has a superior duration to that of the lexical rising tone in Cantonese and Bobai. In Xinyi, the derived rising tone rises much more higher than the lexical rising tone, indicating that it might have a longer duration than the lexical rising tone as well<sup>2</sup>.

### 3. Compensatory lengthening is not specific to syllabic segments

To explain the duration increase of *Pinjam*, O’Melia (1939) et Whitaker (1956) had the intuition that it was to compensate the loss of the elided syllable. A question arises as to the

---

<sup>2</sup> Articulatorily, a complicated tonal contour involving more pitch targets would involve more complicated muscle state change, and thus prefer a longer duration to facilitate implementation. Sundberg (1973, 1979) remarks that a contour with farther-apart pitch targets prefers a greater duration of its carrier. The greater the pitch excursion of a tone, the longer duration it requires. 15 requires thus more time than 13. Ye & Tang does not offer the spectrogram of the derived rising contour of Xinyi, and indicate only that the derived rising tone rises much more higher than the lexical rising tone. We infer that the derived rising tone should also have a longer duration than the lexical rising tone.

nature of this compensatory lengthening: how do we know if it is the vowel or the tone that lengthens? Two possibilities are at hand: the tone lengthens due to vowel lengthening, and the vowel lengthens under the pressure of tone. The first solution seems the only answer to the question: since Goldsmith (1976), only syllabic constituents and/or segmental melodies are likely to lengthen through their association to skeletal positions. Tones, being autosegments, cannot lengthen by themselves. We shall begin by examining vowel CL in different languages in order to see if this is the case in *Pinjam*.

### 3.1 *The nature of CL*

Compensatory lengthening designates a process whereby a segment lengthens *to compensate* the loss of another segment. Based on the history of French, De Chene & Anderson (1979) postulate that there was first of all a coalescence of two vowels with similar timbres — such as in CŪCŪLLĀM > coole > coule “*frock*” or SĀTŪLLĀM > saoule, soûle “*drunk*”. It was after this stage that the changes known under the name “compensatory lengthening” — such as in MŪSCŪLŪM > mosle > moûle (loss of preconsonantal *s*) or MŌDŪLŪM > molle [ˈmɔ̃lə] (monophthongization) > moule [ˈmu:lə] — might contribute to the formation of long vowels. They claim moreover that CL, as a process of structure preservation, only occurs in a language where there is a pre-existing vowel length contrast. However, it has been shown that a pre-existing vowel length contrast is not a necessary condition for CL (Hock 1986, Hayes 1989, Morin 1992, Lin 1997). Hayes (1989) and Lin (1997) particularly show that a distinction between heavy and light syllables is sufficient in the moraic framework. In this sense, it is the mora and not the pre-existing long vowel which is preserved.

Kavitskaya (2002) proposes another vision of CL, justifying that CL processes, i.e. those through consonant loss and through vowel loss, are similar diachronically: both of them result from the phonologization of phonetically long vowel duration, and none concerns the transfer of phonetic duration or of phonological weight. Rather, intrinsic phonetic vowel duration is reinterpreted as phonologically long because of a change in syllable structure. Based on the *listener-oriented model* (Ohala 1981), she distinguishes two types of CL, CVCV > CV:C through vowel loss, and CVC > CV: through consonant loss. We will be primarily concerned with CVCV > CV:C here as there are many words carrying the derived rising tone in closed syllables in Yue dialects. It would be necessary to comprehend the nature of CL in closed syllables in order to see if it is the case in Yue.

Regarding CVCV > CV:C, the change in syllable structure is responsible for the reinterpretation of vowel length as phonemic given that vowels in open syllables are phonetically longer than those in closed syllables. Consequently, when the second syllable is lost (failure to detect the final vowel), the duration of the vowel in the newly-closed

syllable becomes unexplainable, since it is longer than is expected in the closed syllable. The listener therefore parses the longer duration as intended by the speaker, and reinterprets the vowel in question as phonologically long. Here are some examples drawn from Kavitskaya (2002):

(11) a.	Latin		Friulian	
	lupum	> *lupu	> lo:f	‘wolf’
	novum	> *novu	> nu:f	‘pure’
	dekem	> *detʃe	> di:ʃ	‘ten’
	nivem	> *nive	> ne:f	‘snow’
b.	Old Church Slavic		Serbo-Croatian	
	boru	>	bo:r	‘forest’
	rogu	>	ro:g	‘horn’
	medu	>	me:d	‘honey’

The above process is compensatory only in the large sense of the word, i.e. the lengthening of a segment is correlated with the loss of a neighboring segment. However, there is no compensation in the direct sense of the term, since there is neither transfer of duration nor transfer of weight. In other words, the allophonic duration of the first vowel in CVCV is phonologized when the second vowel is lost.

Citing Gess’ work on French, Morin (2007) provides a similar hypothesis: researches on a series of ancient texts convinced Gess (1988) that the coalescence of vowels in ancient French happened only after the middle of the XIII century, longtime after the date normally admitted for the deletion of preconsonantal *s*. The chronology proposed by De Chene & Anderson is thus problematic. Morin remarks furthermore that Wallon de Liège, a French dialect, conserves well the system of vowel length contrast of Western Romance, such as NĀSŪM > [ne:] "nose", MŌSĀ > [mu:s] "Meuse" with a long vowel in open syllables in Romance, and GRŌSSŪM / GRŌSSĀM > [grɔ̃] / [grɔ̃s] with a short vowel in closed syllables in Romance. In other words, the vowel lengthening in Wallon de Liège is conditioned by the syllabic structure of Western romance: the vowel is already long in open syllables, and short in closed syllables.

The hypotheses of Kavitskaya and Morin challenge the nature of CL: if lengthening *always* precedes syncope, it is never “compensatory” in the sense that it does not occur “to compensate” the loss of a segment. There is no transfer of *weight*, but a transfer of the distinctive value of a disappeared element. We refer to these phenomena as a *false compensation*, considering that finalism (a segment is lengthened in order to compensate the loss of another segment) plays no role in CL. Just as in the case of palatalization: [tʲi] gives

rise to the phoneme /tʲ/ when /i/ is lost. The birth of a new phoneme /tʲ/ is not to compensate the inevitable loss of /i/ given that the palatalization of /t/ has happened before vowel loss.

Returning to Yue dialects, what is the ultimate source of the additional duration associated with *Pinjam*? If we explain this additional duration by vowel lengthening, we will encounter the following problem: in the case of Frioulia [lupu] > [lo:f], the first vowel is phonetically long at the beginning since it is in an open syllable. By contrast, in Yue, there is no long vowel duration pre-existing to the loss of the diminutive suffix: in the sequence [mat32 jin25] “little thing” in Bobai, the nominal stem is closed by a consonant; the suffix begins with a consonant as well. The vowel of the nominal stem has no possibility to have a long allophone. In other words, if the additional tonal duration had to be explained by vowel CL, we would have difficulties in explaining why there is a change of duration in closed syllables. Vowel lengthening in closed syllables, if any, is a rather marked process. Now, the additional length is observed systematically in open *and* closed syllables. The possibility of vowel CL is thus excluded. If we posit that the codas in Yue are moraic, we will encounter another problem: it is difficult to understand why, in the case of three entering tones, tonal duration is shortened by final stops in closed syllables in Cantonese, whereas the same final stops are capable of bearing a long rising tone in *Pinjam*.

Now, it remains the only possibility: there is *tonal compensatory lengthening* so that the underlying structure could be preserved. The trigger of the additional duration associated with *Pinjam* is tonal, vowel lengthening being only a correlate of tonal lengthening.

Unlike the two types of CL where the process is always accompanied by a change in syllable structure, in Yue, an additional duration is systematically found in *Pinjam* whereas the syllable structure of the nominal stem remains unchanged: it is always in closed syllables. Given the phonological aberration of vowel lengthening in closed syllables, it is the tone, the only element active, which spreads to the following position released by the elision of the diminutive suffix. We consider that *Pinjam* in Yue dialects constitutes a case of lengthening which is truly compensatory: there is a compensation of the loss of the diminutive suffix by an additional duration associated with *Pinjam*.

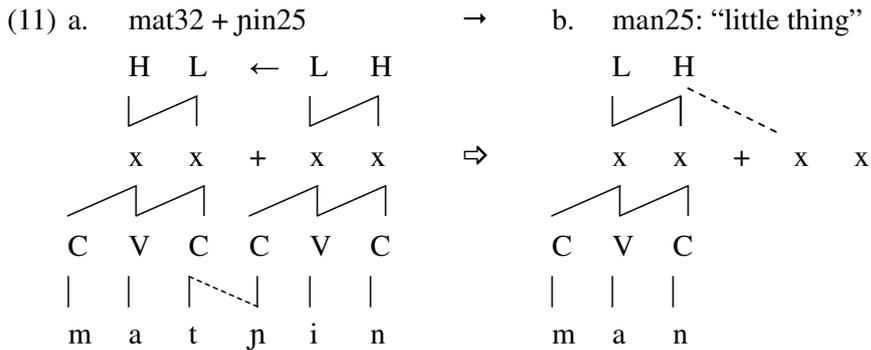

The compensatory nature of *Pinjam* being assured, the successive stages of its development in Yue dialects can be illustrated as in (10):

- (10) a. Suffixation  
       ⇒ ma21 jin25 “little horse” (Bobai)
- b. Nasalization of the occlusive coda  
       ⇒ mat32 “chose” → man25 “little thing” (Bobai)  
       Vowel nasalization  
       ⇒ hɔ 23 “river” → hɔn ʊ “little river” (Xinyi)  
       Emergence of a tonal suffix with compensatory lengthening

- ⇒ kəŋ 53 “jar” → kəŋ ʊ “little jar” (Xinyi)  
 ⇒ tʰəŋ21 “sugar” → tʰəŋ35 “candy” (Cantonese)

We can see that Cantonese is relatively innovative by comparison with other Yue dialects, the tonal suffix being the only morphological marker nowadays.

Nasalization of occlusive codas by the diminutive suffix is shown in (11)<sup>3</sup>:

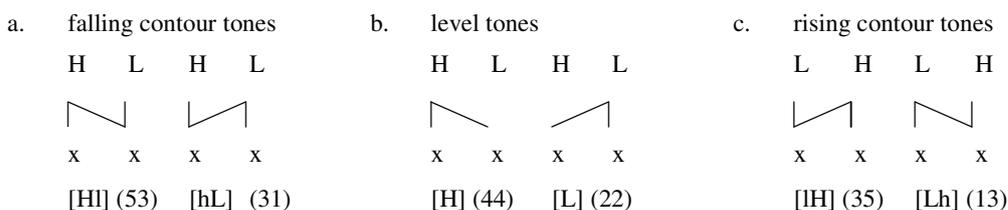

In (11a), the nasal feature provided by the diminutive suffix [jɿn25] nasalizes the coda of the preceding syllable. The rising tone of the diminutive suffix replacing that of the nominal stem, but their temporal positions remain, allowing the second tonal segment of the rising contour to spread to the following position released by tonal replacement. Hence there is the additional duration of the rising contour derived from *Pinjam*.

In sum, it is the tone, the only element active even in closed syllables, which lengthens after the elision of the diminutive suffix, not the vowel. In other words, if there exists vowel lengthening, it is the vowel which lengthens under the pressure of the tone, not the tone under the pressure of the vowel.

### 3.2 Implications of the present hypothesis

Tonal CL shows that tones are not pure melodies in Chinese: just as vowels which lengthen after the loss of final stops, the same thing goes for tones in Chinese. Consequently, tones do have direct access to temporal positions just as syllabic elements onset and rime.

<sup>3</sup> The interaction between tones and temporal positions is proposed as follows: the register is represented by the spreading of a tonal segment to an adjacent position. Notice that the capital letter indicates the register.

The duration increase of the contour tone derived from *Pinjam* reminds us of a study conducted by Carter & Gerken (2004) on the omission of unstressed syllables by English-speaking children. It is well admitted that pretonic syllables such as those in *bañana*, *Caśsandra* are often omitted by children. Traditional metric hypotheses assume that children have similar lexical representations to those of adults, but production constraints prevent them from pronouncing their targets correctly, which impose a reduced prosodic structure obeying to a trochaic feet (Gerken 1991, Demuth 1995). It follows from these hypotheses that omitted unstressed syllables are absent from children’s output. Carter & Gerken consider on the contrary that children simplify their production, deleting only the segmental material of unstressed syllables. The underlying representation of unstressed syllables might be present under the form of compensatory lengthening or other prosodic traces. They examined the duration of reduced dissyllabic forms pronounced by children, and compared them with dissyllabic forms having a real trochaic structure s-w, i.e. *Cassándra~Sandy*, *Lucínda ~ Cindy*. Their phonetic study shows that the average duration of verb-to-noun is longer for reduced formes (“\_cinda”, “\_sandra) than for non reduced forms (“Cindy”, “Sandy”)<sup>4</sup>. The same thing goes for *Pinjam* in Yue dialects, where the additional tonal duration preserves the underlying structure of the diminutive suffix.

### 3.3 Neutralization in Modern Cantonese

Bauer & Benedict (1997) note that there is a neutralization of contrast between the lexical rising tone and the rising tone derived from *Pinjam* in process in modern Cantonese:

*“According to both Benedict (1942) and Chao (1947) who were writing their descriptions of Cantonese tones in the 1940’s, the regular high rising tone had a mid to high rising contour of 35, and the high rising Pinjam had a long, low to high rising contour of 25:.. Based on his experience of learning Cantonese in Guangzhou on 1949-1950, Egerod (p.c. with Bauer, 1994) directly observed this difference in the two tones. However, at some time in the past 50 years the contours of the two tones have become identical and indistinguishable for both Guangzhou and Hong Kong speakers. Speakers now use the mid-low to high rising contour for both tones.”*

This tendency is also confirmed by a study carried out recently by Yu (2007). He

<sup>4</sup> Here are some examples of stimuli used by Carter & Gerken (2004) :

	<b>Disyllabic target names</b>	<b>Trisyllabic target names</b>
<b>Monosyllabic verbs</b>	He pushed Sandy.	He pushed Cassandra.
	He pushed Cindy.	He pushed Lucinda.
<b>Disyllabic verbs</b>	He pushes Sandy.	He pushes Cassandra.
	He pushes Cindy.	He pushes Lucinda.

The average duration of verb-to-noun (He pushed Sandy vs He pushed Cassandra) was analyzed in order to see if there was a trace left by an omitted syllable.

remarks that speakers produce, with subtle phonetic differences, different rising contours derived from *Pinjam*, but are unable to perceive the difference between the lexical rising tone and the derived rising tone. In other words, this difference systematically reported in the 1950s, is disappearing in modern Cantonese. Where does this neutralization come from? Moreover, admitting that, in more conservative dialects, the duration increase results from an elided diminutive suffix, another question arises: why is there no diminutive suffix in Cantonese? Before tackling this problem, it would be necessary to discuss another problematic, which appears to be unrelated to the neutralization in progress in Cantonese: verb nominalization through tone change.

Mai (1995) observes that in Jiansung, another Yue dialect, the word “bag” is realized with the lexical tone 22 among elderly speakers, but among young speakers, “the bag”, be it a big one or a small one, can be pronounced with a derived rising contour 35. This phenomenon illustrates that the derived rising tone, as a nominal marker, comes from the diminutive marker. Mai remarks, on the other hand, that the derived rising tone resulting from the diminutive morpheme has gradually become a derivation marker in adjectival, adverbial and verbal classes, where the function of *Pinjam* is to reduce the force transmitted by verbs or to express an action of short duration. Here are some examples of Xinyi and Cantonese:

(14) a. Xinyi, adjectival class (Ye & Tang 1982)

kam33 tɔ53	“so numerous”	kam33 tɔʔ	“so few numerous”
kam33 tai53	“so tall”	kam33 taiʔ	“so little”
kam33 tʃʰɛŋ11	“so long”	kam33 tʃʰɛŋʔ	“so short”

b. Xinyi, verbal class (Ye & Tang 1982)

mɔ53	“touch”	mɔ53 mɔnʔ	“touch gently”
tʃʰœ23	“sit down”	tʃʰœ23 tʃʰœnʔ	“sit down for a little while”
pʰak33	“hit”	pʰak33 paŋʔ	“hit gently”

c. Xinyi, adverbial class (Mai 1995)

tai22 kʰɔiʔ	“probably”
lœk22 lœkʔ	“a little”

d. Cantonais, verb nominalization (Yu 2007)

sou33	“to sweep”	sou35	“a broom”
pɔŋ22	“to weigh”	pɔŋ35	“a balance”

In other words, in Yue, the derived rising tone was, at the beginning, a diminutive marker. The diminutivization process has spread to other word classes later on. Given that it is in the nominal class that diminutivization was developed the most completely, and that it is

in the nominal class that the rising contour is the most numerous, speakers have taken it as a nominal marker.

Returning to Cantonese, we consider that, just as in Bobai, there was a diminutive suffix with a rising contour to produce nominal diminutivization. At a later stage, there were two ways of deriving diminutives: use of diminutive suffix with a rising contour, and tonal replacement by a long rising tone. Diminutivization by tonal substitution has been spreading to all classes of the language, and has become more and more productif and regular. Consequently, it supplanted the diminutive suffix with a rising contour which was used only in the nominal class. This substitution has provoked the loss of the suffix whose existence became redondant. The suffix loss caused the dissapearance of all traces of affixal positions, so CL cannot occur in Cantonese. As a consequence, the rising contour derived from *Pinjam* confused with the lexical rising tone, and become the only marker of diminutivization.

In sum, the derived rising contour, which was a diminutive marker in the nominal class, has gradually become a nominal marker and a diminutive marker in other word classes. This grammaticalization process creates new forms, introduces categories which had no linguistic expressions, and transforms the whole system (Meillet 1912).

This grammaticalization reminds us of the adverbs formed with *-ly* in English, where three forms were in competition, i.e. suffixation (*-ly*), zero formation (*just, pretty, very*), and compounding (*-wise, -ward, -style*). The derivation by *-ly* has spread later on, and supplanted other forms of adverbial suffixes, such as zero formation (Brinton & Traugott 2002).

### 3.4 *One mechanisme for different derived rising contour tones*

Two questions remain: why does the rising contour derived from *Pinjam* come from 33, 22, 23, 21, 4 and 3 in Cantonese, whereas 5 and 35 are not affected? On the other hand, why does the omitted syllable always carry 5 or 35?

Studying synchronic and diachronic aspects of Cantonese *Pinjam*, Lam (2002) remarks that, in modern Cantonese, there are few words from historical catogories *yinshang* and *yanshang*, i.e. high and low-register lexical rising tones. Moreover, historical categories *yanping*, *yanqu* and *yanru*, all low-register tones, are major “providers” of words having a derived rising tone<sup>5</sup>. This finding shows that the derived tone 35 comes from a passage of low-register tones which give rise to high-register tones. Consequently, the rising contour derived from *Pinjam*, resulting from low-register tones, has profited a system where there are few high melodies and where there are few lexical rising tones. A *virtual* empty space was thus filled through the derived high-register rising tone<sup>6</sup>. If we accept this hypothesis, the

---

<sup>5</sup> Yanping: a low-register level tone historically (voiced onset)

Yangqu: a low-register falling contour historically (voiced onset)

Yangru: a low-register entering tone historically (voiced onset)

<sup>6</sup> By *virtual* empty space, we mean that the lexical contour tone exists in Cantonese, but is less numerous

reason why 5 and 35 are the only two tones which do not give rise to *Pinjam* becomes more clear: they are already high-register tones; 35 is, moreover, a rising contour tone.

However, in syllable contraction, why does the omitted syllable always carry 35 or 5? Recall that in familiar conversation in Cantonese, the aspectual markers *tsɔ35* and *tək5* as well as *iat 5* “one” are often omitted ; the *Pinjam 35* is the only attested surface form :

- (16) a. Omission of the perfective marker *tsɔ35*
- |              |   |        |                              |
|--------------|---|--------|------------------------------|
| pɔŋ22 tsɔ35  | → | pɔŋ35  | “to weigh (PERFECTIVE)”      |

What happens in (16) seems in contradiction with other phenomena found in the process of diminutivization, where the rising contour derived from *Pinjam* results from 33, 22, 23, 21, 4 and 3, whereas high tones (53/55, 35, 5) are not affected. On the contrary, in (16), the omitted syllables always carry 35 or 5. How to explain this paradox ?

Before tackling this problem, we shall mention a phonetic study conducted by Yu (2007). Experiments on different derived rising tones show that their registers depend largely on the lexical tone of the elided syllable: the rising tone derived from the elision of the potential marker *tək5* has a relatively high register compared with that derived from the lexical tone 35.

---

compared with other lexical tones.

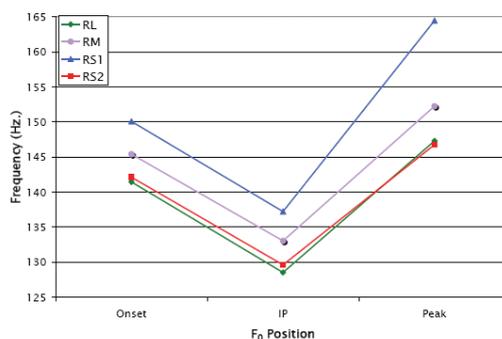

Figure 3

RS2 being a rising tone derived from the elision of the perfective marker *tsɔ35*, its register is the most close to the lexical rising tone (RL). RS1 is derived from the elision of the potential marker *tək5*, its register is the highest among all rising contour tones. The register of the derived rising tone marking diminutivization, RM, is between RS1 and RS2.

We suggest that there is a preservation of the elided syllable in (16), and that the high register induced by *tək5* is the realization of the entering tone 5 on CV or CVN. Consequently, in syllable contraction, 35 and 5 are not affected : 35 is preserved in (16a), and the entering tone 5 is preserved in (16b) and (16c)<sup>7</sup>; the result is necessarily a rising contour.

In sum, we consider that the different derived rising contours indeed originate from one mechanism, given that 35 and 5 are not affected in (16). Although one is a corollary of tonal replacement formerly productif in the language, and the other is a consequence of syllable contraction with register preservation, the two processes give rise to *Pinjam*. And since they have the same mechnisme, the possibility of tonal CL is not excluded in syllable contraction : the elision must have left empty temporal positions. A phonetic analysis might be necessary to verify this eventuality.

#### 4. Conclusion

CL which has been examined shows that tones are not pure melodies in Chinese: they do have direct acces to temporal positions. A theory based on segmental CL will encounter the following problem: if the additional tonal duration had to be explained by the CL of vowels, no change in length would be expected to occur in closed syllables. Now, the additional length is observed in both open and closed syllables in *Pinjam*. Consequently, it is the tone that lengthens under syllable elision, not the vowel. In other words, the vowel lengthens under the pressure of the tone, not the tone under the pressure of the vowel.

Moreover, we hope to have shown why there is neutralization between the lexical rising tone and the derived rising tone in modern Cantonese: the diminutivization process by tonal

<sup>7</sup> Observe that, in (16b) and (16c), the elided syllables always carry a high register lexical tone, i.e. *tək5*, *iat5*, and the preceding syllables always bear a low register tone, i.e. *ki:n33*, *t<sup>h</sup>am23*, *hɔŋ21*, et *tip2*. We postulate that there is a perservation of the register of two syllables. Hence the derived rising tone 35 in the surface form,

substitution has been spreading to all classes of the language, and has become more and more productif and regular. Consequently, it supplanted the diminutive suffix with a rising contour which was used only in the nominal class. This replacement has provoked the loss of the suffix whose existence became redondant. The loss of the suffix caused the disappearance of all traces of affixal positions. Consequently, the process of CL cannot happen in Cantonese.

# Individual differences in production of voicing of French /ʁ/ sounds and the perception by Japanese adult listeners\*<sup>1</sup>

Tomohiko OOIGAWA

Phonetics Laboratory, Sophia University, 7-1, Kioi-cho, Chiyoda-ku, Tokyo, JAPAN

ooigawaferchichi@gmail.com

## Abstract

The present study examines the individual differences in production of voicing of French /ʁ/ sounds and how Japanese listeners perceive and categorize them comparing with French /l/. This study also considers the following vowels and the listeners' knowledge of L2. The results show that some French speakers' /ʁ/ sounds are devoiced even in the initial and intervocalic context and that the individual differences in French rhotic voicing and the following vowels influence the perception and categorization by Japanese listeners. The results also indicate that French /ʁ/ can be categorized into Japanese /h/, /g/, and /r/. The PAM (Perceptual Assimilation Model, Best 1995) does not account for this assimilation pattern and this model should be extended.

**Keywords:** French liquids, voicing of French rhotic, perceptual assimilation, categorization.

## 1. Introduction

The present study examines the individual differences in production of voicing of French /ʁ/ sounds and how Japanese adult listeners perceive and categorize them in comparison with the French /l/ in their own language's phonological system. The vowels following /ʁ/ or /l/ and the listeners' knowledge of L2 (second language[s]) are also taken into consideration. This study also examines whether the PAM (Perceptual Assimilation Model, Best 1995) accounts for the assimilation of French liquids by Japanese listeners. This research aims to identify L2 sound contrasts that are difficult to produce and/or discriminate, and the reasons why they are difficult.

---

<sup>1</sup> This study was partially supported by the Sophia University Open Research Center from MEXT. I am indebted to all the participants of this research.

This paper is structured as follows. After descriptions of French and Japanese liquids in Section 2, this paper points out the problems of the studies of French /l/ and /ʀ/ sounds in Section 3. The experiments and the results are reported in Section 4. This paper discusses and draws the conclusions in Section 5, and closes with some proposals for further studies in Section 6.

## **2. Descriptions of French and Japanese liquids**

Standard French has two kinds of liquids. While /l/ is usually realized as a voiced dental lateral approximant [l], /ʀ/ is usually realized as a voiced uvular fricative. However, this production of rhotic varies considerably among speakers and according to phonetic context (IPA 1999). In addition, this study indicates that voiced uvular trill is also fairly common in French. According to Vaissière (2006), voicing is not contrastive in the case of French /ʀ/. Depending on the speaker, the phonetic context and the prosodic position, French /ʀ/ can be realized as a voiced approximant or as a voiceless fricative, or sometimes as a mixture of the two. These studies suggest that there are individual differences in production of voicing of French rhotic. In other words, French /ʀ/ sounds can be devoiced in the initial and intervocalic context. Hereafter, this paper uses the symbol [ʀ] to refer to the French voiced fricative or approximant and the symbol [ʀ̥] and [ʀ̄] to refer to the voiceless uvular fricative and the voiced uvular trill respectively. Therefore, rat /ʀa/ ‘rat’ can be realized as [ʀa], [ʀ̥a], or [ʀ̄a] in French.

On the other hand, in Japanese, there is no contrast of /l/-/r/. This language has only one liquid phoneme /r/ and it is usually realized as post-alveolar flap [ɾ] (IPA 1999). Japanese syllabic structure is usually CV (one consonant and one vowel) and Japanese has five distinctive vowels. One syllable is written as one letter. Therefore, /ra/ is written as one letter in Japanese.

## **3. Problems**

### *3.1. Production*

Although some studies (Durand 2004, IPA 1999, Vaissière 2006) indicate that French /ʀ/ voicing is not contrastive in the same syllabic position, few researches or investigations on the individual difference in production of French /ʀ/ voicing have

been carried out. Its empirical recording, in particular, is not enough.

### 3.2. Perception

Few studies on the perception of French liquids by Japanese listeners have been conducted. Especially, the comparison of [ʀ], [ʁ] and [ʁ] has not been tested. Yamasaki & Hallé (1999) examined the categorization of French /ʀ/ by Japanese listeners. The results show that they tend to categorize French rhotic as Japanese /r/, /h/, and /g/. However, this study does not consider the speakers' individual differences of voicing. Cole & Iskarous (2001) indicates that the adjacent vowels influence the perception of consonants (especially plosives); this tendency can also be observed in the results of Yamasaki & Hallé (1999). However, this research used only three vowels: /a/, /i/, and /u/ for the stimuli. Therefore, the present study uses more vowels in order to clarify the relations between vowel context and consonant categorization by Japanese listeners.

Our preliminary study (Ooigawa *et al.* 2008) finds these following assimilation patterns by Japanese listeners: [l] is categorized as Japanese /r/ without exception, [ʀ] tends to be written as Japanese /h/; [ʁ] is categorized as /r/ or /h/ (depending on the following vowels, see Table 1). However, this study does not consider the listeners' knowledge of L2. In other words, it does not compare the results between French language learners and naïve listeners.

The PAM (Perceptual Assimilation Model, Best 1995) accounts for many assimilation patterns in diverse cross-language perceptions. According to this model, a foreign sound category is either assimilated into one native sound category or is not assimilated: “1 to 1” or “1 to 0” assimilation; /X/ (L1) → /Y/ (L2). For example, French /l/ is assimilated into Japanese /r/ (Ooigawa *et al.* 2008). According to the results of our preliminary study, however, the assimilation pattern of French [ʀ] exhibits a “1 to more than 2” assimilation pattern: /X/ (L1) → /Y/, /Z/... (L2). In other words, this result shows that one foreign sound category can be assimilated into more than one native sound category (see Tables 2 & 3). In addition, it is problematic that the PAM ignores the vowel contexts of the consonants. The present research aims to provide a further empirical account to extend the PAM.

**Table 1.** Assimilation patterns of French liquids by Japanese listeners (Ooigawa *et al.* 2008)

[l]	→	Japanese /r/
[ʀ]	→	Japanese /h/
[ʁ]	→	Japanese /r/ or /h/ (depending on the following vowels)

**Table 2.** Assimilation patterns of the PAM (Perceptual Assimilation Model, Best 1995)

L2		L1
/X/	→	/Y/, or not assimilable

**Table 3.** Assimilation patterns of French [ʁ] by Japanese listeners (from Ooigawa *et al.* 2008)

L2		L1
/X/	→	/Y/ & /Z/...

## 4. Experiments

This study carried out two experiments in order to examine the speakers' individual differences in voicing of French /ʁ/ sounds and the perception of the sounds by Japanese adult listeners.

### 4.1. Production experiment

#### 4.1.1. Procedures

In the production experiment, four native speakers of French participated in the recordings (see Table 4). No speaking or hearing difficulties were reported by them. The materials consisted of CV mono-syllabic words including /ʁ/ and /l/ followed by the vowels /i/, /e/, /a/, /o/, and /u/ (see Table 5). The speakers read out these words and some distractors at least three times in the carrier sentence as in the following example: 'Dis-moi "rat" et "rat".' /dimwa ʁa e ʁa/ 'Say to me "rat" and "rat".' The utterances were recorded in a sound-proof room of Sophia University Phonetics Laboratory onto a digital recorder (Marantz solid state recorder, PMD671) through a microphone (Sony ECM-959DT) and digitized at 48 kHz with 16 bits.

**Table 4.** Information of the speakers

Speaker 1:	male	22 years old	from Chalon-sur-Saône
Speaker 2:	female	77 years old	from Besançon
Speaker 3:	male	26 years old	from Thouars
Speaker 4:	male	22 years old	from Marseille

**Table 5.** List of the target words, /C<sub>2</sub>V<sub>3</sub>/

/l/:	lit	/li/	‘bed’	/ʁ/:	riz	/ʁi/	‘rice’
	les	/le/	‘the’		ré	/ʁe/	‘re’
	la	/la/	‘the’		rat	/ʁa/	‘rat’
	l’eau	/lo/	‘the water’		rot	/ʁo/	‘burp’
	loup	/lu/	‘wolf’		roué	/ʁu/	‘wheel’

#### 4.1.2. Analysis of voicing

Each part of the /ʁ/ and /l/ sounds of the tokens were judged “voiced”, “voiceless”, or “mixture of them” by the analysis of the spectrograms, the pitch contours, and the voice report of the pulse, using a computer software program Praat Ver.4.5.17 (Boersma & Weenink 2007, see Table 11 in the Appendixes for Praat settings). In other words, the existences of voice bar, pulse wave, fundamental frequency, and quasiperiodic waveform were analyzed. They are the signs of voicing in a sound signal (Kent & Read 1992, Ladefoged 2003).

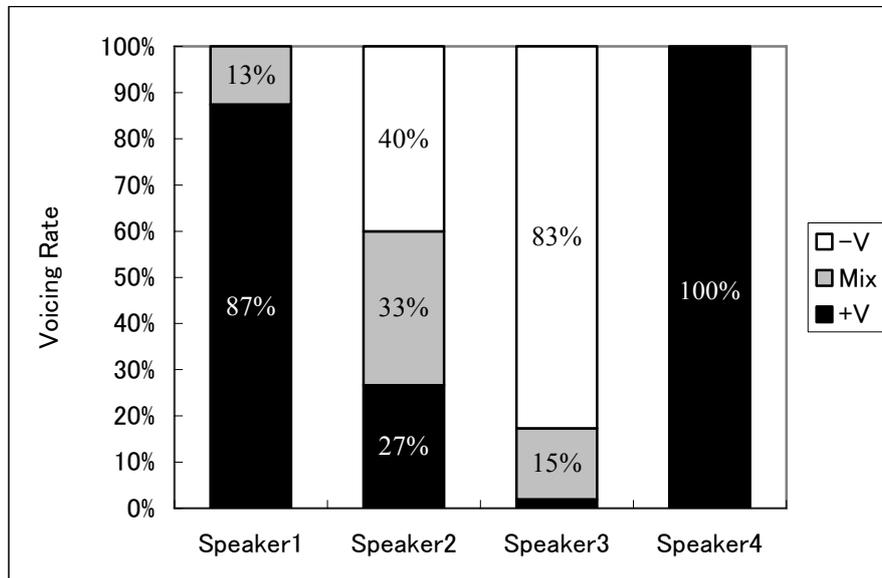

#### 4.2. Results of production experiment

The results show the clear individual differences in production of voicing of French /ʁ/ sounds (see Figure 1). While 87% of /ʁ/ sounds of Speaker 1 were judged “voiced”, Speakers 2 and 3 produced voiceless /ʁ/ sounds at the rate of 40% and 83% respectively. French /ʁ/ sounds are devoiced in the initial and intervocalic context.

There are also individual differences in manner of articulation. While all the tokens of /ʁ/ produced by Speaker 1-3 are fricatives [ʁ̥] or [ʁ], trill [ʀ] is dominant in the utterances of Speaker 4 (95%).

In contrast with /ʁ/, all the tokens of /l/ sounds were judged “voiced”. This result indicates that there are no individual differences in production of voicing of French /l/ sounds. French /l/ sounds are voiced in the initial and intervocalic context.

**Figure 1.** Production result: voicing rate

+V indicates “voiced”. -V indicates “voiceless”, and **Mix** indicates “mixture of the two”.

### 4.3. Perception Experiment

In the perception experiment, this study examined how the Japanese adult listeners perceived French /ʁ/ sounds and categorized them in their own language’s phonological system.

#### 4.3.1. Stimuli

From each of the recorded utterances, *et* “\_\_” /e \_\_/ was excited. For example, the tokens of /e ʁa/ are extracted from ‘Dis-moi “rat” et “rat” /dimwa ʁa e ʁa/. Tokens of voiced uvular fricative [ʁ], voiceless uvular fricative [χ], voiced uvular trill [ʀ], and voiced dental lateral approximant [l] were selected as the stimuli from the speakers (see Table 6). Hereafter, the tokens of [ʁ] recorded from Speaker 2 are indicated by [ʁ1] and [ʁ2] indicates the tokens of [ʁ] recorded from Speaker 3.

**Table 6.** Selected tokens for the stimuli

/ʁ/:	[eʁi] [eʁe] [eʁa] [eʁo] [eʁu]	from Speaker 1	
	[eʁi] [eʁe] [eʁa] [eʁo] [eʁu]* <sup>2</sup>	from Speaker 2	[ʁ1]
	[eʁi] [eʁe] [eʁa] [eʁo] [eʁu]	from Speaker 3	[ʁ2]
	[eri] [ere] [era] [ero] [eru]	from Speaker 4	
/l/:	[eli] [ele] [ela] [elo] [elu]	from Speaker 3	

#### 4.3.2. Listeners

Twenty-two native speakers of Japanese participated in this perception experiment. No speaking or hearing difficulties were reported by them. They were divided into two groups: R-acquired group and Non-R-acquired group. R-acquired group consisted of 12 listeners (19-43 years old, median 23.5 years; 8 women & 4 men) who had studied French or German languages or phonetics and could pronounce /ʁ/ sounds. In other words, they had knowledge of uvular rhotic sounds. Non-R-acquired group consisted of 10 listeners (21-25 years old, median 22 years; 5 women & 5 men) who had never studied French or German languages or phonetics and did not know the /ʁ/ sounds. In brief, they were naïve listeners.

#### 4.3.3. Procedures

In a sound-proof room of Sophia University Phonetics Laboratory, the target stimuli and the distractors were presented diotically and individually at a comfortable listening level through headphones (Sony MDR-CD900ST) connected to a personal laptop computer. The listeners were asked to transcribe each stimulus in katakana script which is used in Japanese to transcribe foreign names and loanwords. The listeners were allowed to ask the experimenter to replay each stimulus up to five times if they required.

---

<sup>2</sup> No tokens of [eʁu] were recorded from Speaker 2. Therefore, this study uses the token [eʁu] as a stimulus.

#### 4.3.4. Analysis of the results

This paper focuses on the transcriptions of consonants. One stimulus equals to one /X/ point\*<sup>3</sup>. The same two consonants from one stimulus equal one /X/ point. The followings are the examples of the way how calculations were worked out. If the listener wrote /era/ in Japanese, it is worth 1 /r/ point. If the transcription is /ekuha/ for French [eʁa], it is valued at 0.5 /k/ points and 0.5 /h/ points. In the case of /erura/ for French [eʁa], it is worth 1 /r/ point.

Some listeners wrote two points (*dakuten*) on the upper right of katakana script of /ri/, /re/ or /ra/. In Japanese transcription these points indicate voicing of consonants\*<sup>4</sup>. As there is no voiceless counterpart of /r/ in Japanese, it is not necessary to add two points to /r/\*<sup>5</sup>. Though this paper does not consider this phenomenon because of its limited tokens, the transcription of /r/ with *dakuten* is indicated by r” (see Figures 2 & 8).

As the numbers of listeners of the two groups are different, this paper uses percentages in order to show the results in Figures 2-9. Statistical analyses were carried out with raw data (see Section 4.4.2).

#### 4.4. Results of perception experiment

##### 4.4.1. Percentage

All the listeners transcribed French [l] stimuli into Japanese /r/. This result is identical with that of our previous study (Ooigawa *et al.* 2008). On the other hand, French /ʁ/ sounds were categorized inconsistently.

The stimuli of [eʁi] and [eʁe] were transcribed largely into Japanese /r/ by the Non-R-Acquired group (85% & 60% respectively, see Figure 2). [eʁa], [eʁo] and [eʁu] were written as Japanese /h/ (100%). The same tendencies are observed in the results of the R-Acquired group, though the rate of /r/ is higher than that of the Non-R-Acquired group for every stimulus of speaker 1 (see Figure 3).

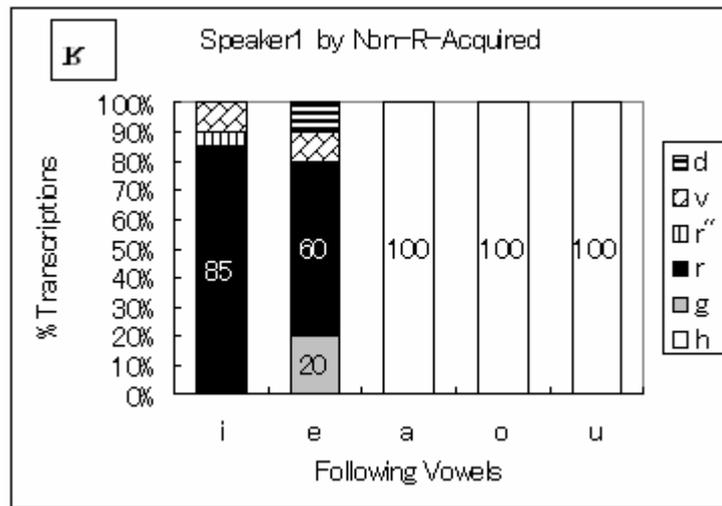

---

<sup>3</sup> X indicates a certain consonant.

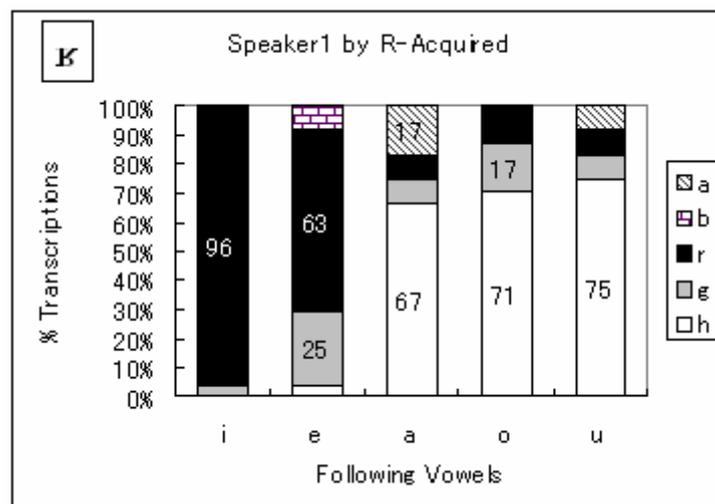

<sup>4</sup> Therefore, /da/ is written as /ta”/ in Japanese transcription.

<sup>5</sup> However, some Japanese cartoons (*manga*) add *dakuten* to the letters of vowels to express sudden fear or surprise, and some textbooks of Arabic language use it to explain the voiced pharyngeal fricative [ʕ].

**Figure 2.** Rate of transcriptions of [ɹ] by the Non-R-Acquired group

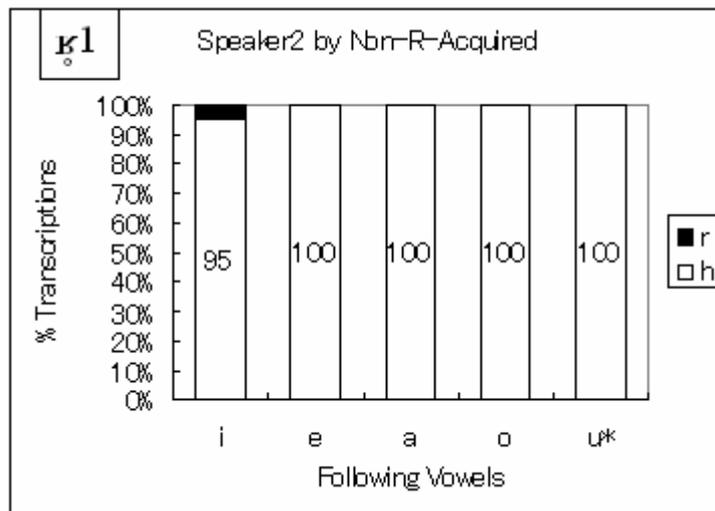

**Figure 3.** Rate of transcriptions of [ɹ] by the R-Acquired group

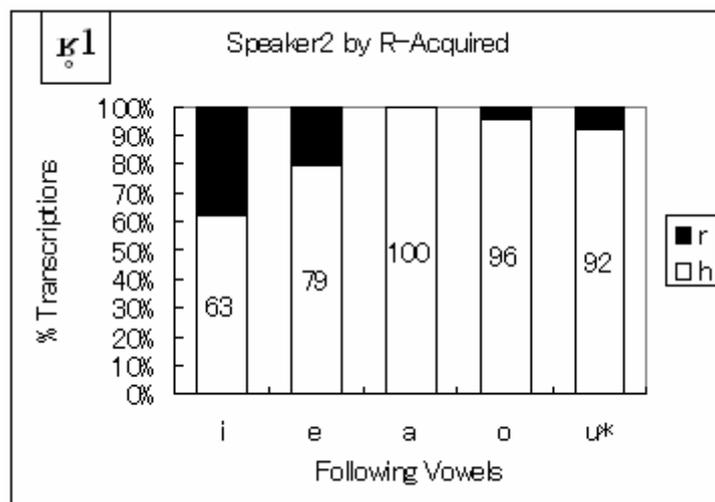

For [ɹ1], all the listeners of the Non-R-Acquired group transcribed [eɹe], [eɹa], [eɹo] and [eɹu] into Japanese /h/, and [eɹi] was categorized into Japanese /h/ at the rate of 95% (see Figure 4). The proportions of /r/ described by the R-Acquired group are higher than those of the Non-R-Acquired group except [eɹa]. Especially, [eɹi] had the largest rate of /r/ (see Figure 5).

**Figure 4.** Rate of transcriptions of [ɣ1] by the Non-R-Acquired group

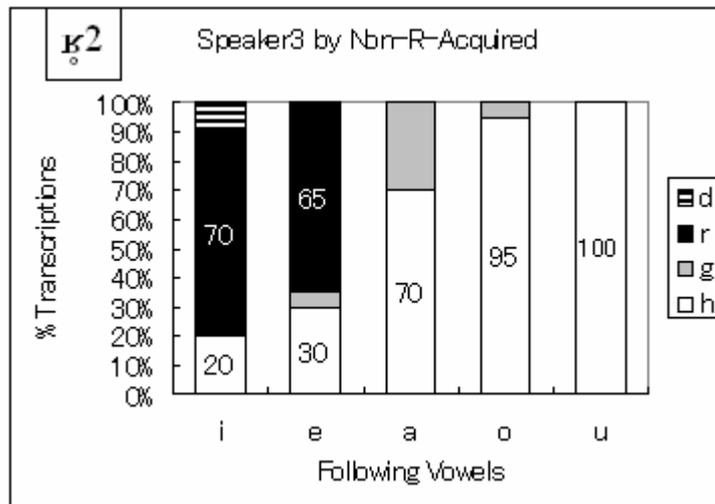

**Figure 5.** Rate of transcriptions of [ɣ1] by the R-Acquired group

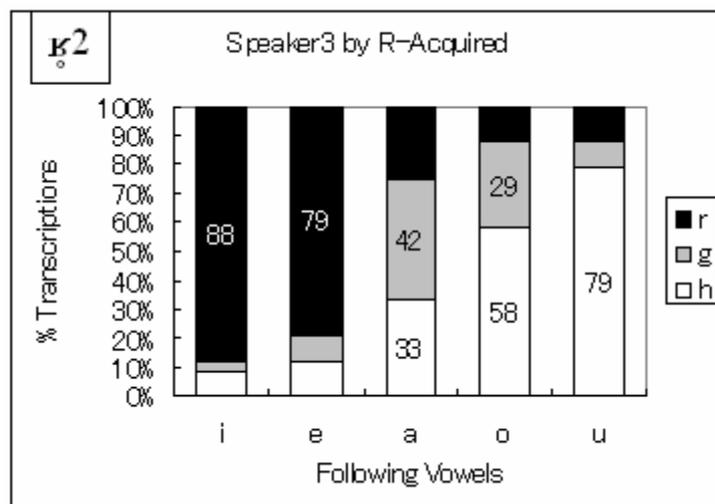

For [ɣ2], the stimuli [ɛɾi] and [ɛɾe] were transcribed largely into Japanese /r/ by the Non-R-Acquired group (70% & 65% respectively, see Figure 6). [ɛɾa], [ɛɾo] and [ɛɾu] were mostly written as Japanese /h/ (70%, 95% & 100% respectively). The same tendencies are seen in the results of the R-Acquired group though the rate of /r/ is higher than those of the Non-R-Acquired group for every stimulus of speaker 1 (see Figure 7). The results of [ɣ2] are rather similar to those of [ɣ].

**Figure 6.** Rate of transcriptions of [ɣ2] by the Non-R-Acquired group

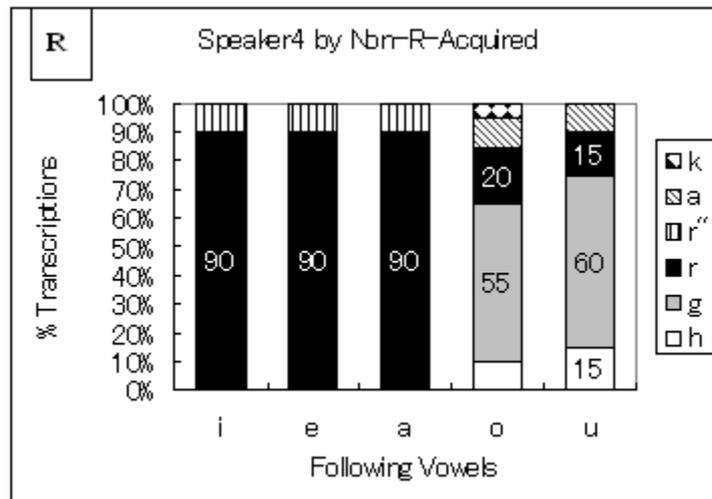

**Figure 7.** Rate of transcriptions of [ɣ2] by the R-Acquired group

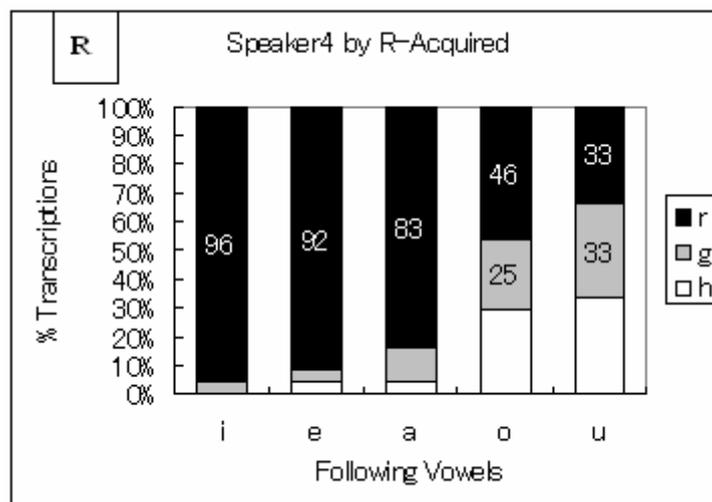

For [R], the Non-R-Acquired group overwhelmingly transcribed [eri], [ere] and [era] into Japanese /r/ while [eɣo] [eɣu] were mostly written as /g/ (see Figure 8). The tendencies of [eri], [ere] and [era] are identical to those for the R-Acquired group. However, the results of [eɣo] and [eɣu] for the R-Acquired group are different. There is no category which gained a majority (see Figure 9).

**Figure 8.** Rate of transcriptions of [r] by the Non-R-Acquired group

**Figure 9.** Rate of transcriptions of [r] by the R-Acquired group

#### 4.4.2. Statistical Analysis

In order to compare the two groups, the /r/ points were analyzed by *t*-test. Although the total /r/ points of the R-Acquired group are higher than those of the Non-R-Acquired group, this difference is not significant ( $t = -1.48, p = 0.147$ ). This result indicates that there is no difference between these groups. Because of this reason, this paper does not consider the knowledge of the listeners during the other comparisons

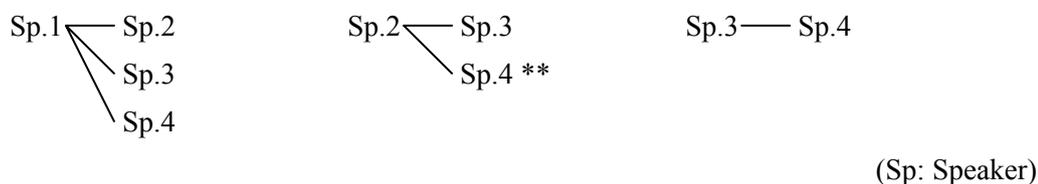

The /r/ points from all the listeners were analyzed by one-way ANOVA, and the significantly different pairs are shown in Table 7 by asterisks. The significant difference

can be seen only between Speaker 2 and Speaker 4 (see Table 7a). This result indicates that the individual differences in French rhotic voicing can influence the perception and categorization by Japanese listeners.

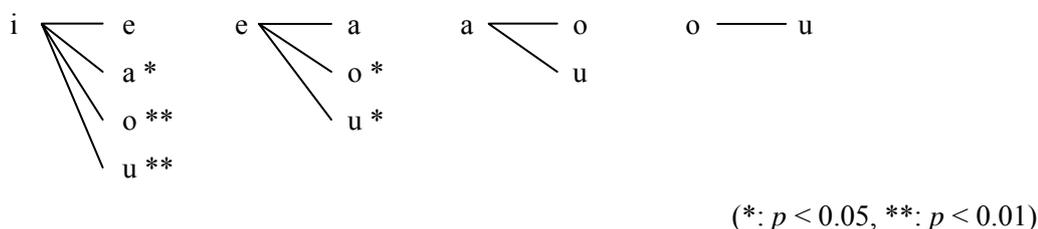

Table 7b shows the clear inter-vowel difference of /r/ points. The most significant differences are the pairs of /i/-/o/ and /i/-/u/: front vowels vs. back vowels. These results indicate that the vowels followed by a consonant in a CV mono-syllable influence the perception or categorization, and that its frontness and backness (either it is a front vowel or a back vowel) is most important.

**Table 7.** One-way ANOVA analysis of the /r/ points from all listeners

(a) *Inter-speaker difference*

(b) *Inter-vowel difference*

## 5. General discussions and conclusions

### 5.1. Production of French lateral and rhotic sounds

#### 5.1.1. Individual differences of voicing

The results of the production experiment of this study lead us to the conclusion that individual differences of voicing exist in the production of /ʁ/ sounds. On the other hand, French /l/ sounds are usually voiced in the initial and intervocalic context.

#### 5.1.2. Individual differences in the manner of articulation

In addition, this research indicates that individual differences in the manner of

articulation also exist. Though this phenomenon is not a new discovery, we should consider it together with the differences of voicing. In conclusion, in French, each speaker has his/her dominant rhotic sounds (see Table 8) while French lateral sounds are usually [l] in the initial and intervocalic context.

**Table 8.** Dominant rhotic sounds in initial and intervocalic context

Speaker 1:	voicing + fricative = [ʁ]
Speaker 2:	(de)voicing + fricative = [ʁ] or [ʁ̥]
Speaker 3:	devoicing + fricative = [ʁ̥]
Speaker 4:	voicing + trill = [ʀ]

## 5.2. Perception of French lateral and rhotic sounds

As all the listeners categorized all the [l] stimuli into Japanese /r/, this paper discusses the perception of /ʁ/ sounds.

### 5.2.1. Influence of listeners' knowledge

Figures 2-9 tell us that the listeners of the R-Acquired group tend to transcribe the French /ʁ/ sounds into Japanese /r/. However, this difference is not significant. Although it is possible that this group boundary is not adequate enough to permit comparisons, this study concludes that is no influence of listeners' knowledge for the perception of French /ʁ/ sounds. Further studies on the relation between listeners' knowledge and L2 sounds perception are needed.

### 5.2.2. Influence of the voicing of French rhotic sounds

It is difficult to conclude that only voicing influences the perceptual assimilation of French /ʁ/ sounds. We should consider it with the vowel context and the manner of articulation.

It is mysterious that the results of [ʁ] and [ʁ̥2] are similar to each other. It is natural to think that the results of [ʁ̥1] and [ʁ̥2] are identical. It is possible that these results indicate the limit of voicing analysis by only sound signals, and that [ʁ̥] has variants or that the voicing of French rhotic sounds is gradual. Further researches on the production of French /ʁ/ sounds are needed.

### 5.2.3. Influence of following vowels

The results of the perception experiment show that the categorization of French /ʁ/ [ʁ] [ʀ] [ʁ] depends on the following vowels. Especially, the frontness and backness are important. While fricatives [ʁ, ʀ] with front vowels /i, e/ tend to be written as Japanese /r/, fricatives [ʁ, ʀ] with back vowels /o, u/ tend to be transcribed as Japanese /h/. While trill [ʀ] with vowels /i, e, a/ tend to be written as Japanese /r/, trill [ʀ] with back vowels /o, u/ tend to be transcribed as Japanese /g/ or /h/ or /r/. Table 9 summarizes these phenomena.

**Table 9.** Perceptual assimilation patterns of French liquids by Japanese listeners

French /l/ →	Japanese /r/
French /ʁ/	
[ʁ] + /i, e/	→ Japanese /r/
[ʁ] + /a, o, u/	→ Japanese /h/
[ʀ1]	→ Japanese /h/
[ʀ2] + /i, e/	→ Japanese /r/
[ʀ2] + /o, u/	→ Japanese /h/
[ʀ] + /i, e, a/	→ Japanese /r/
[ʀ] + /o, u/	→ Japanese /g/, /h/, /r/

### 5.2.4. Proposal for the PAM

From the results of the perception test of French rhotic sounds, this study concludes that the perceptual assimilation pattern of Table 3 in Section 3.2 is possible. In other words, one L2 sound category can be assimilated into more than one native sound category (see Table 10 below).

**Table 10.** Perceptual assimilation patterns of French rhotic sounds

French /ʁ/ → Japanese /r/, /g/, /h/

As the PAM does not include this pattern, it does not account for Japanese listeners' perceptual assimilation pattern of French /ʁ/ sounds. Therefore, this model should be extended.

## **6. Further studies**

In addition to the studies that this paper mentioned in Section 5, the following further researches are needed in order to advance this study.

- 1) Production of Japanese /r/ and French /ʁ/ sounds by Japanese speakers.
- 2) Goodness of Japanese /h/ and /g/ as French /ʁ/.
- 3) Goodness of Japanese /r/ as French /ʁ/ or /l/.
- 4) Production and perception of French liquids in the other syllabic positions such as in the coda and in the cluster.

# Hetero-syllabic Split L-Geminates: English in Singapore and Hong Kong<sup>1</sup>

Wee, Lian Hee

Hong Kong Baptist University  
lianhee@hkbu.edu.hk

## Abstract

Drawing upon data from Singapore English (SgE) and Hong Kong English (HKE), this paper demonstrates that coda /l/ geminates and splits into [-wl-] when sandwiched between a short vowel and another vowel. This split-gemination of /l/ is problematic for the currently established conception that geminates share phonological features. To solve this problem, this paper proposes that non-terminal nodes contain phonological information via correspondences to the terminal nodes.

**Keywords:** Inter-tier Correspondence, L-Gemination, English, Singapore, Hong Kong,

## 1. Introduction

This paper explores the case of the split gemination of /l/ in Singapore English (SgE) and Hong Kong English (HKE). It is difficult to demonstrate split gemination ( $X \rightarrow X_iX_j$ ) because there are after all two distinct consonants. In fact, “split gemination” is an oxymoron given that gemination means doubling.

A good place to begin would be to demonstrate gemination. Both SgE and HKE alike show consonantal gemination in the environment  $V_{\text{short}} \_ +V$ , i.e. a consonant that is preceded by a short vowel geminates when a vowel-initial suffix is attached, shown in (1). Otherwise there is no gemination, shown in (2).

- (1) Root-final Consonant Geminates (SgE and HKE alike)
- |    |    |        |        |     |           |            |
|----|----|--------|--------|-----|-----------|------------|
| a. | i. | [stɒp] | “stop” | ii. | [stɒppiŋ] | “stopping” |
| b. | i. | [put]  | “put”  | ii. | [puttiŋ]  | “putting”  |
- (2) Final Consonant Non-Geminates
- |    |    |        |        |     |          |           |
|----|----|--------|--------|-----|----------|-----------|
| a. | i. | [weit] | “wait” | ii. | [weitiŋ] | “waiting” |
| b. | i. | [paip] | “pipe” | ii. | [paipiŋ] | “piping”  |

The case in (1) is not unique to SgE and HKE. Such hetero-syllabic gemination is also found in Standard English (Hammond 1997). The words in (2) do not apply to SgE because in SgE, these words have short vowels. The standard analysis for such gemination is that the V-initial suffix desires an Onset (triggered by the universal ONSET constraint) while the preceding syllable desires bimoraicity that can only be satisfied if a

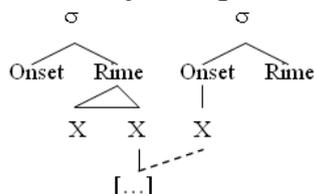

---

<sup>1</sup> This work is supported by FRG/06-07/I-33. This paper is a modified version of Wee (to appear) which concentrates on HKE. The present paper brings SgE into the mix.

The author is grateful to the audience at CIL-18, especially Adam Albright, Bruce Hayes and James Myers for their insightful comments. Remaining errors mine.

short vowel is either followed by a coda consonant or else the vowel must undergo compensatory lengthening (Hayes 1989). In any case, gemination in (1) is understood as spreading, presented in (3).

(3) ONSET-triggered Consonant Spreading

Given (3), it becomes clear that to show that in SgE or HKE a consonant C splits in gemination if in the environment  $V_{\text{short}} \_ +V$ , the singular C surfaces as two distinct segments. Such a split is problematic for a representation like (3).<sup>2</sup>

In (3), the two Xs are linked to the same melody and hence cannot be distinct, contrary to what is needed for a split in the gemination. Split gemination is thus problematic for any theory that is based on such a representation. This paper proposes a possible way out of this problem.

Demonstrating that split-gemination exists is not the only difficulty. New Englishes such as SgE and HKE are hard to define since they typically range from basilectal varieties to acrolectal ones. Also, there are usually many languages involved. SgE for example, is variously considered to have been the combined influences of Standard English, Malay and various Chinese languages (Platt 1975; Lim 1996; Bao and Wee 1999; Goh 2002; Ng 2004; Bao and Hong 2006 among many others). In the investigation of new Englishes, one should be wary of making unqualified assumptions that any English-sounding item would automatically correspond with the English source (Mohanani 1992). For example, unless supported by evidence, it is imprudent to assume that “help” pronounced [heup] in SgE is underlyingly identical to RP /help/; it could have been /heup/ in SgE.

For current purposes, it is unnecessary to define SgE or HKE beyond the loose sense of what any familiar listener can identify as English spoken in Singapore or Hong Kong. The SgE and HKE data reported here comes from the author’s field research in the two cities, mostly over the last 2 years. For the most part, the investigator situates himself in some inconspicuous spot and make notes of what he hears in real everyday life speech of a large number of people. From these notes, a set of test words is constructed for data solicitation from willing informants of both genders, within the 18-35 age range. In so doing, the author presents only the notable and consistent features of the languages investigated.

<sup>2</sup> One way to avoid such a split is to think of it as phonological fission of /l/ which has two parts: an underlying [dorsal] feature and a [lateral] feature (for phonetic evidence, see Sproat and Fujimura 1993). However, the fission account falsely predicts that [-wl-] should appear in when CV prefixes to L-initial stems. Consonants at stem-initial positions do not geminate when CV is prefixed, but if [-wl-] is treated as fission, one would not have any devices left to prevent such [-wl-] from surfacing stem-initially. In short, though /l/ may have a [dorsal] feature, it must be treated like all other consonants in terms of where [-wl-] occurs, making the fission account unviable.

Section 2 demonstrates that split-gemination does occur in HKE and SgE, with respect to /l/. Section 3 provides a theoretical framework within which a solution is formulated in section 4. Section 5 concludes the paper.

## 2. From coda /l/ to split-L in SgE and HKE

This section lays out the context within which one can see that /l/ in SgE and HKE undergoes hetero-syllabic split gemination. To begin, it is noteworthy that /l/ vocalizes in the coda, exemplified here with some data from Hong Kong English (HKE).

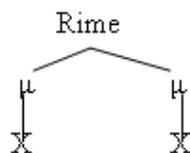

- (4) /l/ → [w] / (coda \_\_)
- |    |    |         |         |     |           |           |
|----|----|---------|---------|-----|-----------|-----------|
| a. | i. | [smaɪw] | “smile” | ii. | [smaɪliŋ] | “smiling” |
| b. | i. | [peɪw]  | “pale”  | ii. | [peɪliʃ]  | “palish”  |

This situation is also found in Malaysian, Estuary (Alterndorf 2003) and Adelaide Englishes (Borowsky 2001). The case for /l/ vocalization in modern SgE is less straightforward, though hints may be found in words like “help”, “milk”, “feel”, etc where the Standard English variety has /l/ in coda. In all these words, the SgE pronounces the <l> as [w]. To see /l/ vocalization in SgE, consider pairs like “smile~smiling”, “feel~feeling” and their SgE variations.

- (5) Two dialects in SgE
- |    | SgE   |        | Dialect A | Dialect B  |
|----|-------|--------|-----------|------------|
| a. | smile | [smaw] | smiling   | [smaw.liŋ] |
| b. | feel  | [fiw]  | feeling   | [fi:.liŋ]  |

One obvious difference between SgE and HKE is that in SgE words, the number of segments in the rime is limited to two, whereas HKE would allow up to three as in HKE [smaɪw]. The two-segment limit of SgE is true only for words where /l/ is involved morpheme-finally (in (2) for example, SgE would allow tri-segmental rimes). What one sees here is that there is a match between the number of morae and the number of segments for cases where there is a final /l/, (6).

- (6) Mora-Segment Match in SgE Rime involving final /l/

HKE does not adhere to (6) strictly since “smile” is [smaɪw] where there are three segments in the time. However, (6) does have an impact on HKE as can be seen in the syllabification of “smiling” in HKE as [smaɪ.liŋ] where the initial syllable no longer contains the [w]. Such an effect is easily accounted for in an Optimality Theoretic framework where the unmarked Mora-Segment Match emerges differently depending

on how it is ranked with respect to faithfulness (for this characteristic of OT, see McCarthy and Prince 1994).

Returning to (5), Dialects A and B are similar in unsuffixed forms, but differ when a vowel-initial is attached. In Dialect B one can see the [w~l] alternation, similar to HKE in (4) except for compensatory lengthening of the vowel in the root. So, it is reasonable to assume that an account for Dialect B would be along the following lines.

(7) Derivation in Dialect B

		/fɪl/	/fɪl + ɪŋ/
Step 1	Syllabification	fɪl	fɪ.liŋ
Step 2	Compensatory lengthening	-	fɪ:liŋ
Step 3	L-vocalization	fiw	-
	Output	[fiw]	[fi:liŋ]

Technically, it isn't so obvious if Steps 2 and 3 are to be ordered, but this is immaterial for the present discussion. In any case, it should be clear that Compensatory lengthening in Step 2 is motivated by demands for the syllable to be bimoraic.

Given this derivation, Dialect B speakers are also likely to take the words in (1) and produce them with vowel lengthening rather than with consonant gemination. This much seems to be supported by my observations, though more reliable statistics would require extensive investigation. Circumstantial evidence thus suggests that for the speaker of Dialect A, the underlying form would have a final /l/ without any preceding /w/. This is also supported by my field observations that many such speakers actually believed they have pronounced an [l] rather than a [w] as the final segment in “bill”, and that the pronunciation is different from that in “beau”. In fact, SgE speakers pronounce both words identically as [biw]. It is only when asked to compare the two utterances that most speakers eventually notice the similarity.<sup>3</sup>

If the explanation given in the preceding paragraphs is correct, then “smile” has moved from RP /smaɪl/ to SgE /smal/ by virtue of (6), and by virtue of the alternation rule in (4) /l/ → [w] to yield SgE “smile” as [smaw]. A picture on the correspondence between the UR forms of RP rimes and the UR forms SgE rimes is provided in (8).<sup>4</sup>

(8) UR of SgE rimes and RP sources

Rime RP source	Rime SgE (UR)	Example
/VC/	/VC/	“bill”
/VVC/	/VVC/	“pipe”, “wait”, “line”
/V:C/	/VC/	“beat”, “peep”
/VVL/	/VL/	“feel”, “smile”

Though (8) is not directly relevant to our understanding of hetero-syllabic split-gemination, the systematicity of the correspondence between RP and SgE (probably a

<sup>3</sup> It is possible to do this because almost all Singaporeans learnt English in school and can spell. Though the effect could have come from influence of “spelling”, the point nonetheless remains.

<sup>4</sup> For simplicity, I have deliberately left out discussions on coda consonant clusters in words like “last”. Such words do not participate in hetero-syllabic gemination anyway.

kind of historical change) shows that SgE patterns exactly like HKE with respect to gemination given the right UR forms.

Like HKE, SgE words with coda /l/ would vocalize into [w] when parsed into the coda. If one recalls the data in (4), one can similarly conclude that [l] and [w] are allophones in HKE at least for words like “smile”. If one further recalls the patterns of hetero-syllabic gemination of consonants in (1), things get interesting. The logical conclusion must be that the words in (9) below must contain a split geminate /l/.

- (9) Split-L Gemination (SgE and HKE alike)
- |    |    |       |        |     |           |           |
|----|----|-------|--------|-----|-----------|-----------|
| a. | i. | [piw] | “peel” | ii. | [piwliŋ]  | “peeling” |
| b. | i. | [hew] | “hell” | ii. | [hewliŋ]  | “hellish” |
| c. | i. | [kaw] | “cull” | ii. | [kaw.liŋ] | “culling” |

The split gemination of /l/ can be understood derivationally as in (10).

- (10) Comparing the Morpheme-final L with Morpheme-final C
- |           |   |                   |   |              |
|-----------|---|-------------------|---|--------------|
| /stɒp+iŋ/ | → | stɒp.piŋ          |   |              |
| /fil+iŋ/  | → | fil+liŋ           | → | fiw.liŋ      |
|           |   | <i>gemination</i> |   | <i>L-voc</i> |

The split-L geminate challenges the standard conception of spreading where two segments are associated to the same set of features. For /l/ to be both [l] and [w] at the same time is paradoxical.

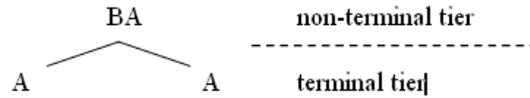

### 3. Inter-tier Correspondence Theory

The split-L paradox can in fact be resolved if one takes phonological outputs as structural representations that allow for content information to percolate across nodes via correspondence, (11).

- (11) Inter-tier Correspondence Theory (Wee 2004; Orgun 1996)
- i. Carriage of information  
All nodes (terminal or non-terminal) are information-bearing.
  - ii. Correspondence of information  
There is a correspondence of the information content between nodes that stand in immediate domination.
  - iii. Violability of correspondence  
Correspondence of information between nodes is not necessarily perfect.

With the setup in (11), the Inter-tier Correspondence Theory (ICT) stands phonological representations on their heads in that terminal nodes are now exactly identical to underlying (input) strings. What is traditionally construed as the phonetic output is now the entire representation with the root node looking identical to the traditional notion of surface strings. To illustrate consider a hypothetical language where /A+A/ → [BA]. In ICT, this would be represented as (12):

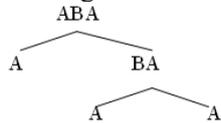

(12)

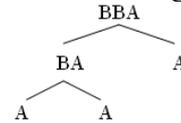

As can be seen in (12), it is the constituency of two adjacent A-s that triggers the “unfaithful” correspondence at the root node. To get the effect in (12), a constraint that favors preservation of information from the right branch would suffice. This can be easily done with positional faithfulness constraints and general faithfulness constraints. The power of ICT can be further illustrated with ternary strings using an additional rule  $CB \rightarrow CD$ , the examples in (13) should suffice:

(13) ICT with reference to Rule-ordering Effects<sup>5</sup>

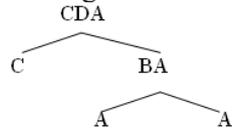

a. Bleeding

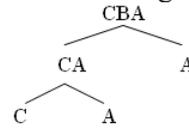

b. Counterbleeding

c. Feeding

d. Counterfeeding

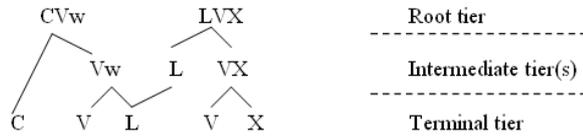

It should be clear from (13) that ICT captures directly the insight that opacity (and for that matter, effects of derivation) is often structurally motivated, something that was built into the levels of Lexical Phonology or the mechanisms of bracket erasures (Mohanam 1986). It further predicts that depending on whether the left-branch or the right-branch is more stable, opaque and transparent derivational effects simply fall out of the way the structure branches. Strictly speaking, there is no derivation in ICT since it is the entire structure and the correspondences of information across nodes that matters, but it would produce effects that pre-OT phonological analyses have described as derivational.

#### 4. Account for Split-L Geminataion

If one accepts the stipulations of ICT, then split-L can simply be represented as (14) where the given input is /CVL+VX/:

<sup>5</sup> The same effects can be achieved with a progressive rule  $AA \rightarrow AB$  coupled with the mirror-images of these structures.

(14) Representing the Split-L in ICT

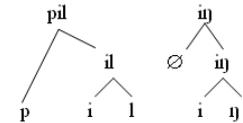

Following ICT, the terminal tier in (14) is identical to the input string /CVL+VX/. This string is then parsed into a structure equivalent to two syllables such that the “L” is doubly associated. Because information corresponds across nodes, higher nodes reconstruct the information of the lower nodes. In (14), there is one unfaithful correspondence: L to [w] in the coda of the first syllable. This unfaithful correspondence is triggered by a constraint that prohibits [l] in the coda of a syllable, which would yield the effect of split gemination.

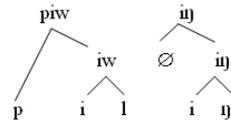

To see how ICT works, consider first a set of possible candidates when given an input such as /pil+iŋ/ “peeling” and /meil+iŋ/ “mailing”.

(15) Candidates for /pil+iŋ/ “peeling”

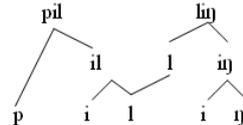

a. Faithful

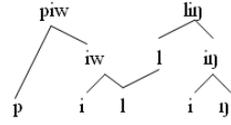

b. Vocalize

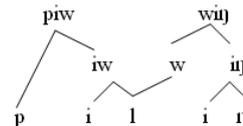

c. Geminate

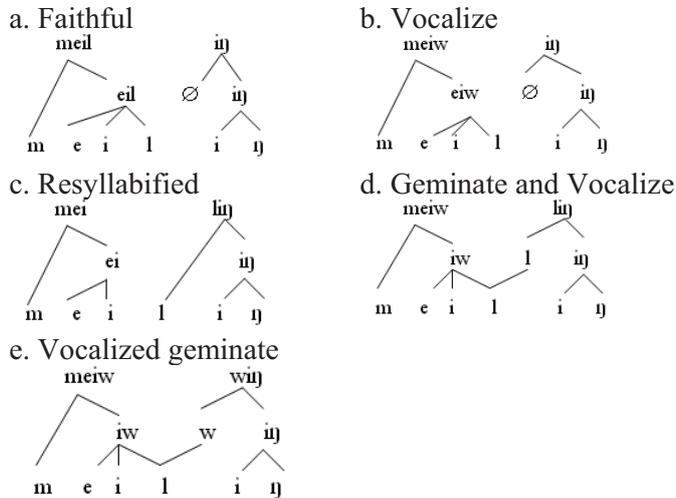

d. Geminate and Vocalize

e. Vocalized Geminates

(16) Candidates for /meil+iŋ/ “mailing” (HKE only)

The above is only a subset of all possible candidates, but that should suffice to illustrate how ICT would correctly predict the split-L gemination. The above candidates vary along various parameters: (i) where the final L is syllabified; (ii) if that L is geminate; and (iii) if correspondent of the L is faithful.

Armed now with the set of candidates, one can evaluate each candidate with respect to the constraints in OT tableaux in (17).

(17) ICT account of Split-L<sup>6</sup>

\*MULT ASSOC

A node cannot be dominated by more than one node.

INTER-TIER FAITH<sup>7</sup>

Dominating nodes must have identical information with subordinate nodes.

\*L-CODA<sup>8</sup>

[l] is not allowed in the coda.

BI-RIME<sup>9</sup>

The rime contains exactly 2 segments

ONSET

All syllables have onsets.

<sup>6</sup>Doug Pulleyblank (p.c.) suggests a classical OT solution where input /l/ has two correspondences [w<sub>i</sub>] and [l<sub>i</sub>]. This predicts languages that allow long distance split correspondence /X<sub>j</sub>/ corresponds to [Y<sub>j</sub>... Z<sub>j</sub>] by virtue of GEN's capacity, which as far as I know are unattested. ICT restricts such split correspondence to adjacency because cross-branching structures are impossible to GEN. Also, multiple correspondences require different IDENT to apply to each correspondent. These IDENT constraints would have to be positional in nature, which is the insight of ICT. So, while the split correspondence approach could in principle generate the L-voc effects, it overgenerates.

<sup>7</sup>This is really a collection of constraints akin to classical Faithfulness.

<sup>8</sup>Whether or not this is universal is immaterial here, but across languages [l] is often vocalized when in the rime.

<sup>9</sup>BI-RIME is most likely the effect of two constraints involving (i) the birmoraicity of the syllable which is the minimal phonological word and (ii) the biuniqueness correspondence of the mora and the segment.

/pil + ij/	*L-CODA	ONSET	*MULT ASSOC	INTER-TIER FAITH
a. Faithful	*!	*		
b. Vocalize		*!		*
c. Geminate	*!		*	
☞ d. Gem & Voc			*	*
e. Voc'd gem			*	**!

/meil + ij/ (HKE only) <sup>10</sup>	*L-CODA	ONSET	BI-RIME	*MULT ASSOC	INTER-TIER FAITH
a. Faithful	*!	*	*		
b. Vocalize		*!			*
☞ c. Resyllabified					
d. Gem & Voc			*!	*	*
e. Voc'd gem				*!	**

Violation counts in the above tableaux are obtained by evaluating each representation candidate at every node against the constraints. For example, in the faithful candidates (a), /l/ is kept as it is in the corresponding higher tier which constitutes a violation of \*L-CODA at that level. It is important to bear in mind that in ICT representations, adjacency and constituency are clearly different. When the /l/ is at the terminal tier, there is no indication of it being in the coda. That information is only available in the dominating tier when /l/ and the preceding vowel form a constituent.

As may be seen in (17), vocalization is only triggered when /l/ is syllabified into the coda.<sup>11</sup> (Recall that hetero-syllabic gemination is due to the need for syllables to have onsets and to the requirement that HKE and SgE rimes must be bimoraic). This explains why /meil+ij/ in HKE does not have split-L gemination, but /pil+ij/ does for both SgE and HKE. Of crucial importance here is the possibility of “unfaithful” inter-tier correspondence because it is this that allows for the same /l/ to surface differently according to its context (i.e. onset or coda positions).

## 5. Conclusion and Implication

Despite its success in resolving the paradox in split gemination, ICT stand phonological outputs on their heads since information at the terminal tiers would now be identical to the input strings, while the strings at the root node(s) would match the phonetic outputs. However, ICT derives for us the effect that depth of derivations is directly proportionate to depth of structural embeddings (cf. (13)). Further, it captures the insight that

<sup>10</sup> The UR for “mail” in SgE is very likely to be /mel/, which surfaces as [meu].

<sup>11</sup> Donca Steriade (p.c.) pointed out that in attributing the geminate and vocalization combination to resyllabification, there must be either (i) no morpheme-internal geminates in words like *silly*, *vanilla* or *dilly-dally* or (ii) these geminates, which do not stem from resyllabification, function differently. In SgE and HKE, *silly* is [si:li:], *vanilla* [wan.lei.la:] and *dilly dally* [di:.li:.de:.li:].

phonological alternations can only be triggered by constituency and not mere adjacency. These two observations have always been taken implicitly. When put this way, the representations generated by ICT are perhaps not as weird as may seem at first blush. In fact, they offer us new possibilities for exploring derivational effects (in particular opaque ones) that plagued much of modern OT.

# Understanding VOT Variation in Spontaneous Speech

yaoyao@berkeley.edu

## Abstract

This paper reports a corpus study on the variation of VOT in voiceless stops in spontaneous speech. Two speakers' data from the Buckeye corpus are used: one is an older female speaker with a low speaking rate while the other is a younger male speaker with an extremely high speaking rate. Linear regression analysis shows that place of articulation, word frequency, phonetic context, speech rate and utterance position all have an effect on the length of VOT. However, altogether less than 20% of the variation is explained in both speakers, which suggests that pronunciation variation in spontaneous speech is a highly complicated phenomenon which might need more sophisticated modeling. Our results also show a great deal of individual differences.

**Keywords:** VOT variation, spontaneous speech, corpus study.

## 1. Background

Voice onset time (VOT) is the duration between consonant release and the beginning of the vowel. English voiceless stops (i.e. [p], [t], and [k]) typically have VOT durations of 40ms – 100ms (Forrest et al., 1989; Klatt, 1975; Lisker & Abramson, 1964). In the broad literature on English VOT, it has been shown that VOT varies with a number of factors, including linguistic factors (place of articulation, identity the following vowel and speaking rate), and non-linguistic factors (age, gender and other physiological characteristics of the speaker). In this study, we report a corpus study on VOT variation that takes into consideration the features of the target word and the running context. We use two speaker's naturalistic speech data from interviews, and built separate regression models. Our main goal is to study the effect of lexical and contextual factors on VOT in running speech. The comparison of the two models also reveals individual differences between the two speakers.

The most well-studied factor in VOT variation is place of articulation. It has

been confirmed in various studies that VOT increases when the point of constriction moves from the lips to the velum, both in isolated word reading and read speech (Zue, 1976; Crystal & House, 1988; Byrd, 1993; among others), and this pattern is not limited to the English language (Cho & Ladefoged, 1999). Speech rate is another conditioning factor. Kessinger and Blumstein (1997, 1998) reported that VOT shortened when speaking rate increases (also see Volaitis & Miller 1992, Allen et al. 2003). It has also been proposed that phonetic context, in particular, the following vowel, has an effect on the length of VOT. Klatt (1975) reported longer VOT before sonorant consonants than before vowels. Klatt also found that voiceless stops typically had longer VOTs when followed by high, close vowels and shorter VOTs when followed by low, open vowels (also see Higgins et al. 1998). In addition, there is also an indirect influence from the following vowel context in that some VOT variation patterns are only observed in certain vowel environments (Neiman et al. 1983; Whiteside et al. 2004).

A different line of research on VOT variation focuses on non-linguistic factors. Whiteside & Irving (1998) studied 36 isolated words spoken by 5 men and 5 women, all in their twenties or thirties, and showed that the female speakers had on average longer VOT than the male speakers. The pattern was confirmed in several other studies (Ryalls et al. 1997; Koenig, 2000; Whiteside & Marshall 2001). Age has also been suggested as a conditioning factor of VOT. Ryalls et al. (1997, 2004) found that older speakers have shorter VOTs than younger speakers, though their syllables have longer durations. A tentative explanation is that older speakers have smaller lung volumes and therefore produce shorter periods of aspiration (see also Hoit et al., 1993). However, no age effect is found in some other studies (Neiman et al., 1983; Petrosino et al., 1993). Other non-linguistic factors that have been studied include ethnic background (Ryalls et al. 1997), dialectal background (Schmidt and Flege, 1996; Syrdal, 1996), presence of speech disorders (Baum & Ryan, 1993; Ryalls et al 1999), and the setting of the experiments (Robb et al., 2005). Last but not least, at least part of the VOT variation is due to idiosyncratic articulatory habits of the speaker. Allen et al's (2003) study shows that after factoring out the effect of speaking rate, the speakers still have different VOTs, though the differences are attenuated.

Despite the large size of the literature on VOT, most of the existing studies use experimental data from single-word productions and therefore typically have a limited set of target syllables and phonetic contexts. (The only two exceptions are Crystal & House [1988] and Byrd [1993], both of which used read speech data from speech corpora.) However, what happens in unplanned spontaneous speech? We know that speakers have more VOT variability in directed conversation than in single-word

productions (Lisker & Abramson, 1967; Baran et al., 1977). But does that mean that the conditioning factors are largely the same, only with aggrandized effects or that additional factors are at play? More importantly, what is the general pattern of variation when all factors are present? The current study is a first attempt to address these questions. We use naturalistic data from interviews and build models of VOT variation with features of the word and the running contexts. The features we consider have been suggested in the literature to affect either VOT (such as place of articulation, phonetic context and speaking rate) or pronunciation variation in spontaneous speech in general (such as word frequency and utterance position).

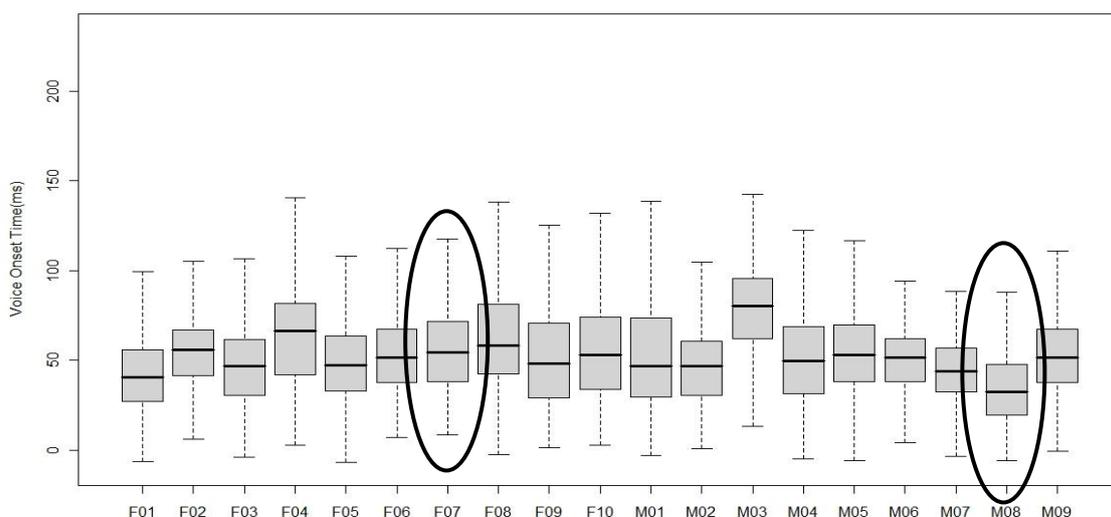

## **2. Methodology**

### **2.1. Data**

The data we use are from the Buckeye Corpus (Pitt et al., 2007), which contains interview recordings from 40 speakers, all local residents of Columbus, OH. Each speaker was interviewed for about an hour with one interviewer. Only the interviewee's speech was digitally recorded in a quiet room with a close-talking head-mounted microphone. At the time of this study, 19 of the 40 speakers' data were available. (In fact, 20 speakers' transcripts were available, but one speaker's data were excluded due to inconsistency in the transcription.) For this study, two of the 19 speakers' data are used. These two speakers, s20 (recoded as F07 in the current study) and s32 (recoded as M08), were selected because they differed from each other in all possible dimensions. F07 is an older female speaker with the lowest speaking rate among all 19 speakers (4.022 syll/s) while M08 is a young male speaker with the highest speaking rate (6.434 syll/s).

Since word-medial stops are often flapped in American English, we limited the dataset to word-initial position only. Speaker F07 has 231 word-initial voiceless stops and speaker M08 has 618 such tokens. An automatic burst detection program was used to find the point of release in each token. More than 57% (N=492) of the tokens were manually checked, and the error was under 3.5ms. 105 tokens (7 of F07 and 98 of M08) were excluded since the automatic program failed to find a reliable point of release in these stop tokens, due to either no closure-release transition or extraordinary multiple releases. (For a detailed discussion on the automatic burst detection program, please see Yao, 2008 in the same volume.) The average VOT of F07 is 57.41ms, with

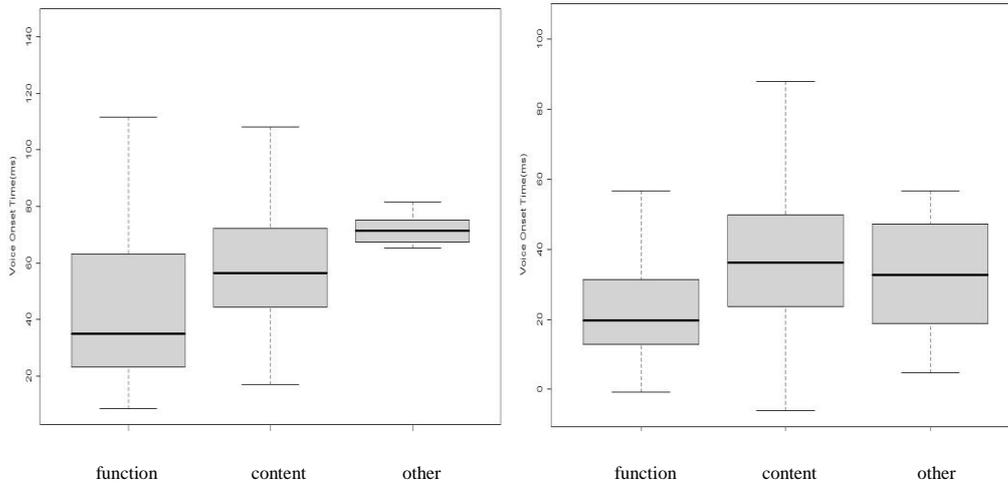

a standard deviation of 26.00ms, while M08's average VOT is 34.86ms, with a standard deviation of 19.82ms. In fact, as shown in Figure 2, M08 has the shorter average VOT of all 19 speakers. The large difference in VOT between the two speakers (~23ms) is probably due to the fact that M08 speaks much faster than F07 in general. Both speakers' VOT values show a great deal of variation (standard deviation > 19ms in both speakers), which will be the focus of the analysis in the rest of the paper.

**Figure 1.** Average VOT of all 19 speakers (F07's and M08's data are circled)

In order to test the effect of surrounding phonetic context, we excluded utterance-initial tokens (14 from F07 and 54 from M08), since the preceding context was not speech sound in these cases. This leaves speaker F07 with 210 tokens and speaker M08 with 466 tokens.

It has been suggested in the literature that content words and function words are processed differently (see Bell et al, to appear and the references in it). In our data, function words have shorter VOTs than content words in both speakers' data (see Figure 2), and the effect still remains after word frequency is controlled for. Since content words comprise the majority of the target tokens (see Table 1), we decided to model the variation of VOT in content words only. Thus, in the final dataset, speaker F07 has 155 tokens and M08 has 346.

**Figure 2.** Average VOT by word class in F07 ( left) and M08 (right)

	<b>Content</b>	<b>Function</b>	<b>Other</b>
<b>F07</b>	155	47	8
<b>M08</b>	346	104	16

**Table 1.** Token counts by word class

### 2.3. Regression model

Linear regression is used to predict the length of VOT in each stop token in the final dataset. Two speakers' data are modeled independently, using the same method. The independent variables that are considered are place of articulation (POA), word frequency, phonetic context, speech rate and utterance position. All predictor variables are added to the model sequentially (in the above order). Adjusted  $R^2$ , a model parameter that indicates how much variation is explained, is used to evaluate model performance. The general principle of modeling is that a predictor variable will stay in the model if  $R^2$  is improved significantly. Thus the results that are reported below should be understood as the difference in model performance after adding the current variable, on top of all previously added variables. For some variables, more than one measure is tested and the most significant one is kept in the model.

### 3. Results

#### 3.1. Effect of POA

The first variable added to the regression model is place of articulation. Various studies have confirmed that VOT in voiceless stops increases as the place of articulation moves backwards, from the lips to the velum. However, this trend is only observed in one of the two speakers in the current study. In speaker F07's data, POA doesn't turn out to be a significant factor for predicting VOT ( $p=0.216$ ), and doesn't explain any variation at all ( $R^2=0$ ). Moreover, the average VOT of [p], [t], and [k] doesn't follow the pattern of increasing VOT in more backward stops ([p]=68.56ms; [t]= 61.56ms; [k]= 68.40ms). For speaker M08, on the hand, POA is an important predictor for VOT ( $p<0.001$ ), with [p] having the shortest VOT (33.14 ms), followed by [t] (44.20 ms) and [k] (47.68 ms), which is consistent with the pattern reported in the literature. POA alone explains about 9.2% of the variation in VOT in M08's data. Figure 3 shows the average VOT of the three stop categories in two speakers. Despite the fact that POA only appears to be a significant predictor in one speaker's data, we decided to keep it in both speakers' models, mostly because it has been claimed to have an important effect on VOT in the literature and it is possible that the effect will show up in the interaction with other predictor variables.

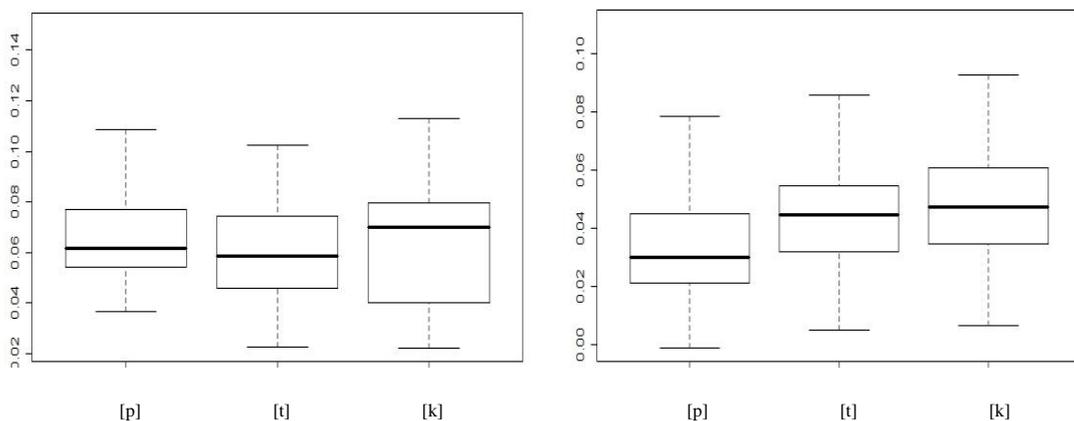

Figure 3. Average VOT by stop category in F07 (left) and M08 (right)

#### 3.2. Effect of word frequency

Word frequency is one of the most well-documented factors on pronunciation variation in spontaneous speech. Frequent words have shorter durations and are more

susceptible to various lenition processes, such as vowel reduction, tapping and palatalization, consonant deletion, etc. (Fidelholz, 1975; Fosler-Lussier and Morgan, 1999; Bybee, 2000; Bell et al., 2003, to appear; Pluymaekers et al., 2005; among others). However, to our knowledge, the effect of word frequency on VOT in connected speech hasn't been investigated yet.

In the current study, two types of frequency measures are examined: one is the log of the word frequency in the CELEX database (Baayen et al., 1995), the other is the log of the word frequency calculated from the Buckeye corpus over all speakers. Not surprisingly, the two measures are highly correlated ( $r=0.826$ ). In both speakers' data, the Buckeye frequency is a better predictor of VOT than the CELEX frequency (see Table 2). Adding the Buckeye word frequency to the model improves the performance by 1.7% in speaker F07 and 0.4% in speaker M08. In both models, there is a negative relation between word frequency and VOT, i.e. more frequent words have shorter VOTs. But the effect is not very strong, as shown in the relatively small change in  $R^2$ .

	Previous $R^2$ (%)	Term added	New $R^2$ (%)
<b>F07</b>	0	Celex frequency	1.3
		Buckeye frequency	1.7
<b>M08</b>	9.2	Celex frequency	9.4
		Buckeye frequency	9.6

**Table 2.** Change in model performance after adding word frequency

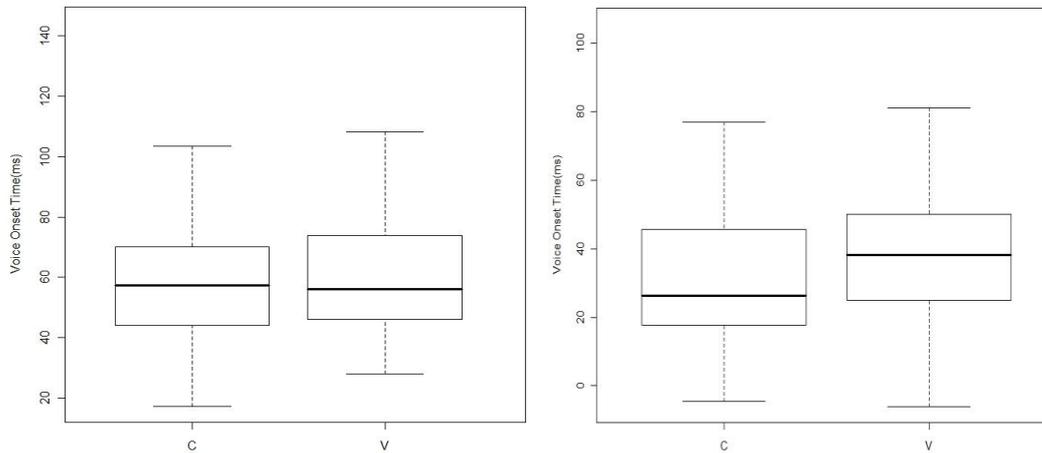

### 3.3. Effect of phonetic context

For studying the effect of phonetic context, we coded each token for whether the preceding/following phone is a consonant or a vowel. Interestingly, in speaker F07's data, only the preceding phone contributes to the prediction of VOT ( $R^2$  increases by 0.2%), but not the following one ( $R^2$  decreases by 1.1%); in speaker M08's data, it is the following phone that predicts VOT ( $R^2$  increases by 0.48%), but not the preceding one ( $R^2$  decreases by 0.33%) (see Table 3). In both speakers' models, however, the category of the preceding/following phone is not a strong factor in VOT variation (see Figure 4).

	Previous $R^2$ (%)	Term added	New $R^2$ (%)
<b>F07</b>	1.7	Category of the preceding phone	1.9
		Category of the following phone	0.6

<b>M08</b>	9.6	Category of the preceding phone	9.27
		Category of the following phone	10.08

**Table 3.** Change in model performance after adding phonetic context

**Figure 4.** Effect of phonetic context (left: average VOT by category of the preceding phone in F07; right: average VOT by category of the following phone in M08)

### 3.4. Effect of speech rate

Speech rate is intuitively easy to understand, but hard to measure in practice. Previous studies on the effect of speech rate have been predominantly using the number of syllables produced per second in the local pause-bounded stretch as a measure of the contextual speech rate. In this study, in addition to the stretch speed measure, two more local speed measures are also tested: duration of the next phone (in ms), and the average speed of the three-word chunk centered at the target word (in number of syllables per second).

In both speakers' regression models, all three speed measures improve the performance of the model, predicting that the faster the speech is, the shorter the VOT. However, among the three measures, the average speed of the three-word chunk, is the best VOT predictor in speaker F07's model ( $R^2$  increases by 9.9%), whereas in speaker M08's model, the most local one, i.e. the duration of the next phone, predicts VOT the best ( $R^2$  increases by 6.54%) (see Table 4). Curiously, the most often used speed measure, i.e. average speed of the local stretch, doesn't turn out to be the best speed predictor for VOT in either speaker's model. One might argue that this is at least partly because the calculation of both 3-word-chunk speed and local stretch speed

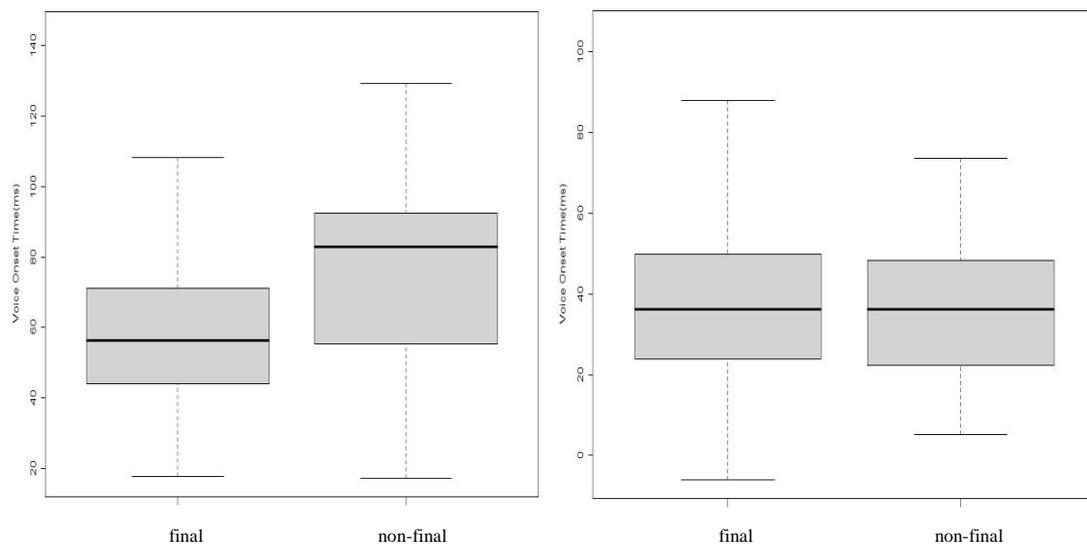

already include the target word (and hence also the predicted VOT) and this inherent correlation is higher in the more local speed measure, which makes it a seemingly better predictor. We agree that a better way to calculate these speed measures is to exclude the target word from the calculation to eliminate the inherent correlation. However, it should also be noted that even with the current calculation, 3-word-chunk speed is not necessarily a better predictor than local stretch speed (as in M08's model), which suggests that despite the different degrees of inherent correlation with VOT, the two speed measures do seem to be measuring different contexts.

	Previous R <sup>2</sup> (%)	Term added	New R <sup>2</sup> (%)
<b>F07</b>	1.9	Duration of the next phone	5.1
		Average speed of the local 3-word chunk	11.8
		Average speed of the local stretch	7.1
<b>M08</b>	10.08	Duration of the next phone	16.62
		Average speed of the local 3-word chunk	12.85
		Average speed of the local stretch	15.07

**Table 4.** Change in model performance after adding speed measures

### 3.5. *Effect of utterance position*

In order to test the effect of utterance position (mostly in the form of utterance final lengthening), each token is coded for whether the immediately following word is silence. Altogether 9 out of the 155 tokens in F07's data and 34 out of 312 in M08's data are coded as followed by pause, i.e. utterance-final. As shown in Figure 5, for speaker F07, utterance-final tokens have significantly longer VOT than utterance-medial tokens, whereas for speaker M08, the two categories have similar average VOTs. Not surprisingly, adding this variable to the regression model improves the performance by 7.31% in F07's model, but decreases it by 3.13% in M08's model (see Table 5).

**Figure 5.** Average VOT of utterance-final and non-utterance-final tokens in F07 (left) and M08 (right)

	Previous R <sup>2</sup> (%)	New R <sup>2</sup> (%)
<b>F07</b>	11.8	19.11
<b>M08</b>	16.62	13.31

**Table 5.** Change in model performance after adding utterance position

### 3.6. Overall performance of the model

Speaker F07’s final regression model has the following five variables: place of articulation, Buckeye word frequency, category of the previous phone, average speed of the three-word chunk centered at the target word, and utterance position. On the other hand, speaker M08’s model ends up with four variables, place of articulation, Buckeye word frequency, category of the following phone, and duration of the following phone. The performance of the models after adding each variable is summarized in Table 6. In the final stage, speaker F07’s model is able to account for 19.11% of the overall variation in VOT while speaker M08’s model is able to account for 16.62% of the variation. In F07’s model, the biggest increase in model performance happens when speech rate and utterance position are added; in M08’s model, it happens when place of articulation and speech rate are added.

	Terms added	R <sup>2</sup> (%)
<b>F07</b>	Place of articulation	0
	Buckeye word frequency	1.7
	Category of the previous phone	1.9

	Average speed of the local 3-word chunk	11.8
	Utterance position	19.11
<b>M08</b>	Place of articulation	9.2
	Buckeye word frequency	9.6
	Category of the following	10.08
	phoneDuration of the next phone	16.62

**Table 6.** Summary of model performance of speaker F07 and M08

#### 4. Discussion

In this study, we use naturalistic data from two speakers to model the variation of VOT in word-initial voiceless stops. The factors that are considered include place of articulation, word frequency, phonetic context, speech rate and utterance position. Overall, the following trends are observed, in at least one speaker's model: (a) VOT increases as the place of articulation moves from the lips to the velum; (b) higher frequency words have shorter VOT than lower frequency words, though the effect is not very strong; (c) when preceded by a vowel, VOT is shorter, and when followed by a vowel, VOT is longer, though the effect is weak; (d) in faster speech, VOT is shorter; (e) utterance-final stops have longer VOT.

The most interesting finding in the current study is that place of articulation is only shown to affect VOT in one speaker's model, but not in the other, though it has been claimed as an important conditioning factor of VOT in the literature. However, this doesn't mean that our results contest the canonical view, instead, our results show that in spontaneous speech, the VOT distinction among three stop categories can be overshadowed by other factors at play. In other words, for some speakers, the VOT distinction among [p], [t], and [k] is not strong enough to always be maintained. Our study also shows that word frequency, though widely reported as an important factor in pronunciation variation, doesn't have strong influence on VOT. In both speakers' model, there is a weak effect of word frequency that predicts shorter VOTs in higher-frequency words.

Speech rate is the only variable that has a strong effect on VOT in both speakers' models. Interestingly, the two speakers are shown to be sensitive to different speed measures. M08's data are best predicted by the most local speed measure, i.e. the duration of the following phone, while F07's data are best predicted by the medium local measure, i.e. the speed of the surrounding three-word chunk.

Even though we only examined two speakers' speech in the current study, they already show a wide range of individual differences. It is possible to attribute the differences to age and gender, since the older female speaker (F07) does have longer VOT than the young male speaker (M08), which is consistent with the results in the current literature. However, we think that a more important reason for the VOT difference is speech rate. As mentioned above, speaker F07 has the lowest average speech rate among all 19 speakers, and M08 has the highest, exceeding that of F07 by about 60%. In addition, our results also reveal individual differences in the variation pattern of VOT that can hardly be attributed to unknown differences in speech style. For one thing, speaker M08 shows a clear pattern of bilabial stops having the shortest VOT and velar stops having the longest one while in speaker F07's data, this pattern is not observed. It is not clear whether speaker F07 has no such distinction even in isolated word production, or the distinction is overshadowed by the various factors that are at play in spontaneous speech. In addition, utterance position is found to condition VOT values in F07, but not in M08, which indicates that the slower speaker slows down in utterance-final position while the fast speaker doesn't. This suggests that in addition to average speech rate, the variation in speech rate can also be an indicator of individual differences in speech style.

Altogether the model is only able to explain less than 20% of the variation in the data. One way to improve this model is to add more predictor variables. The literature on VOT and pronunciation variation has suggested a number of other factors that could potentially explain some of the remaining variation. These factors include contextual probability, prosody, the identity of the following vowel/consonant, neighborhood density and so on. (Note that disfluency is another factor that's not reported here. In fact, we did code cases for following disfluency, including (un)filled pauses and single word repetition, but the resulting division is very similar to that by utterance position.) It is possible that when these factors are considered, the performance of the model will be improved.

The other way to improve the performance is to use a different type of statistical model. As we know, linear regression models are limited to modeling linear relationship between the dependent variable and the independent variables. Therefore, it is inherently unable to model non-linear or non-homogeneous effects, which might exist in the VOT variation phenomenon. In addition, since all independent variables are internally coded as continuous variables, linear regression models also have difficulty in modeling the effect of categorical variables with more than two levels. Thus using a more general regression model might help explain more of the variation of

VOT in spontaneous speech.

## 5. Concluding remarks

In this study, we present a first attempt to understand VOT variation in voiceless stops in spontaneous speech, and in particular, its relation with characteristics of the target word and the running context. Our results show that previously proposed factors, such as place of articulation and phonetic context, are still at play in spontaneous speech but the effect might be attenuated by the presence of other factors. We also show that lexical features, such as word class and word frequency, as well as contextual factors, such as speaking rate and utterance position, also have an effect on VOT, though the size of the effect is subject to individual differences. Finally, the overall low percentage of variation predicted by the linear regression model (despite the fact that we already excluded possibly non-homogeneous data) suggests that the actual variation pattern in spontaneous speech is highly complicated. In order to better model the variation phenomenon, more factors need to be considered and it might be necessary to use more complicated statistical tools.

## Abstract

Although it is generally acknowledged that there must be a non-trivial relationship between music and speech, not enough studies are available to elucidate the interface between these two areas of human cognition (Lerdahl & Jackendoff 1983, Kiparsky 2006). In this context, linguistic chants in cross-linguistic studies provide an invaluable window through which one can investigate the nature of the prosodic structure of a language as well as the musical constraints that are established through an available repertoire of chants. This paper addresses both the musical and linguistic aspects of vocative chant. We first identify conflicts that arise in the melodic and rhythmic realizations in typologically diverse languages, and then argue that the ways these conflicts are resolved are not arbitrary, but are systematically related to the kind of prosodic system that each language manifests.

**Keywords:** vocative chant, music, speech, prosody.

## 1. Introduction

Although it is generally acknowledged that there must be a non-trivial relationship between music and speech, not enough studies are available to elucidate the interface between these two areas of human cognition (Lerdahl and Jackendoff 1983, Kiparsky 2006). In this context, linguistic chants in cross-linguistic studies provide an invaluable window through which one can investigate the nature of the prosodic structure of a language as well as the musical constraints found therein.

It is often noted that there is a hierarchy of melodic forms that “from the least formalized (normal speech intonation) to the most formalized (accompanied singing)” (Gardiner, via Ladd 1978: 525), with the intermediate forms being those that are utilized by rap musicians, talking blues performers, street vendors, auctioneers, train conductors, etc. Even at the most formalized end of the hierarchy, music and language intersect,

albeit in an extremely constrained manner.

For instance, the matching between linguistic tone and musical melody in tonal languages is not random but quite systematic. In the Cantonese opera, the linguistic tones of the text serve in effect as a form of musical notation in the absence of conventional western-style notation; an actual performance is constructed through the mental compositional process of matching linguistic tones with a somewhat limited repertoire of available tunes provided by each performer (Yung 1991). For Mandarin folksongs, Wee (2002) demonstrates how the preservation of contrasts is accomplished between two distinct elements of prominence in music and language. The conflicts that arise when linguistic tone is articulated in the context of a prescribed musical melody are resolved by preserving the tonal integrity of the head syllable, whereas the conflicts in non-head syllables are tolerated and disambiguated by syntactic and semantic cues. Similarly, the intonation patterns of normal speech have been successfully described by means of aligning a sequence of H and L pitch contours with segmental material (Pierrehumbert & Beckman 1988), although in speech the tones are not sustained (or terraced) throughout the syllables that bear a certain pitch as they are in music. In addition, the intonation contours of normal speech are characterized by rhythmic organizations that we often associate with music.

There is a growing body of literature on *vocative chant* (henceforth, VC), where level pitches and durational specifications of stylized intonation clearly beg for interpretations that are both musically and linguistically based. VC refers to a set of tunes for calling people, often from a distance. It is also known as the “calling contour” of Gibbon (1976), the “stylized fall (associated with routineness)” of Ladd (1978, 1996), and the “chanted call” of Hayes & Lahiri (1992) and Gussenhoven (1993).

Most research on vocative chant has been focused on European languages. However, during the past decade or so, important cross-linguistic generalizations have emerged through the studies of vocative chant, concerning the nature of the tunes and the role of lexical and musical prominence. For example, Ladd (1978, 1996) associates a stepping-down sequence of two level tones with the semantic implication of “stereotyped,” “stylized,” and “routine,” rather than to the calling per se.

One of the most salient linguistic characteristics of this sequence is a highly exaggerated voice quality, melody and rhythm. Another significant linguistic generalization, first noted by Leben (1976), is the tendency of the English VC to change pitch only on rhythmically strong syllables, while other chants are less musically constrained and are often characterized by sparsely structured rhythmic patterns and melodies.

In what follows, we will discuss both the musical and linguistic aspects of VC. We will identify conflicts that arise in the melodic and rhythmic realizations in typologically diverse languages, and argue that the ways these conflicts are resolved are not arbitrary, but are systematically related to the kind of prosodic system that each language manifests.

## 2. Melodic realization in vocative chant

Linguistic information related to prominence provides crucial constraints on the melodic realization of VC. In particular, there is a strong tendency to preserve underlying linguistic prominence in VC melody, whether the prominence is derived by the foot structure or tonal structure (Cho & Saiki Forthcoming, 2007).

### 2.1. Language with lexical stress

In English and German, whose phonology is characterized with the distinctive stress system, the accentual H tone (H\*) is associated with the most salient syllable in the metrical structure in their VC, as illustrated in (1) and (2).

#### (1) English

segments: 'Name, where are you?'

VC melody: (L)H\*M L H\* M

a. A-mán-da	b. Vic-tó-ri-a	c. Jó-ohn	d. Jó-na-than	e. Jóh-nny
	\ /		\ /	
L H* M	L H* M	H* M	H* M	H* M

#### (2) German

segments: 'Name, wo bist du?'

VC melody: (L)H\*M L H\* M

a. And-ré-as	b. Mat-thí-as	c. Héi-ko	d. Wíl-helm
L H* M	L H* M	H* M	H* M
e. Mar-tí-na	f. Elí-sa-beth	g. Jú-li-a	h. Kérs-tin
		\ /	
L H* M	L H* M	H* M	H* M

In Dutch VC, just like English and German cases, H\* is associated with the main stress (with the strong foot), M is associated with the secondary stress (with the next strong foot), and, if there is no secondary stress, M falls on the final syllable. Moreover, in all three languages, Tones spread to right in VC.

However, according to Gussenhoven (1993), the last syllable always has a separate pitch level (a boundary tone) in VC. This is illustrated in (3), adopted from Gussenhoven (1993), where dotted lines indicate the stepping down of the pitch level.

(3) Dutch

a. -----	b. -----	c. -----
-----	-----	-----
(véduwe-tje)	---	---
‘widow+DIM’	(álma)(nàk-je)	---
	‘almanac+DIM’	(nép)-(álma)(nàk-je)
		‘fake-almanac+DIM’
		(Gussenhoven 1993)

2.2. Language without lexical stress

Contrary to English, German, and Dutch, in Hungarian and French, which do not have any distinctive lexical stress, the H tone occurs in a fixed location in VC. Just as the regular intonational phonology is determined by predictable phrasal mechanisms, the association of the vocative melody is determined by edge-alignment. Association of HM from the left-edge is observed in Hungarian VC, as in (4), while that of HM from the right-edge is for names in French VC, as illustrated in (5).

(4) Hungarian

a. An-na	b. Ka-ta-lin	or	Ka-ta-lin
			\ /
H M	L H M		H M

(5) French

a. Mo-nique	b. Ja-acques	c. Anne-Ma-rie
H M	H M	L H M

Bengali is another language with predictable stress system. The Bengali VC melody is HM, and the word-melody association is mechanical and not sensitive to stress. According to Hayes and Lahiri (1992), there are variants in VC association based on the number of syllables a word in VC bears. That is, for mono-syllabic words, words with two or three syllables, and words with four syllables or longer, one, two, and three variants are observed, respectively, in their melodic association in VC, as schematized in (6).

(6) Bengali VC variants

a. mono-syllabic word :  $\sigma$

/ \  
H M

b. word with two/three syllables :  $\sigma \sigma$

$\sigma \sigma$	or	$\sigma \sigma \sigma$	$\sigma \sigma \sigma$
			/ \
H M		H M	H M

c. word with four syllables or longer :  $\sigma \sigma \sigma \sigma$

$\sigma \sigma \sigma \sigma$	$\sigma \sigma \sigma \sigma$	$\sigma \sigma \sigma \sigma$
	/ \	\ / \ /
H M	H M	H M

2.3. Language with lexical pitch

In pitch-accent languages such as Serbo-Croatian (Inkelas & Zec 1988), Korean (Ko 1999, Cho 2002) and Japanese (Cho & Saiki Forthcoming), underlying prominence tends to be preserved regardless of whether the prominence is derived from the foot

structure or the tonal structure.

The Serbo-Croatian VC melody is (L)H\*M, and the association proceeds from the right-edge. Any underlying H is preserved by linking it with the accented H\* of the VC melody. Rightward spread of H to any toneless moras and default L insertion produce the surface structure.

(7) Serbo-Croatian

underlying:    Gospodjice    Slobodane  
                   |                    \ /  
                   H\*                    H\*

surface:        Gospodjice    Slobodane  
                   \ / |        | \ / |  
                   H M        L H M

(Inkelas and Zec 1988)

Tokyo Japanese and South Kyöngsang Korean provide another instances of VC where distinctive pitch patters are perfectly mirrored in the realization of the VC melody.

In Tokyo Japanese, the VC melody is MH and its association to the lexical pitches proceeds from the right edge from the vocative text. Regardless of the kind of lexical pitches, the vocative suffix and the penultimate mora are assigned the tunes H and M, respectively, and the other lexical pitches are faithfully reflected in the vocative melody, as exemplified in (8a-b).

(8) Tokyo Japanese

segments:    ‘Name (+tyaN), a- so- bo!’ (=Name, let’s play!)

VC melody:    { L } M    H    L    H\* M  
                   { H }

	a. Ma-yu-mi (+tyaN)	b. Ma-ri-ko (+tyaN)
lexical pitch:	L H H H	H* L L L
	\ /	\ /
VC melody:	L M H	H M H

South Kyöngsang Korean, with the distinctive lexical pitch system, shows a similar case as Tokyo Japanese in its association of the text and the melody in VC. In

this language, there are three lexical tone classes on the sequence of a name and the vocative suffix *+ya/a*, i.e., MHM, H\*M, and HHM, and they exhibit a three way distinction in VC melody. In addition, the alignment of the HM is done from the right edge of the word, as illustrated in (9a-b).

(9) South Kyöngsang Korean

segments: ‘Name *+ya/a*, no-ol-ca!’ (=Name+vocative suffix, let’s play!)

VC melody:  $\left. \begin{array}{l} M \ H \\ H^* \ M \\ H \ H \end{array} \right\} M \quad M \ H^* \ M$

	a. Ho-cun +a	b. Søn-suk+a	c. Kuk-wən+a
lexical pitch:	M H M	H* M M	H H M
		\ /	\ /
VC melody:	M H M	H* M	H M

2.4. Language without lexical pitch

Fukui Japanese and Seoul Korean are among the languages without lexical pitch distinction.

As explained in the above section, whereas the names in Tokyo Japanese VC have two way melodic realization (LMH and HMH), in Fukui Japanese, names are invariably realized as HMH. Similarly, while names in South Kyöngsang are divided into three in its VC melody (MHM, HMM and HHM), all names in Seoul Korean are realized as MHM.

(10) Fukui Japanese

segments: ‘Name (+tyaN), a- so- bo!’ (=Name, let’s play!)

VC melody: H M H L H\* M

	a. Ma-yu-mi (+tyaN)	b. Ma-ri-ko (+tyaN)
	\ /	\ /
VC melody:	H M H	H M H

(11) Seoul Korean

Segments: 'Name +ya/a, no-ol-ca!' (=Name+vocative suffix, let's play!)

VC melody: M H M M H\* M

a. Ho-cun +a      b. Søn-suk+a      c. Kuk-wən+a

VC melody:      M H M              M H M              M H M

Note that Fukui Japanese and Seoul Korean show the case where the musical aspect of their VC takes over language. In other words,

2.5. Conclusion to Section 2

In VC, lexical prominence, whether it is derived from tonal or stress system, is preserved in the mapping between the text and the melody.

3. Rhythmic realization in vocative chant

The interface between language and music also involves the rhythmic structure, which is manifested by the lengthening effect in linguistic chants, including VC.

There are two distinct cases in rhythmic organization in VC: one in which variability in rhythmic lengthening is closely correlated to the presence or absence of lexical stress, as in English and Bengali (Hayes and Lahiri 1992), and the other in which music systematically overrides language by disregarding pitch accent specifications, as in the *Pyongko* rhythm in Japanese (Mitsui and Takahira 2001, Saiki 2003).

3.1. Language with stress system

According to Hayes and Lahiri (1992), one and two syllable words obligatorily lengthen in English VC as illustrated in (12.a-b), and for words with antepenultimate main stress, the antepenult is optionally lengthened, and the final syllable is obligatorily lengthened, as in (12.c-d). They also point out that VC is mapped to the rhythmic structure with alternating strong and weak beats associated with the syllables of the VC

text, and lengthening occurs when a single syllable associates with more than one beat, where the lexical stress is associated with the strong beat in the rhythmic structure.

(12) Lengthening in English VC

- |   |  |
|---|--|
| <p>a. John → Joo-ohn</p> <p style="text-align: center;">   </p> <p style="text-align: center;">H* M</p>   | <p>b. Johnny → Jooh-nny</p> <p style="text-align: center;">   </p> <p style="text-align: center;">H* M</p> |
| <p>c. Melanie → Me-la-niie or Mee-la-niie</p> <p style="text-align: center;">\ /        \ /  </p> <p style="text-align: center;">H* M      H* M</p> |  |
| <p>d. Pamela → Pa-mee-laa or Paa-me-laa</p> <p style="text-align: center;">\ /        \ /  </p> <p style="text-align: center;">H* M      H* M</p>   |  |

While English manifests a “stretchable” VC, Bengali adopts a simple four beat timing in its VC (Hayes & Lahiri 1992), as schematized in (13). Thus, in Bengali VC, the stress pattern is ignored, and the rhythmic structure is optimized.

(13) Lengthening in Bengali VC

- |            |                                  |                                  |                                  |
|------------|----------------------------------|----------------------------------|----------------------------------|
|            | a. $\sigma \sigma \sigma \sigma$ | b. $\sigma \sigma \sigma \sigma$ | c. $\sigma \sigma \sigma \sigma$ |
|            | \ /                              |                                  | /\                               |
| VC melody: | H M                              | H M                              | H M                              |
|            | /\ /\                            | /\ /\                            | /\ /\                            |
| VC rhythm: | [x x] [x][x]                     | [x x] [x x]                      | [x x x x]                        |

3.2. Language with pitch system

*Pyongko* is a rhythm that is almost invariably observed in Japanese traditional folk songs including VC (Mitsui & Takahira 2001, Saiki 2003, Cho & Saiki 2007). According to Mitsui & Takahira (2001), this rhythm is characterized with two musical notes, where the durational ratio between the first and the second ranges from 3:1 to 1:1, where the first note is interpreted as being lengthened.

*Pyongko* lengthening occurs throughout the Japanese VC. More precisely, moras lengthen when embedded under the strong beat of the musical sphere of VC, regardless

of their lexical pitch specification (Cho & Saiki 2007). Thus, for instance, the first mora in the sequence of name and *+tyaN* (vocative suffix) as well as in the word *asobo* ('Let's play!') lengthens, bringing forth the rhythm of Pyongko together with the immediately following mora. These are all illustrated in (14)-(15), where the numerals indicate the ratio in time.

(14) Pyongko lengthening 1 (*Yuri+tyaN*)

	<i>Yu</i>		<i>ri</i>	+		<i>tyaN</i>
lexical pitch:	H		L			L
a.	3	:	1		:	4
b.	2	:	1		:	3
c.	1	:	1		:	2

(15) Pyongko lengthening 2 (*Koga+tyaN*)

	<i>Ko</i>		<i>ga</i>	+		<i>tyaN</i>
lexical pitch:	L		H			L
a.	3	:	1		:	4
b.	2	:	1		:	3
c.	1	:	1		:	2

Note that the Pyongko lengthening explained above implies that musical information totally overrides the linguistic information contained in the Japanese VC text. In other words, the linguistic prominence is ignored in the rhythmic formalization of Japanese VC, bringing forth an instance of the case where music is “winning” over language.

### 3.3. Conclusion to section 3

In summary, whether it is a stress accent language or a pitch accent language, unless musical specifications completely override linguistic information, there are bound to be conflicts between the articulation of linguistic accent and musical melody, on the one hand, as well as conflicts between the realization of rhythmic lengthening and the organization of music, on the other. In lexical stress languages such as English, the strong beat of the VC is mapped onto the stressed syllables. For marginal stress systems, as Bengali, the stress pattern of the text is ignored and the music wins. Lastly, for pitch accent languages, such as Japanese, music wins.

#### 4. Conclusion

In this paper, we have presented a cross-linguistic picture of the “battle” between speech and music both in tone/melody associations, and in rhythmic structure.

Our conclusion is that in the case of a lexical stress system, (e.g. English and German), linguistic accents win the battle and surface as prominent, being accentuated by a “rhythmic lengthening” of the linguistic head. However, in other systems (a pitch-accent system [e.g., Japanese and Korean] or a non-distinctive stress system [e.g., French and Bengali]), music wins by dictating its own logic of metrical structure of duration, and by imposing predictable melodies. A possible explanation might come from the difference between stress and pitch accent, in that the linguistic stress is based on relational prominence, much like musical rhythm, whereas the pitch accent manipulates tones in the parallel fashion to musical melody.

## **Abstract**

In this paper, I report new data on the adaptation of /θ/ and /ð/ from English to Taiwan Mandarin, which shows a substitution pattern which has not been discussed: 1) subjects sometimes substituted /l/ for the voiced /ð/, 2) subjects produced the voiceless interdental correctly more often than the voiced one, 3) the substitution for /θ/ was more consistent while the substitution for /ð/ varied, and 4) for both /ð/ and /θ/, the replacement rate was higher in onset position, and lower in coda position. Two factors are involved in explaining the findings, the difficulty caused by keeping both voicing and the place of articulation and the native interference in onset position.

**Keywords:** second language adaptation, phoneme substitution, interdental, language interference.

## **1. Introduction**

Phoneme adaptation has been the center of research on second language learning. It is commonly assumed that it is strongly influenced by one's native language (NL) (Eckman, Elreyes and Iverson 2003, Weinburger 1990). But how exactly do speakers choose substitutes for foreign language sounds with no native counterparts? Several hypotheses have been proposed to deal with this question, such as phoneme contrast (Brown 1998), acoustic similarity (Brannen 2002) and NL constraint ranking (Lombardi 2000). In this paper, I will report new data from an experiment on adapting English interdentals /θ/ and /ð/ by Taiwan Mandarin speakers, and try to answer this question.

Cross-linguistically, the English interdental fricatives are not common sounds due to their marked place of articulation.<sup>ii</sup> The substitution patterns for /θ, ð/ are reported either as /t, d/ or /s, z/.

(1) Different substitution (data cited from Weinberger 1990: 142)

Language	/θ/ substitution	/ð/ substitution
Russian	θ → t	ð → d
Japanese	θ → s	ð → z
French (European)	θ → s	ð → z
French (Quebec)	θ → t	ð → d (Brannen 2002)
Dutch	θ → t/#_ θ → s/#_	ð → d/#_ ð → s/#_
Hungarian	θ → t	
Mandarin	θ → t/#_ θ → f/#_ (θ → s in Miao 2005) <sup>iii</sup>	
Sinhalese	θ → t	ð → <u>d</u>
German	θ → s	ð → z

Two strategies are generally taken. First, second-language learners substitute /θ, ð/ with a less-marked manner of articulation /t, d/, as in Russian, Quebec French and Sinhalese. Second, second-language learners substitute /θ, ð/ with a less-marked place of articulation /s, z/ and keep the fricative feature, as in Japanese, European French, and German. In a language lacking voicing contrast, like Taiwan Mandarin (hereafter, TM), there are no paired-up sounds like those languages mentioned above to serve as substitutes. Thus, it is interesting to see how TM speakers adapt the English interdentals. And the result of the experiment turned out to show a substitution pattern that has not been discussed.

The remainder of the paper is organized as follows. Section 2 provides the process and results of the experiment. Section 3 introduces the questions raised by the pattern of the adaptation and an attempt to answer these questions from previous hypotheses. Section 4 presents my own hypothesis and section 5 is a conclusion.

## 2. Experiment

I adopted the general methodology for recording subjects. The results were judged by two trained linguists. Four native speakers of TM (two males, two females, aged from 23 to 26) were recorded. All speakers share a similar background of learning English. They all started to learn English in high school in Taiwan, and after college

education, they came to Stony Brook University for graduate education. A wordlist containing /θ/ and /ð/ in different positions, which is randomized with fillers, was constructed. To minimize the influence of vowel and stress, I tried to put words with /θ/ and /ð/ in pairs in the same stress position and before the same vowels. From the limited data I gathered, there is no influence of different vowel qualities on the substitutions.

(2) Wordlist (please see Appendix for the randomized wordlist)

<b>θ_</b>	<b>'θ_</b>	<b>_θ</b>
think	author	teeth
thumb	method	mouth
thousand	Cathy	Beth
<b>ð_</b>	<b>'ð_</b>	<b>_ð</b>
this	weather	breathe
thus	gather	clothe
therefore	soothing	loathe

A frame sentence was provided ("Say \_\_\_\_\_ again").<sup>iv</sup> Subjects were asked to give five repetitions of every word, and only the middle three repetitions were considered. A training session was given before the experiment. A recording of the wordlist was played to the subjects and they could ask to play any word that they were not sure of.

The results are as follows.

(3) /θ/

	<b>Word-initial /θ/</b>	<b>Word-medial /θ/</b>	<b>Word-final /θ/</b>
M1	/θ/ → /s/ 22.22%		
	/θ/ → /θ/ 77.78%	/θ/ → /θ/ 100%	/θ/ → /θ/ 100%
M2	/θ/ → /s/ 11.11%		
	/θ/ → /t/ 33.33%	/θ/ → /ð/ 33.33% <sup>v</sup>	
	/θ/ → /θ/ 55.56%	/θ/ → /θ/ <sup>vi</sup> 66.67%	/θ/ → /θ/ 100%
F1	/θ/ → /s/ 66.67%		
	/θ/ → /θ/ 33.33%	/θ/ → /θ/ 100%	/θ/ → /θ/ 100%

F2	/θ/ → /s/	33.33%		/θ/ → /s/	22.22%
	/θ/ → /t/	22.22%			
	/θ/ → /θ/	44.44%	/θ/ → /θ/	100%	/θ/ → /θ/

The substitution pattern was clear for /θ/: subjects consistently replaced /θ/ with /s/. There were some cases of /t/ and /ð/ substitutes, but they each occurred once for one speaker. If we look at the shaded part, we can notice that subjects were more faithful in producing /θ/ in coda position (words in the third column) than in onset position (the first and second columns). Take subject M1 for example, the correct rate is 100% in coda position. In onset position, subjects were more faithful in producing /θ/ in word-medial onsets (the second column) than in word-initial onsets (the first column). Take M2 for example, the correct rate is 100% in word-medial onset position, and 77.78% in word-initial onset position.

(4) /ð/

	Word-initial /ð/	Word-medial /ð/	Word-final /ð/			
M1	/ð/ → /l/ <sup>vii</sup>	88.89%	/ð/ → /l/	66.67%		
	/ð/ → /t/	11.11%	/ð/ → /θ/	33.33%	/ð/ → /θ/	100%
M2	/ð/ → /l/	66.67%	/ð/ → /θ/	33.33%	/ð/ → /θ/	100%
	/ð/ → /ð/	33.33%	/ð/ → /ð/	66.67%		
F1	/ð/ → /l/	100%	/ð/ → /t/	33.33%		
			/ð/ → /s/	11.11%		
			/ð/ → /θ/	22.22%	/ð/ → /θ/	100%
			/ð/ → /ð/	33.33%		
F2	/ð/ → /t/	66.67%	/ð/ → /t/	33.33%		
	/ð/ → /θ/	33.33%	/ð/ → /t <sup>h</sup> /	44.44% <sup>viii</sup>	/ð/ → /θ/	100%
			/ð/ → /ð/	22.22%		

As for the substitution pattern of /ð/, it is more complex. Subjects replaced /ð/ with /θ/, /s/, /t/, and most interestingly, /l/. As I mentioned earlier, there is no voicing contrast in TM consonant inventory.

(5) Consonant inventory of Taiwan Mandarin

Labials	p	p <sup>h</sup>	f	m
Alveolars	t	t <sup>h</sup>	l	n
Dental sibilants	ts	ts <sup>h</sup>	s	
Palatals	tʃ	tʃ <sup>h</sup>	ç	
Velars	k	k <sup>h</sup>	x/h	ŋ
Retroflex	tʂ	tʂ <sup>h</sup>	ʂ	ʐ <sup>ix</sup>

  
 No voicing contrast

Although TM lacks a voicing contrast, voiceless and voiced stops are adapted as aspirated and unaspirated stops. For example, /p/ is adapted as aspirated /p<sup>h</sup>/ and /b/ as unaspirated /p/. Substituting /l/ for /ð/ seems to imply that TM speakers do perceive the voicing feature of /ð/. The results for /ð/ show the same positional asymmetry as those for /θ/ (as in the shaded parts). Notice that subjects never substitute /l/ in coda position. And the replacement rate of /ð/ is overall higher than that of /θ/.

To sum up so far, four interesting findings are reported. First, subjects sometimes substituted /l/ for /ð/. Second, subjects produced the voiceless interdental correctly more often than the voiced interdental (79.63% vs. 47.22% of correct rates, the shaded part in (6)). Third, the substitution for /θ/ was more consistent while the substitution for /ð/ varied.

(6) Variety of substitution

	/θ/		/ð/	
/θ/ → /s/	12.96%	/ð/ → /l/	26.85%	
/θ/ → /t/	4.63%	/ð/ → /s/	0.93%	
/θ/ → /ð/	2.78%	/ð/ → /t/	11.11%	
/θ/ → /θ/	79.63%	/ð/ → /t <sup>h</sup> /	3.7%	
		/ð/ → /ð/	13.89%	

And fourth, for both /θ/ and /ð/, the replacement rate was higher in onset position, and lower in coda position.

(7) Replacement rate

	/θ/	/ð/
Word-initial	47.22%	88.89%
Word-medial	8.33%	69.44%
Word-final	5.56%	0% (100%) <sup>x</sup>

### 3. Previous hypotheses

Several questions are raised by the patterns found in TM.

- 1) Why did subjects sometimes substitute /l/ for the voiced /ð/?
- 2) Why did subjects correctly produce the voiceless interdental more often than the voiced?
- 3) Why was the substitution for the voiceless more consistent than for the voiced?
- 4) What is the relationship between position and replacement?

I will review some of the previous hypotheses and try to answer these questions and propose my own hypothesis in section 4.

#### 3.1. Phonemic contrast and inventory of NL (Brown 1998)

Brown (1998) proposes that if one's native grammar does not contrast a phonological feature, he or she is therefore unable to perceive or acquire the non-native feature. Based on this hypothesis, if one's L1 does not contain /θ, ð/, but contains /s, z/ (Strident non-contrastive) and /t, d/ (Continuant contrastive), one will replace /θ, ð/ with /s, z/ since one cannot perceive the difference between /θ, ð/ and /s, z/. This approach explain /s/ substitution for /θ/ very well in TM, but does not seem to explain the whole picture of the TM patterns. Based on this hypothesis, TM speakers should not be able to perceive the difference between /θ/ and /s/. Also, voicing is not contrastive in TM, so based on this hypothesis, TM speakers should not be able to perceive the difference between /ð/ and /s/ either. But obviously, from the results of the experiment, TM speakers did perceive some contrast between /θ/ and /ð/. Furthermore, this hypothesis runs into problem when two languages both have Strident feature non-contrastive and Continuant feature contrastive, but choose different substitutes.

- (8) European French /s, z/ } Exact same inventory } All have /t, d/, /s, z/  
 Quebec French /t, d/ }  
 Japanese /s, z/ }

European French, Quebec French and Japanese all have /s, z/ and /t, d/ in their inventory. According to Brown’s hypothesis, speakers of these languages shouldn’t perceive the strident contrast and substitute /θ, ð/ with /s, z/. However, they go for different substitutes. Even languages with the same inventory, as in European French and Quebec French, their choice differs. This implies that phoneme substitution is beyond phonemic contrast in L1.

### 3.2. Acoustic similarity (Brannen 2002)

Aware of the inadequacy of the phonemic contrast hypothesis, Brannen (2002) proposes that phoneme substitution is determined by acoustic similarity; in other words, by calculating the auditory distance, learners match up the closest sound of L1 with L2. English /θ, ð/ are less continuant-like perceptually, and more stop-like, and European French /s, z/ are less continuant-like perceptually. Learners match up the phonetic details of European French /s, z/ with those of English /θ, ð/. On the other hand, Quebec French /s, z/ are more continuant-like perceptually, so they are less similar to English /θ, ð/. Learners thus substitute /t, d/, which are the closest sounds in Quebec French, for the English interdental.

### 3.3. Universal ranking and NL constraint ranking (Lombardi 2000)

Lombardi proposes that, without NL interference, learners choose stop substitutes /t, d/ for /θ, ð/ because universally, markedness constraints ranked higher than faithfulness constraints.

#### (9) Universal approach

/θ, ð/	*θ, *ð	*Cont	*Stop	IDENTMANNER
a. /θ, ð/		*!		
☞ b. /t, d/			*	*
c. /s, z/		*!		

\*Cont ‘No continuants.’

\*Stop ‘No stops.’

IDENTMANNER ‘Manner of articulation of an input must be preserved in its output correspondent.’

Continuants are universally more marked than stops (\*Cont >> \*Stop). Unless the L1 grammar triggers the promotion of faithfulness constraints (the relevant constraint here, IDENTMANNER) higher than markedness constraints, stops will be the optimal substitutes.

(10) NL grammar

/θ, ð/	*θ, *ð	IDENTMANNER	*Cont	*Stop
a. /θ, ð/	*!		*	
b. /t, d/		*!		*
c. /s, z/			*	

This hypothesis does not seem to answer the questions above either, since the substitutes in TM are not of the same manner of articulation.

#### 4. Proposal

In this section, I will explain the TM patterns by positing new hypotheses.

*4.1. Why did speakers of TM use /l/ as a substitute for /ð/, and why was the substitution for /θ/ more consistent than /ð/?*

As I mentioned in the previous section, phoneme contrast can explain /s/ substituting /θ/ by TM speakers and /θ/, /s/, and even /t/ substituting for /ð/ (since voicing is not contrastive), but not /l/ substituting /ð/. My hypothesis is that /l/ substitution results from the attempt to maintain the English voicing. /n/ and /ŋ/ are the other voiced consonants in TM inventory, but /l/ is the closest match to /ð/. As for the ability of perceiving voicing contrast, it is not clear from this experiment alone.<sup>xi</sup> But the fact that subjects used /l/ as substitute and the inconsistency of /ð/ substitution seems to point to the direction that some subjects did perceive the voicing (or some kind of contrast between /θ/ and /ð/, so that they use a different phoneme to substitute /ð/) and try to maintain the contrast. If we assume along with Coetzee and Pater (2006) that [voice] feature should be specified for segments that don't contrast in voicing, then

subjects substituted the only oral voiced sound in TM for /ð/.

4.2. *Why are speakers of TM so much more successful in producing /θ/ than /ð/, when neither occurs in their inventory?*

There is an asymmetry of replacement rate between /θ/ and /ð/ (20.37% vs. 52.78%). From the point of view of previous hypotheses, adapting /θ/ and /ð/ should not be different since neither of the sounds occur in the inventory. If we take the hypothesis posited in 4.1, that is, see voicing as a separate factor, and only consider /θ/→/s, t/ and /ð/→/l, t/ (voicing not considered), then the difference between them becomes similar (20.37% vs. 42.59%). The attempt to maintain both voicing and place causes the difficulty of producing /ð/. Again, although there is no direct evidence of TM speakers perceiving voicing, the lower successful rate of producing /ð/ seems to suggest that they do.

4.3. *What is the relationship between position and replacement?*

The relationship between position and replacement rate is seldom discussed in previous literature. All of the hypotheses mentioned above don't seem to provide an answer to this question. I propose the replacement data reported in this paper with regard to different positions is because of the interference of the NL in onset position.

From a production point of view, fricatives are mispronounced more often in coda position than in onset position, which shows the opposite of the finding in this paper. It is reported that fricatives are produced more correctly as onsets in language acquisition. However, the timing of requiring fricatives in different position is not mentioned. Consider the following data.

(11) Errors in Repetition of Certain sounds within Sentences by Two Subjects (Yeni-Komshian, Kavanagh and Ferguson 1980: 216)<sup>xii</sup>

Sound	No. <sup>xiii</sup>	<u>Initial</u>		No.	<u>Final</u>	
		K.M.	V.S.		K.M.	V.S.
/s/	(6) <sup>xiv</sup>		1	(5)		3
/z/	(1)			(17)	1	15

From a perception point of view, onset consonants should have better cues than coda consonants (cf. Steriade 1997), and word-initial onsets in turn should have better

cues than word-medial onsets. That is to say, subjects should perceive onset /θ, ð/ better than coda /θ, ð/. Also, the proposal of positional faithfulness (Beckman 1997, Lombardi 1996) predicts that onsets should be pronounced more faithfully than codas, so word-initial materials suffer less from phonological processes like assimilation, neutralization or deletion than word-final materials. Again, the result in the experiment shows the opposite.

There is a correlation between the prosodic structure of TM and the replacement rate. In TM, only nasals /n/ and /ŋ/ can occur as coda. My hypothesis is that the absence of coda facilitates the perception of coda interdentals, since there is no interference of native sounds in that position. Similar hypotheses concerning NL interference have been proposed to deal with phoneme adaptation. One of those models is Speech Learning Model proposed by Flege (1987). He proposes that non-native sounds are "equivalence-classified" according to NL based on phonetic similarity. That is to say, sounds in NL are imposed to similar L2 sounds. But new phonological categories, without any similar counterparts in NL imposing on them, are perceived and thus produced more accurately. The model developed by Best (2001) proposes the similar idea that native phonological knowledge strongly affects non-native speech perception, so that listeners perceptually assimilate non-native sounds to native phonemes whenever possible (Best, McRoberts and Goodell 2001). To TM speakers, sounds that come in the coda position are new information. Thus, they pay more attention to it. On the contrary, there is native interference in onset position. TM speakers apply their native phonological knowledge to sounds that come in the onset position. Another piece of evidence supporting this hypothesis from the experiment is that subjects never substituted /l/ for coda /ð/. /l/ interference only occurs in onset position in TM. Thus, subjects were more faithful to /ð/ in coda position.

## **5. Conclusion**

I reported an experiment on adapting English interdentals by TM speakers and found that subjects sometimes replaced /ð/ with /l/. I propose that it is due to the attempt to maintain the English voicing. Although there is no direct evidence that TM speakers did perceive the voicing contrast from this experiment alone, the /l/ substitution, the inconsistency and the difficulty of producing /ð/ all point to the same direction that they did. A perception experiment needs to be done as future research to give direct support of this hypothesis. Also, /ð/ is reported to be sounded more like a stop /d/ in English

(Polka, Colantonio and Sundara 2001). Future research needs to be done on the acoustic properties of TM /l/ to see if the /l/ substitution is simply because of phonetic similarity. Furthermore, a question is worth researching that whether speakers of languages that don't have voicing contrast but have /l/ in the inventory ever substitute /l/ for /ð/. I also propose that the higher accurate rate of producing /θ, ð/ in coda position is due to the less interference of coda position. The prosodically new information increases the perception of coda interdentals. My prediction will be that TM speakers don't perceive /θ, ð/ in onset position. Future research needs to be done on the perception of interdentals in onset/coda position as well.

---

<sup>i</sup> I would like to thank Ellen Broselow and Marie Huffman for their helpful comments and suggestions. I would also like to thank Anastasia Riehl and all the colleagues participating in Phonology III Fall 2007 and Phonology Seminar Spring 2006 for their input on this work.

<sup>ii</sup> It is pointed out that /θ/ and /ð/ are the sounds mastered last and substituted most frequently by English native speakers (Schmidt 1977).

<sup>iii</sup> No /ð/ substitution is reported.

<sup>iv</sup> There was no resyllabification of coda /ð, θ/ with the vowel initial word *again* found for all speakers.

<sup>v</sup> Speaker M2 consistently replaced /ð/ for /θ/ in the word '*author*.'

<sup>vi</sup> M2 and F2 consistently put the target in coda position and pronounced '*method*' as [meθ].

<sup>vii</sup> Using liquids to substitute for fricatives is very rare. Another example of this is Shipibo, a Panoan language spoken in Peru where speakers substitute /r/ for /ð/ (Elias-Ulloa 2007).

e.g. [espaða] "sword" (Spanish) → [ispara] (Shipibo)

<sup>viii</sup> Speaker F2 consistently replace /t<sup>h</sup>/ for /ð/ in the word '*soothing*.'

<sup>ix</sup> The alveolar retroflex fricative is the only voiced consonant in Mandarin. However, Taiwan Mandarin speakers often replace the sound with /l/.

<sup>x</sup> 100% is the percentage when only /ð/→/l, t, s/ is considered (/ð/→/θ/ is not considered).

<sup>xi</sup> Faithfulness constraints universally are ranked lower than markedness constraints. If there is no trigger in a given language to promote faithfulness constraints, then markedness constraints should overpower

---

faithfulness constraints. Thus, in TM, IDENTVOICE should rank low, if it exists in the grammar at all.

<sup>xii</sup> The timing of acquiring fricatives in different position is not mentioned in this report.

<sup>xiii</sup> Number of instances when sound appeared in position.

<sup>xiv</sup> Number of omission of sound.

# **Problems Encountered in the Research of the Voice System in an endangered language**

**Atsuko Utsumi**

Meisei University  
Tokyo, Japan  
utsumi@lc.meisei-u.ac.jp

## **Abstract**

A language used as a research medium is indispensable to fieldwork linguists today. It enables and facilitates our research. At the same time, however, it may distort the direction of the research as well as mislead and confuse our analyses. Further problems arise when the linguistic consultants of the target language are ‘semi-speakers’ who adopted the medium language as their first language. When their intuitions about the target language are already fragile, the language used for the research significantly influences their linguistic decisions in such a way that they unnecessarily resemble the medium language. This presentation aims to give an example of such difficulty and its solution, focusing on the voice system of an endangered Austronesian language.

**Keywords:** Austronesian, Bantik, medium language, voice system, language contact.

## **1. Introduction**

### *1.1. Background*

In this paper, I will present one of the problems that sometimes arises in a linguistic fieldwork research. The area which concerns the below discussion is located in North Sulawesi province in Indonesia. Three varieties of languages are spoken there; Standard Indonesian, Manado dialect of Indonesian and Bantik. Here are brief explanations of each language.

Standard Indonesian, which is sometimes called Bahasa Melayu, is the national language of Indonesia. It is similar to the national language of Malaysia, Brunei, and one of the official languages of Singapore, and is spoken by over 300 million people, first and second language speakers combined. It is understood throughout Indonesia, thus it is naturally the most major medium language for the researches of indigenous

languages in Indonesia.

The Bantik language, which is the target language of the author's research, is said to be spoken by around 10,000 people in the vicinity of Manado, which is the provincial town of the North Sulawesi, but the real number of the fluent native speakers, most of whom are over sixty, would not exceed 3,000 (cf. Noorduyn 1991).<sup>1</sup> It is, like the other indigenous languages in the vicinity, one of the seriously endangered languages. It belongs to Sangiric subgroup of Philippine language group, which in turn belongs to Western Malayo-Polynesian language family (cf. Noorduyn (1991), Sneddon (1984) among others).

In addition to the two languages above, Bahasa Manado, or Indonesian Manado dialect is spoken in this area. Indonesian Manado dialect is one of the dialects of Indonesian, which has its origin in pidgin-derived Malay or, in other words, Trade Malay (cf. Adelaar and Prentice (1996)), then creolized. This is the most widely used language in the North Sulawesi area. All the speakers of Bantik also speak Manado dialect, which has distinct features from Standard Indonesian. Morphological and syntactic features of Manado dialect are simpler than those of Standard Indonesian, and many of its vocabulary items are not found in Standard Indonesian or colloquial Indonesian of other regions.

As already noted, every Bantik speaker can speak Indonesian Manado dialect, and many of them use Manado dialect most in their daily life. In contrast, Standard Indonesian has high prestige and used in government offices, broadcasting, education and religious services. Fluency in Standard Indonesian production varies among Bantik speakers, but all of them have no difficulty in understanding it. Although the influence of Manado dialect cannot be overlooked, only Standard Indonesian, which is the medium language of the research, and Bantik will be focused in the below discussion.

## *1.2. Problems discussed in this paper*

The problem to be discussed in this paper arises under the following conditions.

---

<sup>1</sup> The Bantik language has five vowels /i, e, a, o, u/ and fourteen consonants /p, b, t, d, k, g, s, h, j, P, m, n, N, // . The glottal stop occur only base-finally with a few exceptions. A word consists of a base, or a base with one or more affixes. The basic word order is SVO while VOS word order frequently occurs when the verb is in an Undergoer Voice. Like many other Philippine type languages, Bantik has more than one Undergoer Voices (at least two) in addition to an Active Voice. Verbs in Bantik show tense opposition. This opposition may seem to be that of mood, but in this paper, I take the position that Bantik verbs show non-past vs past tense opposition. For detailed description, please refer to Bawole (1993) and Utsumi (2005).

First, a target language has many similarities with a medium language. Second, a target language is endangered, so there are many semi-speakers. It is sometimes difficult to discern fluent speakers from semi-speakers especially when a researcher who is about to start the research does not have much knowledge on the target language because of the scarcity of literature. Finally, semi-speakers may alter the traditional structure of the target language through language attrition.

Under these conditions, the medium language used in the research can distort data given by semi-speakers through elicitation. Since both the medium language and the target language belong to Western Malayo-Polynesian group of the Austronesian language family, they have similar characteristics at every linguistic level. On one hand, this helps the researcher to prepare the questions to be asked during the session. Quite often she would find one-to-one correspondence between vocabulary items and affixes in both of the languages. Their syntactic characteristics are also quite similar. This makes it easy for a linguistic consultant to compose sentences in the target language and facilitates a researcher to interpret the elicited sentences. On the other hand, the similarity easily misguides research especially when a researcher asks a consultant to elicit sentences in the target language by ‘translating the medium language’. In this case, the sentences that a researcher obtains can be natural utterances, but they can also be directly translated sentences which are not normally used in daily conversations. Moreover, the researcher can easily fail to find constructions that do not exist in the medium languages. Using a medium language that is similar to a target language may be assistance as well as an obstacle.

In the following discussion, I will give an example of difficulty which is encountered in the research of an endangered language, in which a researcher uses similar language as a medium.

### *1.3. Source of the research*

The data which are used in this paper were obtained through my fieldwork research from year 1996 to 2006. Research, which extended three to six weeks, was done once in a year or two. Over twenty Bantik speakers were consulted. Among them, three male linguistic consultants, all of whom were born within 1972 to 1976, gave data of young speakers’ Bantik. Two other male speakers, who were born in 1954 and 1956 helped me to get data of traditional Bantik lexicons and structures. I also used data obtained from three female aged speakers, all of whom were born in 1950s. Unfortunately, no young female Bantik speakers were consulted because very few of

them use Bantik in daily life. Young Bantik speakers who have enough command of the language are mostly male. In contrast, it is easy to find female aged speakers, who were born before 1960.

## **2. Similarities between Indonesian and Bantik**

### *2.1. Overview*

As already mentioned above, both Indonesian and Bantik are Austronesian languages, and they belong to West Malayo-Polynesian language family. The two share cognate lexicons which consist up to 20 - 30 % of the basic vocabulary (cf. Sneddon 1984). Moreover, in Bantik, there are many newly borrowed lexicons from Indonesian. Lexical items which denote abstract notions and technical terms of various fields are in principle do not exist in Bantik, so Bantik speakers usually use terms borrowed from Standard Indonesian or Indonesian Manado dialect.

Both Standard Indonesian and Bantik have rich derivational morphology. Their word formations are similar: a word in these languages can consist of just a base, or of a base and one or more affixes. Basic word order of the two languages is Subject – Verb–Object. Their syntactic features are also similar. For example, they share symmetrical voice system (cf. Himmelmann 2005), but there certainly are differences. One of them will be illustrated below.

### *2.2. The voice systems of Indonesian and Bantik*

Indonesian has two voices; Active Voice (or Agent Focus) and Passive Voice (or Goal Focus). Bantik, on the other hand, has at least three; Active Voice and two Undergoer voices, which will be called Passive Voice and Conveyance Voice in this paper. Bantik verbs are categorized in three groups depending on the number of voice(s) it takes. First group consists of what I call intransitive verbs. They take only Active Voice form. Second group comprises of transitive verbs, which can take Active and Passive Voices. Finally, there are ditransitive verbs which can take all of the three voices; Active, Passive, and Conveyance voices. One or two more voices may be postulated depending on the analysis, but in the current discussion, I take the view that Bantik has three voices. To illustrate the difference in the voice systems of the two languages simply, I will first show examples concerning verbs without derivational affixes, which

will be called ‘simple verbs’ from now on.

Quite often subject nominals of each voice have common semantic features. I will use following terms expressing semantic roles in the below discussion: ‘ACTOR’, ‘PATIENT’, ‘GOAL’, ‘CONVEYED THEME’, ‘LOCATION’, ‘INSTRUMENT’, ‘CAUSER’ and ‘CAUSEE’. ‘CONVEYED THEME’ is used to denote objects which moves as a result of the action denoted by the verb, such as money in ‘buying’ situation.

In Indonesian, the verb denoting ‘to give’ has Active and Passive Voices, as shown in example (1), whereas Bantik verb denoting ‘to give’ has three voices and can take three constructions. In the examples below, the Indonesian sentence in (1a) corresponds to the Bantik sentence in (3a), and (1b) to (3b), but there is no corresponding Indonesian sentence (and verb form) for (3c), as (1c) is ungrammatical. In order to posit the conveyed theme, which is *uang* ‘money’, as subject, the derivational suffix *-kan*, which forms applicative or causative verbs, should be added as shown in (2)b. The corresponding Active Voice sentence with *-kan* is shown in (2)a. In Bantik, no further affix is needed, but the different voice form is sufficient to posit the conveyed theme as a subject. *MaN-* in (3a) is an active voice marker of the non-past tense which alternates with *naN-* in the past tense.<sup>2</sup>

- (1) a. *wati mem-beri uang-nya kepada desi* (Active Voice)  
 Wati meN-give money-NYA to Desi  
 “Wati gives money to Desi”  
 b. *desi di-beri uang-nya oleh wati* (Passive Voice)  
 Desi DI-give money-NYA by Wati  
 “Maarten and Stefanie have split up”  
 c. \**Uang-nya di-beri oleh wati kepada desi*
- (2) a. *wati mem-beri-kan uang-nya kepada desi* (Active Voice)  
 Wati meN-give-KAN money-NYA to Desi  
 b. *Uang-nya di-beri-kan oleh wati kepada desi* (Passive Voice)  
 money-NYA DI-give-KAN by Wati to Desi
- (3) a. *i-wati ma-mihei doiti/ si-desi* (Active Voice)  
 I-Wati maN-give money SI-Desi  
 “Wati gives money to Desi”  
 b. *i-desi bih-an ni-wati doiti/* (Passive Voice)  
 I-Desi give-AN NI-Wati money

<sup>2</sup> *MaN-* is attached to non-past verbs and *naN-* to past verbs. *N* in *maN-/naN-* realizes as nasalisation of the first consonant of a base or insertion of the nasal that is homo-organic with its first consonant. When a base begins with a vowel, insertion of velar nasal will occur.

c. *doiti/ bihei ni-wati si-desi* (Conveyance Voice)  
 money give NI-Wati SI-Desi

Therefore, if a researcher sticks to the translation as a research method of collecting data, she would never find (2c) in Bantik. One's knowledge about Philippine languages, which have at least four voices and are in close relation with North Sulawesi languages including Bantik, will encourage a researcher to search for another voice form resulting in a discovery of the verb form such as in (2c), but it would take some effort in devising the way to extract the expected data. Although less than ten verbs without derivational affixes show this three-way voice alternation, it is frequently observed with verbs with derivational affixes.

When a verb base takes either the prefix *paki-*, which derives causative verbs, or *paN-*, which derives applicative verbs, it becomes transitive or ditransitive. More than half of them are ditransitive, which take Active, Passive and Conveyance Voices, as shown in example (4). In principle, Active Voice verbs have one of the following affixes; the prefix *ma-/na-*, prefix *maN-/naN-*, and infix *-um-/im-*.<sup>3</sup> Passive Voice verbs have the suffix *-AN*, while Conveyance Voice verbs do not have specific affixes to mark the voice.<sup>4</sup> Passive Voice and Conveyance Voice verbs take the prefix *ni-* when they are in past tense.

- (4) a. *i-titin ma-paki-tutuN bono su-ana/=ne* (Active Voice)  
 I-titin MA-CAUS-burn rubbish SU-child=NI.3sg  
 "Titin made her child burn rubbish"
- b. *ana/=ne paki-tutuN-an ni-titin bono* (Passive Voice)  
 child=NI.3sg CAUS-burn-AN NI-Titin rubbish
- c. *bono paki-tutuN ni-titin su-ana/=ne* (Conveyance Voice)  
 rubbish CAUS-burn NI-Titin SU-child=NI.3sg

As for Indonesian Manado dialect, which is the first language of young Bantik people, does not show morphologically distinctive voice alternation. Actor-orientation and Goal-orientation are shown mostly by word order (cf. Prentice (1994)). Since Standard Indonesian has more similar voice system to Bantik than Indonesian Manado dialect, I will compare only the first two, not mentioning Manado dialect.

It is very important to discern ditransitive derivational verbs from transitive ones in order to understand features of each verb base and draw a comprehensive picture of Bantik verbs. When linguistic consultants are second language speakers or semi-

<sup>3</sup> *Ma-* indicates non-past tense and *na-* expresses past tense. Similarly, *-Um-* indicates non-past tense and *-im-* expresses past tense.

<sup>4</sup> The suffix *-AN* has three allomorphs; *-n* occurs after /e, a, o/, *-en* occurs after the serial /a/ + consonant, *-an* elsewhere.

speakers who do not have full knowledge of Bantik, but have full command of Indonesian, which is the medium language, they sometimes fail to give the third voice form of the ditransitive verb. There is also a possibility that they give non-existent voice forms of transitive verbs. These will make a lot of difficulties in extracting traditional (true) three voice alternations in Bantik using Standard Indonesian. The aged speakers of Bantik has full knowledge of the language so as to be able to give sentences in Conveyance Voice, such as (3)c and (4)c when they are asked persistently, but young speakers who undergo language attrition may not be able to do so. In the following section, some instances of the generation difference will be referred to.

### 3. Generation differences

It is widely reported that endangered languages show morphological reduction and structural change (Campbell and Muntzel (1989), Schmidt (1985) among others). In other words, one can find considerable generation difference between older speakers who maintain traditional language structure and younger speakers who lost some parts of the linguistic knowledge in a research of an endangered language. In my research of Bantik too, many different features between aged and young speakers were found. People who were born before 1950s have large vocabulary and complete grammatical knowledge. On the other hand, young speakers, especially those who were born after 1970s, fail to give even basic words such as *ake mimihi* ‘river’, *daki* ‘north’ or *Poboso* ‘kitchen’.

Morpho-phonemic differences are also evident. For example, the younger speakers do not use the linker /N/ (/N/ stands for a nasal which is homo-organic with the following consonant) when a numeral is combined with morphemes such as ‘ten (*puPo*)’, ‘hundred (*hatusu*)’ and ‘thousand (*hibu*)’. Thus the younger speakers would say ‘*dua puPo*’ for ‘twenty’ or ‘*dua hatusu*’ for ‘two hundred’ (*dua* means ‘two’), when the older speakers say ‘*dua-m-puPo*’ or ‘*dua-ŋ-hatusu*’. Similarly, /N/ in the prefixes *maPiN-* (deriving adjectives which mean the states indicated by them are insufficient) and *mahiN-* (deriving reciprocal verbs) are completely omitted by younger speakers. Older speakers, however, realize /N/ when the base begins with a stop and /s/, but realize it as zero elsewhere (i.e., when the base begins with a nasal, a fricative, a flap, or a vowel). It can be said that the younger speakers do not distinguish those two phonological subcategories of bases, and apply the rule for one of them to both of them. Here, we can find over-generalizations of morpho-phonemic rules in younger speakers,

just as reported in Schmidt (1985). This kind of overgeneralizations can be found in the morpho-syntactic level too, as illustrated in the following section. For detailed description of generation difference in Bantik, please refer to Utsumi (2002).

#### **4. Young people's confusion concerning the voice alternations**

Young speakers, as I saw them, are always confident in giving Active and Passive Voice forms of transitive verbs, but are very unsure about the presence of the third Voice, which is Conveyance Voice. A possible reason for this is because Conveyance Voice lacks a clear marker, in contrast to the other two voices which are always clearly marked with voice-indicating affixes, as already noted in section 2. It seems that young generation has lost the voice system owned by aged speakers. They are used to the two-way voice alternation in Standard Indonesian which they use more often than Bantik, so that their idea of Bantik voice system is influenced by it. What I will examine below is an example of change in Bantik structure which is affected by both language contact with Indonesian and imperfect learning of the Bantik language.

Although many young speakers do not realize there are three voices in Bantik, it is often the case that once they recognized that there are three different verb forms reflecting three voices in Bantik, they start to overgeneralise this morpho-syntactic rule and apply a three-way voice alternation to many verbs. Some of them elicited more than twenty simple verbs (i.e. verbs without derivational affixes) as ditransitive, over half of which were not attested to be so by aged speakers. As mentioned above, there are eight simple ditransitive verbs according to aged speakers, and while young speakers fail to point three of them, they insisted that fifteen other verbs, which are in fact transitive, are ditransitive.

As for derivational verbs, young speakers' confusion about the voice system increases radically. I have given an example of derivational verbs in example (4), in which a verb with *paki-*, the causative prefix, forms a ditransitive verb, *ma-paki-tutuN*, from an originally transitive verb base *tutuN*. Sometimes young speakers fail to give the Conveyance form of *ma-paki-tutuN*, which is *paki-tutuN*. Even when they realize there are two Undergoer voices, they are often not able to give grammatical sentences using those forms, because they do not know which Undergoer Voice requires what kind of semantic role for its subject nominal. For example, *paki-tutuN*, the Conveyance Voice form, should take PATIENT as a subject nominal, but young speakers often put CAUSEE as a subject nominal.

One more example of such confusion among young speakers is illustrated below. The prefix *paN-* is a derivational affix which forms applicative verbs when attached to dynamic verb bases, and these applicative verbs take three voice forms. Not every dynamic verb base, however, can take this applicative prefix. Verb bases which take this is lexically determined and thus not predictable. Active Voice form of this applicative verbs is ‘*ma-/na- + paN- + base*’, Passive Voice form is ‘*paN- + base + -AN*’, and Conveyance Voice form is ‘*paN- + base*’.

What is confusing is that the phonologically identical prefix *paN-* forms Locative verbs and Instrumental verbs. A Locative verb is formed with the prefix *paN-*, the suffix *-AN* and a dynamic verb base, which can be schematized as ‘*paN- + base + -AN*’, and it always take a subject nominal whose semantic role is LOCATION. Similarly, an Instrumental verb consists of *paN-* and a dynamic verb base, schematized as ‘*paN- + base*’, and take a subject nominal whose semantic role is INSTRUMENT. Both Locative verbs and Instrumental verbs do not have corresponding Active Voice form that takes the prefix *ma-/na-*. In other words, dynamic verb bases are divided in two groups. The first group consists of around one third of dynamic verb bases which, when *paN-* is attached, can form applicative verbs. These verbs can take all of the three voices, including the Active Voice form which is expressed as ‘*ma-/na- + paN- + base*’. The rest of dynamic verb bases, around two thirds of them, form either a Locative Verb or an Instrumental Verb or both when *paN-* is attached. They never take the form of ‘*ma-/na- + paN- + base*’.

As is apparent from these descriptions, Locative Verbs and the Passive Voice of the applicative verbs have an identical form of ‘*paN- + base + -AN*’. Similarly, the form of Instrumental Verbs is identical with Conveyance Voice form of applicative verbs, that is, ‘*paN- + base*’. Old speakers know which dynamic verb bases are categorized in the first group, and which are not. Young speakers, on the other hand, cannot distinguish the first group from the second.

Table 1 shows the first group of dynamic verb bases and their simple and applicative verb forms. *St* in the table represents something, and *sw* somewhere. Verb bases *bohe/* (rub), *paPeŋ* (take by throwing), *tuPi* (touch), *susu* (pierce), and *dahuŋ* (sew) are bases which take *paN-* to form applicative verbs. A new argument which is required by these applicative verbs are either an INSTRUMENT or a LOCATION nominal. For example, *ma-pa-mohe/* (write something with something), *ma-pa-maPeŋ* (take something by throwing something) and *ma-pa-nuPi* (touch with something), require INSTRUMENT as the third argument, which is posited in a subject slot when the verb is in its Conveyance Voice form. In contrast, *ma-pa-nusu* (pierce something on

something), and *ma-pan-dahuŋ* (sew something onto something) take LOCATION as the third argument, which will be a subject of the Passive Voice form verbs. All of these words take three voice forms; for example, *ma-pa-maPeŋ*, an Active Voice form, will turn into the Passive voice form *pa-maPeŋ-an* and the conveyance voice form *pa-maPeŋ*. Further examples are shown in (5).

Table 1: Applicative verbs with the first group of dynamic verb bases.

root	simple verb	meaning	applicative verb	meaning
<i>bohe/</i>	<i>ma-mohe/</i>	write	<i>ma-pa-mohe/</i>	write with st
<i>paPeŋ</i>	<i>ma-maPeŋ</i>	take st	<i>ma-pa-maPeŋ</i>	take st with st
<i>tuPi</i>	<i>ma-nuPi</i>	touch	<i>ma-pa-nuPi</i>	touch with st
<i>susu</i>	<i>ma-nusu</i>	pierce	<i>ma-pa-nusu</i>	pierce sw
<i>dahuN</i>	<i>man-dahuN</i>	sew	<i>ma-pan-dahu</i>	sew on st

- (5) a. *ia/ ma-pa-nahuŋ nu-konop su-Paku/ ie* (Active Voice)  
 I-1sg MA-APP-sew NU-button SU-clothe this  
 ‘I will sew buttons on this clothe’
- b. *Paku/ ie pa-nahuŋ-an=ku nu-konop* (Passive Voice)  
 clothe this APP-sew-AN=NI-1sg NU-button
- c. *konop pa-nahuŋ=ku su-Paku/ ie* (Conveyance Voice)  
 button APP-sew=NI-1sg SU-clothe this

Examples of verb bases of the second group, which cannot take the prefix *ma-/na-* with the applicative prefix *paN-*, are shown in Table 2. Active Voice forms with the prefix *ma-/na-*, which are shown in table 2 with an asterisk, are sometimes elicited by young speakers. In other words, the younger speakers generate applicative verbs by attaching *paN-* to every dynamic verb base, and make three voice forms. For example, *ma-pa-nekoso/□* from *tekoso?* (steal), *ma-paŋ-gogaha/* from *gogaha/* (break), *ma-pa-ŋaPa/* from *kaPa/* (scoop out), *ma-pa-meŋkoŋ* from *beŋkoŋ* (bend) are the words created by them, but these forms are not attested in the data taken from the older speakers. On the other hand, these bases can form Locative and/or Instrumental verb(s) with *paN-*. Thus, *ma-pa-nekoso/* from *tekoso/□* ‘steal’ in table 2 does not exist but Instrumental verb *pa-nekoso/□* which means ‘to steal by using something’, does exist. Similarly, the locative verb *pa-ŋaPa/-en*, which means ‘to scoop out something from somewhere’ exist, while *ma-pa-ŋaPa/* does not. Young speakers,

however, accept those active voice forms of non-existing applicative verbs.

Although they also gave their meanings as shown in the table 2, young speakers often change their mind about them after a day or two. More importantly, they often fail to point out the third argument of a such verb. Sometimes they say *ma-paŋ-gogaha/* takes INSTRUMENT as the third argument, but at other times they insist that LOCATION is the real third argument.

Table 2: Dynamic verb bases of the second group.

root	simple verb	meaning	applicative verb form	meaning
<i>ki/aŋ</i>	<i>ma-ŋi/aŋ</i>	lift	<i>*ma-pa-ŋi/aŋ</i>	*lift with st
<i>tekoso/</i>	<i>ma-nekoso/</i>	steal	<i>*ma-pa-nekoso/</i>	*steal with st
<i>gogaha/</i>	<i>maŋ-gogaha/</i>	break	<i>*ma-pa-ŋogaha/</i>	*break with st
<i>kaPimu/</i>	<i>ma-ŋaPimu/</i>	make	<i>*ma-pa-ŋaPimu/</i>	*make with st
<i>kaPa/</i>	<i>ma-ŋaPa/</i>	scoop out	<i>*ma-pa-ŋaPa/</i>	*scoop out sw

Sentences in (6) show example sentences using a dynamic verb base of the second group. Whereas sentences (6)b with Locative verb and (6)c with Instrumental verb are attested with aged speakers, (6)a, which contains non-existing Active Voice form of an applicative verb, is not.

- (6) a. *\*i-stenli ma-paŋ-gehe/ nu-pahigi su-kahatasa/*  
 I-Stenly MA-PAN-tear NU-knife SU-paper
- b. *kahatasa/ paŋ-gehe/-an ni-stenli nu-pisou* (Locative verb)  
 paper INST-tear-AN NI-StenlyNU-knife  
 ‘Stenly will tear a piece of paper with a knife’
- c. *pisou paŋ-gehe/ni-stenli su-kahatasa/* (Instrumental verb)  
 knife LOC-tear NI-StenlySU-paper

The over-generalization of the morpho-syntactic rule for the applicative prefix *paN-* is partly caused by existence of Locative verbs and Instrumental verbs which take the phonologically same prefix *paN-*. Inconsistency and uncertainty of meaning which young speakers give, together with rejection of their forms by aged speakers, leads to the conclusion that young speakers show radical language change, possibly undergoing language attrition as a result of imperfect learning.

## 5. A Cognitive Account and the Conclusion

Shibatani (2006) posits, 'voice opposition reflect conceptual distinctions pertaining to the evolutionary properties of an action'. The conceptual distinctions will be reinforced by the formal distinctions of the language one uses everyday. If speakers of an endangered language switches to another language of stronger social and economic power, the voice distinctions of the newly employed language will influence that of less used language. As a result, the conceptual frame of the voice system in an endangered language could be lost.

In Standard Indonesian, the Active vs Passive (or Agent vs Goal) opposition is clearly marked, thus the younger speakers of Bantik do keep the two-way voice distinction, and they do not waver in their decisions about the transitive verbs which have only two voices that corresponds Active vs Passive opposition of Standard Indonesian. They, however, seem to be unfamiliar with a three-way voice alternation. They may not recognize existing ditransitive verbs with three voices, but they may also create non-existing ditransitive verbs.

The prototypical core participants for transitive verbs with Active vs Passive opposition are generally ACTOR and PATIENT, and young Bantik speakers have no difficulty in making sentences with Active and Passive Voice verbs in which either ACTOR or PATIENT occupies a subject position. In contrast, verbs which take a three-way voice alternation in Bantik vary considerably with regard to the member of the core participants. Some of them require ACTOR, PATIENT and BENEFICIARY, others need ACTOR, GOAL and CONVEYED THEME. Causative verbs, as shown in example (4) in section 2, require ACTOR, CAUSER and CAUSEE. Applicative verbs would require either a set which consists of ACTOR, PATIENT and INSTRUMENT, or that consists of ACTOR, PATIENT and LOCATION.

The notion that some verbs exhibits three-way voice alternation and knowledge of semantic roles of their core participants should be deeply embedded in the speakers conceptual sphere in order to generate grammatical words and sentences. However, younger Bantik speakers who adopted Indonesian as their first language has lost the idea of three-way voice alternation, and as a result, they are uncertain whether a verb needs three core arguments, or just two. They are also unsure about what other participant other than ACTOR and PATIENT is required by a ditransitive verb.

Using Standard Indonesian as a medium of research naturally influences decisions of the speakers, which makes it difficult to collect the reliable data of the verbs with a three-way voice alternations. To avoid unreliable data, one should look for an adequate number of linguistic consultants who have different socio-linguistic variables, such as gender, education level, and most importantly, age.

## Abbreviations

1sg	first person singular
2sg	second person singular
3sg	third person singular
-AN	suffix attached to verb bases, which indicates passive voice
I-	a nominative case marker attached to nominals
MA-, MAN-	prefix attached to verb base, indicating non-past tense
NA-, NAN-	prefix attached to verb base, indicating past tense
NI-	a genitive case marker attached to nominals that denote singular human
NU	complementizer
NU-	a genitive case marker attached to nominals that denote non-human and human plural
PAN-	applicative prefix attached to verb bases

# Causative and Politeness

**Chikako Shigemori-Bučar**

University of Ljubljana  
Aškerčeva 2, 1000 Ljubljana SLOVENIA  
chikako.bucar@guest.arnes.si

## **Abstract**

In a contrastive research on causative expressions in Japanese and Slovene, a common phenomenon is observed in relation to the permissive reading of Causative. Both languages combine some means of causative expression with an expression of politeness towards the listener in order to express the desire for, or to give notice of, the speaker's action in formal situations. The phenomenon is closely analysed morpho-syntactically and semantically. Existing literature and statistic facts from corpora show that the causative-for-politeness strategy seems more advanced in grammaticalization in Japanese than in Slovene. The analysis also shows some language-specific uses of grammatical elements with no direct correspondence in the other language, i.e. the Japanese receiving verb and the Slovene dative reflexive.

**Keywords:** polite request, permissive, benefactive, formal situation, Slovene, Japanese.

## **1. Causative in Japanese and Slovene**

### *1.1. Definition of Causative*

This paper is based on a synchronic contrastive corpus research on Causative in Slovene and Japanese. The two languages are contrasted in the framework of a broader definition of Causative.

A causative situation is such that an event is brought about by some outside entity. For example, Comrie (1985) states:

If we take a sentence containing a non-causative verb (or other predicate) to be describing a certain situation [s], then a sentence containing the corresponding causative verb will describe a situation [s/cause/] where some entity (person, thing, abstract force) either brings about situation [s] or, at the very least, fails to

prevent [s]. Syntactically, one of the main differences between non-causative and causative constructions will be the increased valency (or potential valency) of the latter, since in addition to the participants in [s] there will also be the actant that brings about [s]. (Comrie 1985: 330-331)

This broad definition of Causative takes into account not only events in which the causer and causee are animate (e.g. example (1) below), but also those in which the causer (or the "effector", the entity that brings about some situation) is inanimate (e.g. example (2) below), as well as those in which the causee (the entity with which some change occurs) is inanimate (e.g. example (3) below).

- (1) I let my student use a dictionary.
- (2) The explosion made him die.
- (3) The explosion made the house collapse.

According to Teramura (1982) the Japanese causative morpheme *-(s)ase-* is most typically used when both the causer and the causee are human beings, and usually when the causer is superior to the causee. (Teramura 1982: 301) However, there are cases when the morpheme *-(s)ase-* appears even when the causer and/or the causee are inanimate. A research on Agency of the causer and the causee in modern Japanese literary texts also show that Japanese causative expressions with the causative morpheme *-(s)ase-* include all possible combinations (causer [+/- agency] and causee [+/- agency]). (Shigemori Bučar 2006: 198)

Within this semantic framework, the morpho-syntactic means of all causative expressions are contrastively analysed in Slovene and Japanese.

## *1.2. Means of causative expressions*

Types of causative constructions have been generally classified based on the formal fusion between the predicate of cause and that of effect. (Comrie 2003, Moore 2005, Song 2006) They may be firstly divided into lexical and productive devices, the latter may then be further classified into two different types: synthetic and analytic.

Dixon (2000) also mentions various causative mechanisms, i.e. lexical, morphological, complex predicate and periphrastic construction. The latter two correspond to the so-called analytical constructions. Both of the contrasted languages actually possess all these variations for causative expressions, but when frequency is concerned Japanese by far abounds in the morphological type with the productive causative suffix *-(s)ase-*. Slovene, on the other hand, has no comparable productive

morpheme, and therefore causation is often expressed by lexical transitive verbs, and in other cases analytically, either in complex predicate or periphrastic construction.

Formal mechanisms of causative expressions in Japanese and Slovene are summarized in Table 1.

Table 1: Morpho-syntactic forms of causative expressions in Japanese and Slovene

Type of mechanism (Dixon 2000:74)	<u>Japanese</u>	<u>Slovene</u>
Lexical	<i>korosu</i> "to kill" 42%* <i>osou</i> "to attack"	<i>ubiti</i> "to kill" 70% <i>strašiti</i> "to frighten"
Morphological	<i>hashir<u>aseru</u></i> "to let run" 48% <i>nom<u>aseru</u></i> "to make drink"	<i>po<u>mladiti</u></i> "to rejuvenate" ** <i>o<u>srečiti</u></i> "to make happy"
Complex predicate	<i>hashitte morau</i> "to have s.o. run" <i>koroshi wo shiiru</i> "to force killing"	<i>dati</i> <i>piti</i> 3% "to give s.o. s.th. to drink" <i>povzročiti padec</i> "to drop (to cause falling)"
Periphrastic construction	<i>komaru yôni suru</i> "to do that s.o. is in trouble" <i>hashiru yôni iu</i> "to tell s.o. to run"	<i>prositi, naj mi odpusti</i> 18% "to ask to forgive me" <i>dovoliti, da jé</i> "to permit to eat"

\*appearance ratio in a parallel corpus analysis (Shigemori: In press)

\*\* The verbal prefix never has a pure deriving function in Slovene and cannot be

discussed parallel to the Japanese verbal infix *-(s)ase-* which is very productive. For example, the verbal base *mladiti* ("to make young, rejuvenate") without the prefix *po-* also exists as a transitive verb in today's standard Slovene (SSKJ 1995: 560), while *srečiti* does not. (The adjective *sreča* "luck, happiness" is a frequent lexical item.)

Simple example sentences to express the one and the same situation in which both the causer and the causee are animate, "I let my student use the dictionary.", are given below. In Japanese this causative situation is expressed by the productive causative morpheme *-(s)ase-* attached to the verb *tsukau* "to use" [see example (4)]. In Slovene a causative verb combines with the lexical verb *uporabljati* "to use" either in complex

predicate [see examples (5) a. and b.] or in periphrastic construction [see examples (6) a. and b.]. Among several Slovene verbs used in these constructions for causative expressions, *dati* "to give" and *pustiti* "to leave" may be categorized as grammaticalized causative verbs, while other verbs, among them *dovoliti* "to permit" [seen in the example sentences (5) b. and (6) b.], may be called lexical verbs used for causative semantics.

- (4) *Gakusei ni jisho wo tsukawaseru.*  
 'student' DAT 'dictionary' ACC 'use'-CAUS-PRS  
 "(I) make/let my student use a dictionary."
- (5) a. *Študentu pustim uporabljati slovar.*  
 'student'-SG-DAT 'leave-let'-1-SG-PRES 'use'-INF 'dictionary'-ACC  
 "I let the student use a dictionary."
- b. *Študentu dovolim uporabljati slovar.*  
 'student'-SG-DAT 'permit'-1-SG-PRS 'use'-INF 'dictionary'-ACC  
 "I permit/let the student use a dictionary."
- (6) a. *Pustim, \_\_\_\_\_ da študent uporablja slovar.*  
 'leave/let'-1-SG-PRS 'that' 'student'-SG-NOM 'use'-SG-PRS 'dictionary'-ACC  
 "I let the student use a dictionary."
- b. *Dovolim, \_\_\_\_\_ da študent uporablja slovar.*  
 'permit'-1-SG-PRS 'that' 'student'-SG-NOM 'use'-SG-PRS 'dictionary'-ACC  
 "I allow the student use a dictionary."

## 2. Permissive reading of Causative

### 2.1. Semantics of Causative

Song (2006) in discussing semantic types of causation takes into account two distinct levels of description. The first level deals with the relationship between the causing event and the caused event, thus distinguishing direct and indirect causation. The second level concerns the interaction between the causer and the causee, which leads to the distinction between manipulative and directive causation. These distinctions, according to Song, are highly relevant to the three types of causative constructions i.e. lexical, morphological, and syntactic. (Song 2006: 266)

There are several semantic analyses of the Japanese productive causative morpheme

-(s)ase-. (Teramura 1982, Hayatsu 2004, Andô 2005) They all agree on the fact that this morpheme covers several semantic areas: coercion (*kyôsei*), permission (*kyoka*), non-interference (*hônin*), cause-and-effect relationship (*inga kankei*) and others. In case of Slovene, the grammaticalized causative verb *pustiti* ("let", originally "to leave") implies a meaning of non-interference, while the lexical verb *dovoliti* ("to permit, allow") denotes permission. This paper focuses on one of these semantic subcategories of Causative, the permissive reading, i.e. in English often realized by the grammaticalized lexical verb "let". It is an indirect and directive causation. When some permission is issued, the causer does not physically get in contact with the causee, but uses some words (or body movements) to communicate to the causee that the latter's wish to conduct (or not to conduct) some action is permitted.

The Japanese example sentence (4) mentioned in the foregoing section may be interpreted as a coercion "I make my student use a dictionary.", as well as a permission "I let/allow my student (to) use a dictionary.", or even as a case of non-interference "I let/leave my student (to) use a dictionary.", according to the context in which this sentence may appear. In Slovene, this semantic distinction is made by the choice of the causative verb: Non-interference when the verb *pustiti* "to leave" is used [example sentences (5) a. and (6) a.], and permission in the case of the verb *dovoliti* "to permit" [examples (5) b. and (6) b.].

## 2.2. Polite request for permission

One of the common phenomena related to causative expressions of permissive reading is that certain causative forms combine with some expression of interaction between 1st and 2nd person (speaker and addressee) to express *polite requests for permission*. Such expressions are discourse bound, as Podlesskaya (2006) asserts in her discussion on Russian "give" verbs. Permissive expressions show a tendency to be favored in speech acts of requesting a permission rather than in those issuing a permission. (Podlesskaya 2006: 291)

In case of Japanese, the causative morpheme *-(s)ase-* combines with the receiving verb *itadaku* (the humble form of *morau*, "to receive", also used as an auxiliary to the main verb for some beneficial action, in order to make requests polite), e.g.

- (7) *Sensei no jisho wo tsukawasete itadakemasu ka?*  
 'teacher' POSS 'dictionary' ACC 'use'-CAUS 'receive'-POT-POLITE Q  
 "May I use your dictionary?" (to a teacher)

In Slovene, one of several verbs with causative semantics usually occurring in complex predicate or periphrastic construction, *dovoliti* “to permit”, is used in its polite imperative, sometimes also in combination with the dative 1. person pronoun *mi* [example (9)], e.g.:

- (8) *Dovolite, da vam zastavim tole vprašanje.*  
 'permit'-2-PL-IMP 'that' 2-PL-DAT 'put'-1-SG-PRS 'this' 'question'-ACC

“Let me ask you this question.” [found in corpus FidaPlus]

- (9) *Dovolite mi parafrazirati gospoda Woodyja Allena.*  
 'permit'-2-PL-IMP 1-SG-DAT 'paraphrase'-INF 'Mr' Woody Allen-ACC

“Please let me paraphrase Mr Woody Allen.” [found in corpus FidaPlus]

In both languages, the use of causative of permissive reading refers to the fact that the initiative is (or should be) given to the 2nd person (addressee) to let the 1st person (speaker) carry out the action denoted by the lexical verb, i.e. 'to use', 'to ask', and 'to paraphrase' in example sentences (7), (8) and (9) respectively. The Japanese receiving verb *itadaku* "to receive" in (7) denotes that the speaker waits for the permission of the addressee (who is socially higher in rank than the speaker) for the action. Similarly in Slovene, the causative verb *dovoliti* "to permit" in (8) and (9) is in polite imperative which leaves it up to the addressee whether or not the action denoted by the relative clause or the infinitive is possible to carry out.

### 3. Expression of speaker's intention in formal situations

The practices in both language communities show that these constructions have become conventional formulae in giving notice of speaker's own intention for a further action in pragmatically formal situations, i.e. speaking before an audience etc.

Modrijan (2007) reports on Slovene parliamentary proceedings. According to her, formulations like examples (8) and (9) in the foregoing section are conventional forms to gain listener's attention and at the same time, signals that the speaker wishes to keep his turn in conversation. Though the verb is in the imperative form, the formulation does not expect any concrete answer from the listener(s). (Modrijan 2007: 11-12)

Kikuchi (1997) explains that the formulation with *-(s)asete itadakimasu*. (literally, "I receive your favor of letting me do s.th.") is primarily a benefactive expression in which the speaker receives the permission from the hearer to do something, and the

choice of the receiving verb *itadaku* adds the meaning that the hearer is socially higher in rank than the speaker. In some contexts, this expression is used also when nobody in particular is present to give any permission. It has become a conventional phrase just to express the humble attitude of the speaker to talk about his planned action. (Kikuchi 1997: 41-43) See example (10):

- (10) *Watashi kara mo hitokoto go-aisatsu sasete itadakimasu.*  
 I 'from' 'too' 'one word' HON-'greeting' 'do'-CAUS 'receive'-POLITE-PRS  
 "I would also like to say some words to greet you."

Further, the next Slovene example (11) is taken from an E-mail correspondence. The writer tries to be polite in stating the decision for his own action.

- (11) *Dovolil bi si pripisati malo komentarja.*  
 'permit'-PART-M-SG 'would' REFL-DAT 'add' 'little' 'comment'-SG-GEN  
 "I would let myself add some comments."

In both cases, the speaker (1st person) actually does not ask for addressee's permission but takes it for granted that he/she carries out the action mentioned. This is syntactically realised in Japanese [example (10)] by not formulating a question but a formal affirmative, in Slovene [example (11)] by stating the decision for action using the 1st person reflexive (detransitivization). The use of the Japanese formula *-(s)asete itadaku*, as in sentence (10), has recently become very frequent and is observed as a new trend, a handy expression of humble attitude but not necessarily in relation to the hearer/addressee. (Kikuchi 1997) What is common to both expressions in two contrasted languages is that though there is the causative element (the verbal morpheme *-(s)ase-* and the verb *dovoliti*) still present, no definite causer (besides the speaker himself) may be identified.

Though the syntactic strategy seems somewhat similar between the systems of contrasted languages, there are crucial differences between them. The greatest difference is in the type of causative mechanism in each language: While Japanese possesses the productive causative morpheme *-(s)ase-*, Slovene has no comparable morpheme. In Slovene, the causative-for-politeness phenomenon is observed only with one of the lexical causative verbs used in serial verb constructions. The second difference is the function of Japanese giving and receiving verbs for which there is no corresponding verbs with the auxiliary function found in Slovene. The role of giving and receiving verbs in Japanese may be related to the socio-linguistic situation. The Japanese society is sensitive to the interpersonal relationship and how to express oneself according to one's social position in relation to others is regarded quite important

(Matsumoto 1988).

#### 4. Corpus data

The causative-for-politeness formulations, *-(s)asete itadaku* in Japanese and *dovolite (mi)* in Slovene, were searched in large corpora, JapWac and FidaPlus. The frequencies of these conventional formulations in relation to the causative morpheme *-(s)ase-* or the causative verb *dovoliti* are summarized in Table 2 below.

Table 2: Frequency of *-(s)asete itadaku* and *dovolite (mi)* in corpora

Corpus	word (A)	word combination (B)	ratio B/A
JapWac*	<i>-(s)ase-</i> 366,474 hits	<i>-(s)asete itadaku</i> 57,098 hits	15.58%
FidaPlus**	<i>dovoliti</i> 13,522 hits	<i>dovolite (mi)/(mi) dovolite</i> 171 hits	1.26%

\*JapWaC: SketchEngine <http://www.sketchengine.co.uk/> 409,384,405 words

\*\*FidaPlus: <http://www.fidaplus.net/> 621,150,000 words

We must take into account that the two corpora are not directly comparable because of the difference in size and text medium. JapWac is a web corpus using a list of URLs, but FidaPlus is made up of various texts (internet 1.24%, books 8.74%, newspapers 65.26%, magazines 23.26%, rest 1.50%). The causative-for-politeness formulation is discourse bound and thus expected to occur more often in spoken language (or semi-spoken language as in letters or internet texts) in order to gain listener's attention and to talk about speaker's planned action. The frequency ratio of the Slovene phrase *dovolite (mi)* "please allow (me)" may become higher if we are to look for it in a pure web corpus or a corpus of spoken language.

Nevertheless, we may say that the phenomenon of causative-politeness combination is more frequent and more advanced in grammaticalization in Japanese. This is probably due to the existence of the productive causative morpheme *-(s)ase-* and the sociolinguistic conditions of the Japanese language, typically characterised by the grammaticalized function of giving and receiving verbs.

## 5. Conclusion

Though this contrastive research is conducted in the framework of a broad semantic definition of Causative, the current paper focuses on only a part of it, namely, on the use of the permissive reading of Causative, observed in rather formal situations in discourse. This is limited to the spoken or semi-spoken language, and the causer (the listener) and the causee (speaker) are both animate/human.

The contrasted means of causative expressions are productive, in Japanese the morpheme *-(s)ase-*, in Slovene a lexical verb used as a causative verb, *dovoliti* "to permit, allow".

In the specific situation of *speaking in a rather formal situation about speaker's own action in the near future*, it seems universal to make use of Causative, i.e. to make use of an additional valency (additional participant), so that the responsibility for the intended action is at least partly passed on to the additional participant. But it is also common in the contrasted two languages, that the causative-politeness strategy has become conventionalized and the permission of the causer is barely felt in some cases.

This particular framework brought the language-specific uses of some grammatical elements to light: The function and syntactic/semantic mechanism of Japanese giving and receiving verbs on one hand, and the reflexive construction in Slovene on the other.

## Notes

1. I consulted Dr. Andreja Žele, Head of the Lexicological Section of Fran Ramovž Institute of the Slovenian Language, Scientific Research Centre of the Slovenian Academy of Sciences and Arts, for the exact semantics and function of the verbal prefix in the present context.

# Argument Structure Binding and Event Nominal Polysemy

Elisabetta Jezek

Dept. of Linguistics  
Pavia University  
Strada Nuova 65, 27100 Pavia, Italy  
jezek@unipv.it

## Abstract

It is well known that Event nominals tend to have both an *event* and one or more *non-event* interpretations and that non-event interpretations may pick out various aspects of the event, such as the *resulting object* or *state*, the *place*, the *instrument* and so on (Apresjan 1974; Bierwisch 1990/1991, 2008; Pustejovsky 2005). However, the representation of their polysemy can still be improved, especially for that which concerns their non-event interpretations.

For example, it has been assumed that Result nominalizations introduce an argument place over and above those found in the corresponding verb (see among others Asher 1993: 151). Engl. *analysis* for instance introduces reference to an abstract object which apparently is not originally an argument of the verb *analyse*. Not all Result nominals seem to behave this way, however. Some Result nominals fill an argument place of the corresponding verb: for example, *building* introduces reference to an entity which can be identified with the grammatical object of the verb *build*.

Given these premises, the overall aim of this paper is to contribute to the representation of the lexical ambiguity exhibited by event nominals by looking in particular at what argument of the base verb is bound in the non-event interpretations<sup>1</sup>. More specifically, I will be concerned with clarifying under what conditions the argument introduction posited for Result nominalizations takes place and when instead it does not. I will argue that this phenomenon depends to a large extent on the meaning of the underlying verb and that the base verbs of nominals which introduce reference to this extra argument are verbs of *covert creation*.

My analysis is based on the theories of Argument structure and Event structure as developed within the Generative Lexicon model (henceforth GL) (Pustejovsky 1995), which I briefly outline in section 2. The language discussed is Italian but the proposed generalizations may easily expand on a broader perspective.

**Keywords:** event nominals, polysemy, argument structure, binding, result, creation verbs.

---

<sup>1</sup> *Event* is used here as a cover term for all sorts of dynamic eventualities.

## 1. The Process – Result ambiguity

The ambiguity of event nominals has been widely discussed within the distinction posited by J. Grimshaw between *Process* and *Result nominals* (Grimshaw 1990). Following Grimshaw, event nominals tend to be systematically polysemous between a process reading (exhibiting argument structure) and a result reading (exhibiting absence of argument structure):

- (1) a. It. la costruzione (del palazzo) è durata due anni = process  
'the building (of the house) took two years'
- b. It. la costruzione (\*del palazzo) è alta due piani = result  
'the building (\*of the house) is two floors high'

Although the Process-Result distinction captures an important generalization, for various reasons it is insufficient to account for all facets of event nominal polysemy.

First, Grimshaw classifies nominals on the basis of their syntactic properties rather than their semantic interpretation. Consequently, her classes are semantically very heterogeneous. For example, her Result class includes both nominals with temporal structure (*simple event nouns*) and nominals which lack temporal structure completely (*referential nominals*, cf. Borer 1999).

Second, it has been assumed that Result nominals are *argument transforming nominals* (Asher 1993: 151) i.e. that they introduce and fill an argument place over and above those found in the corresponding verb. Engl. *analysis* for instance introduces reference to an abstract object which apparently is not originally an argument of the verb *analyse*. Not all Result nominals seem to behave this way, however. Some Result nominals fill an argument place of the corresponding verb: for example, *building* introduces reference to an entity which can be identified with the grammatical object of the verb *build*.

Third, the Process-Result alternation does not exhaust all the possible semantic interpretations exhibited by event nominals. Non-event interpretations may pick out various aspects of the event besides the resulting state or the resulting object. For example, they can denote the place where the event occurs, the instrument which is used to accomplish the event, and so on (Apresjan 1974; Bierwisch 1990/1991, 2008; Pustejovsky 2005).

Given these premises, the overall aim of this paper is to contribute to the

representation of the lexical ambiguity exhibited by event nominals by looking in particular at what argument of the event expressed by the base verb is bound in the non-event interpretations. More specifically, I will be concerned with clarifying under what conditions the argument introduction posited for Result nominalizations takes place and when instead it does not. I will argue that this phenomenon depends to a large extent on the meaning of the underlying verb. In particular, I will argue that the base verbs of result nominals which introduce reference to this extra argument are verbs which licence a semantic hidden argument (i.e. a semantic participant which cannot appear in the surface as an argument to the verb) in verb-argument composition. This hidden argument denotes an incrementally created entity. For my present purposes, I will call *covert creation* the class of verbs expressing events in which an entity is put into existence which cannot surface in the syntax as an argument.

My analysis is based on the theories of Argument structure and Event structure as developed within the GL model (Pustejovsky 1995), which I briefly outline in section 2. The language discussed is Italian but the proposed generalizations may easily expand on a broader perspective.

## 2. Theoretical framework

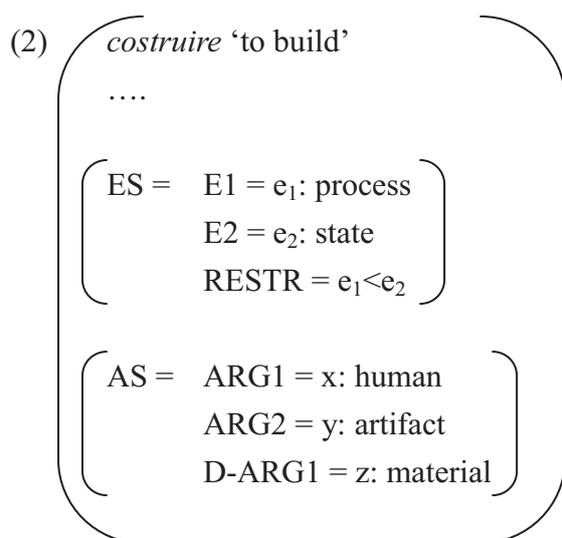

In this section, I briefly outline the components of the GL theory I adopt in my analysis, which are relevant for the present discussion. These are the levels of lexical representation of *Argument Structure* and *Event Structure*.

*Argument Structure* specifies the number and nature of the arguments to a predicate. Within GL, it is assumed that argument structure to a predicate may contain different types of argument, defined on the basis of the conditions which guide and constrain their realization in syntax. Those are: *True arguments*, *Default arguments* and *Shadow arguments* (Pustejovsky 1995: 62-67). A True argument is a semantic parameter which is obligatorily expressed syntactically, such as the internal argument in the expression “Mary rented *a car*”. A Default argument is a parameter which participates in the logical expression but is not necessarily expressed syntactically, such as the goal location in “John left (*the room*)”. A Shadow Argument is a parameter which is semantically incorporated in the verb semantics and can be expressed only by operations of subtyping, such as in “She phoned me *with her new phone*”.

*Event Structure* defines the event type of the predicate and any subeventual structure it may have. Within GL, complex events are represented as tree structures in

which subevents are ordered with respect to their temporal relations and to the prominence they play in the final interpretation (as well as in the mapping of the event arguments to syntax). Event Structures may be *States*, *Processes* or *Transitions* (Pustejovsky 1995: 67-75). States and Processes are durative non-bounded events, while Transitions are binary branching structures encoding change. Transitions may be *left-* or *right-headed*, depending on which one of the two subevents provides the focus of the interpretation. “Mary built a table” is a left-headed Transition and its head is the subevent Process; “The cup broke” is a right-headed Transition and its head is the resulting State.

In (2) I give a partial representation of the It. verb *costruire* (‘built’) using the type feature structure formalism and notation adopted in classic GL to represent lexical structures (ES stands for Event Structure, AS for Argument Structure and < indicates that the first subevent  $e_1$  precedes the second subevent  $e_2$ ):

### 3. Polysemy of Italian event nominals

In this section, I present the result of the corpus investigation I carried out in order to verify what senses nominals take on in context and which participant of the event is bound in the non-event interpretations.<sup>2</sup> From a theoretical point of view, I start

---

<sup>2</sup> In the analysis, I consider both deverbal and simple nouns. I intentionally leave out stative nominals. Recent analyses on the polysemy of Italian event nominals include Gaeta 2004, Melloni 2007 (both from a morphological perspective), Simone 2000 and Jezek 2008.

from the assumption that the potentially restricted senses exhibited by nominals are originally arguments to their corresponding verbs.<sup>3</sup> Also, I assume that binding options for non-event nominals are not limited to syntactic arguments of the base verb but include semantic participants as well. A semantic participant can be roughly defined as *a semantic parameter which participates in the logical expression but need not be discharged syntactically* (sometimes its syntactic projection is ruled out). Summarizing, I assume that event nominals may bind one of the following elements of the event:

- (3) Binding options for event nominals
- i) the event variable;
  - ii) a subevent of the event structure of (i);
  - iii) a true argument of the event;
  - iv) a default argument of the event;
  - v) a shadow argument;
  - vi) the result argument introduced by the nominalization process;
  - vii) an adjunct.

The methodology I adopt to identify the sense alternations exhibited by nominals is basically distributional. In particular, following a methodology proposed in Pustejovsky et al. 2004 and Rumshisky et al. 2007, I automatically extract the typical verbal collocates of nominals organized per grammatical relation, and cluster them into types according to their selectional properties<sup>4</sup> (a key point being the distinction between verbs selecting for events on the one hand and verbs selecting for non temporal entities on the other hand).<sup>5</sup>

---

<sup>3</sup> It has been pointed out to me – Seb. Loebner, p.c. – that the non-event readings exhibited by event nominals may also be interpreted as metonymic displacements. Although I don't exclude that metonymy may be at play in event nominal polysemy, I will limit myself here to verify to what extent the non-event interpretations bind the arguments of the corresponding verbs.

<sup>4</sup> The data are taken from the ITWaC corpus (Baroni and Kilgarriff 2006). In order to speed up the analysis, I use the Sketch Engine (Kilgarriff et al. 2004), a corpus query tool which provides word sketches, i.e. one-page automatic corpus-based summaries of a word's collocational behavior organized per grammatical relation (object\_of, subject\_of etc.).

<sup>5</sup> Although the analysis is carried out using statistical tools, it is meant as a qualitative investigation. Also, the analysis is not meant to answer the question whether there are correlations between the morphological properties of nominals and the polysemy patterns they fall into.

### 3.1. Event

Some nominals apparently tend to exhibit exclusively or predominantly an event reading.<sup>6</sup>

(4) *caduta* ‘fall’<sup>7</sup>

Direct Object:

- (a) event: *anticipare* ‘anticipate’, *rallentare* ‘slow down’, *arrestare* ‘stop’, *accelerare* ‘speed up’, *frenare* ‘slow down’, *affrettare* ‘speed up’, *ritardare* ‘delay’

Head Noun:

- (b) event:  *Brusco* ‘abrupt’, *improvviso* ‘sudden’, *repentino* ‘sudden’, *rapido* ‘quick’, *frequente* ‘frequent’, *precipitoso* ‘rush’, *progressivo* ‘progressive’, *lento* ‘slow’, *continuo* ‘continuous’, *imminente* ‘imminent’, *recente* ‘recent’

The event structure of these nominals may be a bounded Process (5a), a left-headed Transition (5b) or a right-headed Transition (5c). No aspectual constraint seems to be at stake here:

- (5) a. Ho fatto una *dormita* di sette ore  
‘I had a seven-hour sleep’  
b. lo *svuotamento* della vasca fu lento  
lit. ‘the emptying of the pool was slow’  
c. la *caduta* è avvenuta a un chilometro dall’arrivo  
‘the fall occurred one kilometer before the arrival’

If these nominals denote a Transition, next to denoting the change of state, they may denote the effects that such a change typically brings about (see Asher 1993: 150, 157). Hence:

---

<sup>6</sup> We keep out of the present discussion the factive interpretations which, in principle, are available for all nominalizations but which are due to the coercive property of factive predicates rather than the inherent semantics of event nominals (Zucchi 1991, Asher 1993, Pustejovsky 1995). Similar observations hold for manner readings.

<sup>7</sup> The data below is presented following a layout proposed in Rumshisky et al. 2007.

- (6) *il cambiamento* è sotto gli occhi di tutti  
‘the change is there for all to see’

denotes the effects of the change.<sup>8</sup>

In all these cases, I assume that the event interpretation binds the event variable:

- (7) *caduta* (e, x)

Further examples are: *abolizione* ‘abolition’, *sparizione* ‘disappearance’; *guarigione* ‘healing’ *uccisione* ‘killing’; *cambiamento* ‘change’, *inseguimento* ‘pursuing’, *invecchiamento* ‘aging’, *spostamento* ‘displacement’, *svolgimento* ‘development’, *svuotamento* ‘emptying’; *dormita* ‘sleep’, *lavata* ‘wash’; *bocciatura* ‘rejection’, *cottura* ‘cooking’; *rottura* ‘breaking’; *atterraggio* ‘landing’, *montaggio* ‘assembling’ *salvataggio* ‘rescuing’; *dondolio* ‘swing’, *gocciolio* ‘dropping’; *avvio* ‘start’, *crollo* ‘collapse’, *rilascio* ‘discharge’.

### 3.2. Event / State (Result)

Nominals denoting an event encoding a change (that is, a Transition) may licence a result state reading (Bierwisch 1990/1991: 52; Osswald 2005).

- (8) a. *l’abbandono* delle campagne = event  
lit. ‘the leaving of the countryside’  
  
b. una casa in *abbandono* = state  
‘a house in state of neglect’

I assume that the result state reading binds the right sub-event of the event structure:

---

<sup>8</sup> The ontological status of *effects* is controversial: Vendler 1967 considers them temporal object: “effects are not facts or physical objects, but events or processes which are due to other events or processes in the world” (p. 155), “results are not effects, because [...] they are not events or processes at all” (p. 155), “results are facts and they are due to other facts (p. 159)”. To sum up, for Vendler effects last in time, while results don’t.

(9) *abbandono* (e {e1, e2}, x, y)

By definition, nominals denoting Processes or States cannot license this reading, since their event structures do not include a resulting state to which reference can be made. Apparently, only a subset of verbs denoting Transitions, i.e. those defining Target States,<sup>9</sup> are good candidates for result state nominalizations (but see the discussion in Osswald 2005: 259).

Further examples are: *agitazione* ‘distress’, *disoccupazione* ‘unemployment’, *intossicazione* ‘intoxication’; *affaticamento* ‘tiredness’, *inquinamento* ‘pollution’, *arresto* ‘state of arrest’, *assedio* ‘siege’, *degrado* ‘degrade’.

### 3.3. Event / Interval (Time period)

Although in principle all nominals expressing an event involving duration may potentially denote the time span this event covers, some nominals more clearly than others denote an event and the overall period of time over which such event generally occurs:

(10) *il ricevimento* degli ospiti inizia alle 18 = event  
‘the reception of the guests will start at 6 pm’

durante *il ricevimento* si è sentita male = interval  
‘during the reception she felt bad’

---

<sup>9</sup> Following Parsons 1990, it is important to distinguish between the *Resultant state* and the *Target state* of a culminating event. “For every event *e* that culminates, there is a corresponding state that holds forever after. This is “the state of *e*’s having culminated”, which I call the “Resultant state of *e*” or “*e*’s R-state”. If Mary eats lunch, then there is a state that holds forever after: the state of Mary’s having eaten lunch. [...] It is important not to identify the Resultant state of an event with its “target state”. If I throw a ball onto the roof, the target state of this event is the ball’s being on the roof, a state that may or may not last in time (pp. 234-235). “For a large number of verbs, there is a “typical” independently identifiable state that its object is in after the verb is true of it. If the state is transitory, then we come to use the adjective form of the part participle to stand for the transitory state instead of for the permanent resultant state (p. 252)”.

I assume that the interval interpretation binds a time expression (in particular, a time adjunct) (see Melloni 2007: 116). Further examples are: *inaugurazione* ‘inauguration’, *premiazione* ‘prize-giving’, *rivoluzione* ‘revolution’; *allattamento* ‘breastfeeding’, *fidanzamento* ‘engagement’; *fioritura* ‘blooming, blossoming’; *raccolta* ‘harvest’, *cerimonia* ‘ceremony’, *festa* ‘party’.

### 3.4. Event / Abstract Object (Result)

Let us now move to domain-shifting alternations, namely those where one reading introduces reference to a temporal entity and another reading introduces reference to a non-temporal entity, like in the case of *analisi* ‘analysis’, which may denote an event and the abstract object resulting from the mental operation expressed by the verb *analizzare* ‘analyse’:

(11) *analisi* ‘analysis’

Direct Object:

- (a) event: *effettuare* ‘perform’, *eseguire* ‘carry out’, *fare* ‘do, make’, *compiere* ‘make’, *condurre* ‘conduct’, *completare* ‘complete’, *svolgere* ‘carry out’, *concludere* ‘conclude’, *avviare* ‘to start’, *proseguire* ‘go on with’, *ultimare* ‘complete’, *terminare* ‘finish’, *cominciare* ‘begin’, *iniziare* ‘start’, *realizzare* ‘accomplish’, *rinviare* ‘postpone’
- (b) abstract object: *condividere* ‘share’, *confermare* ‘confirm’, *pubblicare* ‘publish’, *contestare* ‘contest’, *smentire* ‘deny’, *citare* ‘quote’, *illustrare* ‘illustrate’, *apprezzare* ‘appreciate’, *commentare* ‘comment’, *diffondere* ‘spread’, *presentare* ‘present’

il ricercatore ha completato l'*analisi* = event  
 ‘the researcher has completed his analysis’

condivido la sua *analisi* e la principale conclusione = abstract object (R)  
 ‘I agree with his analysis and the overall conclusion’

Apparently, the abstract object *analisi* does not bind any of the arguments (true, default or shadow) of the corresponding verb. As we mentioned above, Asher 1993: 151 proposes that the nominalization process in this case introduces an extra argument place which is filled by the output of the event:

(12) *analisi* (e, x, y, R:  $\underline{z}$ )

Further examples are: *autorizzazione* 'authorization', *classificazione* 'classification', *combinazione* 'combination', *descrizione* 'description'; *spiegazione* 'explanation'; *avvertimento* 'warning', *esperimento* 'experiment', *regolamento* 'regulation'; *accordo* 'agreement', *richiesta* 'request'.

### 3.5. Event / Physical Object (Result)

A situation similar to that of *analisi* seems to hold when the result (i.e. the output of the event) has a physical manifestation, as in *disegno* 'drawing':

(13) *disegno* 'drawing'

Direct Object:

(a) event: *eseguire* 'make', *fare* 'make', *completare* 'complete'

(b) physobj: *colorare* 'colour', *mostrare* 'show', *guardare* 'look at', *incorniciare* 'frame', *appendere* 'hang'

fare il *disegno* di una tigre = event

lit. 'to make the drawing of a tiger'

colorare il *disegno* in modo intuitivo = physobj (R)

'colour the drawing in an intuitive way'

Similarly to *analisi*, the result interpretation of *disegno* seems to bind a participant which is not included in the argument structure of the corresponding verb and introduce reference to the output of the event:

(14) *disegno* (e, x, y, R:  $\underline{z}$ )

Not all nominals introducing reference to the physical object brought about by the event seem to behave this way, however. Consider *costruzione* ('construction, building'):

(15) *costruzione* 'building'

Direct Object

- (a) event : *iniziare* ‘start’, *prevedere* ‘foresee’, *finanziare* ‘fund’, *avviare* ‘start’, *permettere* ‘allow’, *ultimare* ‘finish’, *accelerare* ‘speed up’, *impedire* ‘ostacolate’, *autorizzare* ‘authorize’, *vietare* ‘forbid’, *dirigere* ‘direct’
- (b) physical object : *demolire* ‘’, *abbattere* ‘’, *ampliare* ‘’, *vedere* ‘see’, *distruggere* ‘destroy’, *notare* ‘notice’, *circondare* ‘surround’

Hanno terminato la *costruzione* della nuova stazione = event  
lit. ‘they completed the building of the new station’

Presto saranno demolite molte *costruzioni* illegali = physobj (R)  
‘many illegal buildings will be demolished soon’

Similarly to *disegno*, *costruzione* introduces reference to the physical output of the event. In this case, however, the output can be identified with the internal argument of the corresponding verb *costruire*.

### 3.6. Event / Information

Nominals may denote an event and the information which is transmitted during the event (Pustejovsky 2005: 5). This alternation is a specialization of the Event / Abstract Object alternation:

#### (16) *discorso* ‘speech’

Direct Object

- (a) event: *riprendere* ‘start again’, *riavviare* ‘again’, *tenere* ‘hold’, *intavolare* ‘start’, *fare* ‘do, make’, *avviare* ‘start’, *troncare* ‘cut’, *interrompere* ‘interrupt’, *rimandare* ‘postpone’, *imbastire* ‘put together’, *concludere* ‘conclude’, *proseguire* ‘go on with’, *aprire* ‘start’, *rinviare* ‘postpone’, *terminare* ‘finish’, *iniziare* ‘start’, *continuare* ‘continue’, *finire* ‘finish’, *completare* ‘complete’
- (b) info: *apprezzare* ‘appreciate’, *commentare* ‘comment’, *capire* ‘understand’, *semplificare* ‘simplify’, *citare* ‘quote’, *condividere* ‘share’, *giudicare* ‘judge’, *accettare* ‘accept’, *rivedere* ‘go through again’, *criticare* ‘criticize’, *interpretare* ‘interpret’

interrompo il *discorso* per darvi una buona notizia = event  
‘I interrupt the speech to give you good news’

Clinton ha criticato il *discorso* di Arafat = information  
'Clinton criticized Arafat's speech'

The 'info' reading is not to be interpreted as Result, since no output of the event is at stake here. I assume that this reading binds a shadow argument of the event *discorrere* ('talk'), corresponding to the information which is transmitted during the event:

(17) *discorso* (e, x, Sarg:  $\gamma$ )

Further examples are: *dichiarazione* 'declaration', *discorso* 'speech', *esame* 'examination, exam', *intervista* 'interview', *lezione* 'lecture', *seminario* 'seminar', *storia* 'story'.

### 3.7. Event / Food

The Event/Physical Object alternation introduced in 3.5 has various specializations, one of which is the Event/Food alternation (Pustejovsky 2005: 6):

(18) *pranzo* 'lunch'

Direct Object

(a) event: *finire* 'finish', *terminare* 'finish', *fare* 'do, make', *concludere* 'conclude', *interrompere* 'interrupt', *chiudere* 'finish', *cominciare* 'start', *proseguire* 'go on with', *continuare* 'continue'

(b) food: *consumare* 'consume', *gustare* 'try', *cucinare* 'cook', *portare* 'bring', *vomitare* 'throw up', *digerire* 'digest', *comprare* 'buy', *assaggiare* 'taste', *distribuire* 'distribute', *cuocere* 'cook', *buttare giù* 'gobble'

hanno interrotto il *pranzo* e sono corsi a casa = event  
'they interrupted their lunch and ran home'

fare una passeggiata per digerire il *pranzo* = food  
'go for a walk to digest lunch'

As in 3.6, the 'food' reading is not to be interpreted as a Result, since no output of the event is at stake here. I assume that this reading binds a shadow argument of the event

*pranzare*, corresponding to what is consumed during the event:

(19) *pranzo* (e, x, Sarg:  $\underline{y}$ )

Further examples are: *pasto* ‘meal’, *cena* ‘dinner’, *colazione* ‘breakfast’, *picnic*, *spuntino* ‘light meal, snack’.

### 3.8. Event / Mean

Let us now move to a set of readings where the argument which is bound is the external argument. As noted in Bierwisch 1990-1991, nominals may denote an event and the mean used to accomplish the event. As in 3.7, this is again a specialization of the Event / Physical Object alternation:

(20) *riscaldamento* ‘heating’

Direct Object

(a) event: *provocare* ‘cause’, *contrastare* ‘contrast, oppose’, *ridurre* ‘reduce’, *rallentare* ‘slow down’, *evitare* ‘avoid’, *consentire* ‘allow’, *causare* ‘cause’, *produrre* ‘produce’, *frenare* ‘slow down’, *limitare* ‘limit’

(b) mean: *accendere* ‘turn on’, *spegnere* ‘turn off’, *azionare* ‘activate’, *attivare* ‘activate’, *staccare* ‘turn off’, *utilizzare* ‘use’, *sistemare* ‘fix’

un guasto non ha consentito il *riscaldamento* = event  
‘a breakdown prevented the heating’

la notte spengono il *riscaldamento* = mean  
‘at night they turn off the heating’

I assume that the ‘mean’ reading of *riscaldamento* binds the external argument and can be paraphrased as “the mean that Vs” or “the mean by which *y* is Ved”:

(21) *riscaldamento* (e,  $\underline{x}$ , *y*)<sup>10</sup>

---

<sup>10</sup> Note that in addition to binding the external argument and denoting “the mean that Vs”, *riscaldamento* may take on a Result reading (“the output of V”) and bind a default argument: *riscaldamento* (e, x, y, R-Darg:  $\underline{z}$ ).

Further examples are: *illuminazione* ‘lighting, lamp’, *isolamento* ‘isolation’, *imballaggio* ‘packaging’, *imbottitura* ‘filling’.

### 3.9 Event / Human

Less frequently, nominals may denote an event and its agent. This is again specialization of the Event / Physical Object alternation.

(22) *aspettare sempre l'aiuto di qualcuno* = event  
‘always wait for the help of somebody’

*il nostro nuovo aiuto e' portoghese* = human  
lit. ‘our new help is Portuguese’

I assume that in this reading (‘person who Vs’) *aiuto* binds the external argument of the verb *aiutare*:

(23) *aiuto* (e, x, y)

### 3.10 Event / Human Group

The agent of the event may be a single person, as in (22) above, or a human group (institution, organization, company) as in (24) below:

(24) *assumere la direzione dell'azienda* = event  
‘take on the direction of the company’

*parlare con la direzione* = human group  
‘talk to the board of directors’

As with (22), I assume that the ‘human group’ reading binds the external argument of the activity expressed by the verb:

(25) *direzione* (e, x, y)

Further examples are: *organizzazione* ‘organization’, *redazione* ‘editorial staff’;

*schieramento* ‘line-up’; *equipaggio* ‘crew’; *accusa* ‘accusation, prosecution’, *balletto* ‘ballet’, *difesa* ‘defence’, *governo* ‘government’.<sup>11</sup>

### 3.11 Event / Location

Nominals whose base verbs express a change of location may denote an event and the location where the event takes place or where the action is carried out (Apresjan 1974):

(26) *partenza* ‘departure’

Direct Object

(a) event: *ritardare* ‘delay’, *rinviare* ‘postpone’, *impedire* ‘prevent’, *anticipare* ‘anticipate’, *rimandare* ‘postpone’, *posticipare* ‘postpone’, *scaglionare* ‘stagger’, *bloccare* ‘block’, *differire* ‘postpone’, *programmare* ‘schedule’, *spostare* ‘move’, *organizzare* ‘organize’, *aspettare* ‘wait for’, *attendere* ‘wait for’, *annullare* ‘cancel’, *cancellare* ‘cancel’

(b) location: *situare* ‘locate’, *presentarsi (a)* ‘show up at’, *schierarsi (a)* ‘line up at’

hanno ritardato la *partenza* = event  
‘they delayed their departure’

presentarsi alla *partenza* = location  
‘to show up at the departure’

I assume that the location reading of *partenza* (‘place where one V’) binds the default argument of the base verb *partire* ‘leave’:<sup>12</sup>

(27) *partenza* (e, x, Darg:  $\underline{y}$ )

Further examples are: *coltivazione* ‘cultivation, plantation’; *accampamento* ‘campsite’;

---

<sup>11</sup> As noted in Levin 1993, nominals derived from verbs of ruling typically exhibit this reading.

<sup>12</sup> Note that locative readings may bind an element of the event which status with respect to the argument structure of the base verb is not clear. For example, Engl. *exit* in “she was blocking the exit” introduces reference to the place where the motion event takes place and not to the place expressed by the internal argument of the corresponding verb (“exit the *room* through the back door, please”).

*passaggio* ‘passage’, *entrata* ‘entrance’, *fermata* ‘stop’, *discesa* ‘slope’, *uscita* ‘exit’; *arrivo* ‘arrival’, *bagno* ‘bath, bathroom’, *deposito* ‘deposit’, *doccia* ‘shower’, *parcheeggio* ‘parking, parking lot’, *studio* ‘study, office’. In some cases, the location is a route or path: *passeggiata* ‘walk’, *cammino* ‘walk’, *percorso* ‘route’, *ritorno* ‘return’, *viaggio* ‘trip’, etc.

To sum up what I have discussed to far, we can conclude that 1) non-event nominals do not correspond to a fixed argument position within the verb argument structure; 2) all semantic arguments, including those whose syntactic projection is generally ruled out (shadows) or those which are projected but can be left unexpressed (defaults) might be bound in the derivation process; 3) apparently, in some cases, Result nominals cannot be associated with a syntactic argument or a semantic participant of the event expressed by the corresponding verb (*analisi*).

#### **4. Base verbs for Result Nominals**

In the previous section, I have examined the range of interpretations exhibited by event nominals and I have attempted to characterize them with respect to the arguments of their base verb. I have observed that while some Result nominals introduce reference to an entity which apparently does not correspond to a position in the argument structure of the base verb (*analisi*, *disegno*), other Result nominals introduce reference to an entity which does correspond to such a position (*costruzione*). This apparent inconsistent behaviour raises the following theoretical question: why would the nominalization process license an extra argument in some cases but not in others? In this final section, I briefly turn back to Result Nominals with the aim of contributing to clarify this phenomenon, which I assume is conditioned by the lexical semantic properties of the base verbs.

##### *4.1. Overt and covert creation*

Two semantic classes of verbs seem to be particularly relevant with respect to the Result interpretations of nominals and to the issue of the extra argument raised above. I shall call these classes *overt creation* and *covert creation* verbs.<sup>13</sup>

---

<sup>13</sup> It is important to note that not all verbs of creation have corresponding Result Nominalizations and

The base verbs of Result Nominals which bind their internal argument are commonly *overt creation verbs* (Osswald 2005, Melloni, 2007). These verbs express events which put into existence the entity filling the direct object position. The created entity is both an *effected object* and an *incremental theme* (Dowty 1991: 568). *Costruire una casa* leads to the existence of the house, *scrivere un libro* leads to the existence of the book, and so on.

The base verbs of Result Nominals which introduce reference to an argument which is apparently not included in the verb argument structure are different. *Disegnare una casa* does not lead to the existence of the house. Rather, it leads to the existence of a representational object (the drawing). As observed in Badia and Saurí 1991, these verbs share the syntactic property that the entity created by the process described by the verb cannot appear in the surface as an argument, although its identification is relevant to the interpretation of the expressions in which the verb appears.<sup>14</sup> In this case, the *effected object* and the *incremental theme* is represented by this unexpressed entity, not by the entity occupying the object position (see Dowty 1991: 569 for further discussion).

For the present purposes, I shall call these verbs *covert creation verbs*;<sup>15</sup> it should be noted, however, that they are not properly speaking verbs of creation. Although the putting into existence of a new entity plays a role in the interpretation, this is not what the event expressed by these verbs is about: rather, the creation act represents a by-product of the event.

It is still somewhat unclear what the status of the created entity is with respect to the argument structure of the verb. With performance verbs like *disegnare* ‘draw’, which lexically denote an unbounded Process, it seems plausible to interpret this entity (*disegno* ‘drawing’) as a *semantic hidden argument* arising in verb-argument composition. Following this interpretation, while *A Luca piace disegnare* (‘Luca likes to draw’) expresses an activity, *Luca ha disegnato l’albero* (‘Luca drew the tree’) expresses a Transition where a new entity (namely, a representational object) is created

---

that not all Result Nominalizations are derived from verbs of creation. However, the generalization that there is a strict correlation between Result interpretations and verbs of creation seems to hold on a large scale.

<sup>14</sup> Badia and Saurí 2001 also note that reference to this created entity can be introduced via the deverbal nominal or via the adjectival use of the past participle of the verb.

<sup>15</sup> Other labels proposed in the literature for this verb class are *implicit creation verbs* (Osswald 2005), *redescription predicates* (Badia and Saurí 2001), *resultative verbs of creation or modification* (Bisetto and Melloni 2008), *verbs of creation by representation or modification* (Melloni 2007).

(although it is not expressed).

With transition verbs like *ritrarre* ('portray') or *fotografare* ('photograph'), however, which lexically encode the attainment of a result, the situation is less clear. One could assume that in one of its possible senses *ritrarre* means 'make a portrait', i.e. that *ritratto* 'portrait' is a shadow argument of *ritrarre*. This created entity, however, exhibits properties which contrast with the definitorial properties of shadow arguments. Typically, a shadow argument is not created during the event (rather, it is already present in the semantic representation) and its syntactic projection is not completely ruled out, since as we said in 2. it can be expressed by operations of subtyping.

It is possible to identify various subclasses of covert creation verbs. For example, according to Melloni (2007: 162 ff.), cover creation verbs may either leave the entity denoted by the verbal object unmodified or they may tangibly affect this entity. A partial classification based on this distinction would be the following:

(28) Classes of *covert creation verbs*:

- a. verbs which leave the verbal object unmodified:
    - i. verbs of representation: *disegnare* 'draw', *dipingere* 'paint', *ritrarre* 'portray'
    - ii. verbs of mental operation: *analizzare*, *descrivere*, *progettare* etc.[...]
  - b. verbs which produce a concrete modification of the verbal object (affected object): *decorare*, *riparare* etc.
- [...]

It has been noted by several scholars (among others, Ramchand 2008: 68 ff.) that verbs may exhibit polysemy between an *overt creation* and a *covert creation* reading. Apparently, this variation in meaning is induced by the differences in semantic type of the entity occupying the object position. Consider *dipingere* ('paint'):

(29) Who paints *what*?

- a. *dipingere* {un quadro 'a painting', un affresco 'a fresco', un murales 'a mural', un capolavoro 'a masterpiece' ...}
  - *Overt creation verb*
- b. *dipingere* {un paesaggio 'a landscape', un volto 'a face', il cielo 'the sky', un fiore 'a flower', il tramonto 'the sunset', un albero 'a tree' ...}
  - *Covert creation verb*

- c. dipingere {un muro ‘a wall’, il soffitto ‘the ceiling’ ...}  
– *Modification verb*

In a. the entities in direct object position denote a representational object; accordingly, the verb expresses the event of creating that object. In b., the entities in direct object position denote existing objects, natural kinds, locations and so on, and the verb expresses the event of depicting them. In c., the entities in direct object position denote a physical object and the verb expressed the event of covering its surface with paint.

## 5. Concluding observations and future research

In this contribution I have attempted to characterize event nominal polysemy with respect the arguments of the corresponding verbs. In particular, I have attempted to identify which argument is bound in the non-event readings that event nominals may exhibit. The research confirms that non-event nominals do not correspond to a fixed argument position within the verb argument structure; all semantic arguments, including those whose syntactic projection is constrained (shadows) or those which are projected but can be left expressed (defaults) might be bound in the derivation process. Apparently, in some cases, R nominals cannot be associated with a syntactic argument or a semantic participant of the base verb (*analisi*). Result nominals which do not seem to bind any of the arguments of their base verbs tend to be associated with verbs expressing a *covert creation*. The following step is to develop a formal semantic representation that takes these insights into account.

# Latvian Motion Verbs: Telicity Aspect

**Gunta Nešpore**

University of Latvia  
Raiņa bulvāris 29, Rīga, LV-1459, Latvia  
gunta.nespore@lumii.lv

## Abstract

The article deals with two subgroups of motion verbs from the telicity point of view. These subgroups are: verbs denoting running (on foot) and verbs denoting riding a vehicle. Combinations of semantic roles are analyzed to see if the verb in the sentence is telic or atelic. It has been found that most of the verbs can refer to both telic, and atelic motion depending on context. There are several verbs that normally refer to the atelic motion only. But no verbs have been found that can refer to telic motion only in the way that atelic usage would be completely impossible.

**Keywords:** motion verbs, semantic roles, telic verbs, atelic verbs.

## 1. Introduction

In linguistics the semantics of motion verbs is widely analyzed from different points of view (see Talmy 2000, Miller 1972, Asher & Sablayrolles 1995, Levin & Rappaport Hovav 1992 etc.), but there is almost no research done on Latvian motion verbs yet.

Until now the main focus of the research on Latvian motion verbs lied on the paradigmatic (semantic) relations between the verbs (Nešpore 2005). In that research meanings of verbs were split into components and the basic semantic relations (hyponymy, synonymy, incompatibility) in the motion verb group are described.

In this article a small group of Latvian motion verbs is analyzed in the telicity aspect.

Two subgroups of the motion verbs were chosen for analysis:

1. 17 verbs denoting motion on foot — running (RU verbs); verbs referring to running only are taken into account (verbs that may refer to any kind of motion on foot are ignored);

## 2. 12 verbs denoting motion by vehicle (VH verbs).

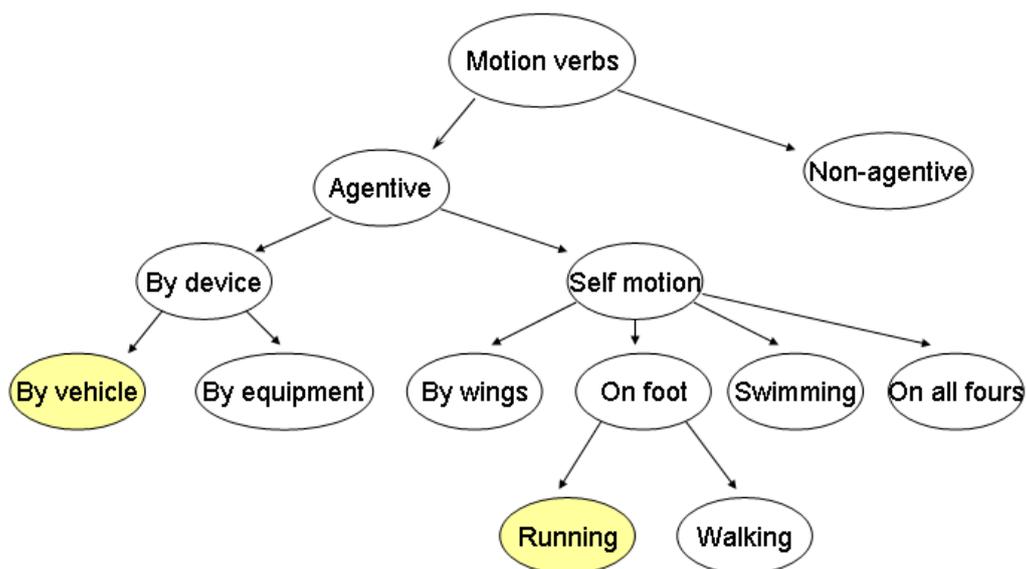

The position of the chosen verbs in the paradigm of motion verbs is shown in Figure 1.

Telic actions are those having a natural completion, finished in some sense (Saeed 2003: 122), these actions (in our case — motion) are goal-directed. For example, if we compare actions in (1) and (2), we see that action in (1) has this natural completion — going home a person sooner or later arrives at home; if the action is interrupted, its purpose is not accomplished. The action in (2) may go on for a long time or for a moment — the result is the same. Consequently, the former action is telic, the latter — atelic.

(1) *iet uz mājām* ‘to go home’

(2) *vizināties pa pilsētu* ‘to take a ride (by vehicle) around a city’

Analyzing the typical combinations of the semantic roles (patterns) in sentences with motion verbs these verbs are described from the telicity aspect — there are certain patterns for telic and atelic motion.

**Figure 1. The analyzed verbs in the system of motion verbs**

## 2. The semantic roles characteristic for sentences with RU and VH verbs

The semantic role<sup>1</sup> is the general relationship between the participant and the main verb of the clause. There are different views on the set of semantic roles that is necessary to describe successfully the function of any word in any sentence. To choose a set of semantic roles for sentences with words of certain thematic group is less problematic. In this research the semantic roles necessary for the analysis of motion verbs are chosen. Their definitions here are adapted for the analysis of motion verbs.

**AGENT** — the participant that performs the action (changes location) intentionally — in the case of motion verbs analysed — when the participant performs self-motion or rides/drives a vehicle.

**GOAL** — the place, the object to which motion is directed — the final point of motion.

**SOURCE** — the place, the object from which motion proceeds — the starting point of motion.

**PATH** — the trajectory of motion — the section between **SOURCE** and **GOAL**.

**PLACE** — the area where the action takes place if it cannot be regarded as **PATH**. Usually it is mentioned when motion is not linear, as in (3), or a broader territory is mentioned, in (4). In the **PLACE** the agent is located all the time of motion — there it usually both starts, and finishes.

(3) *Bērni skraida **pa māju*** ‘Children are running-MULTIDIRECTIONAL **around the house.**’

(4) *Meitenīte **mežā** gāja pa taciņu* ‘A little girl walked along the footpath **in the forest.**’

**DIRECTION** — the direction of motion (*uz priekšu* ‘forward’, *pa labi* ‘right’, *pa kreisi* ‘left’ etc.) that is not the final point of motion.

**VEHICLE** — the device that is used to change place; a special case of the semantic role that is known as instrument (Saeed 2003: 150, Jakaitiene 1988: 63, etc.). As in sentences with motion verbs the instrument always is a vehicle, for convenience the name of the role is made more specific here.

**MANNER** — the manner of motion (*ātri* ‘fast’, *lēni* ‘slowly’, *steigšus* ‘in a hurry’ etc.).

**DURATION** — the duration of motion (*divas stundas* ‘for two hours’, *pusi dienas* ‘for half a day’ etc.).

---

<sup>1</sup> Other terms for the same notion are *deep semantic cases* (Fillmore 1969), *thematic relations* (Jackendoff 1972), *thematic roles* (Saeed 2003), *participant role* (Allan 1986), semantic functions of actors (Jakaitienė 1988) and other.

TIME — the time of motion (*no rīta* ‘in the morning’, *puspiecos* ‘at five o’clock’ etc.).

PURPOSE — the purpose, aim of motion (*braukt slēpot, atpūsties, strādāt* ‘to go to sky, to relax, to work’ etc.).

### 3. General description of the analyzed motion verbs

#### 3.1. Agentivity

All the verbs denoting running and motion by vehicle are agentive — one of its arguments is agent and they denote intentional motion.

#### 3.2. Meaning of the agent

a. The agent of the VH verbs usually is a human (non-human agent can be met if it performs the action normally associated with a human, as in (5)), it follows from the nature of that kind of motion — vehicles are in disposal of people and only people can use them on their own initiative.

(5) *Suns vizinās ar autobusu* ‘A dog goes for a ride (for pleasure) by bus.’

b. The agent of the RU verbs can be human and animal — living beings that are capable of a particular self-motion — running. For several verbs of this subgroup the typical agent is a particular animal, for example, the agent of the verbs *aulekšot<sub>1</sub>*, *auļot<sub>1</sub>*, *lēkšot<sub>1</sub>* ‘to gallop’, *rikšot<sub>1</sub>* ‘to trot’ normally is a horse or other rideable animal; the agent of the verb *bizot<sub>1</sub>* ‘to gallop in order to escape from gadflies’ is a cow.

#### 3.3. Self-motion vs. motion by vehicle

a. RU verbs refer to self-motion of the agent — motion on foot running.

b. VH verbs refer to motion by different kinds of vehicles — part of the verbs can refer to motion by any vehicle (verbs *braukt* ‘to ride a vehicle’, *braukāt* ‘to ride-MULTIDIRECTIONAL a vehicle’, *vizināties* ‘to ride a vehicle for pleasure’), but several verbs refer to a particular vehicle (*kuģot* ‘to go by ship’ — a ship, *plostot* ‘to go by raft’ — a raft, *laivot* ‘to go by boat (for pleasure)’ — a boat) or to a particular group of vehicles (*jāt* ‘to ride an animal’, *jādelēt* ‘to ride-MULTIDIRECTIONAL an animal’ — a horse and other rideable animal, *airēties* ‘to move by rowing’ — a water

vehicle without engine, *lidot* ‘to fly’ — an aircraft).

### 3.4. Media of motion

- a. All the RU verbs refer to motion on the ground.
- b. VH verbs can refer to motion on the ground, by water (*laivot* ‘to go by boat (for pleasure)’, *kuģot* ‘to go by boat’, *plostot* ‘to go by raft’) and by air (*lidot* ‘to fly’) — all the media accessible by vehicles. Most verbs that typically denote motion on the ground (for example, *braukt* ‘to go by vehicle’) may be used also talking about motion in other media, as in (6) and (7), but verbs that typically denote motion by water or air cannot refer to motion on the ground. The possible reason of this asymmetry — motion on the ground is the most natural, neutral for humans, therefore this medium is not central in the meaning of verbs, other features of motion are more important.

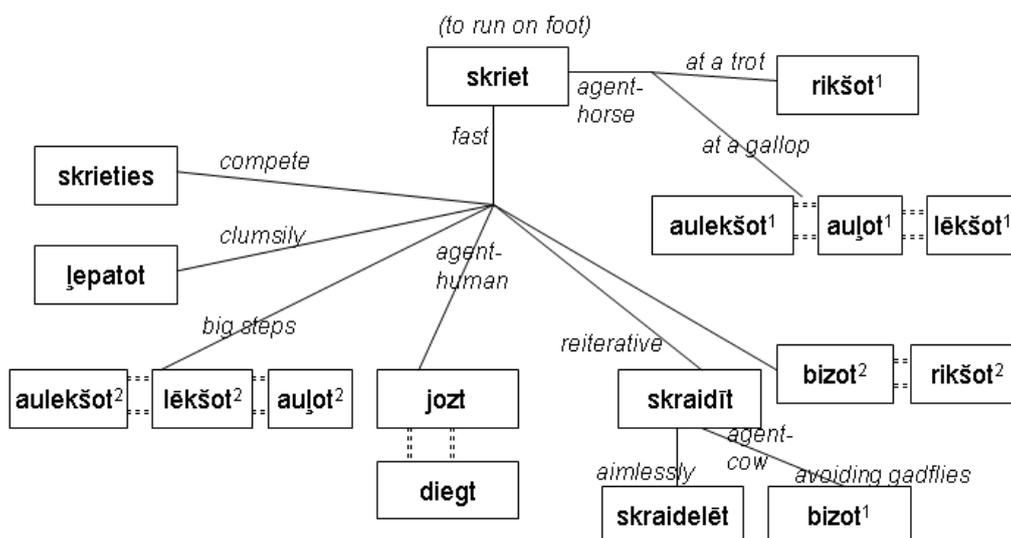

(6) *braukt ar lidmašīnu* ‘to go by plane’

(7) *braukt ar kuģi* ‘to go by ship’

### 3.5. Other features

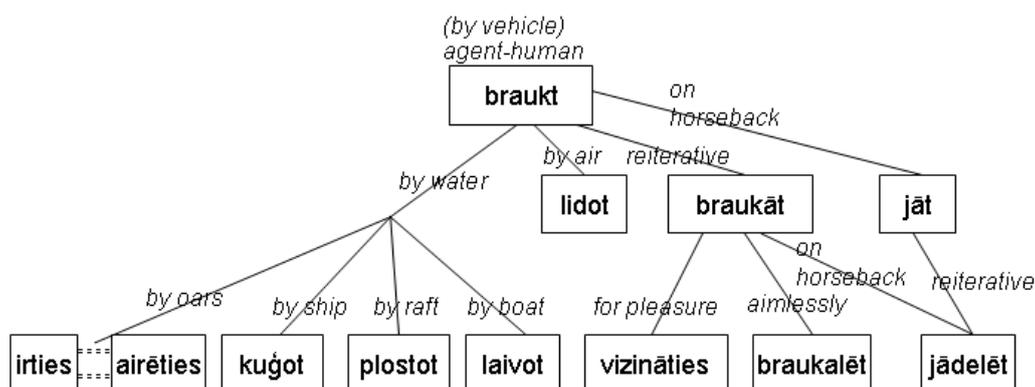

All the Latvian RU verbs with exception of verb *skriet* ‘to run on foot’ (Nešpore 2005: 27–28) have an information about the speed of motion — they denote fast motion; most of these verbs contain information about the manner of motion (‘clumsily’, ‘on trot’ etc.), but VH verbs normally do not contain that kind of information. The only information that is not on the type of vehicle in the meanings of VH verbs is connected with the purpose of motion — *vizināties* ‘to ride a vehicle **for pleasure**’, *braukalēt* ‘to ride a vehicle **aimlessly**’.

One of the reasons to pick two subgroups of verbs was the intention to find out how (if at all) the distribution of these verbs differs in the sentence — what are the typical combinations of semantic roles in both cases. Although differences are not many, semantic roles are basically the same, subgroups differ by the existence of the vehicle mentioned in the sentence and some features of motion resulting from the existence of a vehicle that usually is not reflected in the distribution of the verbs.

**Figure 2. The hierarchic relations of the Latvian RU verbs**

Figures 2 and 3 show the hierarchic relations of the RU and VH verbs. The higher in the hierarchy the verb is situated the more general is its meaning; the meaning components by which the lexical meanings of corresponding verbs differ are shown at the lines. Verbs that are linked with thicker lines (mostly horizontal) are regarded as synonyms.

**Figure 3. The hierarchic relations of the Latvian VH verbs**

#### 4. Telicity of motion

Examining the context where motion verbs occur certain patterns of the semantic

roles can be observed; they help to distinguish if motion described in the sentence is telic or atelic, i.e., whether the result of motion (to arrive in certain place) or the process of motion is of importance in the sentence.

Due to this feature (telicity) the motion verbs can be divided into several groups:

1. Most verbs in appropriate context can refer to both telic, and atelic action — the attention can be focused on the goal, and on the process of motion. For example, *jāt* in (8) and (9); *braukāt* in (10) and (11); *skriet* in (12) and (13).

(8) *jāt uz ezeru* ‘to ride (the animal) to the lake’

(9) *jāt mežonīgos auļos* ‘to ride (the animal) wildly at a gallop’

(10) *braukāt no mājām uz darbu* ‘to go (regularly) by vehicle from home to work’

(11) *braukāt apkārt pa pilsētu* ‘to go by transport about the town’

(12) *skriet uz mājām* ‘to run (on foot) home’

(13) *skriet katru rītu* ‘to run (jog) every morning’

2. Several verbs can denote atelic motion only — the emphasis lay on the process of motion (manner, duration, vehicle etc.), and these verbs normally cannot refer to telic motion. In the sentences with these verbs we cannot see the combinations of the semantic roles characteristic for telic motion. Examples of these verbs are: *vizināties* ‘to ride a vehicle for pleasure’, *braukalēt* ‘to ride a vehicle aimlessly’, *skraidelēt* ‘to run (on foot) about aimlessly’, *laivot* ‘to go by boat for pleasure’.

3. Theoretically, the third group of verbs could be verbs denoting telic motion only. But in the case of motion verbs this group is problematic. There are several verbs that usually refer to telic motion, for example, *jozt* and *diegt* in (14) and (15); still it is not impossible to use them in an atelic way as in (16) and (17), however this usage is not typical. The 3<sup>rd</sup> group could form the verbs that **typically** refer to telic motion.

(14) *jozt prom* ‘**to rush** away’

(15) *diegt uz mājām* ‘**to rush** home’

(16) *jozt ko kājas nes* ‘**to rush** as fast as possible’

(17) *diegt ko kājas nes* ‘**to rush** as fast as possible’

The absence of the clearly telic verbs results from the nature of motion — typically it is durative and it is always possible to focus on the inner structure of the event — to the process of motion.

#### 4.1. Telic motion

The most typical and clear pattern for the sentences denoting telic motion is as follows:

AGENT + VERB + GOAL.<sup>2</sup>

Example:

(18) *Bērni skrien uz mājām.* ‘Children run home.’

Often there are other semantic roles also in the sentence, but they do not give us the information on the telicity of motion, as in (19).

(19) *Mazi bērni ātri skrien uz savām mājām* ‘**Small** children run **quickly** to **their** home’.

In the above mentioned pattern there may be some variations — the aim of motion may be expressed other than by location — the GOAL may be substituted with some other semantic roles: PURPOSE, as in (20), or DIRECTION, in (21), provided that the meaning of the DIRECTION is not in conflict with telic, linear motion, for example, *uz priekšu* ‘forward’, *prom* ‘away’; in this position DIRECTION with meaning ‘back and forth’ is not possible — it is characteristic for atelic motion.

(20) *Bērni brauc slēpot.* ‘Children go (by transport) to sky.’

(21) *Bērni skrien prom.* ‘Children run away.’

Consequently the pattern for telic motion can be the following:

AGENT + VERB + PURPOSE or

AGENT + VERB + DIRECTION.

If there is no GOAL, PURPOSE or DIRECTION in the sentence, it usually means that motion is not telic (22); often in these cases there are other semantic roles in the sentence giving additional information about the process of motion.

(22) *Vīrietis skrien.* ‘A man is running.’

#### 4.2. Atelic motion

The meaning of these verbs is connected with the process of motion (manner, vehicle, location, duration etc.), instead of the result, goal of the motion, for example, verbs *vizināties* ‘to ride a vehicle for pleasure’, *jādelēt* ‘to ride-MULTIDIRECTIONAL an animal’, *plostot* ‘to go by raft for pleasure’, *laivot* ‘to go by boat for pleasure’, *bizot* ‘to gallop in order to escape from gadflies (about cows)’.

The minimal pattern for atelic motion is the following:

AGENT + VERB.

Example:

---

<sup>2</sup> Here and hereafter only semantic roles that help to characterize the telicity of the motion are shown in the patterns.

(23) *Govis bizo* ‘Cows are galloping (in order to escape from gadflies).’

This minimal pattern is not very often met, it is characteristic of few verbs only; still it is possible for all the atelic verbs. Usually this pattern is used with verbs with meaning that gives clear information on the manner of motion, the vehicle (or other feature of motion that is important in the event) and there is no need to give this information in the sentence once more, as in (24) and (25). This pattern clearly emphasizes the manner of motion, other circumstances are not important.

(24) *Govis bizo*. ‘Cows are galloping (in order to escape from gadflies).’

(25) *Zirgs rikšo*. ‘A horse is trotting.’

More often atelic motion is expressed in sentences where apart from verb and AGENT is something more — often it is PLACE, motion is attached to a particular territory:

AGENT + VERB + PLACE.

Example:

(26) *Bērni skraidelē pa māju*. ‘Children is running (on foot) around aimlessly.’

If there is PLACE in the sentence and no other semantic roles with locative meaning (PATH, DIRECTION, GOAL), the motion usually is atelic. SOURCE and GOAL are not known or important, only the territory is mentioned.

Additionally or instead of PLACE there may be TIME, DURATION or MANNER.

Dealing with atelic motion sometimes it is difficult to distinguish PATH and PLACE — it is difficult to say whether the concerned object, for example, meadow, is PATH as a trajectory of motion, or PLACE as territory of the motion. Additionally to PLACE or PATH, DIRECTION with the meaning ‘back and forth’ is met. Then the pattern is:

AGENT + VERB + PLACE/PATH + DIRECTION.

Examples:

(26) *Jānis braukalē pa ceļu šurpu turpu*. ‘John is riding a vehicle (aimlessly) **back and forth**.’

(27) *Linda skraida apkārt pa pilsētu*. ‘Linda is running **around** the town.’

Sometimes DIRECTION with the meaning ‘back and forth; around’ is instead of PLACE, it emphasizes once more the atelicity of the motion, the absence of one GOAL. Still this DIRECTION does not occur very often, because: (a) if the motion is not linear, it is known from the meaning of the verb and the DIRECTION is not essential, (b) some verbs express atelic motion that normally is linear — goes to one direction, for example, *laivot* ‘go by boat (for pleasure)’ or *plostot* ‘to go by raft (for pleasure)’.

For VH verbs additionally to the above-mentioned semantic roles the name of the vehicle may occur:

AGENT + VERB (+ VEHICLE) + PLACE

Example:

(28) *Jānis vizinās ar mašīnu pa pilsētu.* ‘John is taking a ride by car around the city (aimlessly).’

VEHICLE can be also the only semantic role in the sentence apart from the agent. Then it is emphasized (the pattern corresponds to the pattern AGENT + VERB for RU verbs):

AGENT + VERB + VEHICLE.

Example:

(29) *Jānis braukā ar Mercedesu* ‘John is driving-MULTIDIRECTIONAL in Mercedes’.

Mostly the VEHICLE is mentioned in sentences with verbs that can refer to different kind of vehicles (*vizināties, braukalēt, braukt*) — if the kind of vehicle is important, it should be explicitly mentioned. If the verb denotes motion by one kind of vehicles only (*laivot* ‘to go by boat’, *kuģot* ‘to go by ship’, *plostot* ‘to go by raft’), it is not necessary to mention the vehicle once more.

#### 4.3. Verbs denoting both telic and atelic motion

When verbs depending on context can refer to both telic, and atelic motion, patterns characteristic for both types of events can be observed.

In some cases, verbs that are more often used to denote atelic motion may refer to telic motion. They are morphologically reiterative verbs *skraidīt* ‘to run (on foot)’, *braukāt* ‘to ride a vehicle’, *jādelēt* ‘to ride a horse’. As telic verbs they can be used in two ways:

1. To denote repeated movement between SOURCE and GOAL, as in (30). Usually both destinations are known and important, but SOURCE is seldom explicitly mentioned in the sentence (it can be inferred from context and/or situation) — GOAL usually is more important, in (31).

(30) *skraidīt no mājām uz darbu* ‘to run (on foot) from home to work (and back)’

(31) *skraidīt uz darbu* ‘to run to work (regularly)’

The pattern for this is following:

AGENT + VERB (+SOURCE) + GOAL.

2. To denote multidirectional motion in a particular territory, in (32), or to several

GOALS in the territory, in (33): a set of GOALS is known, not individual GOALS.

(32) *braukāt pa pilsētu* ‘to go (by vehicle) around the city’

(33) *skraidīt pa veikaliem* ‘to run to/through shops (to shop around)’

The patterns for these two cases:

AGENT + VERB + PLACE/PATH.

Example:

(34) *Mākslinieki braukā pa Eiropu.* ‘Artists are travelling (by vehicles) around the world.’

AGENT + VERB + GOAL.

Example:

(35) *Sievietes skraida pa veikaliem.* ‘Women run to/through shops (shop around).’

## 5. Conclusions

The analysed motion verbs (RU and VH verbs) are different from the telicity point of view. Most of them in different contexts can refer to both telic, and atelic motion. Several verbs (*laivot, braukalēt, vīzināties* etc.) can denote atelic motion only; it is almost impossible to use them to refer to telic motion. But the group of verbs that would refer to telic verbs only is problematic — there are verbs that normally are used as telic verbs, but it is possible to use them to refer to atelic motion.

**Abstract**

Chinese is showing the effects of internationalization through contact with English. *Lettered words* have emerged as a new phenomenon. Lettered words are primarily abbreviations and *hybrid words* composed of Roman letter and Chinese character components. We surveyed hybrid words in a Chinese newswire corpus to explore their morphological and semantic structure. We find that the orthography of hybrid words belies their essentially Chinese structure: Roman letter morphemes are used as new Chinese *zì* (syllable-morpheme-character), combining with other *zì* to create compounds. Hybrid words are created with the same compounding processes as *zì*-only words, but the Roman letter and Chinese *zì* constituents play different roles. Roman letter morphemes are used primarily as modifiers and Chinese *zì* are used primarily as heads.

## **1. Introduction**

As Chinese society continues to internationalize, the Chinese language is showing the effects of this development through greater contact with English. One resulting trend is the use of new types of words called *lettered words* (*zìmǔcí*). Lettered words are written fully or partly in Roman letters rather than Chinese characters. Many are borrowings from English, and most are initialisms (*WTO*), acronyms (*SARS*), or *hybrid words* composed of a Roman letter constituent and a Chinese character constituent in their written form, such as PC 机 ‘personal computer’ lit. ‘PC-machine’, in which *PC* is written as Roman letters and 机 ‘machine’ as a Chinese character.

Lettered words have become increasingly popular in Chinese in the last few decades and now form a recognized category of new words in the language. They are used frequently in written communication, especially in news writing, technical writing, and computer-mediated communication (Gao 2007). Their use in speech varies based on education, English fluency, personal interests, and age, factors that represent an individual’s level of participation in China’s modernization (Riha 2008).

## **2. Lettered Words as Innovations in Chinese Lexical Borrowing**

Lettered words are unusual because they depart from traditional forms of borrowing in Chinese through the use of Chinese syllable-morpheme-characters (*zì*). Two such traditional processes are loan translation, in which Chinese morphemes are used to translate the meaning of the morphemes in the original (e.g. 热狗 *règǒu* ‘hot dog’, lit. ‘hot-dog’), and transliteration, in which Chinese morphemes are used for their phonetic value only and their individual meanings are suppressed (e.g. 沙发 *shāfā* ‘sofa’, lit. ‘sand-disperse’). In lettered words, Roman letters morphemes replace some or all of what would traditionally have been Chinese *zì*.

To compare the significance of this phenomenon in Chinese with lexical borrowing in English, imagine the widespread use of Chinese syllable-morpheme-characters in English to represent borrowings from Chinese, such as 锅 for *wok* (a type of metal pan) and 豆腐 for *tofu*, and their use to form new words in English, such as 豆腐-burger ‘tofu-burger’. Although this seems improbable in a Western-language context, it is exactly what is happening in Chinese. Roman letter morphemes have been imported into Chinese in both lexical borrowing and in native word formation.

The use of lettered words in Chinese involves new issues regarding the role of the script in lexical borrowing that merit investigation. First, the *script* of lettered words is essential in their formation, a factor not usually considered in the study of the Chinese words or more generally in the study of lexical borrowing. When words are the focus of linguistic analysis, it is assumed that the written form follows the spoken form and that the written form is based on the spoken form (Coulmas 2003). This relationship does not necessarily hold for lettered words in Chinese, however, as a wide variety is used primarily in print (Liu 1999, Zhang 2005). Second, the fact that lettered words use a *foreign* script rather than Chinese characters represents an aspect of their form that has yet to receive attention in writing on lexical borrowing in Chinese, and is addressed only briefly in recent works (e.g. Lin 2001, Li 2004).

### **3. Hybrid words**

Many lettered words are hybrid compounds in which Roman letter constituents are combined with Chinese character constituents. Examples include borrowings (primarily from English) such as X 光 ‘X-ray’, in which *X* is written with a Roman letter and ‘ray’ with a Chinese character, and native creations such as XO 酱 ‘XO sauce’ (XO < extra old [a grade

of cognac]), in which *XO* is written with Roman letters and ‘sauce’ with a Chinese character. The appendix of lettered words in China’s authoritative dictionary of modern Chinese, *Xiàndài Hànyǔ Cídiǎn* ‘Dictionary of Modern Chinese’, includes numerous entries that are hybrid words of this type.

#### **4. Corpus search**

##### *4.1 Research question and method*

Examining the hybrid word entries in *Xiàndài Hànyǔ Cídiǎn* and in Chinese newspapers and other publications, we noticed that most hybrid words in Chinese appeared to be endocentric compounds with a Roman letter component as the modifier and a Chinese *zì* component as the head. Our goal in this study was to determine whether the ‘Roman letter modifier – Chinese *zì* head’ pattern is in fact the prevalent pattern for hybrid words in Chinese.

We used a Python script (<http://python.org>) to randomly select articles containing Roman letter sequences from the Xinhua (People’s Republic of China) and Central News Agency (Taiwan) portions of the *Chinese Gigaword Corpus Third Edition* (Graff 2007). We randomly selected 223 articles from the beginning, middle, and final years (1991, 1998, 2005) of

the two parts of the corpus to find Roman letter sequences. Roman letter sequences were defined as the regular expression

$([A-Za-z0-9-'.!]+)?[A-Za-z]([A-Za-z0-9-'.!]+)?$

which matches any instance of a Roman letter [A-Za-z] optionally preceded by one or more letters, digits, hyphens, apostrophes or periods and optionally followed by one or more letters, digits, hyphens, apostrophes or periods. Examples of Roman letter sequences we found include lettered words such as *IBM*, alphanumeric strings such as *F-16*, and hybrid words such as VCD 视盘机 ‘VCD player’.

#### 4.2 Results

A total of 687 Roman letter strings were extracted and catalogued by hand according to whether they formed compounds with the surrounding Chinese *zì*. Of these strings, 412 were classified as endocentric modifier-noun compounds of the form [M N]<sub>N</sub>. Of those strings, 382 had a Roman letter-based element as the modifier and a Chinese *zì* element as the head noun. Examples include ATM 机 ‘ATM machine’ (ATM < automated teller machine) in which *ATM* is the modifier and 机 ‘machine’ is the head and IT 业 ‘IT industry’ (IT < information technology) in which *IT* is the modifier and 业 ‘industry’ is the head. In addition to modifiers such as *ATM* and *IT* that are initialisms,

the 382 hybrid strings also included compounds in which individual Roman letter morphemes functioned as modifiers. Examples include K 金 ‘alloyed gold’ (K < carat) in which *K* is the modifier and 金 ‘gold’ is the head and X 染色体 ‘X-chromosome’ in which *X* is the modifier and 染色体 ‘chromosome’ is the head. Of the 412 hybrid compounds, only a small number (30) contained a Chinese *zì* modifier combined with a Roman letter-based head (for example, 蚊子 DNA ‘mosquito DNA’).

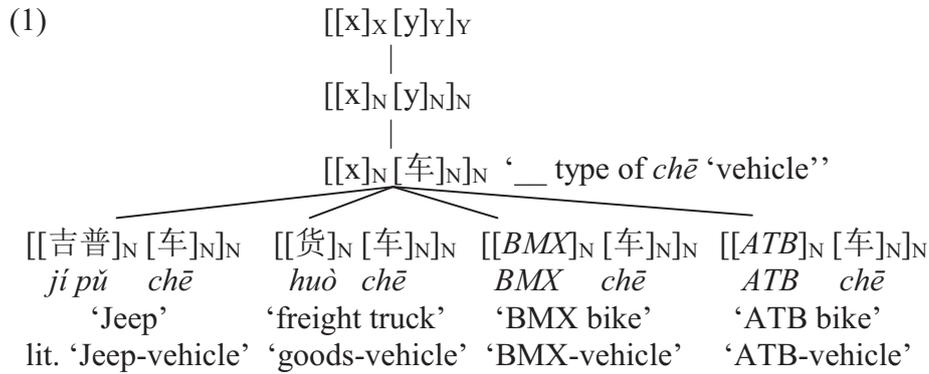

#### 4.3 Discussion

The corpus study results confirm that the ‘Roman letter modifier – Chinese *zì* head’ pattern is most frequent in hybrid compounds. We suggest that the preference for this pattern may be motivated by the opacity of Roman letter-based units relative to their Chinese *zì* counterparts. Roman letter-based units are more opaque than Chinese *zì* in part because they are written with a foreign script. They may therefore be selected to take on the secondary role of modifiers in hybrid compounds rather than the primary role of heads.

In comparing hybrid compounds and their *zì*-only counterparts, we suggest that hybrid compounds are formed by analogy with existing *zì*-only compounds in Chinese using established compounding processes. In particular, compounding *schemas* at various levels of abstraction are used to create both traditional *zì*-only compounds and hybrid compounds. The

notion of schemas has been developed in Construction Grammar (Goldberg 1995, 2006, Kay 1997) to argue that *constructions*, or “learned pairings of form with semantic or discourse functions” (Goldberg 2006: 5) at different levels of abstraction form native speakers’ knowledge of grammar and are used to form new utterances. Booij (2004) applies the concept of constructions at the level of morphology to develop a theory of *Construction Morphology*. Booij argues that morphological schemas are responsible for the formation of new derived words and compounds in a language. Following Booij (2004), we propose that Chinese speakers use schemas to form hybrid compounds by analogy with existing *zì*-only compounds of the same type at various levels of abstraction.

As in Booij’s (2004: 125) model, these levels of abstraction for Chinese compounds include fully abstract schemas such as  $[[x]_X [y]_Y]_Y$ , which combines two free morphemes to form a compound of the form Y; intermediate schemas such as  $[[x]_N [y]_N]_N$ , which combines two nouns to form a compound noun; and partially lexically specified schemas such as  $[[x]_N [chē]_N]_N$ , which combines a noun with 车 *chē* ‘vehicle’ to form compounds meaning ‘a type of vehicle’. These schemas are represented using an inheritance tree in which each lower node inherits the features of its dominating node. The inheritance tree for compounds with *chē* ‘vehicle’ as the head is shown in (1).

Example (2) shows that BMX 车 ‘BMX bike’ (BMX < bicycle motocross) and ATB 车 ‘ATB bike’ (ATB < all-terrain bike) are formed by analogy with other hybrid compounds and compounds expressed entirely with *zì*. They are also formed through the use of at least three compounding schemas: the fully abstract schema  $[[x]_X [y]_Y]_Y$  which combines two elements in a compound to give the lexical category Y, the intermediate schema  $[[x]_N [y]_N]_N$  which creates a nominal compound by combining two nouns, and the partially lexically specified schema  $[[x]_N [车]_N]_N$  in which the first position is filled with a noun and the second is lexically specified as the head *chē* ‘vehicle’. The example shows that even though hybrid compounds include a novel foreign component, they are actually formed with the native compounding schemas in the same manner as *zì*-only compounds.

The role of the lettered modifier is to express a new or foreign concept, while that of the Chinese *zì* head is to express the core lexical and semantic category of the hybrid word. The ‘foreign modifier – Chinese

head' structure also positions hybrid words in Chinese type hierarchies, facilitating their interpretation in terms of native semantic categories. The head 'sinicizes' the hybrid word by serving as its hypernym, and the hybrid word becomes one of its hyponyms. The lettered element is adapted to be a 'type of' the semantic category that forms the Chinese *zì* head. For example, *BMX chē* and *ATB chē* are both hyponyms of *chē*. Thus, although *BMX* and *ATB* denote foreign concepts, they are ultimately categorized as hyponyms of a *Chinese* semantic category, that is, they are types of Chinese *chē* 'vehicle'. The Chinese *zì* head allows speakers to determine the word's basic meaning and syntactic category even if they are not familiar with the lettered element, facilitating the use of the hybrid word in Chinese.

## **5. Conclusion**

We conclude that hybrid words are a unique innovation in modern Chinese. On the one hand, they represent a striking departure in Chinese lexical borrowing since they use Roman letter elements as morphemes, contradicting the tradition that foreign concepts "must be made Chinese in form and character" (Pasierbsky 1989: 102), or "sinicized", before they can enter the Chinese language. On the other hand, hybrid words *are* partly sinicized since they are formed with established compounding

schemas in Chinese by analogy with *zì*-only compounds. Roman letter elements are used to fill slots in existing compounding schemas rather than being used to create entirely new schemas. Thus, the semantic and morphological structure of hybrid words is an extension of existing compounding schemas and borrowing processes in Chinese rather than a departure from them. Hybrid words provide insights into the innovative ways that foreign elements have been incorporated into Chinese, and they reveal the productivity of compounding in absorbing new elements into the language.

## Abstract

As an example of engineering-based semantics, which consists of providing intellectually intuitive forms of language meaning, adjustment methods for semantic networks are proposed to render tangible their contextual structures and to objectively evaluate them. We develop a new windowing method that generates pairs of co-occurring words to be used in constructing semantic networks that are subsequently subdivided by graph clustering algorithms into sets of meaningful components. Computation results are evaluated employing the Modularity Q value and the F-Measure. The effectiveness of these techniques is tested by creating graphs representing the story networks of some literary texts.

**Keywords:** co-occurrence, semantic network, graph clustering, modularity Q, F measure

## 1. Background

### 1.1. What is meaning? -- Essentialist and performance-based semantics

When meaning within a language is considered as being rooted in both physical reality and in human consciousness, it tends to be evaluated from the dualistic view points of *success* or *failure* in terms of passing some test demonstrating intelligence. For example, the Turing test is worth mentioning in this context as it was conceived in order to evaluate a machine's ability to simulate the human faculty of reason. If a computer could successfully make us believe that it was a human individual by simulating the comprehension and production of human-like language, we would have to regard the mechanically-generated 'intelligence' as being completely equivalent to genuine intelligence. While this example comes out of the history of the *amodal theory* of meaning, similar essentialist approaches based on performance results have also been opposing

views on semantic science: Glenberg and Robertson (2000) hold linguistic meaning as being situated in successful *meshing affordance*. According to such protagonists of embodiment theory, meaning, in its ultimate essence, is expressed in and simulated by the experiences of imminent and instrumentally impoverished situations that humans constantly negotiate and resolve by determining the most appropriate alternative solution available to them, often in what appear to be flashes of inspiration. For instance, comparing the afforded meaning in "Marissa forgot to bring her pillow on the camping trip; As a substitute, she filled up her sweater with *leaves*" with the non-afforded example of "As a substitute, she filled up her sweater with *water*", Glenberg and Robertson (2000) affirm that "a sentence is meaningful to a particular reader to the extent that the reader can mesh the objects and activities as directed by the sentence," without providing any clear conceptual connections to explanations about how and why humans can perform well in such instinctive tasks involving meshing affordance.

Such an understanding derives from the essentialist view that, notwithstanding the extent to which linguistic behaviour is being elucidated scientifically, the *black box* still remains largely elusive with the only identifiable aspects being input-output characteristics: a situation that dissuades us from pursuing the internal mechanisms or structures of meaning processing. We must stress the lack of any interface that would allow us to sufficiently articulate the steps necessary to specifically model meaning production and comprehension. However, there is more to it than that. Essentialist approaches to meaning are based at the same time on performance-related concept values that only admit for singular forms of optimization where evaluations would be definitive and strictly binary (sense versus nonsense). Meaning comes into effect if a robot were to succeed in deceiving a human understander into thinking that it were congeneric (Turing) or were capable of determining the optimal match between bodily or physical conditions and situational or environmental ones (Glenberg & Robertson, 2000). It is thus far from being subject to evaluations of schema involving gradual differentiation.

### *1.2. Engineering-based semantics based on semantic networks*

Various approaches to defining meaning within language apparently exist. Essentialist and performance-based semantics leave the black box untouched as a source of meaning after trying to work out the details of linguistic mechanisms. Unlike these types of inquiry, however, we propose in this paper an engineering-based approach to meaning, that is eclectic (because meaning here is not identified with any idealized basis but is rather treated at the surface level of discourse) and interdisciplinary (because

meaning becomes a target for language technology, such as Natural Language Processing).

Our exploration model is neither preoccupied with transcending human understanding in meaning generation, nor with predetermining a special semantic field where detected meanings are unique and right. Instead, we assume that data relating to linguistic meaning must be exhaustively assembled from a target discourse without mystifying some opaque core of signification. It is worth referring to the well-known formula provided by Ferdinand de Saussure, a founder of modern linguistics and natural language processing: “*Language is a system of interdependent terms in which the value of each term results solely from the simultaneous presence of the others.*” If we follow the implicit idea of this thinker, the possibilities of defining semantics can be founded on the “associations” between words. Metaphorically speaking, meaning in language can be considered as being generated from a series of spaces *between* terms. In other words, meaning is by itself a *context*, which is actualized from a chain of words or a block of adjacent terms found in a document.

To that extent, meaning can be manipulated by engineering-based semantics as a form of intellectual intuition about what elements quantify as *entities* (things with distinct and independent existence). One appropriate way to express such transparent representations is to develop and visualize a *semantic network*, as far as meaning may be more or less communicable and thus have an inherent structure or function to convey the signification. Here, a semantic network is represented as a graph form: semantic relationships among words, as *nodes* (or *vertices*), are actualized as *paths* (or *edges*) that may be based on co-occurrence, synonyms or other types of context-shared associations. However, the merits of semantic networks are not limited to their excellent potential to make associations tangible. Their inherent manipulability allows us to generate, as the results of *recombination*, *grafting* and *pruning* operations, multiple graphs or sub-graphs that can be compared and evaluated from various viewpoints free from any commitment to a one-dimensional sense of values. Even the example of *affordance failure* (Glenberg and Robertson, 2000) could be reasonably comprehended by utilizing a set of semantic networks built from a large-scaled corpus and computing the respective connection weights for word strings of “*water pillow*” and “*a sweater in water*”.

Another advantage of our methodology is the availability of algorithms introduced from the science of *complex networks*. Some coefficients relating to graph evaluation turn out to also be useful for optimizing the design of semantic networks. A gradual differentiation schema is proposed from graph theory to construct mediating interfaces that fully employ diversity to be adapted to human viewpoints and utilities.

Meaning, as captured from the interconnected language system, can then be delivered from problems intrinsic to essentialist and performance-based semantics.

## **2. Introduction**

### *2.1. Semantic networks as a form of complex networks*

Rapid advances within network science are helping to transform our ways of understanding the world, by demonstrating that constituent elements are linked together in web-like patterns of connectivity across a range of phenomena from chemical responses cells to human social relationships. By detecting the structures of parts to whole in the world, it is possible to efficiently identify the interactive and explicit relations between constituent elements of a network, and, in turn, to potentially discover latent knowledge and perspectives about such networks. Research achievements by Barabási and his colleagues over recent years have had a major impact on network science, prompting a significant shift in the field due to the concept of "*small world, scale free*" structures.

Within the framework of *complex networks*, linguistic worlds have also been explored by researchers. For instance, studies by Ferrer i Cancho et al. (2001) and by Steyvers et al. (2005) suggest that the generic properties commonly found within natural networks can also be observed within language networks. The notion of linked-worlds can also contribute to a deep understanding of language, especially in yielding extensive insights into semantic worlds. Semantic networks are often used to represent linguistic information in intuitively accessible forms with a graph consisting of vertices that represent words or concepts and edges that represent lexical relationships, such as adjacency, association, or co-occurrence. The basic element of a semantic network is the pairing of two words, together with additional information about the connection weight (i.e., frequency, closeness, or similarity). Thus, the nature of a particular semantic network will depend on word pairings that are determined from a specific source or document according to some rules.

### *2.2. Graph clustering*

The main concern of this study is an analysis of semantic networks by decomposing them into small but strongly connected components. For this kind of graph clustering, the Markov Cluster algorithm (MCL) proposed by van Dongen (2000) is often ap-

plied, as it is effective in subdividing a semantic network into groups of similar or related words or concepts. Through the simulation of random walks within a graph, the MCL computes a stochastic matrix by alternating between the two algebraic operators of *expansion* and *inflation* until the stochastic matrix reaches a convergence. Through that process, a complete network graph would be partitioned into smaller groups without any overlaps among the subdivisions (called hard clustering). MCL allows us to effectively analyze semantic networks in a conceptual level by downsizing the graph structure.

However, as far as the quality of the resultant clusters is concerned, their evaluation is not a simple issue because the relative significance of key words and the granularity of concepts can vary greatly according to how a semantic network is constructed from document data. However, as discussed in our previous studies (Jung et al., 2006, 2007, 2008), the extraordinarily large clusters yielded by this method are undoubtedly a crucial problem for clustering semantic networks. Certainly we have observed many cases where the distributions of words within a document generally follow a power law, but where the distributions in cluster sizes are markedly unbalanced lacking any special features. In order to overcome these deficits, we have developed a series of graph clustering algorithms to improve on MCL in the Recurrent MCL (RMCL) and latent adjacency clustering (Jung et al., 2006, 2007, and 2008).

In contrast, this present study adopts a different approach to the problem, specifically exploring a method of controlling parameter settings so that the most appropriate graphs can be selected based on clustering results. By employing this method, we can obtain multiple semantic networks from the same document source and select from among them according to evaluation results for different purposes or from the standpoints of different analytical readers. The effectiveness of this procedure stems from the following advantage: the multitude of semantic network instances can facilitate the readjustment of concept size when multiple composition themes are untangled by using the derived MCL algorithms mentioned above.

### **3. Selecting word pairs from a document**

#### *3.1. Typical windowing methods*

A semantic network is built by extracting meaningful word pairs from a document. The initial extraction step can be regarded as the most significant work in the

sense that the conceptual structure and other features of a document reflected in the semantic network appear to rely considerably on the selection of word pairs. The pairing relationship between words can represent adjacent, associative, or co-occurring lexical information about the words. The “*window method*” is one well-known way of gathering word pairing data based on co-occurrence. In this method, it is assumed that the strongly-related words are closely located to each other within a context. By controlling some parameters, it is possible to extract different lists of co-occurring word pairs from a single document.

This method was developed and introduced within the Information Mapping Project at Stanford University (by Peters and his group, 1999) and in studies by Schütze (1997) and Takayama et al. (1998). Essentially, a moving frame referred to as a “window” is passed across the target document in order to pick up information about adjoining words appearing inside the window. In this process, the window size is fixed to control for the co-occurrence range of the words, and key words are selected in advance from the document based on frequency so that the window method only collects word pairs co-occurring within the neighbourhood of key words. However, as is also important issue in text analysis, it has been argued that determination of key words in the document should not be judged solely on the criteria of frequency. Rather, key words can be extracted based on analysis results for semantic networks built based on overall lexical co-occurrence data, as that approach would appear to better summarize the characteristics of a document.

However, alternative methods have also been proposed that collect all possible lexical co-occurrence data by incrementally advancing a window across an entire document, rather than a selective search for word pairs centered on key words. For example, Burgess et al. (1998) have advocated an automatic mechanism called HAL (Hyperspace Analogue to Language) for building a semantic information space from a corpus. In HAL, Multidimensional Scaling (MDS) is applied to a global co-occurrence matrix that is generated by a stepping frame collecting the entire neighbouring word relationship. Burgess et al. (1998) take an example of a garden-path sentence “The horse raced past the barn fell” in presenting a distance matrix for the words, as shown in figure 1. With a five-word moving-window frame, the distance value is assigned from 1 to 5 according to the distance between the words. That is to say, each row corresponds to the sum of the distances between the word for that row and preceding words, whereas each column corresponded to the sum of the distances between the word for that column and subsequent words.

	barn	horse	past	raced	the
barn		2	4	3	6
fell	5	1	3	2	4
horse					5
past		4		5	3
raced		5			4
the		3	5	4	2

Figure1. Example of a co-occurrence matrix in HAL

### 3.2. Incrementally advancing window

In building semantic networks in this study, we have essentially adopted the method to exhaustively obtain lexical co-occurrence data, as proposed by Burgess et al. (1998), although a more effective method is also explored from a different perspective. If we define window size  $n$  taking the value of a radius (thus, the diameter is  $2n+1$ ), we need only to extract from the window state  $[w(i-n), w(i-n-1), \dots, w(i), \dots, w(i+n-1), w(i+n)]$  (where  $i$  denote the temporary centre position) only co-occurring pairs based on the rightmost word  $w(i+n)$  to avoid double counting. Overall pairing instances and their frequencies can thus be obtained by incrementally advancing the window to build a graph-based semantic network.

In this method, it is possible to freely set two parameters which bring some advantages. The window size  $n$  can change from 1 to  $p$  and the threshold for word pair frequencies  $\theta$  can vary from 1 to  $q$ . For example, a theta value 3 ( $\theta = 3$ ) would mean that word pairs that appear less than three times in the window would be ignored. Overall pair instances that are weighted due to this use of the threshold  $\theta$  appear to enhance clustering results by grouping together sets similar or tightly related words within a cluster representing a concept, when the MCL is applied to a semantic network built based on such word pairings. Moreover, the two parameters allow us to construct multiple semantic networks. That is to say, when the window size is varied from 1 to  $p$  and the frequency threshold is varied from 1 to  $q$ , it is possible to obtain a total of  $pq$  different semantic networks from a document. Accordingly, the MCL would be run  $pq$  times in order to output  $pq$  semantic networks, which enhances the possibilities of discovering the inherent structures of a text. The next section presents comparison results for multiple semantic networks.

## 4. Graph-based text analysis

#### 4.1. Graph clusters as factors

The graph-based analysis of literary texts has drawn much attention as another effective approach to humanities computing or digital humanities. When the statistical methods of multivariate analysis are applied to windowing data, it is possible to discern implicit information from the lexical co-occurrence patterns gathered from the surface of a text, by yielding a kind of specific thesaurus useful for handling polysemy and synonymy. Graph clustering of semantic networks can highlight the architecture of a document in outputting graph clusters which may be seen as analogous to significant *factors* in multivariate analysis.

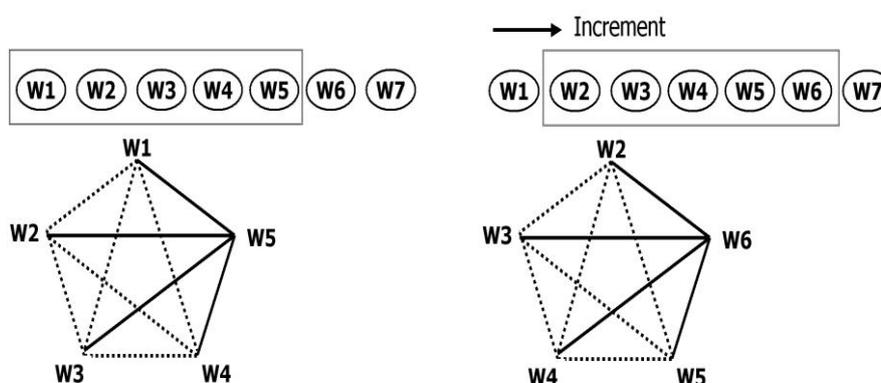

Figure2. Mechanism of our incrementally advancing window

#### 4.2. Text sources

In this study, the incrementally advancing window was applied to two French text sources; *Le Petit Prince* by Antoine de Saint-Exupéry (1900-1944) and a joint text by the two philosophers, Pierre Jean George Cabanis (1757-1808) and Franz-Anton Mesmer (1734-1815). The internationally famous work of the *Le Petit Prince* can now be easily accessed in the public domain because its copyright in Japan has expired. This has prompted the publication of various Japanese versions, which has, in turn, resulted in the situation where some key words have been translated with different meanings and terms (for example, the enigmatic verb, “*apprivoiser*”) bringing about synonymy and polysemy problems. The second source is a joint text written by two contemporary philosophers who shared a similar cultural background that had been influenced by the French Revolution, but who also had radically different thoughts and opinions (Cabanis represented a modern stoicism within the philosophy of medicine, whereas Mesmer

proposed a theory of animal magnetism). Akama et al. (2007) have argued for interesting similarities between these two philosophers based on analyses of their published texts, and this present study extends on that previous research by exploring a method of implicit semantic analysis based on graph clustering to investigate the appropriateness of historical interpretation.

#### 4.3. MCL results

The advantage of graph clustering is the application of parameters and coefficients to complex networks. In this study, we apply MCL to semantic networks built from two literary texts after employing a stop list for French. It is rather interesting that identical characteristics were observed for the two datasets in terms of the numbers of MCL clusters, as a function of changes in the two parameters (as shown in Figure 3): 1) monotonous decreases with increases in window size, when the  $\theta$  values are smaller, and 2) relatively flat curves when the theta values are greater than 4. In Figure 3, the left graph is for the Saint-Exupery network and the right graph is for the Cabanis-Mesmer network. The x-axis represents the window size, and the y-axis indicates the number of Markov clusters generated by the MCL. Each colored line corresponds to a different threshold setting for word pair frequencies. However, these plots raise the question of which line and which point can be regarded as representing the most appropriate results in terms of both rich and essential information. It is necessary to resort to a way of measuring the precision coefficient for each of these clustering results.

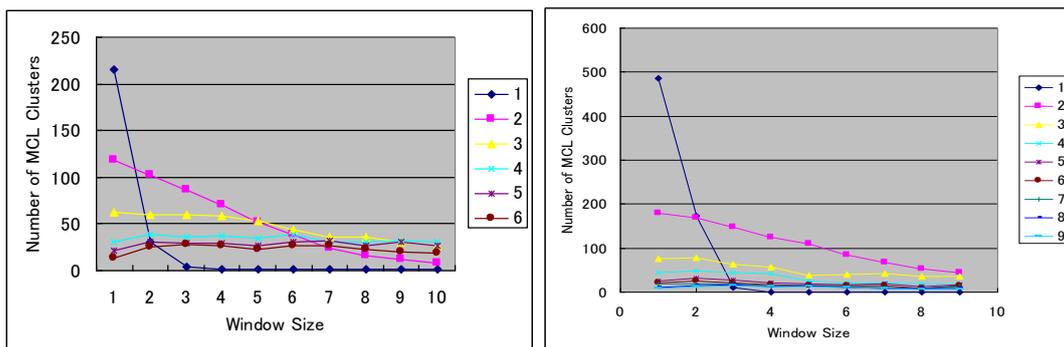

Figure3. Number of MCL clusters: *Le Petit Prince* (left) and Cabanis & Mesmer (right)

#### 4.3. Evaluation

For this, we computed, at the same time, the Modularity Q values as a measure of

the precision of each of the  $pq$  clustering results. Modularity Q (Newman et al., 2004) is a coefficient reflecting differences in edge distributions between graphs of meaningful partitions and random graphs under the same vertex conditions. It can be defined as in the formula,

$$Q = \sum_i (e_{ii} - a_i^2)$$

where  $i$  is the cluster number of cluster  $c_i$ ,  $e_{ii}$  is the proportion of internal links in the whole graph, and  $a_i$  is the expected proportion of  $c_i$ 's edges calculated as the total number of degrees in  $c_i$  divided by the total of all the degrees (2\*the number of all edges) in the whole graph. Clearly, if we regard high Q scores as informative, graph clustering can be considered to be more accurate as window size  $n$  decreases and as the frequency threshold  $\theta$  for word pairs increases.

As shown in Figure 5, however, when Modularity Q reaches a maximum value when window size  $n = 1$  and the threshold is maximally strict, the number of words clustered is at the lowest level. If the conditions for selecting word pairs are set to be the most severe, we can obtain the fundamental topic structure for a document with the smallest number of words and the largest Modularity Q score. Indeed, "The Little Prince" story might be summarized by the keywords contained in such a cluster, as illustrated in Figure 4.

```

{"1(3)", "allumeur", "consigne", "réverbère"}
{"2(2)", "apprivoiser", "renard"}
{"3(3)", "éteindre", "volcan", "ramoner"}

{"12(2)", "monde", "unique"}
{"13(1)", "seul"}
({"Cluster number (number of elements)", "word1", "word2"...})

```

data condition is sufficiently controlled. However, whether this method is also applicable to languages with free word orders or to documents with idiosyncratic features remains an important issue for the future.

Be that as it may, the analysis of semantic networks, by this means, can be founded on a combination of graph theory (clustering of complex networks) and information retrieval (natural language processing evaluation). Our methodology may thus play a crucial role as an example of engineering-based semantics, because it follows some canonical procedures of computational linguistics. Furthermore, it can be construed as an interdisciplinary topic that commences from lexical co-occurrence data and involves artificial intelligence, as well as digital humanities (humanities computing). It may not be too much to say that such knowledge information processing technology can bring promising opportunities to future linguistics research on lexical semantics. Work in the near future will address more general adjustment systems for semantic structures that would allow us to absorb various differences within documents and language data conditions.

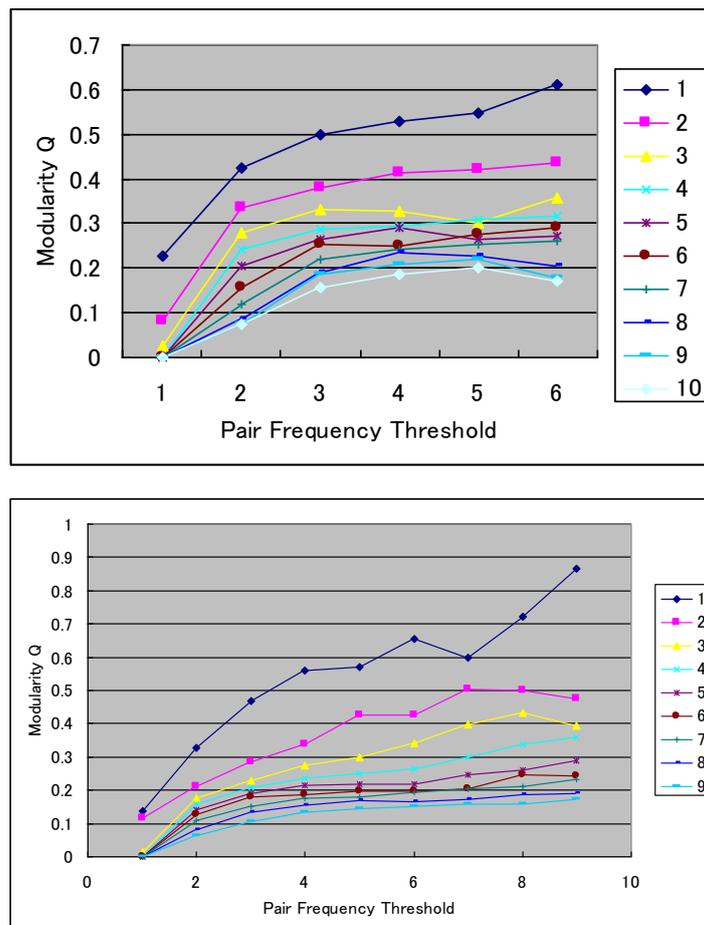

Figure5. Modularity Q: *Le Petit Prince* (upper) and Cabanis & Mesmer (lower)

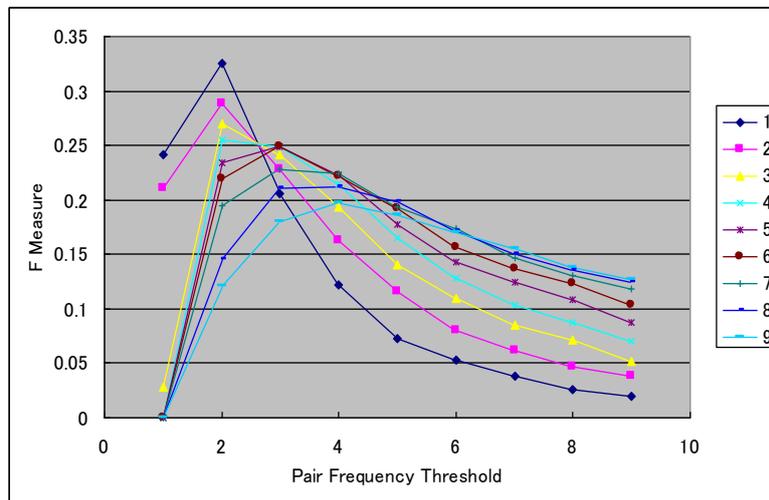

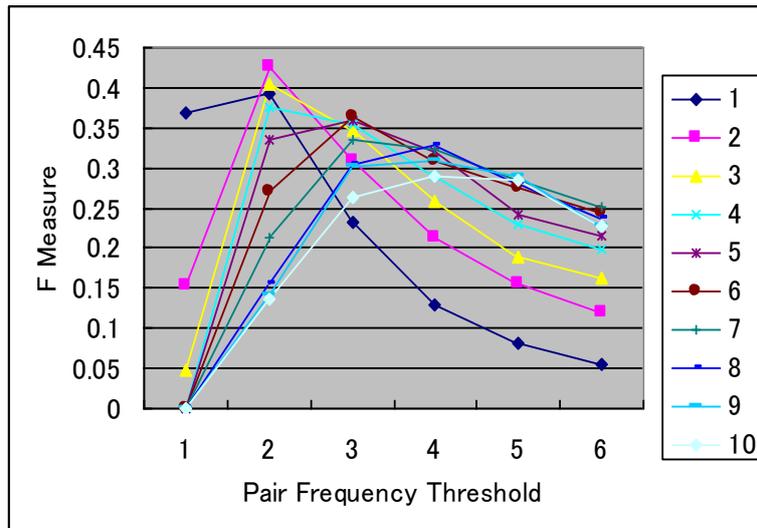

Figure6. F Measures: *Le Petit Prince* (upper) and Cabanis & Mesmer (lower)

## 5. Supplementary Discussion

To date, we have been developing an engineering-based approach to semantic networks starting from an operational definition of meaning. Meaning is not treated here as some opaque essence, but rather as a set of practical quantified entities. The forms of meaning are thus exteriorized and analyzed as graphs, both directed and non-directed and both weighted and non-weighted, with other features such as scale-free nature. The wiring manipulation of graphs provides us with a fine-tune control process in trying to focus on certain constellations of meaning entities. The Modularity Q value and the F measure can play crucial roles in the subtle adjustment process for evaluation. Criteria

for the application of these coefficients are not absolute in nature (treated simply as successful or not) but can be consistently related to the reader's particular interests. In this sense, our method can be a user-oriented approach in the field of scientific and objective hermeneutics (as science of interpretation).

There is an advantage to computing meaning as *patterns*. It can be maximized when a computer program happens to yield unexpected but meaningful results. Outcomes are to be taken as new positive findings obtained through knowledge detection tasks. Text mining combined with humanities computing (digital humanities) has turned out to be effective, as the literary examples presented here demonstrate. In this sense, we might emphasize that an advantage of our model derives from the cognitively clarified insight that meaning is essentially *context dependent*. If we borrow the expression of Burgess et al. (1998), meaning hinges on contextual experience. However, even though our windowing method is partly similar to that of HAL, we cannot agree with the argument advanced by Burgess et al. (1998) that any model deserving the adjective of "semantic" must go beyond episodic experiences and local associative patterns. As Steyvers et al. (2005) purposefully indicate in their network-based analysis, the boundary between *semantic* and *associative* is not so clear. From a slightly different angle, the *paradigmatic* axis strengthened in the research of Burgess should be complemented with situational representations that could be developed by combining various forms of lexicons.

The theory of comprehension advanced by Kintsch (1997) would seem to be promising in this respect if it could be linked to a global theory of complex networks. At present, the networks of the CI model are limited to computation on the *syntagmatic* axis at the episodic level. (For example, the same garden-path sentence is used by Kintsch exclusively for the parsing solution instead of gathering lexical co-occurrence weights: "The horse raced past the barn fell.") Our future research will naturally move towards mediating between the two axis proposed by Roman Jakobson (*syntagmatic* and *paradigmatic*) by the possible application of global semantic networks treated as instances of complex networks. Graph analysis will have to assimilate syntactical factors in order to enhance control over the meaning process and to improve precision and recall values.

# How Discourse/Cognitive Factors Can Influence Argument Realisation: A Case of Object Omission<sup>1</sup>

## Abstract

In recent work several linguists have offered explicit and ambitious proposals for how semantic properties of verbs relate to the overt expression of arguments and predicates. In this paper, I shall argue that these analyses underestimate the role of cognitive and discourse factors that cannot be generalised in those taxonomical analyses. For example, researchers have proposed that causative verbs obligatorily express the argument that undergoes the change of state in all contexts (Browne 1971, Brisson 1994, van Hout 2000 among others). This generalisation is too strong to accommodate the fact that causative verbs do actually allow patient arguments to be omitted under certain discourse conditions and the exceptional cases ultimately lead to a deeper understanding of the general tendencies that exist.

**Keywords:** missing object, change of state verbs, Cognitive Grammar, argument realisation .

## 1 Introduction

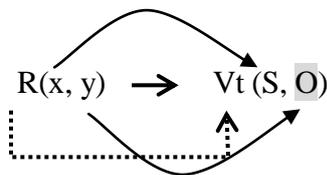

Recent work on lexical semantics shows that a number of linguists have offered explicit and ambitious proposals for how semantic properties of verbs relate to the overt expression of arguments and predicates. These proposals have offered broad taxonomies that divide the lexicon into large semantically uniform classes (e.g. Levin 1993). I contribute to this discussion here by arguing that these analyses underestimate the role of detailed lexical semantics, discourse factors and cognitive aspects that cannot be generalised in those kinds of taxonomical analyses.

Examples which illustrate the non-omissibility of the direct object of the transitive verbs are provided in (1) - (7). The example in (1), for instance, may have a reading where what she has taken in the second utterance is interpreted as 'her medicine'. However, the second utterance in (1) does not permit the direct object to be missed out; the direct object is necessarily retained. The rest of the examples below also

illustrate cases where the object cannot be missed out.

- (1) Has she taken her medicine? - \*She has taken. - Halliday & Hasan
- (2) *In the context where it is perfectly clear that a particular door is in question.*  
\*Did you lock? - Fillmore
- (3) \*I'll open an account if you'll open. - *CGEL*
- (4) \*I'll murder. - Kilby
- (5) The tiger killed \*(someone).
- (6) Chris broke \*(something).
- (7) The heat melted \*(the snow).

Assuming that mapping from the verb's lexical semantics to syntax involves association of arguments of the verb indicated as R in Figure 1, together with their syntactic realisation, we can only describe but cannot explain the above facts; one of two arguments (i.e. x and y) is mapped onto the subject, but the other is not mapped onto any position in syntax.

**Figure 1** Syntactic mapping

As many have observed, there may be a semantic and pragmatic requirement for object omission in English that the speaker must expect the hearer to be able to recover any argument that is omitted either from the lexical meaning of the verb as shown in (8) or the context as shown in (8); recoverability of the missing item may be a licensing condition for omission.

- (8) Recoverability
  - a. Have you *eaten* yet? - *CamGEL*
  - b. They played the club championship and *won*. - *ibid.*

This paper is organized as follows: in section 2, I outline the approach to this problem from lexical semantics. I assume the lexical semantic analysis of Rappaport and Levin (1998), whereby causative verbs obligatorily express the argument that

undergoes a change of state in all contexts, and I claim that Rappaport and Levin's (1998) argument realisation condition is too strong to accommodate real facts and the exceptional cases ultimately lead to a deeper understanding of the general tendencies that exist in lexical semantics and cognitive processes.

In section 3, I show that contrary to the generalisation, there are cases where externally caused change of state verbs do actually allow their objects to be omitted. Next in section 4, further data supporting the claim are presented.

Section 5 shows that (a)telicity, topic and focus do not contribute to object omission of externally caused change of state verbs.

After introducing seemingly relevant factors to explain the omission of the object in section 5, I present in section 6 accounts of object omission from a Cognitive Grammar-based perspective. I argue that the exceptional behaviour of externally caused change of state verbs is explained by this Cognitive Grammar-based analysis.

Finally in section 7, I discuss the implication of my analysis for object omission and further problems yet to be solved.

## **2 Lexical Semantic Analysis**

Before presenting my analysis, let us first have a look at what lexical semantics says about this problem of object omission of transitive verbs, in particular, that of externally caused change of state verbs.

In lexical semantics, the verb's semantic structure reflects the event structure (viz. event structure template) instantiated by the verb. In other words, the event structure is mapped in a consistent way onto syntax. Given that assumption, lexical semantics has the following characteristics in (9)

(9) Lexical Semantics:

- Many aspects of the syntactic structure of a sentence are predicted from lexical properties of the verbs (and other predicates in it).
- Verb meanings provide a key to verb's syntactic behaviour.

A number of researchers have proposed that causative verbs obligatorily express the argument that undergoes the change of state in all contexts (Browne 1971; Brisson 1994; van Hout 2000; Ritter and Rosen 1996, 1998; Rappaport Hovav & Levin 1998). A further condition that has been offered by Rappaport Hovav & Levin (1998) is the

## Subevent Identification Condition.

### (10) Subevent Identification Condition:

Each subevent in an event structure template must be “identified” by an argument and a lexical predicate (e.g., a V(erb), an A(djective) or a P(reposition)) in the syntax. (cf. Rappaport Hovav & Levin 1998: 112)

In most cases this identification comes about as a side effect of the association of the constant with an event structure template in their framework by way of one of the canonical realisation rules: the verb takes its name from the constant, and they assume that the verb also identifies any subevent in the event structure that results from the association of the constant with an event structure template by the relevant canonical realisation rule. The Subevent Identification Condition predicts that an end-state or result subevent may be identified in one of two ways: either it will be overtly identified by a resultative or directional phrase, or it will be implicitly identified by the lexical semantics of the verb (e.g. as with *break* or *kill*).

Following Rappaport and Levin (1998) and van Valin & LaPolla (1997), I assume that Universal Grammar provides an inventory of lexical semantic templates consisting of various combinations of primitive predicates, which correspond to a large degree to the generally acknowledged event types. For this reason, henceforth we refer to a lexical semantic template as an “event structure template”. The inventory of event structure templates assumed here includes those listed below.

- |         |      |  |                  |
|---------|------|--|------------------|
| (11) a. | run  | [x run'] <sup>2</sup>                              | [Activity]       |
| b.      | sing | [x <b>sing</b> ' y]                                | [Activity]       |
| c.      | dead | [x <b>dead</b> ']                                  | [State]          |
| d.      | die  | [BECOME [x <b>dead</b> ']]                         | [Achievement]    |
| e.      | kill | [[x <b>ACT</b> ] CAUSE [BECOME [y <b>dead</b> ']]] | [Accomplishment] |
- (cf. van Valin & LaPolla 1997)

Let us Consider the activity event type and its relation with the verb *sweep*. As illustrated in (12), the verb *sweep* has a variety of uses that qualify as accomplishments, as well as uses that qualify as activities; nonetheless, we assign this verb a basic classification as an activity verb because all its uses entail (or subsume) an activity involving a particular manner of surface contact.

(12) *Sweep*

- a. Terry *swept*.
- b. get things from the cleaning cupboard and stuff. ... I've seen, I've seen her *sweeping*. She *swept* earlier on today! She *sweeps everywhere* continually, she always sleeping, *sweeping* isn't she? I know er she *sweeps* in the hearth at lunchtime [COLT:b142103.cor]
- c. ... but they had to you know use paper and kindle and we *swept with brooms* and my life has never been easier she said [BNC:KBF 2197]
- d. Do you *sweep the floor* before you walk on it so you don't tread on any ants [ICE-GB:S1A-032 #79:1:D]
- e. Tom had *swept the room clean* and had fixed a lamp to a hook on the white plaster ceiling. [BNC: CAB 347]

Within the framework of Rappaport and Levin (1998), *Sweep* of activity sense, exemplified by the sentence in (13), has an event structure template consisting of a single event as in (13), where both participants (*x*, *y*) are associated with the same subevent, in fact the whole event but *only one (i.e. x) of the two (x, y) needs to be expressed* and the other (*y*) is a semantically invoked argument, rather than a structural participant, therefore, *not necessarily expressed* as is represented by *y* being underlined.

(13) Activity

- a. [*x* ACT <MANNER: SWEEP> *y*]
- b. Terry swept [the floor].

In their analysis, Rappaport Hovav and Levin (1998) claim that the notion of external causation is reflected in the complex nature of event structure template that the canonical realisation rules associate with constants naming externally caused change of state. For instance, the externally caused change of state verb *break* has the event structure in (14). In addition, accomplishments are complex events composed of two subevents: the causing event – typically an activity – and the change of state it brings about. Thus, in (14)a, the first subevent (shaded) of an accomplishment has the representation associated with activities, while the second subevent has the representation associated with achievements. More schematic representation of this complexity is illustrated in (14)b .

(14) Accomplishment (externally caused change of state)

- a.  $[[x \text{ ACT}_{\langle \text{MANNER: } \textit{BREAK} \rangle} ] \text{ CAUSE } [ \text{BECOME } [y \langle \textit{BROKEN} \rangle ] ] ]$
- b. The causing subevent → the result subevent [change of state]

Here *x* and *y* represent structure participants in the event structure. The italicised material in angle brackets represents the constant. This constant associated with *break* names a change of state that is conceptualised as “externally caused”. This event structure has two subevents, i.e. a causing activity and a change of state, therefore it is complex. Relevant subevents include simple actions, causes and states, associated with the sort of decomposition familiar from Vendler (1967) and Dowty (1979).

Each subevent is identified by a predicate ( $\text{ACT}_{\langle \text{MANNER: } \textit{BREAK} \rangle}$ ,  $\text{BECOME } [ \langle \textit{BROKEN} \rangle ]$ ) and is associated with argument NPs (i.e. *x*, *y*). Omitting the object would leave a subevent without an associated NP, leading to ungrammaticality (□ (10) & (16)):

(15) Chris broke \*(the vase).

With this much being set as as background, we are now ready to see if the application of Argument Realisation Condition applies to the event structure of an externally caused change of state verb.

(16) Argument Realisation Condition:

- a. There must be an argument XP in the syntax for each structural participant in the event structure.
- b. Each argument XP in the syntax must be associated with an identified subevent in the event structure.

(Rappaport Hovav & Levin 1998: 113)

This condition requires the obligatory expression of both the subject and the direct object of such verbs, since each realises a structural participant (e.g. *x*, *y*,...), one associated with each subevent of the complex event structure of the verbs.

On this account, the causer argument realises as the structural participant of the first subevent and the patient argument as the structural participant of the second subevent. Because they are structural participants and structural participants have to appear in syntax, therefore both arguments (or participants) are obligatorily expressed. In fact, Brisson (1994) and Rappaport Hovav & Levin (1998) say that regardless of the context, the direct object of *melt* cannot be omitted, as shown in (17).

- (17) a. The heat *melted* the snow.  
b. \*The heat *melted*.

In this paper, I shall examine open-ended classes of counter-examples that violate these generalisations, and argue that the generalisations are too strong to accommodate the real facts and the exceptional cases ultimately lead to a deeper understanding of the general tendencies that exist.

### 3 The Problem

As discussed in the previous section, lexical semantics of causative verbs entail that there is a change of state in their patient argument, which is by default expressed by their direct object. Several linguists have argued that causative verbs obligatorily express the argument that undergoes the change of state in *all* contexts.<sup>3</sup> However, causative verbs often do actually allow their direct objects to be omitted, particularly when they are indefinite and non-specific, as shown in (18) and (19).

- (18) Tigers only *kill* at night.  
(19) He'll *lie, steal, murder*--anything to further his ambitions. – Kilby

### 4 The Data

Further examples in (20)-(24) instantiate the claim that causative verbs do actually allow their direct objects to be omitted.

- (20) Some people *build* while others *destroy*.  
(21) a. The chef-in-training *chopped* and *diced* all afternoon.  
b. He *cut* and *chopped* and she felt herself detached from the rotten wood.  
[BNC]  
c. Tigers only *kill* at night.  
d. The police believe the man may *kill* again. [*LDOCE*<sup>4</sup>]  
e. Jailed murderer *killed* again on a day's parole.- *Daily Telegraph* (19/7/2000)  
f. Paroled murderer Jack Abbott, once the toast of New York's literary set,

*killed* again. Last month, he hanged himself. Clive Davis explores the perils of radical chic. A literary celebrity died in America this month, yet his passing aroused little co... - *The Times* (1/3/2002)

- g. Excessive tiredness while driving can *kill*. [OALD<sup>6</sup>]
- h. Cigarettes *kill*. [WordNet]
- i. The Sergeant: We don't *murder*; we *kill*. - *The Big Red One* (1980)
- j. stiff penalties for motorists who *kill*, *maim*, and *injure*. [COBUILD<sup>4</sup>]
- k. It is better to *die oneself* than to *kill*. [COBUILD<sup>3</sup>]
- l. The soldiers specialized in going out in small groups, to *kill* with a very high degree of selectivity. [COBUILD<sup>4</sup>]
- m. Thou shalt not *kill*. [COBUILD<sup>4</sup>]
- n. soldiers are not allowed to shoot to *kill* unless faced with a life-threatening
- o. amplex of money's power to *ruin and destroy* are everywhere, not least in the ... [Bank of English]
- p. for 30 minutes or so, then *rinse and dry* well on a tea towel. Heat oil in ... [Bank of English]

(22) Money markets are the places where people with money *buy* and *sell*.

(23) We *gave*, they *took*.

(24) He must be *convinced* if he is to *convince*. - COBUILD EG

In what follows we concentrate on finding a factor which is required to license object omission with causative verbs.

## 5 Alternative Explanations

### 5.1 Telicity is a relevant factor or not?

Let us start by examining (a)telicity to see if it is a relevant factor for object omission. It may be suggested that (a)telicity could supply the appropriate constraint. Repeated actions are often construed as *atelic* or temporally unbounded events. A simple test for atelicity is that atelic events are compatible with durative temporal phrases such as *for an hour* and incompatible with bounded temporal phrases such as *in an hour*.<sup>4</sup> Most of the iterative and generic contexts in (25) pass this test of atelicity (with the exception of (25), which allows both durative and bounded temporal phrases):<sup>5</sup>

- (25) a. The chef-in-training *chopped* and *diced* \*in an hour/for hours.  
 b. Tigers only *kill* at night \*in a period of their lives/for a period of their lives.  
 c. The singer always aimed to *dazzle* in an instant/for hours.  
 d. Pat *gave* and *gave*, but he just *took* and *took* \*in a year/for years.  
 e. These revolutionary new brooms *sweep* cleaner \*in a year/for years.  
 f. Always *cut* in straight lines \*in the first few years/for the first few years you *sew*.

Many researchers have observed that atelic contexts are more likely to be intransitive than telic contexts (Mittwoch 1971; Hopper & Thompson 1980; Dixon 1991: 288; Aarts 1995: 87; van Hout 1996:166-187; Rappaport Hovav & Levin 1998). However, atelicity *per se* is not necessary for object omission. Thus a telicity is not a sufficient condition for object omission. Notice that the following examples with verbs in the progressive form designate atelic but singular actions and require the patient argument to be expressed:

- (26) a. Scarface was *killing* \*(someone) when he got shot.  
 b. As she was *pleasing* \*(an audience), she thought about her upcoming audition.

Conversely, example (27) is telic, yet the example is fully acceptable:

- (27) Three days later Vernage *killed* again. [BNC]

This shows that atelicity is not a necessary condition for object omission either. The use of *again* in (27) indicates that *Vernage* has killed before. If the action is construed as an isolated occurrence, the sentence is unacceptable:

- (28) ?? Pam *killed* yesterday.

It is clear from the data above that the atelicity is not a sufficient or necessary condition for object omission for causative verbs. It seems that repetition of the action is more relevant than the atelicity of the event.

## 5.2 *Focal or not?*

In this subsection, we examine whether omitted argument is a focus or not. Focal arguments serve to convey the new information in a clause. More precisely, “the relation between the focus element and the proposition is assumed to be unpredictable and non-recoverable for the addressee at the time of the utterance. The focus relation relates the pragmatically non-recoverable to the recoverable component of a proposition and thereby creates a new state of information in the mind of the addressee”.

(Lambrecht 1994: 218)

As we have seen, the omitted patient arguments in the examples in (25) above are all highly predictable given the predicates and the sentence context. They are therefore not candidates for focal status.

## 5.3 *Topical or not?*

A sentence topic can be defined as a “matter of [already established] current interest which a statement is about and with respect to which a proposition is to be interpreted as relevant” (Lambrecht 1994: 119). It follows from this definition that topicality should be recognised as a matter of degree. Even so, the omitted patient arguments are deemed to be non-topical. Topical elements are most often definite, so the indefinite, non-specific nature of the patient arguments makes them ill-suited for topical status. As noted by Fillmore (1986), topical elements can be shown not to allow the type of object omission discussed here:

(29) What happened to *that carrot*?

I *chopped* \*(it).

(30) What happened to *that gazelle*?

The tiger *killed* \*(it).

The possibility of anaphoric reference is another reasonable measure of topicality, at least for entities, since one is likely to wish to continue discussing topical entities. As expected, the omitted arguments under discussion do not provide discourse antecedents as shown in (31) and (32). Topical elements, in contrast, are definite and syntactically active.

(31) The chef-in-training *chopped and diced* all day. \*They were put into a large

salad.

- (32) Tigers only *kill* at night. \*They are easily caught at that time.
- (33) a. This leads people to the following conclusion.  
b. This leads to the following conclusion.  
c. This leads people<sub>i</sub> [<sub>CP</sub> [<sub>IP</sub> PRO<sub>i</sub> [<sub>VP</sub> *t<sub>i</sub>* to conclude what follows]]].  
d. \* This leads [<sub>φ<sub>i</sub></sub>] [<sub>CP</sub> [<sub>IP</sub> PRO<sub>i</sub> [<sub>VP</sub> *t<sub>i</sub>* to conclude what follows]]].

To summarise this section, we have seen that atelicity does not contribute to object omission with causative verbs. In addition, the omitted object is not a focus or a topic in a sentence. It is now worth taking a closer look at this phenomenon from a different perspective, i.e. Cognitive Grammar.

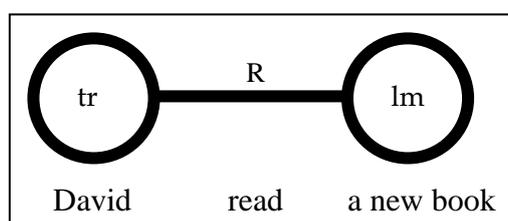

## 6 A Cognitive Grammar Analysis

I assume Langacker's Cognitive Grammar approach to object omission, according to which the contrastive behaviour of the object of the verb *read* as in (34) is due to the different conceptual structures for those constructions.

- (34) a. David *read* a new book.  
b. David is *reading*.  
c. The best way to learn is to *read*.

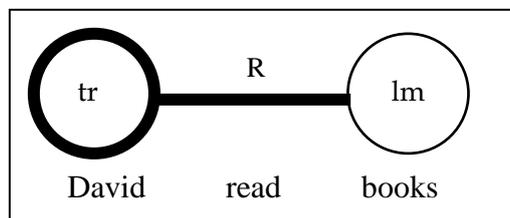

Each image schema in Figure 2 corresponds to each cognitive structure to three sentences in (34), respectively. Schema (a) is a default cognitive image for sentence (34)a, where both the subject and object are prominent (represented in thick line in the figure) in the base of a predication. In Schema (b) corresponding to (34)b, the indefinite object is not prominent in the conceptualiser's construal, therefore omitted in the linguistic structure. Lastly further omission is seen in Schema (c), the counterpart of (34)c, where neither the subject nor the object is prominent (represented in thin line) and they do not show up and the relation indicated by the verb alone is prominent.

a.

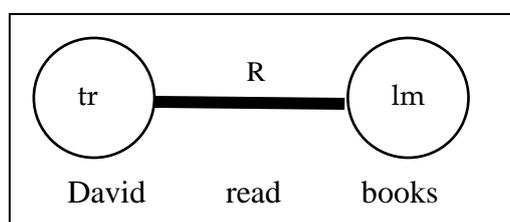

**Trajector [tr]:**  
The figure within a relational profile.  
**Landmark [lm]:**  
A salient substructure other than the trajector of a relational predication or the profile of a nominal predication.  
**Relation [R]:** A diadic relation represented by the verb

b.

c.

**Figure 2** Image schemas for *read*

In the above cognitive schemas, the base of a predication is its domain (or each domain in a complex matrix) enclosed by a square. Its profile is a substructure elevated to a special level of prominence within the base, namely that substructure which the expression “designates”. Thus an expression’s semantic value does not reside in either the base or the profile individually, but rather in the relationship between the two. The key points about this grammar are repeated in (35).

(35)

- Profile on a base
- The base of a predication is its domain (or each domain in a complex matrix)
- Its profile is a substructure elevated to a special level of prominence within the base, namely that substructure which the expression “designates”.
- An expression’s semantic value *does not reside in either the base or the profile individually, but rather in the relationship between the two.*

This Cognitive Grammar analysis extends quite easily to the cases with change of state verbs as in (36) and (37) where no object appears.

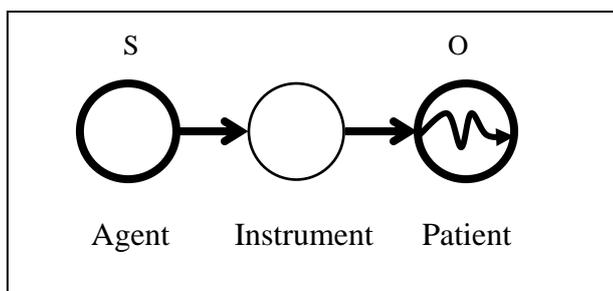

(36) A: When do these animals *hunt*?

B: Beavers *kill* during the day, but tigers only *kill* at night.

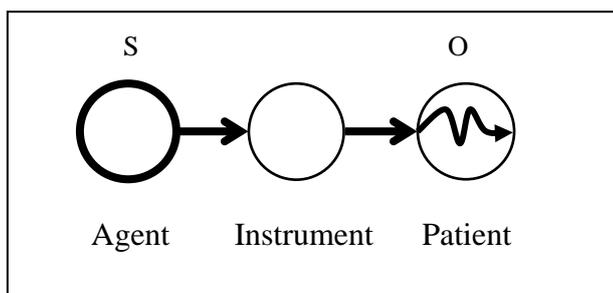

- (37) a. He was always opposed to the idea of *murder*, but in the middle of battlefield, he had no trouble *killing*.  
b. She picked up her carving knife and began to *chop*.  
c. Why would they give this creep a light prison term!? He *murdered*!  
d. How could Griselda get a lighter prison term than Zard? He *burglarized*, but she *murdered*.

The corresponding cognitive image for the structure in which the object turns up is seen in Schema (a) in Figure 3.

a. default

b. Non-default

**Figure 3** Schemas for change-of-state verbs

In other words, Schema in (a) illustrates a default organisation of relevant elements. The non-default case is shown, in contrast, in Schema (b) where the object element is not prominent and therefore does not show up at the surface.

Taking the above Cognitive Grammar analysis into account, what (38) claims is that the patient argument, when construed to be de-emphasized or unprofiled in its relation to the action, can be omitted contra Rappaport Hovav and Levin's Argument

Realisation Condition. That is, omission is possible when the patient argument is not topical (or focal) in the discourse, and the action is particularly emphasized (via implied repetition, strong affective stance, discourse topicality, contrastive focus, etc.). In other words, low discourse prominence or low profile makes it possible for the patient argument not to be made explicit by an elaborate noun phrase, because what should be emphasized or profiled there is the type of the action or the action itself rather than the relatively low-profiled patient argument. This in turn means that a certain discourse factor can override structural requirement imposed by the grammar as far as the suppressed argument, definite or indefinite, can be recovered in the discourse or the verb's lexical semantic content and at the same time the action itself is relatively profiled against the patient argument.

(38) Principle of Omission:

Omission of the patient argument may be possible when the patient argument is construed to be less profiled/emphasized in the discourse in comparison with the action itself via repetition, contrastive focus, etc.

Covert indefinite objects provide further evidence for the principle given above. Note that (39), with an indefinite object invisible at the surface, makes itself a generic statement; it characterises the property of the referent of the subject *He*. Given that covert indefinite objects *do* characterize the property of the subject referent, we correctly predict that the tense of sentence should be present. This is illustrated in (39) - (47), where only (44) with its tense marked as past sounds awkward in contrast to the others with the present tense.

■ covert indefinite objects →generic statements →characterising property

- (39) He likes to *shock*.
- (40) That movie always *shocks*.
- (41) He likes to *please*.
- (42) I'll aim to *please*.
- (43) He never fails to *please*.
- (44) ?His behaviour at lunch *pleased*.
- (45) Jesus *saves*.
- (46) Love *heals*.
- (47) That dog *bites*.

The example in (48), a typical instance of transitive verbs without objects in a contrastive context, may be associated with this property of covert indefinite objects.

- (48) “She *stole* but she could not *rob*.” (Beatles song: She came in through the Bathroom Window)

The analysis of covert indefinite objects presented here, in combination with the principle in (38), leads to the revised principle of (38) as formulated in (49) and makes an explanation of further data in (50) and (51) easier.

- (49) Principle of Omission (revised):

Omission of the patient argument may be possible when the externally caused two-participant event is construed not to be characterising the whole relation consisting of Agent + Predicate.

**Default: the whole relation profiled**

**Non-default: the relation excluding Patient (i.e. action/property) profiled**

- (50) A young woman who I imagined was older than myself got up in a bus to offer me a seat. I *declined*. She *insisted*. I realized she thought I was pregnant and accepted graciously. - M. Spark, *A Far Cry from Kensington*

- (51) Richard had drunk champagne at lunch for the first time in his life--old Amos Kerbes had *insisted* and, with the whole Somerset Club looking on, Richard could hardly have *refused*. - J. Archer, *Kane & Abel*

What I want to claim here is that although the whole relation of a transitive verb is profiled at default, in non-default cases, the relation excluding the patient argument, i.e. action, property or whatever of the subject referent, is more profiled than the object referent, and thus the object is not mapped onto the object position in syntax.

## 7 Conclusion

It is argued that given sufficient attention to lexical semantics and discourse factors in the framework of Cognitive Linguistics, the “exceptions” to object omission with externally caused change of state verbs and in fact their general tendencies themselves follow without additional grammatical stipulation.

A couple of questions remain open, a particularly important one being the behaviours of lexically and semantically related verbs *kill/murder/assassinate*, which we do not report on in detail here. The contrast in (52) shows that there is indeed a difference in grammaticality with these verbs in requiring the direct object.

- (52) a. The terrorists *killed/murdered/assassinated* three political figures.  
b. The terrorists *killed* again.  
c. ? The terrorists *murdered* again.  
d. \* The terrorists *assassinated* again. (Ritter & Rosen 1996)

The analysis sketched out in the previous sections predicts that any externally caused change of state verb, inherently with a complex event structure, should take the direct object. Thus we expect that these accomplishment verbs, because they follow the argument realization condition in (16), will behave in the same manner. However, as shown in (52), there appears a difference in obligatoriness of the direct object, which is probably due to *strength* of transitive verbs as noted by Ritter & Rosen (1996).

An additional issue concerns the omission of the direct object in the so-called recipe contexts or commands. It is generally the case that in recipe contexts, object omission is freely possible as in (53)-(55).

- (53) First warm the pot with hot water. Add one teaspoon of tea for each person and one for the pot. Pour on freshly boiling water, *stir* [ϕ] and *allow* [ϕ] to stand for five minutes. - Ridgways  
(54) Do not *allow* [ϕ<sub>i</sub>] [PRO<sub>i</sub> to boil]. - WPC  
(55) Roll up each piece into a round and *allow* [ϕ<sub>i</sub>] [PRO<sub>i</sub> to rest for 10 minutes]. - WPC

Omission takes place in commands as in (56). Notice the contrast in (57).

- (56) *Catch!* (can be said by the speaker, who threw the hearer a ball)  
(57) \*I threw him the ball but he failed to *catch*.

This phenomenon is extended to the following case where *dry*, an externally caused change of state verb, is used in the utterance of offer.

(58) Shall I *dry* (“the dishes”)? (In a context of washing-up)

(59) \*The dishes were still wet so I *dried* (“them”).

The above case is not explained in my analysis either and for the moment an issue for further research.

## Notes

<sup>1</sup> This text is based on work which was presented at the 18th International Congress of Linguists in Seoul (21-26 July 2008). I would like to thank the reviewers of the abstracts and the audience for their comments and remarks. Special thanks are due to Prof. Dr Sebastian Löbner, the organiser of Lexical Semantics parasession of CIL18. Funding for this research was provided by the Japan Society for the Promotion of Science Grant-in-Aid for Scientific Research *Kiban-kenkyu* (C) 20520444 and by the Great Britain Sasakawa Foundation.

<sup>2</sup> A predicate in bold and with an apostrophe represents a constant predicate in the event structure.

<sup>3</sup> Obviously the generalisation must be relativised to English, since many topic-comment languages instantiated by Japanese, etc. do allow the patient or theme argument to be unexpressed when it represents topical information.

<sup>4</sup> See Jackendoff (1996) and Michaelis (2003), for certain caveats on the use of this test.

<sup>5</sup> Examples such as those in (25) demonstrate that, contra occasional claims made in the literature, causative verbs do not necessarily express telic events (see also Van Valin and LaPolla 1997: 97).

The work presented in this contribution takes place in a broader project proposing a cross-lingual approach of French and Mandarin verbs based on distance in a special kind of graphs. The contribution aims at presenting the aspects of the project which are the most relevant for lexical semantics. This abstract is more a presentation of the project and the level of achievement we plan to reach by the time of the conference. However, we will also introduce some elements of the methodology we will use for constructing lexical graphs based on existing resources.

In a nutshell, we use a method proposed in (Gaume, 2004) which takes traditional dictionaries as input and generates a graph capturing a certain kind of similarity between words. Such a graph can be used to identify in a precise way the senses of a given lemma. This methodology can be applied to any language, given that significant lexical resources are available for it. We will then compare and align the graphs obtained for Mandarin Chinese, French and English. We expect this work to contribute to foundational investigations of lexical structures.

In this project, graphs are instantiated by lexical information : their vertices are verbs and their edges are lexico-semantic relations and more specifically paradigmatic relations (here synonymy and hyperonymy). In order to compare systematically French and Mandarin, a computational model (PROX, Gaume (2004)) calculating the semantic proximity between two lexical entries on lexical paradigmatic graphs allow to develop a “sense metrology” for both languages. PROX is a stochastic method to obtain the metrology and cartography of local and global structures of big sized lexical graphs. PROX transforms a graph in a Markov chain whose states are the vertices of the graph. Energy particles are wandering on the edges of the graph, jumping from vertex to vertex. It is the particles trajectories dynamics that measures the structural properties of the graphs. PROX allows to compute a semantic distance between the words that are vertices of a lexical network.

The independent and drastically different studies we conducted in parallel (psycholinguistics experiments that are not the focus of the present contribution and linguistic modelling based on paradigmatic graphs) allow to perform a cross-validation of our approach. Such a validation is already well advanced on French, for which it has shown that (i) the paradigmatic graph of French verbs is a hierarchical small world, and (ii) the semantic approximates produced during the psycholinguistic experiments are verbs that are very close according to PROX measurement. The project has for aim to push these investigations further for French and to extend them to the Mandarin Chinese case, a language from a different family in order to discover language invariants and variability for French and Mandarin Chinese.

Moreover, the creation of the cross-lingual translation relations enables to measure the topological properties of various lexical areas and to test their dependency to language. The project also consists in determining which structures of the lexical networks are shared between these two languages and at which specificity level they exhibit the same lexical organization. Finally, we also foreseen the development of a multilingual resource consisting of the monolingual paradigmatic graphs and their mappings onto each other.

In order to achieve these tasks, we first need to build the graphs mentioned above. We use existing traditional resources such as dictionaries to create a graph of verbs. In the case of French we are creating the graph (Pgf.v) as a fusion of DicoSyn (a composite synonym dictionary derived from 7 traditional dictionaries), TLFi (a reference general electronic dictionary for French developed at ATILF) and the French graph included in EuroWordNet (Vossen, 1997). Concerning the Mandarin Chinese graph, the source for building (PGm.v) is mostly Chinese WordNet (Huang et. al, 2004), a sense lexicon that has about 8,000 lemmas and over 13,000 senses. In this resource, synonymy link are continuously added with traditional lexicographic methods as well as with automatically and semi-automatically ones. To this resource we will potentially add HowNet, a famous lexical resources that includes synonymy and other paradigmatic relations.

In order to perform cross-lingual experiments we must align French and Mandarin graphs. We plan to use the resources available (the existing Papillon platform as well as the links from French entries to EuroWordnet interlingua indexes) together with Sinica BOW (Huang et al, 2004) English to Traditional Chinese, generating WordNet synset based correspondences. In case of missing translation equivalents our mapping will be completed with traditional bilingual dictionaries. However, since we need

high quality mapping for our experiments all dubious translations for verbs will be manually checked.

From French (PGf.v) and Mandarin (Pgm.v) graphs we will study how local and global properties are propagated across languages through the relation <-t-> (translation equivalence) from one graph to the other. For example, we will measure:

- to what extent the relation <-t-> preserves neighborhood relations in PGf.v et PGM.v (i.e whether two words that are neighbors in one graph are also neighbors in the other one)
- whether edges over-dense areas are preserved by <-t-> and which ones are the best/least preserved.

By the time of the conference, we will be able to present French paradigmatic graphs, that have already been constructed, a version of the Chinese graphs based on existing resources and on the development of the Chinese WordNet (Huang et. al, 2004) and an English graph based on Princeton Wordnet (Fellbaum, 1998) and New Oxford Dictionary of English. Therefore we will propose our first comparisons across languages. We will see how much lexical structures are conserved by the translation relations and propose very rich mapping across monolingual lexical graphs.

### Résumé

Dans ses *Recherches logiques*, Husserl (1972) distingue *lois analytiques* et *lois synthétiques*. Les premières *pures* et *exactes* fondent l'eidétique des mathématiques, et les secondes, *matérielles* et *inexactes* fondent l'eidétique de la phénoménologie. Ces dernières sont porteuses de *signification langagière sémiotisable* et *adduction/abduction* en font partie. Dans le cadre d'une théorie *sémiophénoménologique* du langage (Cassirer 1972), nous allons montrer l'implication de ces principes dans la constitution sémantique d'une langue comme le français, mais sans s'y réduire, car *adduction* et *abduction* sont des universaux du langage, des principes que transposent toutes les langues du monde, selon leurs différentes façons de catégoriser l'expérience sensible correspondante.

**Mots clés** : sémiologie, phénoménologie, adduction, abduction, lexique, langue.

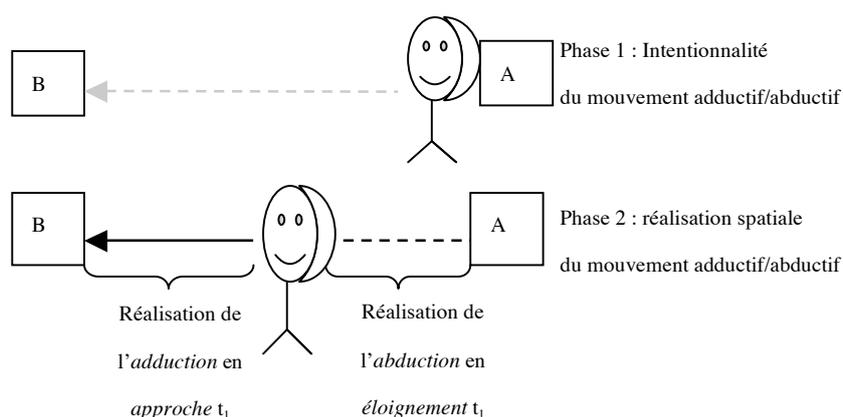

### Introduction

Quand il bâtissait sa théorie de l'*abduction*, Peirce avait en tête de créer une théorie sémiotique du langage. Mais en quoi ses travaux nous éclairent-ils sur le langage naturel parlé par les hommes ? Ses préceptes et raisonnements sur l'abduction relèvent plus de l'axiomatique mathématique que de la sémiolinguistique. Peirce a défini l'*abduction* en termes de « process of forming an explanatory hypothesis », une forme d'inférence mathématique permettant de formuler des hypothèses face à un dilemme posé. Peirce a dépouillé l'*abduction* de son caractère matériel et phénoménologique essentiel. Il l'a sortie de son cadre matériel et significationnel d'expression, l'a dépossédée de son contenu sémantique. Il a fait de l'*abduction* un simple principe abstrait, une coquille vide sans véritable consistance. En fait, la différence de traitement de l'*abduction* entre nous et Peirce, rentre dans le cadre de la fameuse dichotomie énoncée par Husserl (1972) entre lois matérielles synthétiques significatives et lois formelles

analytiques axiomatiques, les premières fondant l'eidétique phénoménologique constitutive du langage, et les secondes, l'eidétique mathématique dont l'*abduction* de Peirce fait partie. Aussi, d'un point de vue phénoménologique, on ne peut parler d'*abduction* sans parler d'*adduction*. Les deux principes se conditionnent réciproquement et c'est ce que nous allons démontrer dans les lignes qui vont suivre, au plan de leur transposition par le langage naturel.

## 1. Phénoménologie de l'*adduction* et *abduction* en mouvement aller $T_1$ .

Ce sont deux *facettes opposées et instantanées* du mouvement spatial, comme illustré ci-dessous :

*Abduction* et *adduction* sont liées par une causalité naturelle intrinsèque. Une instantanéité les caractérise dans leur nature phénoménologique d'être. L'*adduction* en  $T_1$ , c'est le *mouvement spatial aller vers* et l'*abduction* en  $T_1$ , *l'écart, la séparation, l'éloignement,...* qui se creusent derrière. Donc, c'est dans le sillage de l'*adduction* que l'*abduction* se développe, et chaque moment particulier de saisie de l'*adduction* comporte une contrepartie *abductive*. L'*adduction* étant un « *mouvement vers* », nous dirons spécialement qu'elle est *versive*.

La figuration ci-dessus présente deux phases : une *phase intentionnelle* et une *phase physique*. Dans la phase intentionnelle, le sujet a justement l'*intention d'aller* quelque part. L'*adduction* intentionnelle, c'est l'*envie d'aller vers...*, et l'*abduction* conséquente, l'*envie de se séparer du point de départ, de s'en écarter, s'en éloigner*. La phase 2 fait suite à la phase 1 intentionnelle. À cette phase 2, le sujet matérialise le mouvement de l'*adduction/abduction* dans l'espace. En même temps qu'il performe l'*adduction*, i.e., son mouvement spatial

vers la cible B, il se creuse entre lui et son point de départ A, un écart, un éloignement. La réalisation ultime de l'adduction se fait quand le *contact* ou la *fusion* est établi entre le sujet et le point d'arrivée B. À ce niveau, l'adduction a épuisé son mouvement, elle est devenue statique. La contrepartie abductive de cette phase est la *rupture* du mouvement adductif T<sub>1</sub>. Donc, le mot *rupture* - qui est *abductif* - peut signifier, soit *rupture d'un état statique adductif initial*, soit *rupture d'un mouvement adductif*. L'adduction est un mouvement causal : elle est au centre de tous les mouvements qui causent ou qui permettent les réalisations d'actions, d'objets, l'établissement de relations, la visualisation, la perception, etc. Elle est donc très riche en termes de transpositions sémantiques.

### 1.2. Affirmation/négation et expression de l'adduction/abduction intentionnelles.

L'adduction et abduction intentionnelles sont transposées en langue par le couple *affirmation/négation*. En effet, *affirmer*, *asserter*, *acquiescer*, etc. sont tous *adductifs intentionnels*. *Je veux manger* = *adduction intentionnelle* vis-à-vis de l'action de manger. D'un point de vue intentionnel, *manger* est une idée regardante réalisable en praxis et dont les séquences matérielles sont : *prendre de la nourriture*, *la mettre dans la bouche*, *mâcher*, *avalé*, etc. L'adduction intentionnelle veut dire *adduction* entre le sujet intentionnel et cette action. En disant : *je mange*, l'adduction intentionnelle est en train de se convertir en *mouvement adductif praxéologique*, celui de la réalisation de quelque chose qui est présentement *manger* ; action dans laquelle, on va vers la *nourriture* (mouvement adductif T<sub>1</sub>), on la *prend* (destination du mouvement T<sub>1</sub>), on la *ramène vers* sa bouche (mouvement adductif retour T<sub>2</sub>), et on la *mange* (destination du mouvement adductif T<sub>2</sub>).

En ce qui concerne l'*abduction intentionnelle*, habituellement traduite par la négation, elle traduit la *distance* entre le sujet intentionnel et une action de praxis. *Je ne mange pas* veut dire qu'il y a *rupture*, *écart* entre moi et l'action de manger qui relève de la praxis. L'*abduction intentionnelle* se réalise en toute forme d'expression de la négation (*ne*, *ne..pas*, *jamais*, *personne*, *rien*, etc.). Il faudrait donc, dans une étude plus détaillée, voir les modalités d'incrustation de l'adduction/abduction intentionnelles dans les différentes formes linguistiques d'expression de l'affirmation et de la négation.

### 1.3. Les termes adductifs spatiaux en $T_1$ (en mouvement aller $T_1$ ).

Tout terme de n'importe quelle langue qui laisse transparaître dans son sens un *mouvement versif en aller  $T_1$*  ou en *retour  $T_2$*  est *adductif*, ce mouvement pouvant être transposé dans sa *totalité générique* ou dans ses phases, *initiale, en cours, terminale, statique*. On peut donc créer des sous-classes de termes *adductifs*.

#### 1.3.1. Adductif dynamique $T_1$ initial.

Les termes de cette catégorie transposent la dynamicité de l'adduction en *mouvement aller  $T_1$* , mais cette dynamicité est transposée en phase initiale de sa réalisation. Il s'agit par exemple de *commencer, débiter, entreprendre, engager, entamer, introduire, partir*, etc. Leurs adductions sont incertaines au point de vue de leur aboutissement. Parmi les critères caractéristiques de ces termes, en plus de leur nature *adductive*, il y a le fait que leur adduction soit *dynamique*, qu'elle se conçoive dans le cadre du *mouvement aller  $T_1$* , et que cette dynamicité soit saisie à son *début*. D'autres critères peuvent s'y greffer: le critère de la destination du mouvement ou de son incidence (*hétéro-incidence*, si le mouvement est incident sur un objet autre que le sujet; *auto-incidence*, s'il est incident sur le sujet), le critère de sa performance (*auto-performé*, si c'est le sujet lui-même qui performe le mouvement; *hétéro-performé*, si c'est un sujet extérieur qui le performe). On pourrait aussi prendre en compte les critères de la *mécanicité* du mouvement, de sa *durabilité* (bref, long,...), etc.

De manière générale, ce sont les conditions de réalisation de l'adduction qui vont fixer ses caractéristiques, ce mouvement étant en lui-même un universel du langage. En disant: *je m'en vais à Paris*, je suis en même temps l'*auteur intentionnel* de mon propre *mouvement*, son performateur mécanique (auto-performance), et l'incidence de mon mouvement est Paris (hétéro-incidence). Il faudrait à l'avenir inventer un langage sémiotique viable qui cataloguerait l'ensemble des marques contextuelles de réalisation de l'adduction/abduction dans un usage donné.

#### 1.3.2. Termes adductifs dynamiques $T_1$ « en cours ».

Ici, la dynamique de l'adduction est saisie dans son *cours de réalisation*. Les termes et expressions: *marcher, courir/course, trotter, rouler, aller, se déplacer, avancer, cheminer, serpenter, conduire, voler, développer, aller*, etc. sont

tous *adductifs dynamiques* « en cours ». Par exemple, *marcher* = *adductif dynamique* « en cours »  $T_1$  avec *alternance de pas* ; *courir* = *adductif dynamique* « en cours »  $T_1$  avec *accélération de l'alternance des pas*, etc. L'*adductif dynamique* « en cours » peut connaître en soi des variantes en fonction des paramètres de *vitesse*, du *caractère étapiste* du mouvement adductif, etc. *Accélérer, hâter, se dépêcher,...* sont *adductifs dynamiques* « en cours » (ou même *initiaux*) avec indice relatif *vitesse* +. En intégrant les paramètres de *l'auto-incidence, hétéro-incidence, auto-performation, hétéro-performation, guide, mécanicité, intentionnalité*, etc. nous constatons que la situation se complexifie encore un peu plus. Exemple : *se hâter* est *auto-performatif, hétéro-incident*, en plus d'être *adductif  $T_1$ , dynamique, initial/« en cours », vitesse* +.

### 1.3.3. *Adductif dynamique terminatif $T_1$ .*

Il s'agit de termes et expressions au contenu sémantique dynamique en soi, mais qui transposent cette dynamicit  dans sa phase terminale d' tiolement. Comme exemples, nous avons : *aboutir/aboutissement, conclure, finir, achever, terminer, parachever, clore, arriver/arriv e, venue,  tioler*, etc. Ces termes transposent le mouvement adductif  $T_1$  dans sa phase terminale. Ils sont *adductifs dynamiques terminaux  $T_1$* . En plus des param tres  nonc s plus haut, des perspectives diverses peuvent influencer sur la saisie de leur adduction,   l'exemple des jeux de *protension* et *r tension*. Si je parle de *l'arriv e/venue de Paul*, il s'agit de *l'adductif dynamique terminal protensif* (perspectiv , imminence). Mais si je dis : *je viens/arrive de Paris*, c'est plut t l'effet de *r tension* sur le point de d part *paris* qui est mise en saillance. *Je viens de paris* = *adductif dynamique terminal  $T_1$  r tensif sur point de d part*.

### 1.3.4. *Adductif statique terminatif $T_1$ .*

De mani re g n rale, tout terme ou expression d notant en soi un * tat* statique r sultatif d'un mouvement adductif initial est *adductif statique terminatif  $T_1$* . Il s'agit par exemple de *contact, contigu t , voisinage, fig , fix , proximit *, etc. En effet, les situations spatiales que ces termes d notent ne peuvent qu' tre r sultatives de mouvements adductifs initiaux d'apport ou de rapprochement d'objets. Aussi, tous les  tats statiques r sultatifs de mouvements adductifs sont *adductifs statiques terminaux  $T_1$* ,   l'exemple de *l' tat d' tre assis, l' tat d' tre pos , l' tat d' tre arriv *, etc. qui sont des aboutissements des mouvements adductifs de *s'asseoir, poser, arriver*, etc. Ces termes construisent leurs

différences autour des modes de transposition des états adductifs statiques qu'ils sémiotisent. *Contiguïté*, par exemple, implique *l'adduction statique* selon que les éléments concernés *se touchent*; *voisinage/voisin*, selon que les objets concernés *se perçoivent réciproquement*; *entourage*, selon que les éléments concernés *entourent un élément situé au centre*, etc. Peut-on alors penser que *l'adductif statique initial* puisse exister? Cette situation pourrait correspondre à l'étape d'avant le Big-Bang.

#### 1.3.5. Les fonctions support adductif/ apport adductif/ adjuvant adductif.

Par *adjuvants adductifs*, nous entendons les termes comme *vis, clou, colle, puce, trombone, fermeture, épingle, gravité terrestre*, etc.; bref, tous les termes qui dénotent ces petits éléments qui permettent d'établir des relations adductives entre parties/contenus d'objets, et donc entre objets eux-mêmes. Parmi ces objets, on distingue des *supports adductifs* fonctionnels et des *apports adductifs*. Par exemple, quand on fixe une image au mur, le *mur* = support adductif, *l'image* = apport adductif, *clou* = adjuvant adductif. Une *table* est un support adductif des objets posés dessus, et ces objets, des apports adductifs. La *gravité* qui permet leur adduction est un adjuvant adductif. La *chaise* est support adductif de l'apport adductif: « celui qui est assis dessus ». La *route* est *support adductif* fonctionnel de l'apport adductif *voiture* qui roule dessus. La relation *support/apport adductif* peut être relative. Par exemple, la *chaise* est *apport adductif* par rapport au *support adductif* primaire *terre*, mais par rapport à la *personne* qui est assise dessus, la *chaise* est *support adductif* second. Donc, le contexte propose une relativité du rapport apport/support adductif. Mais dans la langue, il existe des termes qui sont prégnants sur leur fonction de *support fonctionnel adductif*, à l'exemple de: *sol, table, siège (chaise, canapé,...), lit, voiture, corps humain*, etc. En contexte des rapports partie/tout, le *tout* est support adductif de ses *contenus* qui sont ses *apports mérologiques adductifs*. *L'adduction* se trouve partout où il y a simple contact/contiguïté/voisinage physique/relation entre objets.

#### 1.4. Les termes abductifs spatiaux en $T_1$ (en mouvement aller $T_1$ ).

Tous les termes et expressions employés pour désigner linguistiquement *l'abduction*, à savoir: *rupture, séparation, écart, distance, éloignement*, etc. sont *abductifs*. S'y rattachent aussi les effets de *l'abduction* que sont: *évanouissement, disparition, absence* (termes *abductifs effectifs*). Ces effets participent des notions

de *manque, carence, insuffisance, défaut*, etc. qui sont elles aussi *abductives*. Les termes comme *arrêter/arrêt, ralentir,/ralentissement, freiner/freinage, ralentir, affaiblir*, etc. sont *abductifs*. En effet, ils sont tous *anti-adductifs* par essence. Ils prospectent en aval la rupture processive d'une dynamique adductive. Ils transposent le deuxième sens abductif de *rupture* qui est *rupture d'une dynamique adductive* (Vs *rupture d'un état statique*). Cette rupture de dynamique ne se fait pas d'un coup, elle se fait par *ralentissement*; et les termes *arrêter/arrêt, ralentir, freiner/freinage, ralentir, affaiblir*, etc. transposent cet état de chose. C'est pour cela que nous disons qu'ils sont *abductifs terminatifs* ( $T_1$ ). Ils sont différents de *rétrograder, régresser, arrière*, etc. qui sont *abductifs* plutôt *rétroversifs* que *terminatifs* (voir 2.1).

#### 1.4. Termes adductifs/abductifs partitifs en $T_1$ .

Il s'agit de voir l'importance de l'adduction/abduction dans la catégorisation des termes partitifs.

##### 1.4.1 Abductif partitif en $T_1$ .

Il s'agit des termes qui expriment le partitionnement comme *rompre, briser, casser, couper, scier, trancher, partager, diviser, disperser, disloquer, dissiper*, etc. Ils sont tous *abductifs partitifs* ( $T_1$ ). Ils transposent les idées de *rupture* d'unité de constitution avec *séparation* potentielle des parties/contenus. Par ailleurs, ils prospectent tous des états abductifs terminaux (l'état d'être cassé, brisé, etc.).

*Casser*, dans sa pratique, est évidemment un *mouvement adductif  $T_1$  vers*: c'est sa partie *adductive* nécessaire à la réalisation de l'acte en soi. Par son *mouvement adductif* donc, il cause un *effet*: celui de la *cassure* de l'objet. Mais dans son sémantème, son *adduction* est subduite, rendue implicite: ce qui est rendu saillant est *l'effet abductif* qu'il cause, à savoir: la *casse de l'objet*. *Casser* n'a de sens que par ce qu'il y a cassure de l'objet, et sans cette cassure, on ne saurait parler de *casser*. Cette explication est aussi valable pour tous les autres termes *abductifs partitifs*. Il faudrait se souvenir de ce que nous avons dit: *l'adduction est un mouvement causal: elle est au centre de tous les mouvements qui causent des situations ou qui permettent les réalisations d'actions, d'objets, l'établissement de relations, la visualisation, perception*. Quand *casser, briser, couper, diviser*, etc. portent sur un objet extérieur, on dira d'eux qu'ils sont *adductifs partitifs  $T_1$  hétéro-incidents*. Mais quand ils sont incidents sur le sujet

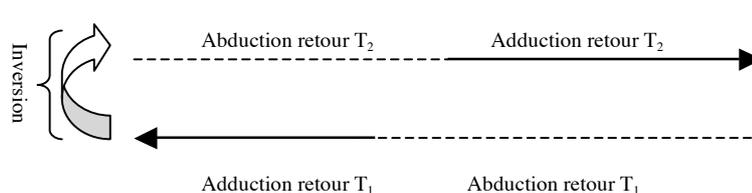

lui-même, comme dans *se casser la jambe, se briser les côtes*, on dira qu'ils sont *auto-incidents*. On pourrait aussi prendre en compte les critères de *l'auto-performance/hétéro-performance* pour les caractériser contextuellement.

#### 1.4.2 Adductif partitif en $T_1$ .

Il s'agit de *former, fabriquer, construire, composer, façonner, assembler, unir, synthétiser*, etc. Ils sont tous *adductifs partitifs en  $T_1$* . En substance, ils traduisent une dynamique adductive d'apport d'éléments dans le cadre d'une *formation, fabrication*, etc. d'objets de valeur scopique supérieure dont ils seraient des constituants. Également, les adductifs partitifs peuvent être *hétéro-incidents* (*fabriquer une voiture, construire une maison*, etc.), ou *auto-incidents* (*se former, se construire*,...). Etc.

## 2. Phénoménologie de l'adduction/abduction en mouvement retour $T_2$ .

L'adduction et l'abduction spatiales peuvent aussi se concevoir en *mouvement retour*. Les mêmes conditions de réalisation de l'*adduction/abduction en aller* (ou *adduction/abduction  $T_1$* ) se retrouvent en retour (*adduction/abduction  $T_2$* ). Mais ici, un nouveau paramètre entre en jeu : celui de *l'inversion/opposition* à d'une *situation adductive* acquise en amont. Cela peut schématiquement être représenté de la façon suivante, en se passant de la phase intentionnelle.

Le moment de *l'inversion/opposition* au mouvement *adductif/abductif  $T_1$* , est un moment essentiel qui détermine l'adduction et abduction *en retour*. Et nous verrons que les termes du français qui transposent *l'adduction/abduction  $T_2$*  (i.e., en mouvement retour) sont prégnants sur cette *inversion/opposition* à un *état, à une situation adductive/abductive aller  $T_1$* . Mais nous devons comprendre que les mêmes conditions et effets de réalisation de l'adduction/abduction en  $T_1$  sont transposées en  $T_2$ .

### 2.1. Termes abductifs $T_2$ .

Il s'agit par exemple de *dépoussiérer, dévêtir, débarquer, déridier, dénaturer, dépoussiérer, dévêtir, dévoiler, dévier, détourner, éviter, esquiver, dévoiler, etc.* Tous ces termes s'opposent à une situation *adductive initiale* (apport de poussière, port de vêtements, embarquement, apparition de rides, etc.). Leur *abduction*, pour se réaliser, a nécessairement besoin d'*adduction* (les mouvements de réalisation qui leur sont associés). Mais leur saillance sémantique est focale sur les idées abductives de *séparation/éloignement* de *poussière, habits, rides, etc.* *Éviter, esquiver* sont abductifs en  $T_2$ , car ils instituent des comportements réactifs vis-à-vis de mouvements adductifs  $T_1$  antérieurs incidents sur le sujet, par opposition/esquive de ceux-ci. *Dévoiler* veut dire : *enlever le voile* initialement en situation *adductive avec le visage, le corps*, avec effet de découverte. *Déplacer* est *abductif*  $T_2$ , car s'opposant à un état initial adductif de placement.

Considérons spécialement le couple *pousser/repousser* : si je dis, *l'ennemi a été repoussé*, dans cet usage, *repoussé* est *abductif*  $T_2$  *rétroversif intensif*. Il est *abductif* puisqu'il introduit l'idée de réalisation d'un *écart* entre le sujet et l'objet, *rétroversif*, car l'action *s'oppose* à un mouvement adductif initial  $T_1$  considéré sur son *propre itinéraire* (voir ci-dessous 2.1.1), et finalement *intensif* puisque cette abduction nécessite un investissement substantiel de force pour contrer une force adductive opérante.

Supposons que je dise: *il repousse l'échéance* ; *repousser* est *abductif*  $T_1$  *itératif temporellfutur*. Il est abductif en  $T_1$ , car son abduction n'est pas inverse de situation antérieure. Il est *itératif*, car son préfixe *re-* apporte l'information que son abduction est répétitive d'une abduction antérieure; et *temporel*, puisque l'idée de *repousser* est orientée dans le futur. Sur le cas de *pousser*, si je dis :*Paul pousse la voiture*, l'intention de Paul n'est pas d'établir un écart entre lui et la voiture. Son intention est de la faire *mouvoir*. Nous sommes donc en contexte d'*adduction* forcée. Mais si je dis : *pousse-toi*, l'intention est qu'il y ait écart entre nous deux. Dans ces circonstances, *pousser* est *abductif*  $T_1$ . Donc, le contexte est primordial dans la détermination du profil sémantique adductif ou abductif d'un terme.

### 2.1.1 Termes abductifs $T_2$ rétroversifs.

La *rétroversion* est une forme spécifique *d'inversion/opposition* au mouvement adductif  $T_1$  se réalisant sur l'itinéraire propre de ce mouvement. Les termes immédiatement concernés sont: *arrière, reculer, régresser, refluer, repousser, refouler, rétrograder, etc.* Ils sont tous *abductifs*  $T_2$  *rétroversifs*. Ils

sont *abductifs*, car s'opposant à un mouvement adductif initial  $T_1$ , et *rétroversifs*, car cette opposition emprunte l'itinéraire du mouvement adductif  $T_1$  en sens inverse. Quand vous dites aux gens : *reculez-vous*, ils font le contraire de leur mouvement adductif initial  $T_1$  vers vous sur le même itinéraire. Étant donné qu'ils performant eux-mêmes ce retrait, on parlera donc d'*auto-rétroversion*. Mais si je parle de *faire reculer la voiture*, nous nous retrouvons en contexte d'*hétéro-rétroversion*.

### 2.1.2. Quelques termes abductifs partitifs en $T_2$ .

*Soustraire, extraire, retirer (de l'argent), prélever, ...* sont *abductifs partitifs quantitatifs* selon les circonstances, la quantité prélevée pouvant être *numérale* ou *massique*. Alors que *retirer de l'argent* est *abductif partitif quantitatif*, « *se retirer* » de la course est lui *abductif rétroversif auto-performé*. L'abduction se reconfigure ainsi contextuellement. Les termes comme *réduire, diminuer, simplifier, perdre, ...* sont *abductifs partitifs quantitatifs  $T_2$*  ou *abductifs partitifs intensifs  $T_2$*  (diminuer d'intensité, diminuer de force,...). Leur *abduction* commune se conçoit en  $T_2$  par rapport à une situation adductive  $T_1$  précédente d'apport de quantité, d'intensité.

*Détacher, désassembler, désunir/désunion, dépiécer, démembrer, déconstruire, démonter, défaire, etc.* expriment aussi l'*abduction partitive (qualitative) en  $T_2$* . Cette abduction s'inscrit à l'inverse d'un mouvement  $T_1$  d'apport d'éléments dans le cadre de leur *assemblage, mise en union, montage, etc.* *Détacher* suppose en amont une situation  $T_1$  acquise d'adduction se donnant en termes d'*attache* (le verbe *attacher* étant adductif). *Détacher* induit donc un *mouvement retour  $T_2$*  à l'opposé (donc *inversif/oppositif*) du *mouvement aller* d'*attache* : c'est la raison pour laquelle nous disons qu'il est *abductif partitif  $T_2$* . *Désassembler* suppose lui aussi un *mouvement adductif initial d'assemblage* et un *état assemblé* conséquent. Il s'oppose à l'état assemblé initial en faisant le mouvement inverse (donc *rétroversion*) qui a abouti à cet état. Pareil pour *désunir/désunion, dépiécer, démembrer, démonter, etc.* Ce sont tous des termes *abductifs partitifs* (qualitatifs)  $T_2$  chacun selon ses propres critères spécifiques.

### 2.2. Exemples de termes adductifs en $T_2$

Le mouvement *adductif  $T_2$*  est un *mouvement versif* selon qu'il se conçoit en phase retour par rapport à un *mouvement versif initial aller  $T_1$*  ayant abouti à

un *état*, une *situation adductive*. Parmi les *termes adductifs*  $T_2$ , nous avons par exemple : *revenir, retour, déduire, représenter*, etc. Considérons le cas de *revenir* auquel nous opposons sa forme non préfixée *venir*. *Revenir* (avec préfixe *re-*) est *adductif*  $T_2$  *réensif point de départ* ; alors que « *venir de* » (sans préfixe *-re*) est *adductif*  $T_1$  *réensif point de départ*. Alors que le premier est  $T_2$ , le second est  $T_1$ . En effet, si je dis : *je viens de paris*, il n'y a pas nécessité que je m'y sois d'abord rendu en aller  $T_1$ . Cette nécessité est incontournable dans « *revenir de* ».

*Déduire* se conçoit par rapport à un *mouvement adductif-inductif aller*  $T_1$  du particulier vers le général. Son *mouvement adductif*  $T_2$  (du général vers le particulier) se définit donc par rapport au mouvement adductif  $T_1$  de l'induction. Par ailleurs, il existe un *usage abductif de déduction* où il signifie *soustraction*. En effet, la *soustraction* est *abductive*  $T_2$  par rapport à un mouvement adductif  $T_1$  *d'ajout de quantité*.

*Retour* est *adductif*  $T_2$  puisqu'il se conçoit par rapport à un mouvement adductif aller  $T_1$ . *Recevoir* est *adductif*  $T_2$  le plus souvent par rapport à un mouvement adductif aller de (*re*)quête, *recherche, demande*,... (*j'ai reçu mon examen, j'ai reçu mon courrier*, etc.). Supposons que je dise cette fois-ci: *j'ai reçu une fiente d'oiseau sur la tête* : *recevoir* est toujours *adductif* en  $T_2$ , non par rapport à un *mouvement adductif initial*  $T_1$  *de quête de fiente par le sujet* (hypothèse improbable), mais par rapport à un *mouvement adductif initial*  $T_1$  *de venue de fiente incident sur le sujet*. Donc les deux perspectives de validation du caractère  $T_2$  de son *abduction* sont admises. *Retourner* (chez soi) est *adductif*  $T_2$  par rapport à un *mouvement adductif*  $T_1$  *de venue*. Etc.

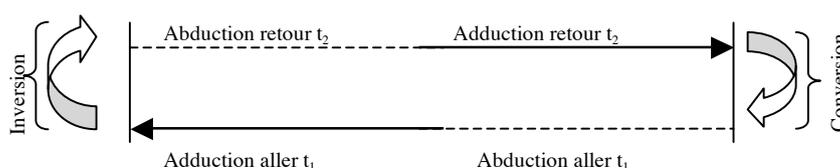

### 3. L'adductif/abductif vertical.

Si *monter, élever, grimper, hausser, ascendant, accroissement*, etc. sont *adductifs verticaux*  $T_1$  (ascendant), en ce qui concerne *descendre, baisser, Abaisser*, etc., ils sont eux *adductifs verticaux*  $T_2$  (descendants). *Dévaler, dégringoler, tomber, choir*,... sont eux aussi *adductifs verticaux*  $T_2$ , mais ils intègrent en plus une *modalité catastrophique* puisque leur mouvement est causé par une force supérieure qui échappe au sujet (la force de la gravité, de la loi, du destin, etc.). *Tomber* est un *mouvement adductif vertical catastrophique*  $T_2$  s'opposant à un état initial  $T_1$  (être debout, suspendu, monté, etc.). Les termes comme *altitude, plafond, hauteur*, transposent *l'aboutissement statique relatif du mouvement adductif vertical*  $T_1$ . Ils sont *adductifs statiques verticaux relatifs*  $T_1$ . *Plafonner* est

un *mouvement adductif vertical*  $T_1$  visant un niveau relatif suspensif qui est le « *plafond*. ». L'adduction verticale en  $T_1$  possède des qualités de *conquête*, *recherche*, *effort*,..., tandis que l'adduction verticale en  $T_2$  possède un relent *catastrophique*, *fataliste* de retour à une *assignation ontologique*.

#### 4. L'adductif conversif.

Si le *mouvement adductif retour*  $T_2$  connaissait lui-même, à son terme, une *inversion*, on aboutirait à une situation de *conversion* schématiquement représentable de la façon suivante.

La *conversion* exige que le mouvement adductif/abductif  $T_1$  soit converti en un autre mouvement de même nature  $T_1^2$  (ou substantiellement différent), avec possibilité que celui-ci soit converti à son tour en un autre mouvement de même nature  $T_1^3$ , ainsi de suite. Le conversif peut prendre les formes de l'*itération*, *duplication*, etc. Il a pour effets l'*intensification*, la *célérité*.

##### 4.1. Quelques termes adductifs conversifs.

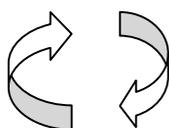

De nombreux termes du français préfixés en « re-, ré- » expriment l'*adduction converse*. Il s'agit par exemple de *reprendre*, *recomposer*, *relire*, *réinventer*, *redynamiser*, *retomber*, *revoir*, *reconsidérer*, *réimprimer*, etc. En eux, le préfixe « ré-, re » introduit un sens dit *duplicatif*, *itératif* opposé au sens *oppositif/inversif/réversif/rétroversif* que ce même préfixe peut introduire en abduction (voir 6.). *Reprendre* est *adductif conversif itératif* : il est *adductif*, car il profile l'idée d'un mouvement adductif d'ajout ; *conversif*, car ce mouvement n'est pas envisagé dans son opposition à un autre, mais dans son itération. *Redynamiser* est *adductif conversif intensif*, le préfixe « re- » introduisant la modalité *intensive* de l'itération. Nous avons dit que l'*intensité* est un effet de l'*adduction converse*. *Retomber* est *adductif vertical*  $T_2$  *conversif itératif*.

##### 4.2. Les termes abductifs conversifs.

Il s'agit par exemple de *re-écarter, re-séparer, re-éloigner,...*; *recasser, recouper*, etc. Considérons *retrancher* : il peut dénoter une *abduction T<sub>2</sub> itérative* (trancher une seconde fois). Mais dans sa forme réflexive *se retrancher*, il signifie une simple *abduction T<sub>2</sub> auto-performée* (*se retrancher derrière le mur*, etc.).

## 5. L'adductif conversif pur et transposition lexicale.

Il s'agit de la conversion en soi, hors de tout contexte de mouvement aller/retour. On pourrait la représenter de la façon suivante :

Ce mouvement *circulaire itératif, répétitif, fermé sur soi* nous rappelle le mouvement de la *roue* qui tourne autour de son axe. Ses variantes sont le *tore, tourbillon, tornade*, etc. Ce mouvement est *purement adductif conversif, itératif, duplicatif, intensif*, etc. Et pourrait-on y déceler de contrepartie abductive ? Mais en ce qui nous concerne, les termes qui transposent en soi l'*adductif conversif pur* sont, par exemple : *rouler, tourner, tourbillon/tourbillonner, tornade, tore, vriller/vrille*, etc.

Considérons les cas de *tourner* et *retourner*. Le premier (*tourner*) est *adductif conversif T<sub>1</sub>* pouvant être *itératif*. Dans : *la terre tourne*, le verbe *tourner* est *adductif conversif itératif auto-performé* avec *incidence nulle* (le mouvement étant convulsif en soi et sur soi). En ce qui concerne le second (*retourner*), son *re-* préfixal peut introduire un sens *inversif* contraire au mouvement conversif initial introduit par *tourner* : il serait ainsi *adductif inversif conversif*, ou simplement *adductif conversif T<sub>2</sub>* (sa conversion adductive T<sub>2</sub> étant contraire à la conversion adductive T<sub>1</sub> initiale). Son *re-* préfixal peut aussi introduire un sens *conversif itératif* : *retourner* signifierait ainsi *tourner une seconde, une troisième fois*, etc. Il y a donc possibilité de prédictibilité des sens, sans nécessairement passer par des enquêtes textuelles. *Rouler* est *adductif conversif itératif* en T<sub>1</sub> avec *effet de déplacement horizontal*, et *roue* est l'agent/ou objet de la *conversion itérative pure*. Etc.

## 6. Conflit adduction/abduction répercuté en langue.

Nous avons vu qu'*adduction* et *abduction* étaient instantanées. En même temps qu'elles s'opposent, elles se complètent aussi. Cela, le lexique et certaines particules grammaticales le reflètent aussi. Dans les termes : *désunir*, *désassembler*, *désosser*, etc. le préfixe *dé-*, *dés-* possède une *valeur abductive* (dite *négative*). C'est ce préfixe qui introduit l'abduction en ces termes. Par contre en *départ*, *dépendance*, *décupler*, *démultiplier*, etc., ce préfixe possède une *valeur adductive* dite *positive*. Même cas pour le préfixe *a-* qui est *adductif* en *arriver*, *approcher*, *amarrer*, etc., et *abductif* dans *asocial*, *amoral*, etc. L'élément initial/préfixal *in-*, *im-* est *adductif* en *intérieur*, *inviter*, *inféoder*, *importer*, *important*, etc. et *abductif* en *impossible*, *impropre*, *inclassable*, etc. Dans *reprendre*, *relire*, *rétablir*, etc. *re-* initial est *adductif conversif* et dans *retrait/retirer*, *repousser*, *renvoyer*,... il possède une *valeur abductive* contextuelle. Le fait qu'un même préfixe (en français, en anglais ou dans n'importe quelle langue) puisse avoir, selon les contextes, une *valeur adductive* ou *abductive* relève de la nature phénoménologique de ces deux principes qui sont duaux et toujours associés.

Par ailleurs, en français, l'adverbe *plus* peut être *adductif* (je veux *plus* de points – avec réalisation sonore du /s/ final), ou *abductif* (je *ne* veux *plus* de riz). Le mot *pas* est *adductif* dans le nominal *le pas* où il introduit *l'idée de réalisation d'un mouvement*, et *abductif* dans la construction négative *je ne veux pas* où il est un morphème de la *négation*. Le mot *licence*, en profil sémantique *adductif*, signifie une *autorisation* (*licence* d'exploitation), et en profil *abductif*, un *renvoi*, une *exclusion* (il a été *licencié* de l'entreprise). *Gâter* (être *gâté*) en *abduction*, désigne une situation de *dégénérescence*, *destruction* (la voiture est *gâtée*), et en *adduction*, une situation de *profusion* (cet enfant est *gâté* de jouets). L'expression «*se douter de*», selon les usages, peut induire l'*adduction* (confirmation) ou l'*abduction* (infirmité). *Déposer* est *adductif* T<sub>2</sub> dans *déposer le sac par terre* (après l'avoir pris auparavant), mais dans *le roi a été déposé*, il est *abductif* T<sub>2</sub> (après avoir été mis en place). Le mot *indubitable*, bien qu'il soit *abductif*, induit causalement un effet *adductif mental* de *confirmation*, *acceptation*,... Pareil pour *inlassable* qui est *abductif* (qui ne se lasse pas), mais qui introduit une *interprétation adductive* (idée de continuité du mouvement, de l'action concernée). Etc. Ces quelques exemples nous montrent la forte dépendance de l'*adduction/abduction*, et la complexité de leur étude en langue.

## Conclusion

Dans les grammaires, la notion d'*adduction* transparait dans l'étude de l'*aspect verbal* que M. Riegel (1994) définit en termes « *d'angle de déroulement interne d'un procès.* ». L'aspect accompli/perfectif correspond au *terminatif statique* de l'*adduction*, l'aspect inaccompli correspond au *dynamique en cours* de l'*adduction*, l'aspect *inchoatif* au *dynamique initial*, l'aspect *terminatif* au *dynamique terminal*, et l'*aspect itératif* au *conversif itératif*. La notion d'*aspect* est vague et incomplète: les points de vue relatifs qu'elle théorise sont des facettes de l'*adduction*. Donc, au lieu de rester sur une notion vague d'*aspect*, il faudrait revenir à l'essentiel qui est la théorisation de l'*adduction/abduction* pour une catégorisation lexico-sémantique plus large et riche. Nous avons présenté ces deux principes uniquement dans leur aspect spatial. Ces concepts sont aussi temporels et il faudrait voir comment permettent-ils la catégorisation du temps d'une façon générale, temps et espace étant liés. Par exemple, si je dis : *il repousse ses examens*, le verbe *repousser* (abductif) n'a pas d'ancrage spatial dans cet usage: il a un *ancrage temporel*, il est donc *abductif temporel itératif*. Les vues que nous avons développées sont des préliminaires à une analyse bien plus dépouillée de l'*adduction/abduction* et de leur incrustation en langue et en discours. Ces deux principes caractérisent le langage à tous les niveaux, prenant des couleurs diverses, se rentrant en conflit, s'harmonisant, se perspectivant, selon les contextes de leur réalisation.

## Abstract

This paper explores the nature of syntactic V-V compounds including *iku* ‘go’ or *kuru* ‘come’ as the first verb on the basis of image-schemas. Although *iku* and *kuru* have similar meanings, an asymmetry exists between the *iki* ‘go’-V and the *ki* ‘come’-V compounds. There are far fewer *ki*-V compounds than *iki*-V compounds. This asymmetry arises from the difference in deictic characterization encoded in the meanings of *iku* and *kuru*. Some restrictions are imposed on the *ki*-V compound, because *kuru* requires the speaker’s deictic center as the goal of directed motion. Thus, the goal of this paper is to clarify how the deictic characterization of *iku* and *kuru* are related to the meanings of syntactic V-V compounds including *iku* or *kuru*.

**Keywords:** deictic verb, syntactic V-V compound, motion verb, image-schema.

## 1. Introduction

This paper is a small part of a large-scale empirical investigation into the nature of V-V compounds in Japanese on the basis of image-schemas, fitting squarely in the realm of cognitive semantics. Kageyama (1989, 1993) divided V-V compounds in Japanese into two types, lexical V-V compounds and syntactic V-V compounds. The two types of V-V compounds share some common characteristics. Morphologically, the second verb inflects for tense. The compound constitutes one morphological word. This paper, in particular, explores the nature of syntactic V-V compounds including *iku* ‘go’ or *kuru* ‘come’ as the first verb. The theoretical construct ‘image-schema’ is defined here as follows: Image-schemas are continually connected with embodied action and simulations of experience. Thanks to their embodied basis, image-schemas are powerful motivating factors.<sup>1</sup> Image-schemas are not necessarily represented schematically. The primary goal of this paper is to clarify how the deictic characterization of the verbs *iku* and *kuru* are related to the semantics of syntactic V-V compounds including *iku* or *kuru* as the first verb. This paper proceeds as follows. In order to provide the

image-schematic approach with an appropriate context, Section 2 briefly explains what the PATH schema is and how it is crucial to the investigation of the verbs *iku* and *kuru*. Section 3 explicates the nature of syntactic V-V compounds including *iku* or *kuru* as the first verb on the basis of the image-schemas. Section 4 offers some conclusions.

## **2. The PATH schema**

Image-schemas organize our experience independently of language. At the same time, they play an important role in connecting language to experience. Image-schemas can be formally characterized as follows (see Johnson & Rohrer 2007: 37): (1) recurrent patterns of bodily experience; (2) 'image'-like in that they preserve the topological structure of the perceptual whole, as evidence by pattern-completion; (3) operating dynamically in and across time; (4) structures which link sensorimotor experience to conceptualization and language; (5) realized as activation patterns in and between topological neutral maps; and (6) structures which afford normal pattern completions that can serve as a basis for inference. Image-schemas are traditionally described as a preverbal and pre-reflective emergent level of meaning. Some researchers such as Johnson (1987, 2005), Lakoff (1987), and Mandler (2004) note that image-schemas are not the same as real images and are more abstract than real images. Image-schemas are viewed as abstractions over experiences rather than as the specificity of rich experiences. In a sense, image-schemas are permanent properties of embodied experience.

By contrast, it is argued that image-schemas are generally understood as experiential *gestalts* that arise from recurring patterns of embodied experience, although it is widely acknowledged that image-schemas are essential aspects of thought and language (see Gibbs 2005).<sup>2</sup> This means that it is a mistake to assume that image-schemas are mental representations that are abstracted away from experience. Gibbs (2005) claims that image-schemas are different kinds of simulated action on the basis of real-life actions and potential actions that a person may engage in. In this regard, image-schemas as embodied simulations created in the very moment of understanding, which Gibbs claims, are completely opposite to ones as abstractions over experiences, which Johnson (2005) maintains. Image-schemas are not separated from embodied experience, but they are not structured as pre-conceptual entities. Even if image-schemas typically function without our conscious awareness of how they organize our experience, it is sometime possible to be reflectively aware of the image-schematic structure of a certain experience. Image-schemas are emergent

properties of human self-organizing systems that are continually recreated and re-experienced during cognitive and perceptual activity (Gibbs 2005: 132). Image-schemas are, therefore, stable states of embodied experience. This paper follows the latter idea of image-schemas as experiential gestalts.

Johnson (1987: 28) illustrates the traditional PATH schema, as shown in Figure 1.

Figure 1. The PATH schema

The PATH schema is one of the most fundamental image-schemas arising from our bodily experience and perceptual interactions with the world.<sup>3</sup> As shown in Figure 1, the PATH schema always consists of three elements, a source point A, a goal point B, and a vector tracing a path between them. Lakoff and Johnson (1999: 33) point out that the PATH schema itself is topological. It is obvious that the PATH schema is closely related to our understanding of motion. As Miller and Johnson-Laird (1977: 527) point out that ‘the verbs that describe movement are first learned, most frequently used, and conceptually dominant,’ our understanding of motion is without doubt related to the earliest and most basic bodily experiences.

The most typical verbs of directed motion in Japanese, as in probably most other languages, are the deictic motion verbs *iku* ‘go’ and *kuru* ‘come.’ Their typical uses are not quite different from those of English *go* and *come* (see e.g., Clark 1974, Fillmore 1971, Radden 1996). In the time specification, *iku* and *kuru* are respectively source-oriented and goal-oriented, as in (1).

- (1) a. *Taroo wa rokuji mise ni it-ta.*  
 Taro Top six.o'clock Loc shop Goal go-Past  
 “Taro went to the shop at six o'clock.”
- b. *Taroo wa rokuji ni mise ni ki-ta.*  
 Taro Top six.o'clock Loc shop Goal come-Past  
 “Taro came to the shop at six o'clock.”

In (1a) the time adverbial expression *rokuji ni* ‘at six o'clock’ represents the time of leaving the source place, while in (1b) it represents the time of reaching the goal. Also, in the specification of directional orientation, *kuru* basically requires the speaker’s deictic center as the goal of directed motion, but *iku* can take any place as a source place,

that is to say, the speaker's place or somewhere else, as in (2).

- (2) a. *Taroo wa mise ni it-ta.*  
Taro Top shop Goal go-Past  
“Taro went to the shop.”
- b. *Taroo wa mise ni ki-ta.*  
Taro Top shop Goal come-Past  
“Taro came to the shop.”

(2a) does not necessarily imply that the subject Taro started out from the place where the speaker was, while (2b) implies that the speaker was in the shop. It should be emphasized here that *iku* is an unmarked verb of directed motion that can be used in neutral descriptions, where the speaker is neither at the source nor at the goal, and that the asymmetry between *iku* and *kuru* exists.

This paper presents the IKU schema and the KURU schema as image-schemas, as shown in Figure 2 and Figure 3.

Figure 2. The IKU schema

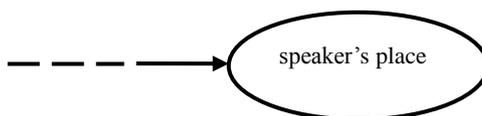

Figure 3. The KURU schema

The speaker's place as a source of directed motion, that is to say, the speaker's deictic center, is not always shown explicitly in the IKU schema, but the speaker's place as a goal of directed motion is absolutely necessary in the KURU schema. It is clear that the IKU and the KURU schemas are strongly related to the PATH schema. The distinction between these two schemas depends on what part in the PATH schema is highlighted. The KURU schema is always required to focus on the goal part. Consequently, as syntactic V-V compounds including *iku* or *kuru* as the first verb are generally related to motion, it is hypothesized that the meanings of such syntactic V-V compounds are based at the very least on the IKU or the KURU schema. In the following section, this paper explores the nature of syntactic V-V compounds including *iku* or *kuru* as the first verb

and demonstrates whether the meanings of such syntactic V-V compounds emerge from merely a process of composition or not.

### 3. Syntactic V-V compounds including *iku* or *kuru* as the first verb

The beginning part of this section demonstrates some characteristics of syntactic V-V compounds very briefly. Syntactic V-V compounds involve a particular complement structure. They are divided into two groups, aspectual compounds which take aspectual verbs, as in (3a), and non-aspectual compounds, as in (3b).

- (3) a. *Taroo wa uta o utai-hajime-ta.*  
Taro Top song Acc sing-begin-Past  
“Taro began to sing a song.”
- b. *Taroo wa kinoo hirugohan o tabe-sobire-ta.*  
Taro Top yesterday lunch Acc eat-miss-Past  
“Taro missed the chance of eating lunch yesterday.”

The second verbs in syntactic V-V compounds are limited to some classes of verbs. On the basis of Kageyama (1989: 75, 1993: 96), Matsumoto (1996: Ch.7), and Himeno (1999: 29-30), this paper lists 23 verbs co-occurring with *iku* or *kuru* as the first verb. As shown in Table 1, the 23 verbs are divided into aspectual and non-aspectual verbs on the basis of their meanings of syntactic V-V compounds. Also, the aspectual and the non-aspectual verbs are respectively divided into motion and non-motion verbs on the basis of their original verbal meanings.

	aspectual	non-aspectual
motion	<i>dasu</i> (bring.about) ‘begin’ <i>makuru</i> (roll) ‘continue actively’ <i>toosu</i> (pass) ‘finish completely’	<i>sugiru</i> (pass) ‘exceed’
non-motion	<i>hajimeru</i> (begin) ‘begin’ <i>kakaru</i> (hang) ‘be about to’ <i>kakeru</i> (hang) ‘be about to’ <i>tsukusu</i> (fulfill) ‘do something completely’ <i>tsuzukeru</i> (continue) ‘continue’	<i>aguneru</i> (struggle) ‘struggle’ <i>au</i> (join) ‘do each other’ <i>akiru</i> (get.tired) ‘get tired of’ <i>kaneru</i> (be.reluctant) ‘be reluctant to’ <i>machigaeru</i> (mistake) ‘mistake’ <i>naosu</i> (re-do) ‘re-do’ <i>nareru</i> (get.used) ‘get used to’ <i>okureru</i> (be.late) ‘miss the chance of’ <i>sobireru</i> (miss) ‘miss the chance of’ <i>sokonau</i> (fail) ‘fail’ <i>sokoneru</i> (miss) ‘miss the chance of’ <i>tsukeru</i> (attach) ‘get used to’ <i>wasureru</i> (forget) ‘forget’

Table 1. Second verbs co-occurring with *iku* or *kuru* in syntactic V-V compounds

The following subsections show that there is an asymmetry between the *iki*-V and the *ki*-V compounds, and they examine where the asymmetry originates.

### 3.1. Aspectual V-V compounds

In aspectual V-V compounds taking non-motion verbs as the second verb, the second verbs are aspectual verbs. Table 2 shows the second verbs co-occurring with *iku* or *kuru* in aspectual V-V compounds taking non-motion verbs.

	second verb	<i>iku</i> ‘go’	<i>kuru</i> ‘come’
initiation	<i>hajimeru</i> ‘begin’	<i>iki-hajimeru</i> ‘begin to go’	<i>ki-hajimeru</i> ‘begin to come’
	<i>kakaru</i> ‘be about to’	<i>iki-kakaru</i> ‘be about to go’	<i>ki-kakaru</i> ‘be about to come’
	<i>kakeru</i> ‘be about to’	<i>iki-kakeru</i> ‘be about to go’	<i>ki-kakeru</i> ‘be about to come’
continuation	<i>tsuzukeru</i> ‘continue’	<i>iki-tsuzukeru</i> ‘continue to go’	<i>ki-tsuzukeru</i> ‘continue to come’
achievement	<i>tsukusu</i> ‘do something completely’	<i>iki-tsukusu</i> ‘go to all the places’	

Table 2. Non-motion verbs co-occurring with *iku* or *kuru* in aspectual V-V compounds

Both *iku* and *kuru* co-occur with *hajimeru* ‘begin,’ *kakaru* ‘be about to,’ and *kakeru* ‘be about to’ representing initiation, as in (4), and *tsuzukeru* ‘continue’ representing continuation, as in (5).

- (4) a. *Gakusei wa hachiji ni daigaku ni iki-hajime-ta.*  
 Student Top eight.o'clock Loc university Goal go-begin-Past  
 "Students began to go to university at eight o'clock."
- b. *Gakusei wa hachiji ni daigaku ni ki-hajime-ta.*  
 Student Top eight.o'clock Loc university Goal come-begin-Past  
 "Students began to come to university at eight o'clock."
- (5) a. *Gakusei wa hachiji ni daigaku ni iki-tsuzuke-ta.*  
 Student Top eight.o'clock Loc university Goal go-continue-Past  
 "Students continued to go to university at eight o'clock."
- b. *Gakusei wa hachiji ni daigaku ni ki-tsuzuke-ta.*  
 Student Top eight.o'clock Loc university Goal come-continue-Past  
 "Students continued to come to university at eight o'clock."

*Iku* and *kuru* in aspectual V-V compounds taking non-motion verbs retain their deictic characterization. With respect to the time specification, in (4a) and (5a), the time adverbial expression *hachiji ni* 'at eight o'clock' represents the time of leaving the source place, whereas in (4b) and (5b) it represents the time of reaching the goal. With respect to the directional specification, (4a) and (5a) do not necessarily imply that the subject students started out from the place where the speaker was, whereas (4b) and (5b) imply that the speaker at the university.

The verb *kuru* cannot co-occur with both the verb representing termination such as *owaru* 'finish' and the verb representing achievement such as *tsukusu* 'do something completely.' Since the *ki-V* compound can occur only in the area of initiation and continuation, one restriction appears to be imposed on the *ki-V* compound: The speaker's place which the verb *kuru* expresses should not conflict with the focus of motion that the second verb expresses in the V-V compound. With respect to the first verb *kuru* and the second verb representing termination or achievement, the speaker's place where *kuru* expresses conflicts with the focus of motion which the second verb expresses, that is to say, the goal of motion. *Kuru* in syntactic V-V compounds cannot co-occur with the second verb representing termination or achievement. From a different standpoint, *kuru* focusing on the goal of motion on the PATH schema, as mentioned in Section 2, is likely to have priority over aspectual second verbs representing termination or achievement in syntactic V-V compounds. As a result, (6) means that all the students have already arrived at the station. However, (7) sounds strange or it is unacceptable, and (8) is not acceptable.

- (6) *Gakusei-tachi ga kuji ni eki ni ki-ta.*  
 Student-Pl Nom nine.o'clock Loc station Goal come-Past  
 “Students came to the station at nine o'clock.”
- (7) ?\**Gakusei-tachi ga kuji ni eki ni ki-owat-ta.*  
 Student-Pl Nom nine.o'clock Loc station Goal come-finish-Past  
 “Students finished coming to the station at nine o'clock.”
- (8) \**Gakusei-tachi ga kuji ni eki ni ki-tsukushi-ta*  
 Student-Pl Nom nine.o'clock Loc station Goal come-do.completely-Past  
 “Students finished coming to the station at nine o'clock.”

The first verb *iku* cannot co-occur with the second verb representing termination, but it can co-occur with the one representing achievement. As *iku* is unmarked with respect to the speaker's place, the speaker's place does not play an important role in determining the meanings of the syntactic V-V compounds including *iku*. However, it is the focus of motion that is crucial to the meanings of such syntactic V-V compounds. *Iku* inherently focuses on the source of a movement on the PATH schema. We cannot construe both the first verb *iku* and the second verb representing termination which focuses on the goal of a movement concomitantly, because the path between the source and the goal on the PATH schema is not highlighted in the situation where the speaker's place is uncertain. Therefore, (9) sounds strange or it is unacceptable.

- (9) ?\**Gakusei-tachi ga kuji ni eki ni iki-owat-ta.*  
 Student-Pl Nom nine.o'clock Loc station Goal go-finish-Past  
 “Students finished coming to the station at nine o'clock.”

By contrast, *iku* can co-occur with the second verb representing achievement, *tsukusu* ‘do something completely,’ as in (10).

- (10) *Taroo wa Kyooto no kankoochi o iki-tsukushi-ta.*  
 Taro Top Kyoto Gen sightseeing.spot Goal go-do.completely-Past  
 “Taro went to all the sightseeing spots throughout Kyoto.”

Generally speaking, the object of *V-tsukusu* is plural. In (10), the object *kankoochi* ‘sightseeing spot’ is plural. (10) shows that as a result of visiting one sightseeing spot after another, Taro went to all the sightseeing spots throughout Kyoto. The source, the goal, and the path between them on the PATH schema are all highlighted. We can

construe all these three elements on the PATH schema, even if the speaker's place is uncertain. The path in (10) represents the events of visiting sightseeing spots, and the goal represents the resultant state, that is to say, the state that Taro has visited all the sightseeing spots throughout Kyoto.

With respect to the distribution of syntactic V-V compounds, aspectual V-V compounds taking motion verbs as the second verb are fundamentally the same as the ones taking non-motion verbs, as shown in Table 3.

	second verb	<i>iku</i> 'go'	<i>kuru</i> 'come'
initiation	<i>dasu</i> (bring.out) 'begin'	<i>iki-dasu</i> 'begin to go'	<i>ki-dasu</i> 'begin to come'
continuation	<i>makuru</i> (roll) 'continue actively'	<i>iki-makuru</i> 'continue to go actively'	<i>ki-makuru</i> 'continue to come actively'
achievement	<i>toosu</i> (pass) 'finish something completely'	<i>iki-toosu</i> 'finish going'	

Table 3. Motion verbs co-occurring with *iku* or *kuru* in aspectual V-V compounds

*Iki-dasu* 'begin to go' in (11) is roughly equivalent to *iki-hajimeru* 'begin to go' in (12).

- (11) *Hachiji ni shoogakusei ga gakkoo ni iki-da-su.*  
 Eight.o'clock Loc pupil Nom school Goal go-begin-Npst  
 "At eight o'clock pupils begin to go to school."
- (12) *Hachiji ni shoogakusei ga gakkoo ni iki-hajime-ru.*  
 Eight.o'clock Loc pupil Nom school Goal go-begin-Npst  
 "At eight o'clock pupils begin to go to school."

However, there is a remarkable semantic difference between aspectual V-V compounds taking motion verbs and the ones taking non-motion verbs, that is to say, between (11) and (12). This is because *dasu* (bring.out) 'begin,' *makuru* (roll) 'continue actively,' and *toosu* (pass) 'finish something completely' are originally motion verbs. (11) conveys the implication of a vivid, lively expression with respect to initiation, but (9) which does not imply such an expression conveys objective reporting. The vivid, lively implication could arise from the original motion verb *dasu*. Consequently, it is pragmatically impossible to replace *iki-dasu* with *iki-hajimeru*. The same is true of all other aspectual V-V compounds taking motion verbs. The second verb *makuru* in (13a) involves implications of 'more frequently than is necessary.' However, (13b) merely conveys objective reporting.

- (13) a. *Kyonen Hanako wa madonna no konsaato ni iki-makut-ta.*  
 Last.year Hanako Top Madonna Gen concert Goal go-raise-Past  
 “Last year Hanako continued to go to the Madonna concert more frequently than was necessary.”
- b. *Kyonen Hanako wa madonna no konsaato ni*  
 Last year Hanako Top Madonna Gen concert Goal  
*iki-tsuzuke-ta.*  
 go-continue-Past  
 “Last year Hanako continued to go to the Madonna concert last year.”

As the second verb *toosu* in (14) conveys a sense of accomplishment, (14) conveys the implication of a sense of fulfillment and satisfaction.

- (14) *Taroo wa itsukakan no shuutyuukoogi o*  
 Taro Top five-days Gen intensive.program Acc  
*iki-tooshi-ta.*  
 go-finish.completely-Past  
 “Taro finished going to the five-day intensive program.”

Both *toosu* ‘finish something completely’ and *tsukusu* ‘do something completely,’ as in (10), represent achievement, but they convey different meanings. There is, therefore, no equivalent compound in aspectual V-V compounds taking non-motion verbs as the second verb.

To summarize this subsection, the meanings of syntactic aspectual V-V compounds are based on a process of composition. This means that despite different internal relations, aspectual V-V compounds do not convey additional meanings which are not reducible to each meaning that each verb originally has. At the same time, it should be stressed here that the image-schemas illustrated in this subsection can answer the question not only why grammatical aspectual V-V compounds are based on a process of composition, but also why ungrammatical aspectual V-V compounds do not emerge from a process of composition.

### 3.2. Non-aspectual V-V compounds

The second verb occurring in non-aspectual compounds taking motion verbs is only *sugiru* (pass) ‘exceed.’ It is necessary to account for the characteristics of the

V-*sugiru* compound before scrutinizing two V-V compounds, *iki-sugiru* and *ki-sugiru*. Generally speaking, V-*sugiru* is the syntactic V-V compound and it means ‘exceed’ with respect to number, amount, or degree. However, the V-*sugiru* compound can represent both the lexical V-V compound and the syntactic V-V compound, if the first verb represents motion. *Sugiru* in the lexical V-V compound means ‘pass,’ as in (15a), while *sugiru* in the syntactic V-V compound means ‘exceed,’ as in (15b).

- (15) a. *Taroo wa mise no mae o iki-sugi-ta.*  
 Taro Top shop Gen front Loc go-pass-Past  
 “Taro went past the shop.”
- b. *Taroo wa Hanako no tokoro ni iki-sugi-ta.*  
 Taro Top Hanako Gen place Goal go-exceed-Past  
 “Taro went to Hanako very frequently.”

One linguistic fact should be emphasized here: *Ki-sugiru* represents only the syntactic V-V compound, as in (16), whereas *iki-sugiru* represents both the lexical and the syntactic compounds, as in (15).

- (16) a. lexical V-V compound  
 \**Taroo wa mise no mae o ki-sugi-ta.*  
 Taro Top shop Gen front Loc come-pass-Past  
 “Taro came past the shop.”
- b. syntactic V-V compound  
*Taroo wa Hanako no tokoro ni ki-sugi-ta.*  
 Taro Top Hanako Gen place Goal come-exceed-Past  
 “Taro came to Hanako very frequently.”

To ascertain where the asymmetry originates, it is necessary to explain why the lexical *ki-V* compounds cannot exist very briefly. First, the sequence of the two verbs in the lexical compound corresponds to the natural temporal order of events: The event that the second verb expresses never precedes the one that the first verb does. This temporal characteristic is pivotal in determining the meanings of lexical V-V compounds including *iku* or *kuru* as the first verb. Second, such a temporal sequence supports the hypothesis that the meaning of a lexical V-V compound is based on the IKU or the KURU schema, as mentioned in Section 2. With respect to the verbs *iku* and *kuru*, while *kuru* must be used when the goal is the speaker’s place, that is to say, the

speaker's deictic center, *iku* cannot be used where *kuru* is called for. The verb *iku* is unmarked with respect to the speaker's deictic center. Obviously, these two restrictions are imposed on the lexical *iki-V* and the lexical *ki-V* compounds. The lexical *iki-V* compounds can exist, but the lexical *ki-V* compounds cannot. Therefore, one tight restriction is imposed on the lexical *ki-V* compound: The event that the second verb represents should not temporally occur after the speaker's place that the first verb represents. This means that the KURU schema plays a vital role in determining the meaning of the lexical *ki-V* compound.

The verb *sugiru* originally means 'pass.' It is closely related to motion. As shown in Figure 4, the SUGIRU schema is clearly based on the PATH schema.

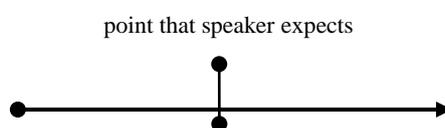

Figure 4. The SUGIRU schema

With respect to the meanings of *iki-sugiru* and *ki-sugiru* as lexical V-V compounds, two image-schemas, the IKU or the KURU schema are required to be juxtaposed with the SUGIRU schema. *Iki-sugiru*, as in (15a), is interpreted as a clear manifestation of the IKI-SUGIRU schema, as shown in Figure 5.

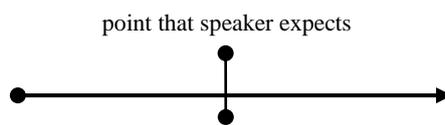

Figure 5. The IKI-SUGIRU schema

As *iku* is unmarked with respect to the speaker's place, a point that the speaker expects in the SUGIRU schema is not always equivalent to the speaker's place. However, a point that the speaker expects in the SUGIRU schema is equivalent to the speaker's place in the KURU schema. The KI-SUGIRU schema is shown in Figure 6, but it cannot be construed.

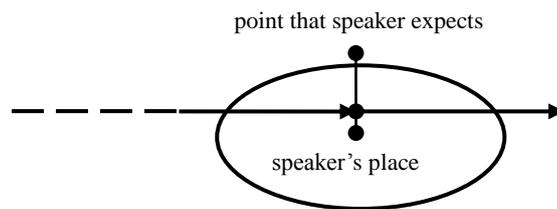

Figure 6. The KI-SUGIRU schema

Because of the restriction on the lexical *ki-V* compound, as mentioned above, the KURU schema cannot be juxtaposed with the SUGIRU schema. Indeed, the KI-SUGIRU schema cannot exist at all and also the lexical compound *ki-sugiru* itself cannot exist. (16a) is thus unacceptable.

The image-schematic approach goes one step further and demonstrates that the syntactic compounds *iki-sugiru* and *ki-sugiru* are also interpreted as clear manifestations of the IKI-SUGIRU and the KI-SUGIRU schemas. As Clausner & Croft (1999: 16) point out, the PATH schema and the SCALE schema are strongly related and are variants of the same schema, because both schemas accept an orientation or a directionality.<sup>4</sup> The SCALE schema is considered as a specified type of the PATH schema, since ‘SCALARITY does seem to permeate the whole of human experience, even where no precise quantitative measurement is possible (Johnson 1987: 123).’ With respect to the syntactic V-V compound, the arrow line in the SUGIRU schema, as shown in Figure 4, stands for excess. In other words, the arrow line representing ‘passing’ in the lexical V-V compound is transformed into the one representing ‘the degree of excess’ in the syntactic V-V compound. As a result, both the IKI-SUGIRU and the KI-SUGIRU schemas function in the area of syntactic V-V compounds. Indeed, *iki-sugiru* in (15b) and *ki-sugiru* in (16b) are acceptable.

This subsection ventures to explore the possibility that lexical and syntactic compounds including the verb *iku* or *kuru* as the first verb are not distinguished on the image-schemas, although both the semantic and the syntactic distinctions based on their internal relations between them are recognized. The IKI-SUGIRU and the KI-SUGIRU schemas could indicate a continuum between lexical and syntactic compounds with respect to image-schemas. The two image-schemas illustrate that both lexical and syntactic compounds have experiential realities. *Iki-sugiru* and *ki-sugiru* can be interpreted as manifestations of the compound image-schemas, the IKU schema or the KURU schema and the PATH schema. It is reasonable to conclude that image-schemas are different kinds of embodied simulations created in the very moment of understanding.

Finally, with respect to non-aspectual V-V compounds taking non-motion verbs as the second verbs, the *ki-V* compound cannot occur. At present there is no convincing explanation of why there are no *ki-V* compounds as non-aspectual V-V compounds taking non-motion verbs. There are some doubts as to whether the speaker's place and the focus of motion with respect to the verb *kuru* are related to non-motion verbs as the second verb or as to whether the meanings of non-aspectual V-V compounds taking non-motion verbs are based on a process of composition. Nevertheless, one of reasons why the *ki-V* compound cannot occur could be how much weight the deictic characterization and the focus of motion where the verb *kuru* involve carry on determining the meanings of the compound. Although this still remains a moot question, it would be fair to say that *kuru* can co-occur with only a motion verb in the area of non-aspectual V-V compounds.

#### **4. Concluding remarks**

Following Gibbs (2005), this paper maintains that image-schemas are continually connected with simulations of experience created in the very moment of understanding. It is reasonable to conclude that image-schemas are different kinds of simulated action on the basis of real-life actions and potential actions that a person may engage in. This paper illustrates that syntactic V-V compounds including *iku* or *kuru* as the first verb enhance the understanding of form-meaning pairings on the basis of image-schemas and it assumes that the interpretation of the image-schemas has enhanced research. This paper also clarifies how the deictic characterization and the focus of motion where the verbs *iku* and *kuru* involve are directly related to the meanings of syntactic V-V compounds including *iku* and *kuru*, and to some extent it demonstrates that the limited distribution of the *ki-V* compounds depends whether the original verbal meaning of the second verb represents motion or not as well as the characteristics of the motion verb *kuru*.

#### **Notes**

The abbreviations used in the examples are as follows: Acc=accusative; Gen=genitive; Goal=goal; Loc=locative, Nom=nominative; Npst=non-past; Pl=plural; Top=topic; and Past=past.

1. Researchers have emphasized the key role of image-schemas in structuring the conceptual system (e.g. Johnson 1987, Lakoff 1987, Gibbs & Colston 1995, Cienki 1997, Clausner & Croft 1999), metaphor (e.g. Lakoff 1990, Lakoff & Turner 1991), children's acquisition of concepts (e.g. Mandler 2004), historical change (e.g. Sweetser 1990), and detailed analyses of the spatial terms (e.g. Lindner 1981, Vandeloise 1991).
2. Experiential gestalts emerge throughout sensorimotor activity as we manipulate objects, orient ourselves spatially and temporally, and direct our perceptual focus for various purposes (see Lakoff & Johnson 1980, Lakoff 1987). In other words, experiential gestalts are ways of organizing experiences into structured wholes.
3. Mandler (1996: 373, 2004: Ch.4 & 5) points out that the first image schema that infants form is the PATH schema. The PATH schema is the simplest conceptualization of any object following any trajectory through space, without regard to the characteristics of the object or the detail of the trajectory itself.
4. Johnson (1987: 121-124) points out that the PATH schema is differentiated from the SCALE schema on several points. For instance, scales are inherently directional, but paths are not.

# ***Eyes and Hands Expressions: Embodiment of Lexical Meanings***

Shelley Ching-yu Hsieh & Elena Kolodkina

National Cheng Kung University, Cheng Shiu University

## **Abstract**

This paper focuses on compounds and idiomatic expressions containing body-part terms for the eye(s) and hand(s) in Mandarin Chinese, Russian and English. Conceptual metaphor (Lakoff & Johnson 1980) and THE PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION (Lakoff 1987) are our theoretical background. It is found that (1) there are different conceptions in three languages, and (2) The BODY AS FUNCTION is equally displayed in all three analyses languages, but (3) BODY AS EMOTION as a particular conceptual model is characteristic only of Chinese. In Russian, BODY AS EMOTION is subcategorized in BODY AS FUNCTION. *Eyes* and *hands* are integral parts of languages, speakers of different languages who then project their own cultures and life experiences to create interesting language diversities.

Keywords: body-part expressions, Chinese, Russian, Cognitive semantic, body as emotion

## **1. Introduction**

The cultural experience and knowledge we gain while submerged in our culture inevitably shape our worldview, making our mind enculturated. The role of body-part metaphors in constructing a nonliteral world is considered particularly important. Rosch (e.g., 1973), Lakoff (1987), Johnson (1987), and others explicate the relationship between body-part metaphors and learning; children understand the world on the basis of their bodies and the relationship of their bodies to the world, and they build knowledge from the concrete to the abstract by metaphorically extending body relationships to new domains.

This study focuses on compounds and idiomatic expressions (viz. fixed expressions) containing body-part terms for the *eye(s)* and *hand(s)* in Mandarin Chinese, Russian and English. Data taken from three corpora form the database of the present study in order to provide a cross-linguistic comparison. The three corpora are:

*Academia Sinica Balanced Corpus of Mandarin Chinese, The National Corpus of the Russian Language, The British National Corpus and The American National Corpus.*

We take the theoretical perspective of conceptual metaphor (Lakoff & Johnson 1980) and THE PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION (Lakoff 1987: 382). Evidence is taken from the corpora in order to provide a cross-linguistic perspective and in support of the claim that our bodily experience conceptualizes mental faculty and cultural values.

The bulk of the paper is as follows: (1) Introduction, (2) literature review and theoretical framework, (3) the presentation and discussion of the Chinese, Russian & English data under the categories of conceptions, and conceptual metaphor, (4) conclusion.

## **2. Literature review and theoretical framework**

There are a good number of research on body parts. This section presents those that focus on cross-linguistic comparison and those that concentrate on the body parts which our research purpose is oriented to. The theories of conceptual metaphor (Lakoff & Johnson 1980) and THE PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION (Lakoff 1987: 382) will then be introduced.

### *2.1. Research on Body Part*

The mainstream of body part linguistic research is in the sphere of contrastive studies. Alekseenko & Khordy (1999), Nad (1996), Nad (1997), and Šileikaite (1997) focus on the problem of equivalency of Russian, Polish, Hungarian, Lithuanian phraseologisms. Mugu (2002) focuses on structural and semantic analysis of some

polysemous body part words in Russian, German and Adug languages, such as *head*, *heart*, *arm*, *hand*, *leg*, *foot*, *eye*, *ear*, and *nose*. Sakarugi & Fuller (2003) compare English and Japanese to see the perception of translatability based on body-part metaphors.

Wei (2001) focuses on national specifics of some Chinese and Russian body part expressions. He emphasizes that without knowing non-verbal language and body-part gestures in particular, it is impossible to make cross-cultural communication and contacts. And to master the non-verbal language, it is necessary to know what national specifics can be revealed in body-part expressions. The author postulates that body part expressions like other utterances have dual meaning: the meaning of visual activity and interpretative (connotative, symbolic) meaning. According to Wei, if we take into account both these meaning, we will find many equivalents in Chinese and Russian, e.g., *woshou3* 握手 ‘hold-hands = to shake hands’ and *polozha ruku na serdtse* *положа руку на сердце* ‘having put the hand on the heart = frankly’. But there are also many so called partially equivalent body part expressions with the foregrounding of interpretative meaning.

Some linguists also focus on particular body parts and study them on the basis of different research framework, using different methods. For example, Zacharenko (2004) concentrates on the cultural senses of the somatism *legs*. Yu (2000) studies *face*, and (2001) examines on *finger* and *palm* in Chinese and English. Ro, Friggel, Lavie (2007) investigate *face*.

Wang (2005) aims at cognitive analysis of *hand* metaphor. He compares and contrasts *hand* expressions in Chinese and English with Lakoff’s ICM and Johnson’s Image Schema. His conclusions state: (1) people have similar cognition toward the objective world; that is, object cognition and space cognition. (2) the metaphorical

meanings of *hand* expressions conform to this cognitive regular pattern in English and Chinese. (3) with the different cultural influences, the semantic *hand* expressions reflect difference cognition tendency in oriental and western world.

Cao, Cai & Liu (2001) observing the grammaticalization of body part metaphors in Chinese have detailed discussions. They think that *head* and *face* have become suffixes through grammaticalization, such as *shang4tou2* 上頭 ‘up’ and *shang4mian4* 上面 ‘the higher ups’, in which *head* is only focusing on a point, while *face* has wider distribution. Cao, Cai & Liu (2001) at the same time observe that body parts metaphors often evolve into measure words, such as head in *yi4tou2niu2* 一頭牛 ‘a cow’.

Hollenbach (1995) studied the body part nouns *face* and *foot* in the Mixtecan family of languages, spoken in Mexico, and found out an interesting series of semantic extensions and syntactic category shifts from nouns to prepositions. Two words demonstrate a surprising range of uses. Thus, the meanings *face* include not only the literal body part, but also ‘front of’, ‘top surface of’, ‘in front of’, ‘on top of’, ‘in the measure of’, ‘to’, ‘in place of’, ‘place (where)’, ‘time (when)’, ‘when’ and ‘if’. The meanings for *foot* include ‘bottom of’, ‘beginning of’, ‘basis of’, ‘at the foot of’, ‘at the beginning of’, ‘for the benefit of’, ‘on behalf of’, ‘about’, ‘in exchange of’, and ‘because’.

Sakuragi and Fuller (2003) focus on the body-part metaphors in the research of the mental lexicon. They attempt to refine the theory of second language lexical acquisition by incorporating into Kellerman’s (1978, 1983, 1986) theory the effect of perceived distance of the target language and by specifying the basis (appearance and function) of the perception of similarity between the prototype and its metaphorical

extensions. They examined the effects of the similarity between the human body part and the metaphorical expression in appearance and function; the frequency of the use of the metaphor in the native language; and the perceived distance between the first language and the target language. The results showed that both similarity in appearance and similarity in function correlated positively with translatability, while the effect of the former was stronger than the latter. Frequency correlated positively with translatability for the Americans, but not for the Japanese.

Some body part studies can be found in the mainstream of modern linguistics, focusing on the research of cognitive metaphors. According to an analysis of metaphoric transfers over three centuries, made by Smith, Pollio, & Pitts (1981), human body is consistently the most frequent source of metaphors. The richness of body-part metaphor derives from the combination of the universal, cultural, and individual dimensions of our figurative thought.

Soon we will realize that body code among codes of culture is an important issue in linguistics. Phraseology of any language is anthropocentric. According to Gak, a human is egocentric, he puts himself into the center of the universe and, comprehending and categorizing the surrounding world, he compares it with himself. Thus, the names of the upper parts of objects come from the notion of *head*, lower ones – from the notion of *foot*, central ones – from the notion of *heart*, and sides are defined by the notion of *hand* (to the right hand, to the left hand) (Gak 1998: 702).

We are especially interested in cross-comparative studies of body part expressions in Mandarin Chinese, Russian and English.

## 2.2. *Related Theories*

Conceptual metaphor (Lakoff & Johnson 1980) and THE PHYSIOLOGICAL

EFFECTS OF AN EMOTION STAND FOR THE EMOTION (Lakoff 1987) are the theoretical background of this study. We review them in turn below.

### 2.2.1. *Conceptual metaphor*

Lakoff & Johnson (1980) put forth that concepts can be reached out from the range of literal ways and are used repeatedly in our daily-life language in a figurative way; these are conceptual metaphors. They examine English and give a number of examples:

#### LOVE IS MADNESS

I'm *crazy* about her.  
She drives me *out of my mind*.  
He constantly *raves* about her.  
He's gone *mad* over her.  
I'm just *wild* about Harry.  
I'm *insane* about her. (Lakoff & Johnson 1980: 49)

#### HAPPY IS UP

I'm feeling *up*.  
That *boosted* my spirits.  
My spirits *rose*.  
You're in *high* spirits.  
Thinking about her always gives me a *lift*.

#### SAD IS DOWN

I'm feeling *down*.  
I'm *depressed*.  
He's really *low* these days.  
I *fell into a depression*.  
My spirits *sank*. (Lakoff & Johnson 1980: 15)

In the example LOVE IS MADNESS, the words “crazy”, “drives me out of my mind”, “rave about”, etc. are hints to show up the madness of the affection. They are our life experience expressed in a series of conceptual metaphors such as LOVE IS

MADNESS, HAPPY IS UP, SAD IS DOWN. They exist in our daily life natural languages. Such metaphors are used not only in our language but in our daily life, and also in our thoughts and actions.

They claim that most of our conceptual system is metaphorically structured; in other words, “most concepts are partially understood in terms of other concepts” (1980: 56). For example, the concept UP is grounded from the bodily experience that we have bodies and our bodies stand erect. Conceptual system is grounded in simple spatial concepts. Human spatial concepts like UP-DOWN, FRONT-BACK, IN-OUT, NEAR-FAR are relevant to our everyday bodily functioning. They further explain that physical experience is “never merely a matter of having a body of a certain sort; rather *every* experience takes place within a vast background of cultural presuppositions” (1980: 57). The same basic embodied experiences, in which many conceptual metaphors are grounded, may be defined differently by different cultural beliefs and values (Gibbs, 1999).

Our body is essential not only for living but also the indispensable candidate of our language. Body parts are taken enormously into languages to express a variety of concepts in different cultures. We hope a comparison between body-part expressions in Chinese, Russian and English will give a picture.

It is noted that the present research focuses on a division of daily language to study conceptual metaphors, viz. fixed expressions. Fixed expressions are different from creative literary expressions and personal usages. They are commonly accepted and used language device.

A fixed expression is traditionally defined as a string of words behaving as a unitary lexical item. Various terms are used to describe fixed expressions, such as freezes, binomials and frozen locutions (Pinker and Birdsong 1979, McCarthy 1990,

Landsberg 1995, Moon 1998). According to Moon (1998: 2), who proposes a broader approach to fixed expressions, they include metaphors, similes, proverbs, sayings, frozen collocations, grammatically ill-formed collocations and routine formulae.

### 2.2.2. *Body as Emotion*

To continue with Conceptual Metaphor, Lakoff (1987) puts forth a principle that THE PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION (1987: 382). This principle is based on physiological effects of our body. When getting angry, our body heat increases and the internal pressure caused by blood pressure and muscular pressure will also increase. As a result, the effect agitates and interferes with the accurate perception of the body. Lakoff (1987) believes that all these effects including body heat, internal pressure, agitation, and redness in face and neck area are integrated into languages and bring in a system of metonymies for anger, such as in English:

#### Body heat

- Don't get *hot under the collar*.
- Billy's a *hothead*.
- They were having a *heated argument*.
- When the cop gave her a ticket, she got all *hot and bothered* and started cursing.

#### Redness in face and neck area

- She was *scarlet with rage*.
- He got *red with anger*.
- He was *flushed with anger*. (Lakoff 1987: 382)

Since increased body heat and/or blood pressure are supposed to make happen redness in the face and neck area, therefore such redness can also metonymically be a sign of anger. These data give evidence that emotions are not feelings alone and devoid of conceptual content, emotions have complex conceptual structure.

Consequently, Lakoff (1987: 383) claims that “the body is a container for the emotion” as shown in the conceptual metaphor below:

The body is a container for the emotion

- He was *filled* with anger.
- She couldn't *contain* her joy.
- She was *brimming* with rage.
- Try to get your anger *out of your system*.

When the ANGER IS HEAT metaphor connects to fluids, that is, combines with the metaphor THE BODY IS A CONTAINER FOR THE EMOTIONS, the central metaphor of the system produced:

Anger is the heat of a fluid in a container

- You make my *blood boil*.
- *Simmer* down!
- I had reached the *boiling point*.
- Let him *stew*.

The central metaphor is productive in both lexical items and mapping from source domain to target domain. Take lexical items as example, “the words and fixed expressions of a language can code, that is, be used to express aspects of a given conceptual metaphor to a greater or lesser extent” (Lakoff 1987: 384). The lexical “simmer” and “stew” above are of this kind. “Simmer” refers to a low boil and “stew” has a hot fluid in a container. Both give heat. In a word, Lakoff & Johnson (1999) concluded that our mind is embodied in the profound sense and that the structure of our thoughts comes from the natural character of our body.

Based on these theories, the present study will show that fixed expressions in terms of the body parts *eyes* and *hands* in Chinese, Russian and English not only support these theories, but show a cognitive model that is attained from the cross-linguistic comparison.

### 3. Data in Chinese, Russian & English

The eyes and hands are external body parts. According to encyclopedia, the eye is “the organ of vision and light perception. In humans the eye is of the camera type, with an iris diaphragm and variable focusing, or accommodation” (*The Columbia Encyclopedia*, 2007). The hand is a “grasping organ at the end of the forelimb of certain vertebrates, exhibiting great mobility and flexibility in the digits and in the whole organ.” (*Encyclopædia Britannica*, 2007). In man, the hand is used mostly for feeling and grasping (Wenig [*Encyclopedia Americana*], 2007). We present and discuss the body part expressions in figures of *eyes* (Chinese *yan3* and *mu4*, Russian *glaz*) and *hands* (Chinese *shou3*, Russian *ruka*) in the given languages according to the conceptions they express as well as the conceptual metaphors that are revealed.

#### 3.1. Conceptions

“Metaphor is an essential cognitive tool in that it structures many concepts, especially abstract ones, in our conceptual systems” (Yu 2003: 13). Groups of body-part expressions in our data show the same phenomenon. In what follows, we attempt to outline the cultural model for, or culturally shared understanding of *eyes* and *hands*. The conceptions of them in the given languages are abstracted and listed in Table 1.

Table 1. Conceptions of *eye & hand* expressions in three languages

Parts	Chinese	Russian	English
Eye	<p><b>Doer:</b> informer, spy, witness  <b>Abstract:</b> personality, wisdom, vision, judgment, attention, ability, means, power, ideas, consciousness, reason, goal, presence, action, vigor, profit, time, experience, thinking, cognition, care</p> <p><b>Personal quality:</b>            disdain, might, dignity</p>	<p><b>Doer:</b> eater, drinker, measurer, observer</p> <p><b>Abstract:</b> personality, sight, power, (any) condition (state), memory, accuracy, observation, absence/presence, supervision, darkness, source of tears, flirting, darkness, eyesight, sense of reality, impression, evil magic power, attention</p>	<p><b>Abstract:</b> goal, observation, attention, sight, discovery, sexual interest, interest, concern, time, power, practice, ability, sense, taste, understanding, reason, lifeblood</p> <p><b>Emotion:</b> love, affection</p>

	<p><b>Emotion:</b> happiness, anger, love, astonishment, fright</p> <p><b>Measurement, kind, orientation:</b> bull-like, frog-like, phoenix-like, dragon-like, mouse-like, chicken-like, as if of a phoenix, small, trifles, critical, tense</p> <p><b>Concrete &amp; others:</b> environment, life, good person, hole</p>	<p><b>Emotions:</b> malice, insincerity, greediness, calmness</p> <p><b>Measurement, kind, orientation:</b> instantly, approximately, nothing, never, direction, in front of, imperceptibly, anywhere</p>	<p><b>Measurement, kind, orientation:</b> small, extremely quick, standard</p>

### 3.1.1. Eyes

The conceptions of *eyes* shared by all three languages are vision, sight, power (supervision), attention, and time as shown in examples (1)-(4).

#### (1) vision

- a. *yinglyan3* 鷹眼 ‘eagle-eyes = vision (car name), chrysler; sharp expression in one's eyes’
- b. *khot glaz vykoli хоть глаз выколи* ‘eye cut out = completely dark’
- c. bird's eye view ‘a view from a very high place which allows you to see a large area’

#### (2) sight

- a. *yan3hua1* 眼花 ‘eye-flower = blurry eyesight’

- b. *idti kuda glaza glyadyat* *идти куда глаза глядят* ‘to go where eyes look = to follow one's eyes (to follow one's nose)’
- c. the naked eye ‘If something can be seen with the naked eye, it can be seen without the help of an instrument’

(3) power

- a. *tiang1yan3* 天眼 ‘god-eyes = eyes with supernatural power’
- b. *ruki ne dorosli* *руки не доросли* ‘hands didn't grow long enough = not possible to reach, having no power to get’
- c. the evil eye ‘a magical power to injure or harm people by looking at them’

(4) attention

- a. *diu1ren2xan4yan3* 丢人现眼 ‘throw-people-show-eyes = to lose face in front of people’
- b. *zakruvat glaza na chto-to* *закрывать глаза на что-то* ‘to close eyes on something = not to pay attention to something, to overlook’
- c. meet somebody's eye ‘to look at someone directly while they are looking at you’

The most popular conceptions expressed in the form of *eyes* are judgment, love, presence in Chinese. In Russian are vision, personality, opinion, supervision, and in English is attention. These productive conceptions form conceptual metaphors and will be discussed in the following section.

The vehicle *eyes* can convey measurement or show orientation. The measurement is ‘small’ and the orientation is ‘in the front side’ which shows the physical size of *eyes* in comparison with that of other organs and the location of eyes. The examples are: trifles (*yu2mu4hun3zhu1* 魚目混珠 ‘fish-eye-mix-pearl = pass off fish eyes as pearls; pass off the sham as the genuine’) and bull-like (*niu2yan3* 牛眼 ‘cattle-eyes = big eyes but look dumb’) in Chinese; approximately (*na glaz na glaz* ‘by eye, approximately’) and in front of (*pered glazami* *перед глазами* ‘in front of the eyes’) in Russian; as well as small (*hook and eye* ‘a device for fastening clothes consisting of a small bent piece of metal into which a hook fits’) in English.

The vehicle *eyes* can express personal qualities, such as proud, dignity, and frankness in Chinese, e.g., *bi4yan3zi3ran3* 碧眼紫髯 ‘jasper-eyes-purple-beard = to describe somebody who has a nice appearance and a mighty imposing manner’ and *mei2xin1yan3* 沒心眼 ‘no-heart-eye = frank’. In Russian, *glaz* ‘eye’ can also be used to refer to observation, supervision, e.g. *u semi nyaneck ditya bez glazu y semi nyaneck ditya bez glazu* ‘seven nurses leave the baby without an eye (supervision) = everybody’s business is nobody’s business; too many cooks spoil the broth’.

Furthermore, many conceptions are expressed only in a certain language: wisdom, means, profit, time, thinking in Chinese; sense of reality, memory in Russian; affection, taste, lifeblood, and sexual interest in English. The vehicle *eyes* is particularly favored in showing senses, for instance, vision, taste, sexual interest, interest, affection can be expressed with *eyes*. Below are some examples.

(5) Senses in the form of English *eyes*

- a. (sense) have an eye for something ‘to be good at noticing a particular type of thing’
- b. (sexual interest) give somebody the glad eye ‘to look at someone in a way that shows sexual attraction’

Thus, we see that basic conceptions of *eyes* shared by all three languages are vision, sight, power (supervision), attention, and time. But some conceptions are presented in two languages and still more conceptions are language specific.

3.1.2. *Hands*

Many conceptions of *hands* are shared by all three languages, such as owner, helper, leader, labor, control, possession. Given below (6)-(10) are some examples.

(6) owner

- a. *qian2shou3* 前手 ‘before-hand = predecessor; former owner’

- b. *perekhodid iz ruk v ruki nepexodit' iz ruk v ruki* 'to come from hands to hands = to come from one owner to another'
- c. second-hand 'not new; having been used in the past by someone else'

(7) helper

- a. *bang1shou3* 幫手 'help-hand = helper'
- b. *podat ruku pomoshchi komu-to podat' ruku pomochi komu-to* 'to give the hand of help to somebody = to help somebody'
- c. give/lend somebody a helping hand 'to help someone'

(8) leader

- a. *shou3xia4* 手下 'hand-under = subordinates; under the leadership'
- b. *pravaya ruka pravaya ruka* 'the right hand = the major assistant'
- c. leading hand 'the most experienced person in a factory, etc.'

(9) control

- a. *song1shou3* 鬆手 'loose-hand = to let go, to ease off on hold'
- b. *korotki ruki u kogo-to korotki ruki u kogo-to* 'short hands somebody has = somebody has no control over something'
- c. ready to hand UK 'close to you and therefore available for use when necessary'

(10) possession

- a. *tuolshou3* 脫手 'peel-hand = get rid of, sell (property, stocks)'
- b. *pribrat k rukam pribrat' k rukam* 'to take to hands = to possess'
- c. A bird in the hand (is worth two in the bush) 'said when you recognize that you should not risk losing something you already have by trying to get something you think might be better'

The vehicle *hands* can also convey measurement or show orientation. They are again extended from the physical size of a hand and the function of hand being able to carry things. The physical size of a hand is not only small (in comparison with the whole body) in that what it can hold is small, but also what the hands can carry usually has a limitation of weight, thus, 'portable' is an important concept found in all three languages, such as small (*shou3ti2bao1* 手提包 'hand-bring-bag = a handbag; a purse') and portable (*shou3ti1shi1 da3zi4ji1* 手提式打字機

‘hand-bring-kind-typewriter = a portable typewriter’) in Chinese. *Hand luggage* ‘the small cases or bags that a passenger carries with them onto an aircraft or bus’ and *hand grenade* ‘a small bomb consisting of explosive material in a metal or plastic container that can be thrown easily’ in English. In Russian the concept ‘small’, ‘portable’, expressed by the adjective *ruchnoi* *ручной* ‘related to hand’, can be met in many expressions, such as *ruchnye paltsy* *ручные пальцы* ‘hand fingers = handcuffs’, *ruchnaya melnitsa* *ручная мельница* ‘hand mill’, *ruchnoi platok* *ручной платок* ‘handkerchief’.

Other examples to show measurement and orientation are: kind, sort (*kakoi ruki* [*zhelezo*] *какой руки [железо]* ‘what hand is the [iron]’ = what kind of the [iron]) in Russian; direction (right-hand ‘on or to the right’), transfer (hand something around ‘to pass or offer something to all the people in a group’) in English.

Cultures attach special importance to the *hands*. Many conceptions are expressed only in a certain language. Love, desire, sexual interest, duty in Chinese, e.g., *qiang2tong2shou3zu2* 情同手足 ‘love-same-hand-feet = (the two) are close like brothers’; *guan1cai2li3shen3shou3* 棺材裡伸手 ‘coffin-timber-inside-stretch out-hand = to stretch a hand out from the coffin; someone who views money as more important than life’. In Russian, newsmaker, musician, bread-winner, e.g., the proverb *nogi nosyat, ruki kormyat* *ноги носят, руки кормят* ‘legs carry, hands feed’ opposes legs as the means of transportation and the hands as the major breadwinner as they not only feed, but also support, provide sustenance. In English, fate, truth, common sense, e.g., *hand in glove* ‘working together, often to do something dishonest’; *know something like the back of your hand* ‘to have very good and detailed knowledge of something’.

Besides, Chinese *hands* can also be used to represent concrete objects like weapon (*da3chu1shou3er* 打出手兒 ‘hit-out-hand-son = throw weapons back and forth on stage’), Russian conveys more conceptions of doer (laborer, buyer, newsmaker, etc.) than the other two languages, while English *hands* do not show emotions like Russian and Chinese.

The same conception is sometimes expressed with different vehicles in different languages. For example, sexual interest is expressed with the vehicle *eyes* in English (eye somebody up ‘to look at someone with sexual interest’), but *hands* in Chinese. Hence, *have a roving eye* ‘sexually interested in people other than their partner’ has a similar expression in Chinese *mao2shou3mao2jiao3* 毛手毛腳 ‘hair-hand-hair-foot = to take liberties with a woman by the actions of one's hands’.

Again, the conceptions expressed are mostly the function of that body part, e.g., *hand* for action, thus ‘help,’ e.g., Chinese *shu4shou3wu2ce4* 束手無策 ‘fold-hand-no-idea = to feel helpless’ and Russian *u nego ruki umelye y nego umelye pyku* ‘he has skillful hands = he knows how to help’. Functions of the *hands* and *eyes* stand for the related conceptual metaphors that are in the focus of the next section.

The most popular conceptions in terms of *hands* in Chinese are ability, action, control, power. In Russian are labor, power, possession and in English are power, direction, transfer. This will be further elaborated shortly.

All three languages give most “abstract” conceptions, for example, judgment (*bie2ju4hui4yan3* 別具慧眼 ‘other-have-wise-eyes = have special opinion or insight’) and ability (*shua3shou3yi4* 耍手藝 ‘play-hand-art = make a living by some skill’) in Chinese, standard (not look somebody in the eye/face ‘too ashamed to look

at somebody directly and speak truthfully to them’) and understanding (be more to this than meets the eye ‘it is more difficult to understand or involves more things than you thought at the beginning’) in English. The Specialization of Form (Lakoff 1987) is operating in these expressions. This approach says that a metaphorical mapping can be that of from physical action or physical space to a mental concept. The container schema tells the inner and the outer of an entity—the body. It is due to the transfer of various spaces, viz. body and business, or body and objects.

Finally, at the level of linguistic instantiation, Yu (2004: 663) indicates three major forms of both similarities and differences between Chinese and English. We see that adding Russian doesn’t change the result of the observation. These similarities and differences take: (1) similar expressions with similar meanings, (2) similar expressions with different meanings, and (3) different expressions with similar meanings, as shown in the example (13) below. This indicates that, although imagination is comprised in these metonymic and metaphoric expressions, “they seem to have experiential roots in common bodily experiences as they arise from the interaction between culture and body” (Yu 2004: 663).

### 3.2. *Conceptual metaphor*

The interaction between common bodily experiences and diverse cultural experiences decides the extent to which conceptual metaphors can be universal, widespread, or culture-specific. Meanwhile, as Gibbs (1999) indicates, the same basic embodied experiences, in which many conceptual metaphors are grounded, may be defined differently by different cultural beliefs and values. The conceptual metaphors emerged in our data are shown in Table 2. We give some examples below:

(11) (Chinese) EYES AS JUDGMENT

*bu2shun4yan3* 不順眼 ‘not-sequence-eyes = dislike someone or something’

*bie2ju4hui4yan3* 別具慧眼 ‘other-have-wise-eyes = have special opinion or insight’

*gua1mu4xian1kan4* 刮目相看 ‘scrape-eye PRT-see = regard somebody with special esteem’

*ming2yan3ren2* 明眼人 ‘bright-eyes-person = a person with a discerning eye; a person of good sense’

*kan4zou3yan3* 看走眼 ‘look-walk-eyes = to misjudge’

(12) (Chinese) EYES AS LOVE

*tao2hua1yan3* 桃花眼 ‘peach-flower-eyes = (eyes) to be good at sending emotion; a charming eye’

*dui4yan3* 對眼 ‘yes-eyes = have the same opinions’

*pulmei2meng2yan3* 鋪眉蒙眼 ‘spread-eyebrow-cover-eyes = to make eyes at somebody’

*yan3zhong1ren2* 眼中人 ‘eye-inside-person = someone like’

*yan3zhong1ding1* 眼中釘 ‘eye-inside-nail = someone dislike’

*yan3hong2* 眼紅 ‘eye-red = covetous’

(13) (Chinese) HANDS AS CONTROL

*jie1shou3* 接手 ‘catch-hand = take up matters left unfinished by predecessor; assistant’

*cuo4shou3bu4ji2* 措手不及 ‘handle-hand-can't-reach = too late to do anything about it’

*sa1shou3* 撒手 ‘cast-hand = let go the hand, also wash hands of matter’

*song1shou3* 鬆手 ‘loose-hand = to let go, to ease off on hold’

*ai4shou3* 礙手 ‘obstruct-hand = (affair) difficult to handle’

(14) (Chinese) HANDS AS POWER

*shou3wu2cun4tie3* 手無寸鐵 ‘hand-without-inch-iron = a man unarmed, not a scrap of metal’

*zha1shou3* 扎手 ‘prick-hand = “prick the hand” (of affair) difficult to handle’

*Lu4si3shei2shou3* 鹿死誰手 ‘deer-die-who-hand = at whose hand will the deer die; who will win the prize’

(15) (Russian) EYES ARE OPINION

*v glazakh kogo-to v glazakh kogo-to* ‘in the eyes of somebody = in somebody's opinion’

*vysoko stoyat v glazakh druzei* ВЫСОКО СТОЯТЬ В ГЛАЗАХ ДРУЗЕЙ ‘to stand high in the friends' eyes = to stand high in the friends' opinion’

*nizko past v glazakh druzei* низко пасть в глазах друзей ‘to fall low in the friends' eyes = to stand low in the friends' opinion’

(16) (Russian) EYES ARE ATTENTION

*brosatsa v glaza* бросаться в глаза ‘to be striking for the eyes = to strike/catch one's eye, to arrest one's attention’

*bit v glaza* бить в глаза ‘to be striking for the eyes = to strike/catch one's eye, to arrest one's attention’

*vertetsa pered glazami* вертеться перед глазами ‘to turn around in front of somebody's eye = to arrest somebody's attention’

*pyalit glaza* нялить глаза ‘to open one's eyes wide = to stare’

(17) (Russian) HAND AS ACTION

*po rukam bit po rukam* бить ‘to untie somebody's hands = to give somebody the freedom of action’

*derzhat ruku chyu-nibud* держать руку чью-нибудь ‘to keep somebody's hand = to support somebody’

*vilyu davit rukam* волю давать рукам ‘will (freedom) to give to the hands = to use hands, to fight’

*goloi rukoi ne tron* голый рукой не тронь ‘with a bare hand don't touch = do carefully, cautiously’

(18) (Russian) HAND IS POWER

*imet kogo-nibud, chto-nibud v svoikh rukakh* иметь кого-нибудь, что-нибудь в своих руках ‘to have somebody, something in one's hands = to have power, control on somebody, something’

*derzhat kogo-nibud, chto-nibud v svoikh rukakh* держать кого-нибудь, что-нибудь в своих руках ‘to keep somebody, something in one's hands = to have power, control on somebody, something’

*korotki ruki u kogo-to* коротки руки у кого-то ‘short hands somebody has = somebody has no power’

(19) (English) EYES AS ATTENTION

cast an/your eye over something ‘to look briefly at something’

run your eye over ‘to look quickly at the whole of something’

turn a blind eye 'to ignore something that you know is wrong'  
easy on the eye/ear 'pleasant to look at/listen to'  
eye-catching 'particularly attractive or noticeable'  
out of/from the corner of your eye 'If you see something out of/from the corner of your eye, you see it but not clearly because it happens to the side of you'

(20) (English) HANDS AS POWER

free hand 'the right or authority to do anything you consider necessary'  
bite the hand that feeds you 'to act badly towards the person who is helping or has helped you'  
go cap in hand to somebody 'to ask someone in a polite and sincere way for something, especially money or forgiveness'  
The hand that rocks the cradle (rules the world) 'said to emphasize that women have a strong influence on events through their children'

(21) (English) HANDS AS TRANSFER

hand something in 'to give something to someone in a position of authority'  
hand something out 'to give something to each person in a group or place'  
hand/give in your notice 'to tell your employer that you intend to leave your job after a particular period of time'  
give/hand something to somebody on a plate 'to allow someone to get or win something very easily'

A comparison between Chinese and English data reveals two differences. First, the conceptual metaphor "CONTROL IS HOLDING IN THE PALM OF THE HAND" is not richly manifested in English, although it is in Chinese. Second, the conceptual metaphor "THE FINGER IS THE DOER" is well manifested in English, but it is not realized in Chinese (Yu 2000: 159).

The conceptual metaphor THE HAND SHOWS DIRECTION is well manifested in English and Russian, but it is not realized in Chinese. Nevertheless, Chinese, Russian and English also share the conceptual metonymy PERCEPTUAL ORGAN STANDS FOR PERCEPTION, THE HAND IS THE DOER, as well as THE HAND IS THE CONTROLLER as in the following examples.

(22) PERCEPTUAL ORGAN STANDS FOR PERCEPTION

**Chinese:** *zhou2yan3* 著眼 ‘put to-eye = have something in mind’; *zheng1yi4zhi1yan3, bi4yi4zhi1yan3* 睜一隻眼 閉一隻眼 ‘open one eye close one eye = Turn a blind eye to something’; *bie2ju4hui4yan3* 別具慧眼 ‘other-have-wise-eyes = have special opinion or insight’; *gua1mu4 xian1kan4* 刮目相看 ‘scrape-eye PRT-see = regard somebody with special esteem’; *ming2yan3ren2* 明眼人 ‘bright-eyes-person = a person with a discerning eye; a person of good sense’

**Russian:** *skazat pravdu v glaza skazat pravdu v glaza* ‘to say the truth in the eyes = to say the truth to somebody’; *nazvat negodyayem v glaza nazvat negodyayem v glaza* ‘to call a villain in the eyes = to call a person a villain’; *v glaza ne vidat v glaza ne vidat* ‘in eyes not to see = never to see, not to see at all’

**English:** *see eye to eye; not look somebody in the eye; meet somebody’s eye*

(23) THE HAND IS THE DOER

**Chinese:** *zhuo2shou3* 著手 ‘mark-hand = to begin (to write, build, etc.)’; *ba4shou3* 罷手 ‘stop-hand = stop’; *xiu4shou3pang2guan1* 袖手旁觀 ‘sleeve-hand = look on with folded arms, hands in sleeves--not willing to help’; *yan3gao1shou3di1* 眼高手低 ‘eyes-high-hand-low = high in aim but low-rate in execution, have high ambition but no real ability; fastidious and demanding but inept’

**Russian:** *delo v opytnykh rukakh delo v opytnykh rukakh* ‘the business is in the experienced hands = business is done by experienced workers; *rabota izvestnoi ruki rabota izvestnoi ruki* ‘the work is of a famous hand = the work is of famous master’; *malo svobodnykh ruk malo svobodnykh ruk* ‘few spare hands = few spare workers’

**English:** *hired hand; handyman; working hands*

(24) THE HAND IS THE CONTROLLER

**Chinese:** *jie1shou3* 接手 ‘catch-hand = take up matters left unfinished by predecessor; assistant’; *cuo4shou3bu4ji2* 措手不及 ‘handle-hand-can’t-reach = too late to do anything about it’; *ding3shou3* 頂手 ‘top-hand = take over’; *song1shou3* 鬆手 ‘loose-hand = to let go, to ease off on hold’

**Russian:** *byt pod chyei-nibud rukoi byt pod chyei-nibud rukoi* ‘to be under somebody's hand = to be under somebody’s control’; *tverdaya ruka tverdaya ruka* ‘hard hand = strong control’; *byt v rukakh u kogo-nibud byt v rukakh u kogo-nibud*

*в руках у кого-нибудь* ‘to be in the hands of somebody = to be under somebody’s control’

**English:** *firm hand; iron hand; to fall into somebody's hands; to suffer at somebody's hands; to get out of hand*

Table 2. Conceptual metaphors involving *eyes & hands* in three languages

	EYES	HANDS
Chinese	JUDGMENT, ATTENTION, LOVE, PRESENCE	ABILITY, ACTION, CONTROL, POWER
Russian	PERSONALITY, VISION, ATTENTION, OPINION, SUPERVISION	ACTION, POSSESSOR, POWER, SKILL, PERSONALITY
English	ATTENTION	ABILITY, CONTROL, POWER, DIRECTION, TRANSFER

The above examples (11)-(12) indicate that the central conceptual metaphor the EYES JUDGE AND SHOW AFFECTION is well manifested in Chinese *yan* 眼.

It is worth mentioning that the alternative of *yan* is *mu* 目. It takes this part of conceptual metaphor in Chinese vehicle *eyes*: EYES (MU) PROVE PRESENCE. In other words, *mu* is a vehicle that gives neutral connotation—the existence and being, unlike the affection and evaluation that the other vehicle *yan* is responsible for. *Mu* was the sole vehicle for Chinese *eyes* in old Chinese; its main semantic responsibility had been taken by *yan* after the reanalysis of semantic structure. Not only many expressions that were used to be expressed with *mu* can be now expressed with *yan*, such as *mu4qian2* 目前 ‘eye-before = present’ and *yan3qian2* 眼前 ‘eye-front = present’, *yan3zhong1ci4* 眼中刺 ‘eyes-center-thorn = hate someone very much’ and *mu4zhong1ci4* 目中刺 ‘eyes-center-thorn = hate someone very much’. Most of the semantic development of Chinese *eyes* is given by *yan*. *Mu* now assists *yan* to reach

the semantic completion of Chinese *eyes*.

Furthermore, the EYES JUDGE AND SHOW AFFECTION in Chinese realized the THE PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION as Lakoff (1987) brings out. That is to say, BODY AS EMOTION is manifested in Chinese *eyes*.

As for Chinese *hands*, HANDS DO AND GIVE POWER is the central conceptual metaphor. Action shows ability, can possess and control, thus showing power, both positive (e.g., *shou3xia4liu2qing2* 手下留情 ‘to show mercy; to be lenient; to pull one's punches; to hold one's hand(s)’) and negative (sexual harassment, e.g., *mao2shou3mao2jiao3* 毛手毛腳 ‘hair-hand-hair-foot = to take liberties with a woman by the actions of one's hands’). Action and power are achieved by the motion of hands. In other words, BODY IS FUNCTION is well manifested in Chinese vehicle *hands*.

On the other hand, ability, control, or power say human behavior which takes 43.16% of our collected Chinese data of *hands* and expresses the central conceptual metaphor HANDS DO AND GIVE POWER. Further, the vehicle *hands* can be used metonymically to present people (21.58% of the data). For example, *sha1shou3* 殺手 ‘kill-hand = a killer’, *zhu4shou3* 助手 ‘help-hand = an assistant’, *lao3shou3* 老手 ‘old-hand = a person with rich experience’.

In Russian, the conceptual metonymy EYES AS PERSONALITY is very productive. As in the following examples: *srazat prevdu v glaza skazat' pravdu v glaza* ‘to say the truth in the eyes = to say the truth to somebody’, *nazvat negodyayem v glaza nazvat' negodyayem v glaza* ‘to call a villain in the eyes = to call a villain in the

eyes' and *v glaza ne vidat v glaza ne vidat* 'in eyes not to see = never to see, not to see at all'. On the other hand, it is often backed by conceptual metaphor EYES AS EMOTION, thus, emotions, expressed by a person, are expressed through his eyes, e.g. *trevozhnye glaza тревожные глаза* 'anxious eyes'. In the conceptual metaphor EYES STAND FOR VISION in Russian VISION IS MOVEMENT, such as running, walking, sticking, eating, and measuring. For example, *probegat glazami пробежать глазами* 'to run one's eyes over something to skim something, to scan something', *provizhat hlazami провожать глазами* 'to follow somebody with one's eyes' and *vprivatsya glazami впиваться глазами* 'to stick by the eyes to stare hard at somebody'.

It should be mentioned that in Russian conceptualization of vision not only eyes fulfill different movements to see something, but the objects have to make some movements to attract the eyes attention, they strike, cut, throw themselves on. Thus, EYES ARE ATTENTION, as in *brosatsa v glaza бросаться в глаза* 'to be striking for the eyes = to strike/catch one's eye, to arrest one's attention'. And vice versa, if the person is attentive, he opens and moves his eyes, trying to peer at something or somebody, as in *otkryt glaza na chto-to открыть глаза на что-то* 'to open eyes on something = to pay attention to something'. In the conceptual metaphor EYES ARE OPINION in Russian *eyes* form an opinion about something or somebody, as in *v glazakh kogo-to в глазах кого-то* 'in the eyes of somebody = in somebody's opinion'. Conceptual metaphors UP IS GOOD and LOW IS BAD are also revealed in EYES ARE OPINION, as in *vysoko stojat v glazakh druzei высоко стоять в глазах друзей* 'to stand high in the friends' eyes = to stand high in the friends' opinion'.

EYES AS SUPERVISION is also productive in Russian, where *eye* is equivalent to supervision and control, as in (25).

(25) (Russian) EYES AS SUPERVISION

*tut svoi glaz nuzhen тут свой глаз нужен* ‘here the own eye is necessary = here the personal supervision is necessary’

*nuzhen glaz da glaz нужен глаз да глаз* necessary ‘eye and eye here necessary = serious supervision is necessary’

*u semi nyaneck ditya bez glazu u семи нянек дитя без глазу* ‘seven nurses leave the child without care = too many cooks spoil the broth’.

As for *hand* in Russian, the central conceptual metaphor is HAND AS ACTION, which comprises various actions. The paramount importance of this metaphor is connected with the role of hand in the process of labor. Different types of actions can be fulfilled by means of hands, as in (17). It is important whether hands are clean or dirty in the process of action. *Imet chistye ruki иметь чистые руки* ‘to have clean hands’ means to be honest, irreproachable, vice versa, dirty hands are characteristic of dishonorable, disreputable action, as in *marat ruki марать руки* ‘to make hands dirty = to interfere with an unpleasant, scandalous affair’, *na ruki nechist на руку нечист* ‘on the hands is not clean = dishonest’. The proverb about accomplices in an improper action *ruka ruku moyet рука руку моет* ‘a hand washes a hand’ means that swindlers cover each other. HAND AS A POSSESSOR, resulting from the main function of hands to take, grasp and manipulate objects. The above metaphor is closely connected with HAND IS POWER as is presented in (18), as to have something in hands, to possess means to have power on something or somebody, as in *imet kogo-nibud, chto-nibud v svoikh rukakh иметь кого-нибудь, что-нибудь в своих руках* ‘to have somebody, something in one's hands = to have power, control on somebody, something’. The metonymy HAND AS PERSONALITY in Russian is represented by the fixed expressions in (26).

(26) (Russian) HANDS AS PERSONALITY

*rabota izvestnoi ruki работа известной руки* ‘the work is of a famous hand = the work is of a famous person’

*uznat chto-to iz pervykh, vtorykh ruk* *узнать что-то из первых, из вторых рук* ‘to know smth from the first, second hands = to know from the first person, second person’  
*delo ruk kogo-nibud* *дело рук кого-нибудь* ‘the work is of hands of somebody = somebody is to be blamed for this affair’.

It has a variant HAND AS A PROTECTOR, as in *imet silnyuyu ruku* *иметь сильную руку* ‘to have a strong hand = to have a strong protector’. HAND AS DIRECTION is revealed only by three fixed expressions, but their frequency of occurrence in everyday speech is very high.

Thus, the analysis of Russian conceptual metaphors and metonymies mainly follow the model BODY AS FUNCTION. Still, there are some metaphorical set expressions both with vehicle *eyes* and *body* that can be conceptualized as BODY AS EMOTION. But Russian is very productive in creating metonymies with *eyes* and *hands* preceded by an attribute, denoting emotion, as in *krotkiye, nezhnye glazki* *кроткие, нежные глазки* ‘calm tender eyes’, *mstitelnaya ruka* *мстительная рука* ‘revengeful hand’.

In English, EYES GIVE ATTENTION is the sole conceptual metaphor shown by the data we have collected so far. In this case, an abstract concept, attention, is partly structured by a conceptual metaphor BODY IS FUNCTION. The conceptual metaphor has the human body as its source domain. This result disagrees with that in Yu (2004: 663) where Yu found that Chinese and English share the conceptual metaphors SEEING IS TOUCHING AND THINKING, KNOWING, or UNDERSTANDING IS SEEING.<sup>1</sup>

The reason for the diversity is presumably due to that our data are fixed expressions while Yu takes literary expressions as well, such as his example (5)

---

<sup>1</sup> These conceptual metaphors can not be clearly seen from English eye and hand fixed expressions. In Chinese, the first part (judge) of the central conceptual metaphor EYES JUDGE AND SHOW AFFECTION can be interpreted as understanding too.

(*Liang ren-de mu-guang peng-dao yiqi* 兩人的目光碰到了一起 two persons' eye-light bump together 'The two persons' eyes met = Their eye lights bumped each other', *Ta-de yan-guang ruili, shenme shiqing dou man-bu-guo ta* 她的眼光銳利, 什麼事情都瞞不過她 'her eye-light sharp-pointed whatever things all unable-hide-from her = You can hide nothing from her sharp eyes'). Yu (2004: 666) and many of his examples are used only in Mainland China, such as his example (8) (*zhao1yan3* 招眼 'beckon-eye = eye-catching', *chu4yan3* 觸眼 'touch-eye = eye-catching; striking; conspicuous', *da3yan3* 打眼 'beat-eye = catch the eye; attract attention') (Yu 2004: 668). As for *hands*, the central conceptual metaphor is HANDS SHOW POWER AND GIVE DIRECTION. Having power, thus shows ability and control. Again, the function of hands is realized and BODY IS FUNCTION is also manifested.

To compare *eyes* and *hands* in Chinese, the functions of both body parts are transferred to language. We therefore come to the conclusion that BODY IS FUNCTION.

Table 3. Central conceptual metaphors involving *eyes & hands* in three languages

	EYES	HANDS
Chinese	EYES JUDGE AND SHOW AFFECTION	HANDS DO AND GIVE POWER
Russian	EYES MAKE MOVEMENTS TO SEE, GIVE AND GET ATTENTION, EXPRESS OPINION AND SUPERVISE	HANDS ACT, POSSESS AND HAVE POWER, PROTECT
English	EYES GIVE ATTENTION	HANDS SHOWS POWER AND GIVE DIRECTION

#### 4. Conclusion

*Eyes* and *hands* are integral parts of languages, revealing a new dimension of the mind and presenting thought in action. Although the human body is a potentially universal source domain for expressions structuring abstract concepts, cultural groups set up different conceptions in their languages.

Kövecses (2000), and Huang (2002) propose that metonymic processes play a much bigger role in the understandings of emotion in Chinese than in English. Our data agree with this proposal. In Russian, both metaphor and metonymy are very productive in creating body-part expressions. Moreover, in metonymies EYES and HANDS FOR A PERSON metonymies are very often backed by adjectives, denoting emotions. On the other hand, many examples, such as (1), (2) and (4), describe the bodily acts or gestures expressive of certain emotions, just like Huang (2002) points out that the core of an emotion is not simply a psychological state or process, but a readiness to act in a certain way.

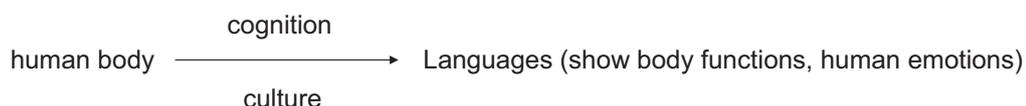

Furthermore, the EYES JUDGE AND SHOW AFFECTION in Chinese realized THE PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION as Lakoff (1987) brings out; BODY AS EMOTION is manifested in Chinese *eyes*. In Russian, EYES MAKE MOVEMENTS TO SEE, GIVE AND GET ATTENTION, EXPRESS OPINION AND SUPERVISE are central conceptual metaphors for *eyes*; HANDS ACT, POSSESS AND HAVE POWER, PROTECT are central conceptual metaphors for *hands*. Thus, BODY AS FUNCTION is mainly realized in our Russian data. Nevertheless, BODY AS EMOTION is displayed in a wide range of Russian fixed expressions and trite metonymies with adjectives, denoting emotions. In English, EYES GIVE ATTENTION and HANDS SHOW POWER AND GIVE DIRECTION are the central conceptual metaphors emerged

from our English data; BODY IS FUNCTION is operating here.

Therefore, we can draw to the conclusion that BODY AS FUNCTION is equally displayed in all three analysed languages, but BODY AS EMOTION as a particular conceptual model is characteristic only of Chinese. In Russian, BODY AS EMOTION is subcategorized in BODY AS FUNCTION, representing different movements, reflecting physiological effects of emotions, thus reflecting the model THE PHYSIOLOGICAL EFFECTS OF AN EMOTION STAND FOR THE EMOTION.

Yu (2003: 27) points out that “culturally constructed and shared concept ... manifested in conventional metaphorical expressions in the form of proverbs, idioms, and compounds”—they are fixed expressions. In sum, we would like to make the following hypothesis for a cognitive model under a cross-cultural perspective based on the above observation between Chinese, Russian and English.

**Figure 1**  
**Dynamic cognitive model of body-part expressions in languages**

Human body is projected onto languages by means of utilizing body part terms in various fixed expressions through human inherent cognition which yet featured by assorted cultures to abstract body functions, describe human behavior and express human emotions. These differences consist in the choice of a part (eye or hand) over the whole (body) as a result of cultural preferences with different expressions. However, all generated from the central conceptual metaphor: BODY IS FUNCTION.

## **Abstract**

The present paper accounts for the semantic differences between two types of scalar modification - by prefixes and by prepositions. Our analysis is based on a case study of the pairs *beyond/au-delà de* and *over-/sur* which denote similar meanings when modifying scalar predicates. Whereas all these items function as predicate intensifiers, the type of intensification differs in the case of prefixes and prepositions. We oppose the pairs *beyond* and *over-* in English as well as *au-delà de* and *sur-* in French, in order to observe their connotational value. It appears that some predicates modified by the prefixes in question can acquire a negative connotation which is constrained by contextual elements and the types of predicate and scale.

**Keywords:** bound morphemes, free morphemes, prefixes, prepositions, connotation, scalarity, intensifiers, degree, discourse.

## **0. Introduction: scalar prefixes and prepositions**

According to Whittaker (2002:1, 21-28), scalarity, a linguistic phenomenon which goes back to Plato, consists in breaking down a phenomenon into degrees. The notion of scalarity is closely related to that of comparison, for it implies a standard of comparison with respect to which objects are ordered following the degree of possession of a given property (Sapir 1944). One of the most common expressions of scalarity is intensification: for example, *very strong* is ordered higher than *strong enough* and *strong* on a scale of strength<sup>1</sup>. Contrary to what one may think, intensification implies scaling a property both up (amplification) or down (downtoning) (Bolinger 1972:17).

Adler and Asnes (2004, 2007a, 2007b, to appear) have dealt with scalarity conveyed by prepositions such as *au-delà de* (*beyond*) and *jusqu'à* (*up to*). It is now time to expand the research on scalar modification so as to include the possibility to express a more or less similar meaning by both the free morpheme *beyond* and the bound morpheme *over-* (as in: *qualified beyond expectations* vs. *overqualified*). It appears indeed that both in English and French there exist prepositions and prefixes which are capable of conveying scalarity meanings<sup>2</sup>:

---

<sup>1</sup> Scalarity can be quantitative if it relates to a scale of numbers or qualitative if it relates to a scale of properties. Rivara (1990) refers to a qualitative scalarity as an "evaluative quantification" implying a subjective scale.

<sup>2</sup> This study is carried out within the theoretical framework of the semantics of scalarity which has benefited from an extensive research during the last years (Ducrot 1996, Kennedy et McNally 1999, Piñón 2000, Kennedy 2001, Whittaker 2002).

- Prepositions: *up to/jusqu'à, beyond, past/au-delà de, above/au-dessus de, below/au-dessous de*

- Prefixes: *over-, out-/sur-, under-, sub-/sous-, mini-, maxi-, super-, hyper-, hypo-, ultra-, extra-, arch-/archi-, trans-, ultra-, mega-/méga.*

This paper explores the analogies and differences of scalarity conveyed by prepositions and prefixes. Our analysis focuses on the particular case of *beyond* and *over-* and their French counterparts *au-delà de* and *sur-*:

- (1) a. Talented **beyond** (all) measure  
b. Doué **au-delà de** toute mesure
- (2) a. **Overtalented**  
b. **Surdoué**

How to motivate the choice of these particular items? More precisely, why not to compare the usages of *over* both as a preposition and a prefix? On the other hand, why not to oppose the preposition *beyond* to the prefix *trans-* which seems, at a first glance, more closely related to *beyond* than *over*?

A single answer may be given to both questions, if we keep in mind the scope of the present study. Since we are dealing here exclusively with scalarity operators and not with spatio-temporal meanings, the preposition *over* as well as the prefix *trans-* are immediately ruled out: they denote spatial meanings. Only the prefix *over-*, but not the preposition, conveys the scalar meaning. Secondly, the prefix *trans-* (as in: *transatlantic, transsibirean*), meaning "beyond", covers only the spatio-temporal values of *beyond*.

The first part of this study accounts for the semantic differences emerging from the two types of scalar modification - by prefixes and by prepositions -, already observed in examples (1) and (2). The second part deals with the types of scales along which the modification is being made. The third part examines the restrictions imposed by *beyond/au-delà de* and *over-/sur-* on the types of predicates. Finally, in the fourth section, we oppose the pairs *beyond* and *over-* (3a) in English as well as *au-delà de* and *sur-* (3b) in French, in order to observe their discursive value, for it appears that what may be considered as quasi-synonymous morphemes do not convey the same message:

- (3) a. *Qualified beyond expectations /overqualified*  
b. *Qualifié au-delà de ce qu'on pouvait attendre / surqualifié*

## 1. Semantics of *beyond/ au-delà de* and *over-/ sur-*

### 1.1 Semantics of the prepositions *beyond/ au-delà de*

According to the *Merriam Webster* dictionary, for English, and the *Trésor de la Langue Française*, for French, *beyond* and *au-delà de* have three main usages: spatial, temporal and scalar. The common denominator for all of these values would be the notion of distancing with respect to a stated reference point or, in other words, a surpassing of a limit. This limit varies according to the type of value:

Spatial :

- (4) a. *To live **beyond** the ocean*  
b. *Habiter **au-delà de** l'océan*

Temporal :

- (5) a. *To work **beyond** 8 hours a day*  
b. *Travailler **au-delà de** 8 heures par jour*

As for PPs headed by the scalar operator *beyond* and its French counterpart *au-delà de*, there is a surpassing of a contextually defined standard value of a process, a state or a property (cf. Adler and Asnes 2007a, 2007b), as seen in examples (6)-(8):

- (6) a. *Paul is happy **beyond** expectations*  
b. *Paul est heureux **au-delà de** ce qu'on pouvait attendre*  
(7) a. *To love **beyond** words / (all) reason*  
b. *Aimer **au-delà de** toute expression*  
(8) a. *Brave **beyond** measure / belief*  
b. *Courageux **au-delà de** toute mesure*

*Beyond* and *au-delà de* function as operators establishing a relation between a property, a state or an event and a degree on a scale, such that the degree in question is superior to a reference degree (given by *beyond/au-delà de XP*) of that property, state or process.

For instance, the proposition in (6) is true if, and only if, there is a property of being happy, assigned to Paul, whose reference degree is represented by *expectations*, and if the position of Paul on the scale of happiness is superior to 'what could be expected'.

To sum up, *beyond* and *au-delà de* share the same denotational value. The next section will reveal if that is still the case for the prefixes *over-* and *sur-*.

## 1.2 Semantics of the prefixes *over-/sur-*

The prefixes *over-* and *sur-* can both function as scalar operators when prefixed to verbs, adjectives, participles and deverbal or deadjectival nouns.

- (9) a. *To overprotect/ surprotéger*  
c. *Overfull/ surcomplet*  
b. *Overprotected/ surprotégé*  
d. *Overprotection/ surprotection*

This section compares prepositional and prefixational usages of *over(-)* and *sur(-)*. Both prefixes evolved from a basically spatial preposition into a polyfunctional prefix. This paper focuses exclusively on the scalar value of these prefixes. The values of the corresponding prepositions will be provided only for the sake of comparison.

### 1.2.1 Over

#### 1.2.1.1 The preposition *over*.

The preposition *over* has the following usages:

##### 1. Spatial usage:

a. **spatial concrete**: indicates a motion or a situation in a position which is higher than another (*flew over the lake*), position or movement downwards (*lay a blanket over the child*), "through" (*over the house*), "on the other side" (*over the river*)

b. **spatial abstract**: possession of authority, power, superior hierarchical position : *respect those over him*, medium of communication – *over the radio*

##### 2. Temporal: meaning "through", "during" (*over the last 20 years*)

4. **Theme** : denoting an object of concern (*trouble over money*)
3. **Quantificational** : functioning as a modifier of quantifier (*cost over 5 \$*)

#### 1.2.1.2 *The prefix over-*.

The prefix *over-* can add various meanings to the stem. Among others:

1. **Spatial** (concrete and abstract)
  - 1.1. Meaning: “upper”, “outer”, “over”, “above” – *overalls* (suit), *overcoat* (n), *overcast* (n, adj, v -cover, darken)
  - 1.2. Meaning: “Above”, “beyond”, “across” - *overcast*, *overhang*, *overhead* (both physical position and expenses), *overland*, *overlap*, *overlook*<sup>3</sup>, *overpass*, *overseas*, *overview*
  - 1.3. Hierarchical meaning: “superior in rank or importance” - shows that someone or something has power or authority over another: *overrule*, *overpower*, *override*, *overthrow* (this meaning is also shared by the preposition *over*)
  - 1.4. Meaning “to an inverted or reverse position” – *overcome*, *overhaul* (to examine thoroughly, to revise), *overturn*, *overwhelm*
2. **Temporal-scalar usage** (meaning “too long”)
 

*Oversleep*, *overstay*, *overlive*, *overtime*.
3. **Scalar**: meaning “too much, additional” - shows that an action is done to too great an extent, excessively:
 

*overcharge*, *overeat*, *overestimate*, *overrate*, *overwork*, *overconfident*, *overcrowded*, *overdo*, *overdrawn*, *overflow*, *overjoyed*, *overload*, *overpopulated*, *overpower*, *overpriced*, *overrated*, *overreact*, *oversleep*, *overstep*, *overuse*, *overweight*, *overwork*

It seems that the value of the prefix *over-* depends on the nature of the modified predicate:

1. before non-scalar predicates, the prefix *over-* tends to have spatial meanings
2. before scalar predicates, the prefix *over-* acquires a scalar meaning: *overeat* is a higher degree of eating on the scale: *eat a little* – *eat enough*- *eat more*- *eat much* – *overeat* ("eat beyond what is considered to be necessary")

In section 3 we will examine more in detail the types of predicates compatible with the scalar prefix *over-*.

Contrary to the preposition, the prefix *over-* has a scalar meaning. As a scalar operator, *over-* is an intensifier. However, according to Bolinger (1972), when *over-* attaches to a degree verb, it does more than merely intensify; it conveys the meaning of excess ("too much") (cf. as well Quirk et alii (1972)), as in *overconfident*, *overconscientious*, *overdressed*, *oversimplify*, *overeat*, *overdo*.

Intensifiers share the property of a heightening effect on some unit of the sentence. Roughly, three semantic subclasses can be distinguished: emphasers, amplifiers, downtoners (Quirk et alii 1972). According to this typology, *over-* seems to be an amplifier: it scales upwards from an assumed norm. Let's notice that the Merriam Webster dictionary quotes only the scalar value of *over-* which seems to be the predominant one.

---

<sup>3</sup> *Overlook* = to skip something. *Overlap*, *overcast* = to lap over, to cast over = to cover something completely. This paper is not about the spatial meanings of *over-*, but it would be worthwhile in the future to explore the different modes of spatial relations between the prefix and the radical.

The scalar prefix *over-* is synonymous to other prefixes such as *hyper*, which means “over, excessive, more than normal”; *ultra-*; *super-* (*hyperactive*, *ultrareligious*, *supernatural*).

One of the most salient properties of *over-* as a scalar prefix is that it may alter the discursive value of the predicate. Thus, with certain predicates, it may suggest negativity (i.e. convey a negative effect). Let's note that what is altered is the prefixed stem, and not the stem in itself:

(10) *Protect* – a positive activity, *overprotect* – a negative activity  
*Overprotect* may become a disturbing behavior provoking antagonism on the part of the protected person. The same goes for *sweet-oversweet*, *generous-overgenerous*, *optimistic* – *overoptimistic*. When these stems are related to *over-*, they may reflect a negative attitude.

The effect of the resulting negative connotation may be related to the fact that the prefix *over-* denotes a surpassing of a certain norm to which the predicate is being compared, and this deviation from the norm is considered to be negative (sometimes, even “not normal”). We will come back to this issue in section 4 *infra*.

Let's notice that the excess denoted by *over-* can be quantitative or qualitative:

- (11) a. *Overcharge* – to charge more than needed (quantity) (to charge **how much**?)  
b. *Overreact* – to react more strongly than needed (quality) (to react **how**?)

Another surprising property of the prefix *over-* is that it seems to have a syntactic function, more precisely, that of a modifier, unlike other prefixes which are normally not being assigned a syntactic behavior, cf. (12):

- (12) a. *Overachieve* – achieve more  
b. *Overstimulation* – excessive stimulation  
c. *Overfat* – fat to an excessive degree

In these examples *over-* is attached to a verb (12a), a noun (12b) and an adjective (12c). The abovementioned paraphrases reveal that *over-* functions as a modifier:

- a) before verbs it functions as an adverbial: “too much” or “more than expected, needed”  
b) before nouns it functions as an adjective: “excessive”  
c) before adjectives it functions as an adverb of degree (intensifier): “to an excessive degree”.

This function of modifier explains the analogy between the prefix *over-* and the adverbial PPs headed by *beyond*:

- (13) a. *To overachieve*  
b. *To achieve beyond expectations*

*Over-* in (13a) functions similarly to *beyond expectations* (13b): both modify the predicate *achieve*.

To sum up, *over-* in its scalar usage represents a surpassing of some standard reference point, just like *beyond XP* implies a contextually defined standard. It is impossible to talk about, for example, overdoing something without implying that one knows what is considered to be the norm.

## 1.2.2 *Sur-*

### 1.2.2.1 *The preposition sur.*

According to the *TLF* dictionary, the French preposition *sur* is extremely polysemic. Therefore, we will only provide here its most prototypical meanings:

#### 1. Spatial

- a. antonym of *under (sous)*: *sur la table*
  - b. a target place : *marcher sur Rome, se précipiter sur quelqu'un*
  - 2. Temporal or temporal-causal** : *sur le matin, sur demande*
  - 3. Abstract meanings** – reference point (measure, quantity – *sur dix mètres, avoir avantage sur quelqu'un*)
- 1.2.2.2 *The prefix sur-*.

According to the same dictionary (*TLF*), the prefix *sur-* has the following meanings:

**1. Spatial meaning**

a. **Superiority**

(14) *surtitre, surmaillot, survoler; surplomber, surrénal*

b. **Hierarchy**

(15) *surarbitre, surexpert, surclasser, surpasser, surhumain, surnaturel*

**2. Temporal - Posteriority**

(16) *survivre, surlendemain*

**3. Iteration, repetition**

(17) *surimposer, surimprimer, sursemer, surdorer, surinfection*

**4. Scalar value**

a. **Excess**

(18) *surabondance, surcapacité, surpuissance, surpesanteur, survitesse, suralimenter, surchauffer, surexploiter, surestimer, surévaluer, surpayer, surtaxer, surdoué, surexcité, surpeuplé, surdéveloppé, surendetté, surnourri, surproduction, suradministration, surconsommation, suremploi, surirritation, surprotection*

**b. Hyperbolic (exaggeration) in the spoken, familiar language:**

(19) *Le bus était surcomplet*

*Sur-* is associated to an adjective that already has an absolute value. Here, the prefix has a function of an intensifier and it may alternate with *super* or *hyper*.

In hyperbolic usages, *sur-* does not alter the connotational value of the predicate, it is just an intensifier.

The examples above show that *sur-* denotes an excess or an extreme degree (ex: "*surpopulation*", "*surutilisé*", "*surproduction*"). Contrary to other prefixes which function as intensifiers, *sur-* seems to be the only one which may add a negative connotation to the modified item. While *protéger* seems to be a positive mode of behavior, *surprotéger* is not recommended by psychologists.

Nonetheless, it is still possible to find cases where the primary value of the stem is not altered. Let us compare *surdoué* and *surqualifié*. As opposed to *surqualifié* which means "excessively qualified" and may be used negatively, *surdoué* means "extremely gifted" and preserves the positive value of the stem. Why is it so? In order to answer this question, we have to look for the differences in the semantic properties of the stem. It appears that while *doué* is an individual-level predicate denoting a permanent property, *qualifié* is a stage-level predicate denoting a temporary property. These properties are preserved after the addition of the prefix *sur-*. Moreover, *surdoué* is an intransitive adjective standing for itself and, as such, does not require any point of reference. On the other hand, *qualifié* and *surqualifié* are transitive and do not stand for themselves in the sense that one is always qualified for something. Therefore, one can be overqualified for one position, but not enough qualified for another.

As we have shown before, *sur-* can also have a hyperbolic usage in which it alternates with *super/hyper*. However, when *sur-* is not hyperbolic, it may not be considered as a synonym of *super* and *hyper*. Let's compare (20a) and (20b):

(20) a. *Superqualifié, hyperqualifié*

b. *Surqualifié*

While *superqualifié* and *hyperqualifié* have a positive connotation and stand for a colloquial form of exaggeration, *surqualifié* may be used negatively. In the case of *sur-* there is a standard which is imposed by a certain institution and a surpassing of that standard will create a disadvantageous situation for a certain institution with given requirements. On the contrary, *superqualifié* and *hyperqualifié* express subjective judgments, not involving any kind of institutionalized norm.

As for *hyperdoué / superdoué* vs. *surdoué*, all of these seem to denote the same values and there is no reversal of connotational value. The three adjectives are used to portray a person whose intellectual capacities are superior to the average. They all intensify the degree of the predicate and imply a standard of comparison<sup>4</sup>. However, in some cases they seem to be in complementary distribution: for instance *hypercorrection* is a term used in grammar while *surcorrection* belongs to the field of ophthalmology.

### 1.2.3 Comparison *over-* vs. *sur-*

The comparison of the scalar modification by the prefix *over-* in English with its French counterpart *sur-* reveals that *over-*, as a scalar prefix, is much more productive than *sur-*. *Sur-* seems to merge with the stem to become a lexical entry. *Over-*, on the other hand, can be added more freely to different stems.

In modern French, *hyper-* and *super-* are the ones sharing the same productivity as *over-* in English. Thus, while *overhappy* is perfectly acceptable in English, *surheureux* is non grammatical in French. The colloquial forms *superheureux* or *hyperheureux* are, on the contrary, acceptable.

## 2. Types of scale

One major difference between the scalar modification made by free (prepositions) and bound (prefixes) morphemes is related to the type of the scale along which the predicate is intensified. More precisely, in the case of prepositions, the modified predicate is evaluated along an explicitly stated scale. This scale can be either constrained or not by the lexical properties of the predicate (cf. Adler and Asnes 2007a, 2007b). Quantitative and qualitative scales (see examples (21), (22)), are thus constrained by the predicate type, i.e. the quantitative predicate is measured along a quantitative scale, while the qualitative predicate is measured along an intensity scale.

### **Quantitative scale (100lbs, 50kg):**

(21) a. *To lose weight beyond 100 lbs*

b. *Maigrir au-delà de 50 kg*

---

<sup>4</sup> This paper is not about prefixes such as *hyper-* or *super-*. However, it is interesting to observe the outcome of combining *hyper-* with a non scalar stem, such as in *hypercorrection*: since, in principle, it is impossible to intensify a non scalar predicate, *hypercorrection* actually means *incorrectness*, i.e. a negation of the predicate.

**Qualitative scale (love-adoration: hyperonym /hyponym relation):**

- (22) a. *To love beyond adoration*  
b. *Aimer au-delà de l'adoration*

On the contrary, the epistemic scale is compatible with any type of predicate.

**Epistemic (external) scale (words, reason, expression):**

- (23) a. *To love beyond words / (all) reason*  
b. *Aimer au-delà de toute expression*

As opposed to prepositions, the scalar modification by prefixes relies solely on the lexical properties of the modified predicate, and there is no other explicitly stated scale (cf. (2), where the modification exploits the inherent scale of the predicate *talented*).

Another example would be *anxious* and *overanxious*, where *over-* intensifies the lexical property of being anxious and denotes that the “acceptable” degree of anxiety has been surpassed. This is a value judgment: the level of anxiety is measured with respect to an 'acceptability' norm.

Precisely because of the absence of the explicitly stated scale, the prefixational usages are less productive: thus, it is impossible to find a prefixational equivalent for every prepositional usage:

- (24) a. *To love beyond adoration - \*overlove*  
b. *Aimer au- delà de l'adoration - \*suraimer*

### 3. Types of predicates

#### 3.1 Predicates compatible with *beyond / au-delà de*

As for the predicates modified by *au-delà de/beyond XP*, there is no restriction on the syntactic category: the modified term can be an adjective, a noun or a verb provided that it is scalar. Semantically speaking, the modified predicates can belong to the following categories:

▪ **Open/closed-scale predicates<sup>5</sup>**

The open-scale predicates are compatible with proportional modifiers such as *completely/complètement, partially/partiellement, half/à moitié*. Thus, *to fill/remplir* is a closed-scale predicate, the maximal degree of which is lexically inherent. On the contrary, in the case of the open-scale, (*to love/aimer, happy/heureux*), no maximal degree is associated with the predicate. (*\*completely/ complètement, partially/partiellement, half / à moitié*).

▪ **Open-scale:**

- (25) a. *Heureux au-delà de toute expression*  
b. *Happy beyond all expression*

▪ **Closed-scale:**

---

<sup>5</sup> The dichotomy open/closed-scale exists alongside other classifications. One could establish an analogy between the notions of open/closed-scale, belonging to the domain of scalarity, and those of telicity/atelicity, respectively, belonging to the domain of aspect. Thus, *to fill* is a closed-scale, telic predicate.

- (26) a. *Remplir la salle au-delà de sa capacité maximale*  
 b. *To fill the room beyond its maximal capacity*
- **Stage-level and individual-level predicates (cf. A. Kratzer 1995).**
    - **Individual level :**
- (27) a. *Beau au-delà de toute expression*  
 b. *Beautiful beyond all expression*
- **Stage-level**
- (28) a. *Heureux au-delà de toute expression*  
 b. *Happy beyond all expression*
- **Psychological predicates**
- (29) a. *Aimer au-delà de toute expression*  
 b. *To love beyond all expression*
- **Activity predicates Vendler (1967)**
- (30) a. *Communiquer au-delà des mots*  
 b. *To communicate beyond words*
- **Accomplishment predicates Vendler (1967)**
- (31) a. *Remplir la salle au-delà de sa capacité maximale*  
 b. *To fill the room beyond its maximal capacity*
- **Achievement predicates Vendler (1967)**
- (32) a. *Surprendre au-delà de l'imaginable*  
 b. *To surprise beyond one's wildest dreams*

### 3.2 Predicates compatible with *over-/sur-*

The previous paragraphs show that the scalar PPs headed by the prepositions *beyond* and *au-delà de* denote a high degree and do not impose any restriction on the syntactic category of the modified predicate as long as it is scalar.

As for the prefixes *over-* and *sur-*, in cases in where they are attached to non scalar predicates, they do not convey intensity:

(33) *Overprint/surimprimer*

In (33), both prefixes have an iterational meaning ("printing over something that is already printed")

(34) *Surinfection* – "secondary infection consequent to the primary one".<sup>6</sup>

When *over-* and *sur-* are attached to scalar predicates, similarly to the prepositions, they are compatible with adjectives, nouns and verbs.

Semantically speaking, the modified predicates can belong to the same categories as the predicates modified by the prepositions:

- **Open/closed-scale predicates**
    - **Open-scale:**
- (35) a. *Surcontent, surdoué*  
 b. *Overhappy overviolent, overgifted*

---

<sup>6</sup> Other cases which have to be taken into consideration:

-*Surmonter/overcome* – non-compositional meaning of prefix and stem (and therefore not in the scope of this paper).

-incompatibilities due to the type of the stem: *Danser* - *\*surdanser*; *Dance* – *\*overdance*; *\*Sur/sous-tuer* (atomic predicates).

- **Closed-scale:**
  - (36) a. *Surremplir la salle, surcharger le camion*
  - b. *Overfill the room, overload the truck*
- **Stage-level and individual-level predicates (cf. A. Kratzer 1995).**
  - **Individual level :**
    - (37) a. *Surdoué, suractif*
    - b. *Overthin; overgifted; oversweet*
  - **Stage-level**
    - (38) a. *Surfatigue, surqualifié, surexcité, surirrité, suroccupé*
    - b. *Overtiredness, overhappy, overqualified, overoccupied, overirritated*
- **Psychological predicates**
  - (39) a. *Surexciter, surirriter*
  - b. *Overexcited, overirritate*
- **Activity predicates (Vendler (1967))**
  - (40) a. *Surfumer*
  - b. *Oversmoke*
- **Accomplishment predicates (Vendler (1967))**
  - (41) a. *Surremplir, surperformer*
  - b. *Overfill, overperform*
- **Achievement predicates Vendler (1967)**
  - (42) *Oversucceed, overachieve*

We have already evoked the potential change of the connotational value of the predicate modified by the prefixes *over-/ sur-*. It is now the appropriate moment to ask whether this change is correlated with the stem type. In other words, is the predicate type responsible for the negative connotation?

If one compares predicates such as *overqualified* and *overgifted*, one may think that the dichotomy stage/individual-level might be responsible for the negative effect. Thus, *overqualified* which is a stage-level predicate may be used negatively, to disqualify someone, whereas *overgifted* which is an individual-level predicate preserves its positive value. However, if we compare *overgifted* to another individual-level predicate such as *overnice*, one sees that *overnice* changes its fundamental connotational value as opposed to *overgifted*: *gifted* is considered to be a positive, recommendable, property and that seems to be the case for the prefixed stem as well. *Nice* seems to be a positive quality but *overnice* may become a problematic property.

On the other hand, if we now compare two stage-level predicates, such as *overhappy* and *overqualified*, we see again that *overhappy* remains positive while *overqualified* may acquire a negative connotation.

Is there still a way to explain these changes of connotational value? We suggest that this additional value is context-sensitive, i.e. the same item can be either 'positive' or 'negative' in different contexts: In (43) the possible change of connotation is connected to the cause of being overexcited:

- (43) *Overexcited:*
  - a. *Your son was not able to sleep since he was overexcited* (the utterer expresses a negative attitude)
  - b. *Your son is overexcited about going to America.* (the utterer expresses a positive attitude)

(44) *Overqualified*:

- a. *You cannot be hired for this job since you are overqualified* (negative)
- b. *Don't waste your time in this job. You are overqualified and can find a much better job that suits your qualifications* (positive)

In other cases, the change of connotational value may depend on whether one is being qualified by himself or by others:

(45) a. *I am overhappy*

- b. *What happened to your son? He seems a little overhappy (implying that he is not behaving as usual and even maybe awkward: is he on drugs?)*

In addition, the intensified property can be, what one may call, internally or externally oriented:

(46) *Nice to everybody vs. \*happy to everybody*

The property is internally oriented or reflexive if it qualifies the person and has no effect on the environment (e.g. *happy* concerns exclusively the owner of the property). The property is externally oriented or transitive if in addition to qualifying a person, it has an effect on the environment. The transitive properties, such as *nice*, tend to alter their connotational value. In the case of reflexive properties, the reading depends on the context (i.e. the cause) in which it is used: *happy*.

Thus we see the influence of discourse on the possible change of connotation. The notion of "excess" expressed by *over* or the subtle transition of "more than" into "excess" is also to be put on the account of discourse. Moreover, certain qualifications are already institutionalized/ standardized and thus considered as concepts (*overprotective* - psychology, *overqualified* - the job market). In such cases the connotational value of the term is fixed.

There still remains the question of antonymy: why is it that French *surdévelopper*, *surexciter*, *surcomplet*, *surabondant* exist but not *\*sous-développer*, *\*sous-exciter*, *\*sous-complet*, *\*sous-abondant*? Why is it, on the other hand, that English *overdevelop*, *overexcite*, *overshy*, *overnice* exist but not *\*underdevelop*, *\*underexcite*, *\*undershy*, *\*undernice*? Is it connected to the type of the predicate as in, for instance, *develop*, which is a telic predicate and, as such, imposes a final boundary? It would be therefore awkward to add *under* which will prevent the completion of the process (i.e. by contradicting the inherent aspectual properties of the predicate). That would explain, by the same token, why the participle of such verbs is nonetheless possible (*sous-développé*, *underdeveloped*): the participle expresses the resulting state at which it is possible to judge if the process has indeed reached its term or not. On the other hand, *sur/sous-estimer* and *over/underestimate* pose no problem since they are atelic (Vendlerian activities) and, as such, don't have an inherent term. At each point of the activity of *estimating* the process is true<sup>7</sup>. The prefix in such a case is not being contradictory with the aspectual properties of the predicate. In fact, in the case of *underdeveloped*, *under* means "not completely", and in the present case, *under* means "not enough".

With adjectives, such as *shy*, *nice*, the impossibility of *under* is definitely connected to a different source, which will be explored in a further study.

---

#### 4. Modification by bound and free morphemes: the question of connotation

We are tempted to use the following set of examples ((47)- (48)) in order to show that when the modification is made by free morphemes, as in the case of the epistemic scale, the inferences being made possible are different from that in which modification is made by bound morphemes: in the former case, the connotational value of the stem is being preserved and of course intensified by the modifier, in the latter, there is a change of connotational value due to the possible negative judgment or incompatibility to a certain standard being fixed.

(47) *Qualified beyond expectations /Overqualified*

(48) *Qualifié au-delà de ce qu'on pouvait attendre / surqualifié*

In the job market, if a person is overqualified, most probably s/he will not be accepted to the position he applied to. On the contrary, if s/he is qualified beyond expectations, this means that s/he has made an extraordinary impression on her/his employers and will surely get the desired position. At a first glance, it appears then that *over-* triggers a negative inference related to the notion of excess whereas *beyond* simply denotes a high degree. Both excess and high degree are evaluative meanings and, as such, establish a comparison with respect to a certain norm on a reference scale which is surpassed. Nevertheless, these two meanings differ by their pragmatic orientation: as opposed to the high degree meaning, excess implies a negative surpassing of a limit (cf. Amiot 2004).

Unfortunately, the situation is much more complex. As far as prepositions are concerned, this connotational value varies according to the type of scale. When a predicate is modified along an epistemic scale, its connotational value depends on whether the judgment is negative or positive. Compare:

(49) *Qualified beyond what is needed/ beyond expectations*

Since *beyond expectations* expresses a positive judgment, *qualified* is a positive property. On the contrary, *beyond what is needed* is grasped as negative judgment, thus the overall is negative.

In the case of the qualitative scale, the modification by *beyond* goes along with the fundamental connotational value of the predicate:

(50) a. *To love beyond adoration* (intensifying in a positive sense)

b. *To terrify beyond horror* (intensifying in a negative sense)

Finally, as for the quantitative scale, there is no qualitative judgment and the quantities expressed may entail positive or negative judgments according to extra-linguistic knowledge.

As far as prefixes are concerned, *overqualified* seems at the first glance a problematic property, as previously shown, especially when it serves as the cause for which one is not being accepted to a certain job. Yet, all in all, it is better to be overqualified than under-qualified.

Still, there is another aspect to take into consideration (cf. (51)-(52)):

(51) a. *Surestimer*

b. *Estimer au-delà de sa valeur*

c. *Estimer au-delà de toute expression*

(52) a. *Overestimate*

b. *Estimate beyond its real value*

c. *Estimate beyond expression*

These examples demonstrate that the prepositional modification may also make use of the internal scale. The same result may thus be achieved by both the prefixational and the prepositional modification: (a) and (b), but not (c), exploit the inherent scale of the predicate.

## 5. Conclusion

Scalarity is about denoting a property which can be possessed to a certain degree (Rivara 1990). It has been shown in the present paper the extent to which free and bound morphemes modify scalar predicates, i.e. intensify their natural degree. The issue of negative connotation emerged in the process of comparing the scalar modification by prefixes and prepositions. According to Sapir (1944) the kinsaesthetic aspect of scalarity implies an ordering of elements from the smallest to the biggest: the upwards movement is generally associated to a favorable effect while the downwards movement is associated to an unfavorable effect. The present study shows several cases in which although the movement is towards the upper limit, the inference is yet unfavorable. Thus connotational value does not depend on the orientation of the scale (upward or downward movement). Rather it is constrained by contextual/discursive elements and the types of predicate and scale. As for the modification itself, the bound and free morphemes examined in the present paper both function as intensifiers. Bound morphemes usually do not have a syntactic function in the sentence, they are part of the lexicon. Our study shows however that they may be analyzed as modifiers as well, the same as prepositional phrases. Yet, there exists a major difference between bound and free morphemes: the former are much less productive than the latter. Furthermore, productivity is also language dependent: *over-* is much more productive than *sur-*.

# The semantics of the verb of giving in Thai and Vietnamese : A contrastive study<sup>\*</sup>

Suthatip Mueanjai

Department of Linguistics, Chulalongkorn University  
suthatip.a@gmail.com

## Abstract

In this study I investigate the meanings of the verb of giving in Thai and Vietnamese, namely, *hây* and *cho* and discuss the semantic relations among the meanings of *hây* and *cho*. It is found that *hây* in Thai has the following meanings: (1) the basic meaning of an action of possession transfer, (2) the dative-marking, (3) the benefactive-marking, (4) the malefactive-marking, (5) the causative-marking, and (6) purposive-marking. On the other hand, the meanings of *cho* in Vietnamese are as follows: (1) the basic meaning, (2) to put something in a container, (3) to give an opinion, (4) the dative-marking, (5) the benefactive-marking, (6) the malefactive-marking, (7) the causative-marking, and (8) purposive-marking. The semantic relations among the meanings are accounted for by means of metonymic and metaphoric processes.

**Keywords:** the verb of giving, metonymy, metaphor, Thai, Vietnamese

## 1. Introduction

The verb of giving has been extensively investigated across languages as evidenced by a large amount of research works such as Huang and Ahrens (1999), Bisang (1996), Iwasaki (1997), Newman (1993, 1996), Rangkupan (1997), Song (1997), Thepkanjana and Uehara (2008), Viberg (2002), Xu (1994), and Yap and Iwasaki (1998). The verb of giving in Thai and Vietnamese, namely, *hây* and *cho* respectively, will be examined contrastively in this study. Thai and Vietnamese have many properties in common; both are isolating and serializing languages with the SVO word order. Previous studies show that the verb of giving across languages has similar patterns of semantic extension. Therefore, it is worth investigating the range of similarities and differences in semantic properties exhibited by the verb of giving in two

---

\*

This paper is based on some findings presented in my M.A. thesis entitled "A Study of Lexical and Grammatical Meanings of CHO 'give' in Vietnamese" at the Department of Linguistics, Faculty of Arts, Chulalongkorn University. This paper is supported by Center of Excellence on Program in Language, Linguistics and Literature, Faculty of Arts, Chulalongkorn University. I would like to thank Kingkarn Thepkanjana for providing a valuable comments on this paper. I am grateful to Tran Tri Doi, Head of Department of Linguistics, University of Social Sciences and Humanities, Vietnam National University, Hanoi, Vietnam, for giving a permission to me to collect data at the university, Vu Thi Thanh Huong, Institute of Linguistics, Vietnamese Academy of Social Sciences, for allowing me to use the Vietnamese corpus and Tu Anh Thi Do, Nguyen Ngoc Binh and Nguyen Le Huong, for contributing data in Vietnamese. Finally, I thank the audiences of lexical semantics session at the 18<sup>th</sup> International Congress of Linguists at Korea University, Seoul, Korea, for giving very helpful questions and comments.

typologically similar languages in the same linguistic area. In this paper, I investigate the meanings of *hây* and *cho* and discuss the semantic relations among the meanings of *hây* and *cho*.

I first begin with a brief description of the typological characteristics of Thai and Vietnamese and the basic meanings of *hây* and *cho*. Then, I examine the similar and different extended meanings of these two words and the processes of semantic extensions. The next section presents the semantic network of *hây* and *cho*. Finally, a conclusion of the paper is presented.

## 2. Background

Thai is a language in the Tai branch of the Tai-Kadai family. Vietnamese is a language in the Viet-Muong branch of the Mon-Khmer sub-family, which is a part of the Austro-Asiatic family. Typologically, Thai and Vietnamese are isolating, tonal, topic prominent, serializing and verb-rich languages with SVO word order.

The basic meaning of the verb of giving in Thai and Vietnamese depicts the volitional transfer the possession or the control of a thing from an animate giver to an animate recipient. According to Newman (1996), the act of giving has a relatively rich structure as it typically involves three easily distinguishable entities: the GIVER, the RECIPIENT, and the THING being transferred. However, the typical act of giving something to someone is additionally complex in so far as three very distinct entities are involved and interact in particular ways. This act deals with the volitional transfer of possession or control of a thing, the physical interactions between the three entities, the movement of the thing to a new point, the recipient as the goal of the act, the and/or benefits resulting from the act etc.

The verbs *hây* and *cho* in the basic meaning must appear in the following syntactic pattern.

### Thai

(1) [Agent *hây* Theme (kàæ) Recipient]

(2) *Dææŋ hây ɲən kàæ Dam*  
Dang give money to Dam  
'Dang gave Dam some money'

(3) *Dææŋ hây ɲən sǒmchaay*  
Somsak give money Somchaay  
'Dang gave Dam some money'

### Vietnamese

(4) [Agent *cho* Recipient Theme]

(5) *Tôi cho nó hai cuốn sách*  
I give he two classifier book  
'I gave him two books.'

The verbs *hây* and *cho* exhibit the difference in word order in the syntactic pattern as seen in (1) and (4). The verb *hây* must be followed by the theme and the recipient preceded by the optional preposition *kàæ* respectively. Whereas the verb *cho* must be followed by the recipient and the theme respectively. According to

Haspelmath (2005), the constructions in which the verbs *hây* and *cho* appear with their basic meaning are called the indirect-object construction and the double-object construction which are the types of “ditransitive construction”. The verb *hây* is in both the indirect-object construction as in (2) and the double-object construction as in (3), whereas *cho* is in the double-object construction as in (5). Although exhibiting the double-object construction, the word order in which these two verbs appear is different.

### 3. The extended meanings of *hây* and *cho*

This section is divided into two parts: the extended meanings found in both *hây* and *cho*, and the extended meanings found in Vietnamese only. I will also discuss the process by means of which each meaning is derived.

#### 3.1 The extended meanings found in both *hây* and *cho*

In this part, I will investigate the extended meanings as found in *hây* and *cho*, namely, dative-marking, benefactive-marking, malefactive-marking, causative-marking, and purposive-marking.

##### 3.1.1 Dative-marking

The words *hây* and *cho* function as the dative marker indicating the recipient of a given thing. The words *hây* and *cho* appear with the transitive verbs which involve volitional manual manipulation of something such as the verbs corresponding to ‘send’, ‘return’, ‘hand in’, ‘present’, ‘sell’, ‘throw’, ‘grab’ etc. as illustrated below.

##### Thai

(6) *Dææŋ yǎn ɲən hây Dam*  
 Dang hand in money give Dam  
 ‘Dang handed some money to Dam.’

##### Vietnamese

(7) *Hoa gửi thư cho Lan*  
 Hoa send letter give Lan  
 ‘Hoa sent a letter to Lan.’

The words *hây* and *cho* exhibit the divergence in the extent of the co-occurring verbs in the dative-marking meaning. Both verbs can appear with different groups of verbs. According to Thepkanjana and Uehara (2008), *hây* can co-occur with the verbs denoting volitional physical motions which are carried out by different body parts on the human face such as *yím* ‘smile’, *yák khǐw* ‘raise one’s eyebrows’, and *lìw taa* ‘wink, look with one eye closed’ as illustrated in (8). These verbs can be either transitive or intransitive verbs.

(8) *sǒmsàk yím hây sǒmchaay*  
 Somsak smile give Somchaay  
 ‘Somsak smiled at Somchaay.’

The word *cho* can co-occur with the communicative verbs such verb as *gọi điện thoại* ‘to telephone’, *đánh điện* ‘to telegram’, and *nhắn* ‘to leave (a message)’ as illustrates in (9).

(9) *Tôi gọi điện thoại cho bố mẹ*  
 I telephone give father mother  
 ‘I called my parents.’

It is noted that the sentence (9) is ambiguous as it can be interpreted as the benefactive meaning. However, the native speakers of Vietnamese usually use *cho* with the communicative verbs to convey the dative-marking meaning. To express the benefactive meaning with this group of verbs, it tends to employ the word *giúp* or *hộ* ‘help’ or *thay mặt* ‘on behalf of someone’ with the word *cho*.

The dative-marking function extends from the basic meaning by means of metonymy which is currently playing a crucial role in cognitive linguistics. According to Kövecses (2002), metonymy is a cognitive process in which one conceptual entity, the vehicle, provides mental access to another conceptual entity, the target, within the same idealized cognitive model. Metonymy is therefore an important cognitive process consisting of the transfer of meaning based on associations between contiguous ideas in the same cognitive domain. It can give rise to a new primary meaning of a word which used to be a covert element in the original meaning of the word. For the case of the dative-marking, the recipient which is a covert element in the basic meaning is highlighted by the metonymic process as a new primary meaning of *hãy* and *cho*. There is evidence supported this extension, that is, the crosslinguistic grammaticalization path of GIVE postulated by Heine and Kuteva (2002).

### 3.1.2 Benefactive-marking

The act of giving typically brings about a benefit or a good effect to the recipient which is prototypical of the action of giving. The benefactive meaning results by means of metonymy from promoting the beneficiary role of the recipient, which is a covert element of the semantic structure of GIVE.. The examples illustrated as below.

#### Thai

(10) *Dææŋ tham aahǎan hây Dam*  
 Dang make food give Dam  
 ‘Dang cooked (food) for Dam.’

#### Vietnamese

(11) *Liên xây nhà cho Lan*  
 Lien build house give Lan  
 ‘Lien built a house for Lan.’

Typically, the beneficiary is an animate entity especially a human being. This fact includes the word *hãy* in Thai but it is an exceptional case to *cho* in Vietnamese. The beneficiary in Vietnamese can extend to cover inanimate entities, which is considered a peripheral case as shown in (12) and (13).

(12) *Bố mua lốp mới cho chiếc xe cũ*  
 father buy tyre new give classifier car old  
 ‘Father bought a new tyre for the old car.’

- (13) *Anh ấy để dành tiền cho tương lai*  
 He save money give future  
 ‘He saved money for the future.’

The sentences (12) and (13) show that the noun phrases *xe cũ* ‘old car’ and *tương lai* ‘future’ are figuratively viewed as the entities benefiting from the actions of buying a new tyre and saving money, respectively.

There are two more peripheral cases of the benefactive *cho*. The first case is that *cho* appears in sentences with stative verbs as the syntactic pattern described in (14) and exemplified in (15).

- (14) [NP1 stative verb (NP2) *cho* NP3]

- (15) *Vì tính có ích cho nhiều người*  
 Computer have benefit give plural people  
 ‘Computers are useful for a large number of people.’

The latter peripheral case is that *cho* appears in isolated noun phrases, or in other words, non-sentences as described in (16) and shown in (17)

- (16) [NP1 *cho* NP2]

- (17) *Tiếng Việt cho người nước ngoài*  
 language Vietnam give people country outside  
 ‘Vietnamese for foreigners.’

These peripheral cases of the benefactive *cho* are argued to have the semantic role as the target rather than the benefactive. Since the target and benefactive roles share some semantic properties. I therefore count them in the same category with a remark about their prototypical and peripheral statuses as the benefactive entity.

### 3.1.3 Malefactive-marking

The act of giving brings about not only a benefit or a good effect as in the case of the benefactive but also a bad effect to the recipient. The case for a bad effect is called the malefactive. The malefactive *hãy* and *cho* typically co-occur with the group of verbs expressing harmful actions such as the verbs corresponding to ‘punch’, ‘slap’, ‘kick’, ‘scold’, ‘hit’, ‘bite’ as shown in (18) and (19).

#### Thai

- (18) *raway khǎw cǎ? dǎa hǎy*  
 be careful he will scold give  
 ‘Be careful. He might scold you.’

#### Vietnamese

- (19) *Đừng chọc con chó. Nó cắn cho đấy*  
 do not bully classifier dog it bite give particle  
 ‘Do not bully the dog. It might bite you (and have a bad effect on you.)’

As in the case of the benefactive-marking, the malefactive-marking is derived by means of metonymy from the benefactive meaning. The person who receives a bad effect from an action carried out by an agent, which is a covert element or contiguous to a good effect of an action of giving, is promoted as a new primary meaning of the word *hãy* and *cho*.

### 3.1.4 Causative-marking

The word *hây* and *cho* can function as a causative verb marking an indirect causation in the analytic causative construction. In indirect causation, the causer lets, or does not prevent, the causer from accomplishing the caused event; the causer does not bring about the caused event directly (Suthatip and Kingkarn, to appear). Sentences (20) and (21) exemplify the causative-marking of *hây* and *cho*.

#### Thai

- (20) *Dææŋ hây Dam yîn khîn*  
Dang give Dam stand go up  
'Dang let Dam stand up.' or  
'Dang had Dam stand up.'

#### Vietnamese

- (21) *Chị cho tôi mượn cái kéo*  
you (f) give I borrow classifier scissors  
'You(f) let me borrow the scissors.'

It is noted that the causative-marking in Thai and Vietnamese typically conveys a permissive interpretation rather than a coercive interpretation. However, it is likely to convey the coercive meaning, which depends on a conversational context and a real-world knowledge of the speakers.

The causative verb *cho* in Vietnamese constitutes an interesting case from a typological perspective because it can co-occur with the verbs *biết* 'to know', *thấy* 'to see' and *đến* or *tới* 'to arrive' in the causative construction. Whereas the similar concepts are expressed by single verbs in Thai as discussed below.

The first combination which is the causative *cho* and the verb *biết* 'to know' in the causative construction literally expresses the indirect causative meaning of letting somebody know something as exemplified in (22). This meaning is realized as single verbs in Thai such as *bòk* 'to tell' and *cææŋ* 'to inform'. It is found that the causee is optional in the causative construction of *cho biết* 'let know'.

- (22) *Tôi cho anh Nam biết ngày mai tôi cưới vợ*  
I give brother Nam know tomorrow I get married  
'I told Brother Nam (let Brother Nam know) that I will get married tomorrow.'

The second combination which is the causative *cho* and the verb *thấy* 'to see' in the causative construction literally expresses the meaning of letting someone see something as in (23). This meaning is realized by single verbs in Thai such as *sədææŋ* 'to show'. It is common that the causee is not present in the causative construction of *cho thấy* 'let see'.

- (23) *Điều này cho thấy tiếng Anh rất quan trọng*  
thing this give see language English much important  
'This thing shows (lets see) that English is very important.'

The last combination which is the causative *cho* and the verb *đến* or *tới* 'to arrive' literally means to let (time) proceed until a certain point in time. The causing event is to let time proceed and the caused event is that time has reached a certain point. This causative meaning is equivalent to the preposition *conkrathǎŋ* 'until' in Thai.

The noun phrases co-occurring with the causative *cho đến* must correspond to time only. Sentence (24) illustrates this causative construction.

- (24) *Khu nhà chúng tôi sống hết sức êm đềm,*  
 surrounding area house we live extremely peaceful  
*hầu như chưa xảy ra sự cố gì cho tới hôm nay*  
 almost not yet happen problem what give arrive day this  
 ‘The surrounding area of the house where we live is very peaceful.  
 There has never been any problems up until now.’

Suthatip and Kingkarn (To appear) suggest the reason for the lack of the causee in the causative verb *cho* and another verb indicating the caused event as described above is that the causative constructions are now on the way to become lexicalized phrases expressing single concepts of telling, showing and until.

The causative-marking of *hây* and *cho* are derived by means of a metaphoric process from the basic meaning. The metaphoric process is a cognitive process involving the understanding an entity in an abstract domain in terms of an entity in a concrete domain. The transfer of possession or control of an entity from the giver to the recipient, which is the basic sense of the act of giving, metaphorically extends to the transfer of control of an action from the causer to the causee. The situation in which the causer lets the causee perform an action is equivalent to the transfer of control of an action from the causer to the causee, which is in turn metaphorically viewed as the transfer of possession or control of an entity.

### 3.1.5 Purposive-marking

The words *hây* and *cho* can function as the connector, appearing between two verbs, indicating a purpose in carrying out an action. The meaning that *hây* and *cho* conveys here is a purposive-marking meaning. Newman (1996) treats the purposive construction as a biclausal construction in which, the action of the first clause is done in order that the action or event of the second clause may take place. However, the second event does not necessarily take place because it merely represents the purpose of the agent in the first clause in performing the action. The purposive-marking sentences are exemplified in (25) and (26).

#### Thai

- (25) Dææŋ bòk hây Dam tham kaanbân  
 Dang tell give Dam make homework  
 ‘Dang told Dam to do homework.’

#### Vietnamese

- (26) *Em sẽ hát cho anh nghe*  
 I will sing give you listen  
 ‘I will sing for you to listen.’

The minor differences exhibited in the purposive-marking are concerned with the types of verbs in the first clause. From the data, It is found that *hây* in Thai can co-occur with a wide range of verb types as opposed to *cho* in Vietnamese. Therefore, it can be said that *hây* exhibits the productivity in the purposive meaning whereas with *cho*, the occurrence is more restricted.

Both *hây* and *cho* can co-occur with the communicative verbs such as the verbs corresponding to ‘persuade’, ‘ask for’, ‘command’, ‘request’, ‘tell’ in the first clause in the jussive constructions which is identified by Rangkupan (1997) but in Vietnamese, it is preferable for the use of this kind of verbs without *cho*. The sentence (27) illustrates the jussive constructions with *hây* and (28) exemplifies the jussive one with *cho*, which is optional.

- (27) *Dææŋ bðk hây Dam maa*  
 Dang tell give Dam come  
 ‘Dang told Dam to come.’
- (28) *Chị ấy bảo (cho) anh ấy mở cửa*  
 she tell (give) he open door  
 ‘She told him to open the door.’

*Hây* can be preceded by the verbs expressing desire such as *yàak* ‘want’, *tŋkkaan* ‘want’, and *pràatthanăa* ‘desire’. The construction in which *hây* appears with the verbs of desire is called the complementation constructions by Rangkupan (1997). The sentence (27) illustrates the complementation constructions with *hây*.

- (27) *sŏmsàk yàak hây sŏmchaay maa hăa*  
 Somsak want give Somchaay come see  
 ‘Somsak wanted Somchaay to come.’

The purposive-marking meaning of the words *hây* and *cho* are derived from the causative-marking meaning by means of metonymy. Support for this extension is found crosslinguistically in evidences by Yap and Iwasaki (1998) and Thepkanjana and Uehara (2008). The volition of the causer in doing something to the causee so that the causee will perform another event, which is contiguous to the causative-marking meaning is promoted to be a primary meaning.

### 3.2 *The extended meaning as found in Vietnamese only*

In this part, I will investigate the extended meanings which are found in Vietnamese but are missing in Thai. The extended meanings are lexical meanings, namely, to supply or to put something in a container and to give an opinion.

#### 3.2.1 *To supply or to put something in a container*

*Cho* can function as a verb conveying the act of supply or put something into a container as exemplified below.

- (28) *Mẹ cho than vào lò*  
 mother give charcoal enter stove  
 ‘Mother put the charcoal in the stove.’

The verb *cho* is followed by two noun phrases indicating the entity in motion and the container respectively. It is noted that the verb *cho* must co-occur with the word ‘*vào*’ in case of the occurrence of the container. If not, there must be no container.

The metonymic process plays a role in promoting a covert meaning from the basic meaning to a new primary meaning. The new primary meaning focuses on the motion of the theme. The notion of recipient in a giving action extends to that of the container in a moving action. The recipient and the container notions share a semantic property in that both function as the goal of the giving and the moving actions.

### 3.2.2 To give an opinion

*Cho* can function as a verb meaning to give an opinion which occurs in combination with *rằng* or *là* which functions as a complementizer and is followed by a clause. It is importantly noted that the subject of the verb *cho* must be human and there is no a direct object following it as illustrated in (29).

(29) *Tôi cho rằng quyển sách này sẽ bán rất chạy*  
 I give COMP classifier book this will sell much run  
 ‘I suppose that this book will sell very well.’

According to Suthatip and Kingkarn (to appear), the meaning of giving an opinion is derived metaphorically from the basic action of giving. The transfer of possession or control of an entity is metaphorically mapped to the action of transferring an opinion from the speaker to the listener. The thing given is mapped to the opinion or message that the speaker wants to convey to the hearer.

## 4. The semantic network

This section presents a semantic network of the verb of giving in Thai and Vietnamese. The multiple meanings of the verb of giving can be exhibited in terms of a schema. The schema exhibits the relationship between the meanings: which meaning is a basic meaning and which meanings are closely related?

The semantic networks of the verb of giving in Thai and Vietnamese are different (see figure 1 and 2) in terms of the number of meanings as *hãy* consists of six meanings which are identified as a grammatical meaning, whereas *cho* consists of eight meanings which are both grammatical and lexical meanings. But if we consider the meaning extension, it is seen that the schemas exhibit the same extension. There are two extended meanings from the basic meaning which are the dative meaning and the causative meaning. The benefactive meaning is closely related to the dative meaning because of the derivation from the dative meaning. This claim for the extended benefactive is different from the claim by Heine and Kuteva (2002) in which the benefactive extends from the basic meaning. I propose that the dative is more basic than the benefactive because the dative includes both the recipient and the beneficiary readings and it incorporates with the verbs of manual manipulation only. While the benefactive can be interpreted as the benefactive only and it incorporates with any verb types. The malefactive meaning is derived from the benefactive meaning and this is the reason why these two meanings are closely related. The purposive meaning extends from the causative meaning. If the first verb functioning as a main verb in the purposive sentence is deleted, the sentence will have the same structure as the causative and

constitute the causative reading. This can tell us why the causative and the purposive are closely related.

It is importantly noted that these two schemas don't imply any chronological extension of *hây* and *cho* due to this work is synchronically studied. They present the relationship between meanings only.

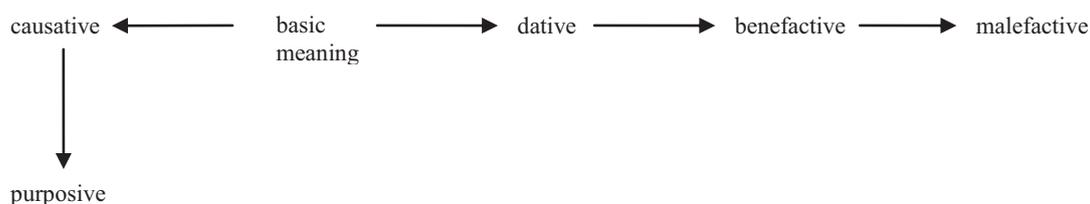

Figure 1: the semantic network of *hây*

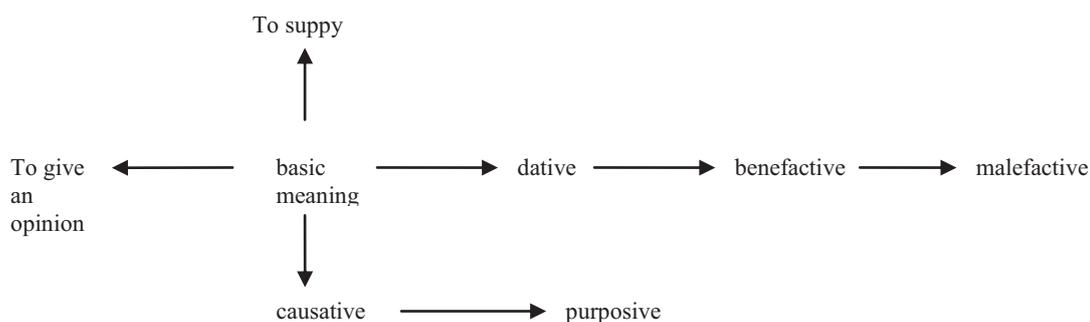

Figure 2: the semantic network of *cho*

## 5. Conclusion

In this paper, I have examined the extended meanings of the verb of giving in Thai and Vietnamese, namely, *hây* and *cho*. The extended meanings found in both Thai and Vietnamese are as follows: (1) the basic meaning of an action of possession transfer, (2) the dative-marking, (3) the benefactive-marking, (4) the malefactive-marking, (5) the causative-marking, and (6) purposive-marking. On the other hand, the extended meanings found exclusively in Vietnamese are as follows: (1) to put something in a container, and (2) to give an opinion. It seems that *hây* and *cho* exhibit more similarities than differences in meanings. Regarding the differences between these two words, it is found that *cho* has more lexical extended meanings than *hây*. In other words, almost all extended meanings of *hây* are grammatical rather than lexical. From a crosslinguistic point of view, the Vietnamese verb of giving is unique in that many lexical meanings are derived from the basic meaning, a feature which is not found in most languages. These two words in Thai and Vietnamese also exhibit minor differences within certain functional categories. These minor differences are concerned

with the scope of meaning of each functional category and the type of word that co-occurs with the verb of giving in each functional category. The semantic extensions of *hây* and *cho* are accounted for by means of metonymic and metaphoric processes. However, it is found that metonymic processes play a more crucial role in deriving extended meanings of the verb of giving in both languages. The findings show that Vietnamese exhibits more variations and employs the verb of giving in more dynamic and flexible way than Thai.

# When Two Kinds of Mandarin Collective Modifiers Meet Two Kinds of Control

Wei-Chih Chuang, Mao-Hsun Chen, Chih-Hao Weng

u8720731@mail2000.com.tw, maohsun.chen@gmail.com

steven668866@yahoo.com.tw

## Abstract

This passage mainly discusses the relationship between the collective reading and two Mandarin collective modifiers: *yiqi* and *gongtong*. Conclusively, we maintain that *gongtong* is the strict part-structure modifier inducing the essential collective reading while the collective reading *yiqi* induces is a dynamic reading derived from the temporal-spatio proximity. With inquiring *yiqi* and *gongtong*, the definition of the collective reading and the ways which it is derived from and concepts about groups will be peered in a brand new way.

**Keywords:** group, the collective reading, the temporal-spatio proximity, integrated wholes, part-whole structure.

## 1. Motivation and literature review

### 1.1 Data

When it comes to the Mandarin collective modifiers<sup>1</sup>, two dominating ones: *yiqi* and *gongtong*, considered to be counterparts of English *together*, are viewed as lexical items displaying the collectivizing force as shown in (1) and (2).

(1) *Zhangsan han Lisi zhuchi huiyi* (mix reading)

Zhangsa and Lisi hold meeting

“Zhangsa and Lisi held the meeting”

(2) *Zhangsan han Lisi yiqi/gongtong zhuchi huiyi* (only collective reading left)

Zhangsa and Lisi together/jointly hold meeting

“Zhangsa and Lisi together/jointly held the meeting.”

However, examples (3)-(6) serve as strong evidences supporting that *yiqi* and *gongtong* are distinct from each other.

---

<sup>1</sup> We would like to deliver our gratitude to Professor Kuo Chin-man, Professor Shyu Shu-ing and Professor Hsin Ai-li for their kindly suggestion and sincere inspiration. Furthermore, special thanks to Professor Loebner and two anonymous reviewers for their insightful comments. Finally, those related to the implementation and the presentations of this passage are appreciated from the bottom of our hearts.

- (3) Jean<sub>1</sub> wondered **【whether PRO<sub>1+</sub> to apply together for the grant】** (PC)
- (4) Jean<sub>1</sub> invited Mary<sub>2</sub> **【 PRO<sub>1+2</sub> to go to Taipei together】** (EC)
- (5) Zhangsan<sub>1</sub> tiyi Lisi<sub>2</sub> **【PRO<sub>2+</sub> yiqi/\*gongtong zhuchi huiyi】** (PC)  
 Zhangsan propose Lisi together/\*jointly hold meeting.  
 “Zhangsan proposed Lisi to hold the meeting together.”
- (6) Zhangsan<sub>1</sub> tiyi Lisi<sub>2</sub> han Wangwu<sub>3</sub> **【PRO<sub>2+3</sub> yiqi/gongtong zhuchi huiyi】** (EC)  
 Zhangsan propose Lisi with Wangwu together/jointly hold meeting.  
 “Zhangsan proposed Lisi and Wangwu to held the meeting together.”

Clearly, examples (3)-(6) illustrate that English *together* and Mandarin *yiqi* allow two kinds of constructions: Partial Control (PC) and Exhaustive Control (EC), while *gongtong* only allows EC (Landau (1999, 2003), Chuang 2008). Thus, here rises a question: why *yiqi* allows PC and EC both while *gongtong* only allows EC? This question ignites our curiosity about *yiqi* and *gongtong* and we believe that, with digging this question, we can appreciate concepts related to groups and the collective reading with a brand new perspective.

#### *Literature review*

To uncover the distinctions between *yiqi* and *gongtong*, Kuo (2006a,b,c and 2007), following Moltamn’s integrity theory (1997, 2004), argues that *yiqi* and *gongtong* are both part-structure modifiers requiring their arguments to have the property integrated-whole (INT-WH). He further proposes that *yiqi* is the most neutral one, presenting four readings of the adverbial *together*: the group-action, the coordinated-action, the spatio and the temporal proximity reading (Lasersohn 1990, Moltamn 2004), but *gongtong* only expresses the coordinated-action reading. The following sentences represent diverse readings of *yiqi* and the cooperative reading of *gongtong*.

- (7) Zhangsan han Lisi yiqi zai shudian gongzuo. (the coordinated-action reading)  
 Zhangsan and Lisi together in bookstore work.  
 Zhangsan and Lisi work together in a bookstore.
- (8) Zhangsan han Lisi yiqi tai zhejia gangqin shanglou. (the collective-action reading)  
 Zhangsan and Lisi together lift this piano upstairs  
 Zhangsan and Lisi lifted this piano upstairs together.
- (9) Zhangsan han Lisi yiqi chifan han shuijue. (the spatial-temporal proximity reading)  
 Zhangsan and Lisi together dine and sleep  
 Zhangsan and Lisi together dine and sleep.

Although Kuo achieves in preliminary observation, his theory has two defects. Firstly, as shown in (10), *gongtong* indeed exhibits a group-denoting use, a use that cannot be obtained in Kuo's theory.

(10) *ouzhou-gongtong-ti*  
‘European Community’

Secondly, as illustrated in (11) and (12), Kuo cannot provide answers to a cardinal question: why *gongtong* has the adnominal use, but *yiqi* does not.

(11) *ouzhou-gongtong-ti* ‘European Community’  
(12) \**ouzhou-yiqi-ti* ‘European Community’

Thus, to get rid of the defects which Kuo's theory has encountered, in the following, based on Moltmann's theory and some of Kuo's finding, we will provide our analysis on *yiqi* and *gongtong*.

## **2. The Mandarin modifier *yiqi* and the temporal and spatial proximity**

### *2.1 The interaction between the collective reading and the temporal-spatial proximity*

Unlike Kuo's analysis of *yiqi*, we suggest that *yiqi* is a modifier focusing on the temporal or spatial proximity use in essence. Put further, the coordinated-action reading or the collective-action reading induced by *yiqi* is nothing but an extension of the temporal or spatial proximity of action or activities by participants. Our analysis is grounded by the phenomenon that most cases of the collective or group reading get company with the temporal or spatial proximity of actions and activities, which are usually physically required to realize the collective reading. However, we have to bear in mind that the temporal-spatial proximity is neither a sufficient condition, nor a necessary one for the collective reading.

In addition to the association of the collective reading and the temporal-spatial proximity, the ideas of Lasnik (1990) and Kemmer (1993) about the collective reading also reinforce our stance. To explain why the collective reading and the temporal and spatial proximity uses are conveyed by the same lexical item *together*, Lasnik provides a possible answer to this question as shown below:

Perhaps this [the ambiguity of *together*] is simply because the most salient sorts of event play out in a particular area, at a particular time. Perhaps it is also due

partly to the fact that many types of collective action require their participants to be spatially near each other and to act at the same time.

(Lasersohn 1990: 204)

The above paragraph suggests that group action or coordinated action is closely and physically related to temporal or spatial proximity. Therefore, this implies that the collective reading, to some extent, is based on the temporal and spatial proximity of actions or activities of participants.

In addition, the mixture reading and the configuration reading of the adnominal *together* provided by Moltmann (2004) is another sort of evidence supporting our analysis of *yiqi*. Consider (13)-(16) shown below:

- (13) The vinegar and the wine together tasted terrible.
- (14) The pictures together look nice.
- (15) John and Mary together are a nice sight.
- (16) John and Mary together form an interesting couple.

The NP arguments modified by *together*, like the mixture of the vinegar and the wine in (13), and the spatial configuration consisted of the individual pictures in (14), or the perfect couple by John and Mary in (15) and (16), they all become integrated wholes or groups by the spatial or social approximation. In other words, the integrity of (13)-(16) is formed by the spatial or social closeness between entities or individuals. Examples (13)-(16) imply that the integrity modified by *together* can be formed via the spatial and social closeness of entities.

## 2.2 Another piece of evidence: the postverbal *yiqi*

In Lasersohn (1990) and Moltmann (1997, 2004), the postverbal *together* is said to only express the spatial proximity use. For example, *together* in the sentence *John and Mary sat together* only has the spatial proximity use and no other use is available. Such phenomenon is also observed in Mandarin *yiqi*. Consider examples (17)-(19).

- (17) *Zhangsan han Lisi yiqi beiguan.*  
Zhangsan and Lisi together jailed  
“Zhangsan and Lisi together are jailed.”
- (18) *Zhangsan han Lisi beiguan yiqi.*  
Zhangsan and Lisi jailed together  
“Zhangsan and Lisi are jailed together.”

- (19) *Qing bang wo ba hongcha han lucha bao yiqi.*  
 Please help we BA black tea and green tea package together  
 “Please package my black tea and green tea together.”

In Mandarin, the postverbal *yiqi* is widely and frequently used to indicate the spatial proximity. For example, (17) points out that Zhangsan and Lisi are jailed at the same time, but **not** necessarily in the same room. In (18), however, it is necessary for *Zhangsan* and *Lisi* to be jailed in the same room.

However, such postverbal *yiqi* can express an iconic kind of group reading extended from the spatial proximity. Consider examples (17) and (18).

- (20) *Zhangsan han Xiaomei shi yiqi DE<sub>mod</sub>.*  
 Zhangsan and Xiaomei be together DE<sub>mod</sub>  
 “Zhangsan and Xiaomei are together.”
- (21) *Chaersi wangzi han Kamila zai yiqi de xiaoxi zhenjing le quan Yingguo.*  
 Chaersi Prince and Kamila at together DE<sub>mod</sub> news shock ASP entire English  
 “The news that Prince Charles and Camille are together shocked UK.”

Intuitively, (20) does not mean that *Zhangsan* and *Xiaomei* are in the same place, but indicates that *Zhangsan* and *Xiaomei* are a couple. Such explanation also applies on (21). Example (21) states that the company ship of Charles and Camille shocks UK. Apparently, *Zhangsan* and *Xiaomei* in (20), and, Prince Charles and Camille in (21), form groups with a much closed relationship. The postverbal *yiqi* in (20) and (21) is used to point out iconic groups which consist of individuals with (social) closed relationship. According to examples (17)-(21), the postverbal *yiqi* expresses the spatial proximity use and the iconic group use. Therefore, the postverbal *yiqi* introduces the spatial proximity and social iconic groups extended from the abstract spatial approximation and closeness. Based on the postverbal *yiqi*, the assumption that *yiqi* only concerns the temporal or spatial proximity in essence is confirmed.

### 2.3 distinctions between *yiqi* and *gongtong*

Besides the postverbal *yiqi*, the contrast between the modifier *yiqi* and the adnominal *gongtong* is the most persuasive evidence supporting our analysis. Consider examples (22) and (23).

- (22) *Ouzhou-gongtong-ti*  
 Europe together community

- “European Community”  
 (23) \**Ouzhou-yiqi-ti*  
 Europe together community  
 “European Community”

Example (22) is the term that denotes the well-known financial group, European Community. When *gongtong* is replaced by *yiqi*, the term shown in (23) is excluded. Such ungrammaticality results from the inability of *yiqi* to be an adnominal modifier. More pieces of evidence of the inability of *yiqi* to be adnominal are given in (24) and (25).

- (24) *gongtong de mengxiang*  
 together DE<sub>mod</sub> dream  
 “a sharing dream”  
 (25) \**yiqi de mengxiang*  
 together DE<sub>mod</sub> dream  
 “a together dream”

The grammatical (24) and the ungrammatical (25) are noun phrases which contain an adnominal modifier, a modification marker *de*, and a head noun. The excluded example (24) indicates that the modifier *yiqi* cannot be adnominal. Here arises a question: why can *gongtong* be used adnominally, but *yiqi* cannot? If *yiqi* is indeed a collective reading marker, it should be able to introduce atomic group elements as well as the adnominal *gongtong*. However, obviously, the ungrammatical examples (23) and (25) point out that *yiqi* cannot be adnominal and cannot introduce atomic group elements like the adnominal *gongtong*.

Therefore, we propose that *gongtong* is a strict part-structure modifier, concerns the group or collective reading without regarding the temporal or spatial proximity of actions or activities, but *yiqi* cannot introduce group elements like that. The ungrammaticality of (23) and (25) indicates that a group element induced by *yiqi* has to consider possibilities of the temporal or spatial proximity. When such possibility is impossible or hard to come by, *yiqi* would fail in introducing groups. Example (26) is another piece of evidence positively verifies our analysis.

- (26) *Zhangsan han Lisi yiqi zai shudian gongzuo.*  
 Zhangsan and Lisi together in a bookstore work  
 “Zhangsan and Lisi work together in a bookstore.”

The most dominating and natural reading of (26) is the collective reading, indicating that *Zhangsan* and *Lisi* form an integrated-whole or a group by being employees of a bookstore. However, note that a bookstore in (26) is existentially closed and refers to a specific bookstore. What really suffices the collective reading in (26) is the spatial proximity of Zhangsan's and Lisi's working events. When a bookstore is not existentially closed and denotes two different bookstores varying with agents, i.e. Zhangsan and Lisi, the collective reading would fail, which induces the distributive reading later. Therefore, (26) manifests a fact that the collective reading induced by *yiqi* can not but respect the temporal or spatial proximity of actions or activities, even though such temporal and spatial proximity are not relevant in situations.

To sum up, the discussion so far has stated that the modifier *yiqi* is a part-structure modifier, which essentially focuses on the temporal or spatial proximity uses. Consequently, the collective-action or coordinated-action use induced by *yiqi* is merely an extension from the temporal or spatial proximity of activities or actions.

Based on the formulae of Moltmann (1997, 2004) and Kuo (2007), the following is my formula of *yiqi*.

- (a) For any world  $w$  and time  $t$ , and an intensional relation  $R$  which expresses time or space where events and states occur or hold:

$$[[YIQI]^{w,t}(R)=\{ \langle d,e \rangle | \langle d,e \rangle \in R^{w,t} \& \langle d,f_e \rangle \text{ InT-WH} \} YweQwe^{w,t} \}$$

### 3. The Mandarin modifier *gongtong* and the strict collective reading

#### 3.1 Is it possible for the adverb *gongtong* to exhibit the collective reading?

Kuo (2007) argues that the agent-oriented modifier *gongtong* requires its focused element to be plural and *gongtong* cannot co-occur with inherent distributive predicates and with predicates expressing an action. As a result, the modifier *gongtong* cannot express the temporal and spatial proximity uses and the collective-action use, but just marks the coordinated-action use. His analysis is grounded by examples (27) and (28).

(27) *Laoban han yuangong yiqi chuangye.*

Boss and employees together start an enterprise

“The boss and the employees start an enterprise together.”

(28) *Laoban han yuangong gongtong chuangye.*

Boss and employees together start an enterprise  
“The boss and the employees together start an enterprise.”

Example (27) is vague between the temporal proximity use and the collectivizing use, while in (28), the boss and the employee just started their enterprise cooperatively. Kuo’s argumentation is also well-motivated by the unacceptable collocation between inherent distributive predicates and *gongtong*. Consider (29)-(32).

(29) *Zhangsan han Lisi yiqi shuijue.*

Zhangsan and Lisi together sleep  
Zhangsan and Lisi sleep together.

(30) \**Zhangsan han Lisi gongtong shuijue.*

Zhangsan and Lisi together sleep  
Zhangsan and Lisi sleep together.

(31) *Zhangsan han Lisi yiqi qili.*

Zhangsan and Lisi together stand up  
Zhangsan and Lisi stand up together.

(32) \**Zhangsan han Lisi gongtong qili.*

Zhangsan and Lisi together stand up  
Zhangsan and Lisi stand up together.

Examples (30) and (32) are excluded because *sleep* and *stand up* are inherent distributive predicates which cannot be participated in by any others and cannot co-occur with *gongtong*.

However, it is questionable that the modifier *gongtong* cannot exhibit the collective-action use. Consider examples (33) and (34) as shown in the following:

(33) *Apple han Microsoft yiqi xuanbu wei Eee PC kaifa Windows zuoyexitong.*

Apple and Microsoft together declare for Eee PC develop Windows system  
Apple and Microsoft together declared to develop Windows system for Eee PC.

(34) *Apple han Microsoft gongtong xuanbu wei Eee PC kaifa Windows zuoyexitong.*

Apple and Microsoft together declare for Eee PC develop Windows system  
Apple and Microsoft together declared to develop Windows system for Eee PC.

In our world knowledge, Apple and Microsoft are always competitors. In (33), intuitively, Apple and Microsoft are competitors in developing Windows system for Eee PC. We cannot get any collective-action use or coordinated-action use in (33)

because *yiqi* in (33) induces the temporal proximity reading, not a collective one, which matches our world knowledge. Contrary to (33), (34) illustrates that Apple and Microsoft, as a group, will develop Windows system for Eee PC. Under such condition, only one system for Eee PC would be produced by Apple and Microsoft. Thus, (34) indeed expresses the collective-action use and further indicates that *gongtong* can accompany the collective reading. Examples (33) and (34) indicate that *yiqi* cannot break our world knowledge to further induce the collective-action use or the coordinated-action use, but *gongtong* can.

### 3.2 *The incompatibility between inherent distributive predicates and gongtong*

Furthermore, as observed by Kuo (2007), the adverb *gongtong* cannot co-occur with inherent distributive predicates. We argue that such incompatibility accounts for Lasersohn's notion of the collective reading. Lasersohn (1990) argues that, often in a collective reading, we do not require that individuals of a group directly involve in the action, but we indeed require that such individuals of a group do share the collective responsibility of that action. For example, in this sentence *the soldiers killed their rivals*, the individual soldiers are indeed co-responsible for the killing even though there may be some soldiers which do not perform any actual killing. In sum, what suffices the collective reading is the collective responsibility shared by members of a group, not the temporal-spatio proximity of action and activities.

Note that inherent distributive predicates denote actions or activities of atomic individuals, not of sum of individuals or a group. Hence, the collective responsibility is unavailable and impossible for inherent distributive predicates. For example, the inherent distributive predicate, *sleep*, is an action performed by an individual and only that individual can take responsibility of the sleeping. Therefore, the collective reading *gongtong* induces conflicts the semantic content of inherent distributive predicates because no collective responsibility is available in inherent distributive predicates. Such confliction between *gongtong* and inherent distributive predicates strengthens our analysis that the adverb *gongtong* indeed introduces the collective-action or coordinated-action use.

Besides, defining *gongtong* as an agent-oriented part-structure modifier cannot explain the grammaticality of (35). Consider (35) shown below:

- (35) *Zhangsan han Lisi gongtong bei panchu jiaoxing.*  
Zhangsan and Lisi together PASS sentence hang  
Zhangsan and Lisi together are sentenced to be hung.

Example (35) reports that *Zhangsan* and *Lisi* are patients or themes, not agents, which are sentenced to be hung for their crimes. Following Kuo's analysis, (35) should be excluded because the plural subjects are not agents, but themes or patients. However, the grammaticality of (35) suggests that *gongtong* is not the agent-oriented modifier.

To sum up, *gongtong* is not limited to an agent-oriented part-structure modifier and, just like *yiqi*, it can introduce the collective-action reading certainly.

### 3.3 Groups on NP

Also, group-denoting and entity-denoting compounds with *gongtong* positively verify our analysis. Such kinds of compounds usually consist of nouns and the adnominal *gongtong*. Consider examples (36) and (37).

(36) *ouzhou-gongtong-ti*

European Community

European Community

(37) *gongtong-zhanghu*

joint account

joint account

Examples (36) and (37) are compounds denoting a group and an atomic element, respectively. In (36), *ouzhou-gongtong-ti* is the term of the well-known financial organization, European Community; in (37), a joint account is interpreted literally as *an* account shared by more than one user. With (36) and (37), it is relevant that the adnominal *gongtong* is used to mark atomic groups and entities. Thus, undoubtedly, the modifier *gongtong* can induce the collective-action use.

Based on examples (33)-(37), we suggest that *gongtong* functions as a strict part-structure modifier, establishing the integrity via property-overlapping and responsibility-sharing. More evidence supporting our analysis is presented below:

(38) *Zhangsan han Lisi de gongtong xingqu shi kanchezhan.*

Zhangsan and Lisi DE<sub>poss</sub> common hobby is watch auto-show

Zhangsan's and Lisi's common hobby is watching auto-show.

(39) *Zhangsan han Lisi de gongtong mubiao shi goujin yitai paoche.*

Zhangsan and Lisi DE<sub>poss</sub> common goal is buy a sports car

Zhangsan's and Lisi's common goal is to buy a sports car.

In (38) and (39), *Zhangsan* and *Lisi* are perceived as a group or an integrated-whole by their common hobby and common goal: watching auto-show and buying a sports car. In fact, the lexical items, *hobby* and *goal*, express two sets of properties of individuals, respectively. Take *hobby* for example. One is said to have hobbies when doing something joyfully delights him. We can say that Zhangsan likes gardening, riding and watching auto-show, and gardening, riding and watching auto-show are Zhangsan's hobbies. What Zhangsan likes are informative to properties of Zhangsan. Therefore, the lexical item *hobby* would denote a set of properties of an individual. Thus, as shown in (38) and (39), the adnominal *gongtong* quantifies over NPs, *hobby* and *goal*, which are two sets of properties of individuals.

The argumentation that *gongtong* quantifies over properties of plural individuals or entities is further reinforced by inherent properties of individuals or entities. Consider examples (53) below:

(40) *sida mingmo de gongtong tese shi meili ji youfu hao shencai.*

Four famous models DE<sub>poss</sub> common features is beauty and having a good shape  
The common features of these four famous models are pretty and having a good shape.

In (40), the adnominal *gongtong* modifies the head noun *tese* 'features', which denotes sets of properties of individuals or entities. More specifically, when we say someone possesses some good features, such as kindness, friendly, or being wise, which are properties almost permanent, not temporary in his life, we just talk about the individual-level features. Therefore, the modifier *gongtong* indeed quantifies over properties of individuals because *gongtong* can modify the head noun *tese*.

Again, take the example (53) into consideration. In (53), the plural subjects, *four famous models* form an integrated whole or a group by their overlapping properties: *beauty* and *having a good shape*. These overlapping properties are inherently individual because they are individual-level predicates which are true throughout the existence of individuals. Therefore, we can conclude that *gongtong* can establish the integrity via property-overlapping and responsibility-sharing. The following are the formula of the part-structure modifier *gongtong*.

(a) For any world  $w$  and time  $t$ , and intensional relation  $R$  which concerns properties of individuals or entities.

$$[[\text{GONGTONG}]]^{w,t}(R) = \{ \langle d, e \rangle \mid \langle d, e \rangle \in R^{w,t} \ \& \ \langle d, f_e, \text{INT-WH} \rangle \text{GONGTONG}^{w,t} \}$$

### 3.4 Answers to the impossibility for *yiqi* to be adnominal and control problems

Return to the question that *yiqi* cannot be used adnominally. Based on our analysis, stating that *yiqi* mainly and essentially establishes the integrity via the time and space dimensions, the integrity induction will be crumpled when groups or integrated wholes are not formed through the temporal or spatio proximity. Thus, the adnominal use of *yiqi*, which is unrelated to time and space of action or activities, is hard to come by.

Back to the control problems we have encountered in the beginning of this passage: English *together* and Mandarin *yiqi* allow both PC and EC while Mandarin *gongtong* only allows EC. We propose that such distinction results from different positions where *yiqi*'s and *gongtong*'s arguments stay in. Generally speaking, phrases that indicate time and space often merge into or move to nodes in high positions, such as IP, CP, or even across the boundary of sentences. That is, the information of time and space can be retrieved in discourse. On the contrary, NPs that denote entities often originally dwell in VP or vP. Therefore, it is effortless for *yiqi*, the quantifier which mainly establishes the integrity via the time and space dimensions, to meet its plural arguments in discourse or across phases. However, *gongtong*, which induces the integrity via property-overlapping in essence, mainly relies on its plural arguments unrelated to time and space and can not help but narrow down its domain. Thus, positions of *yiqi*'s and *gongtong*'s arguments guide their allowance to EC and PC.

#### **4. Conclusion**

To sum up, we have surveyed the Mandarin part-structure modifier: *yiqi* and *gongtong* in terms of the integrity theory. Each of them, just like English *together*, exhibits the collectivizing force and needs its plural arguments to form an integrated whole or a group in compatible dimensions. In addition to this common collectivizing force, *yiqi* and *gongtong* each has its unique lexical meaning and functions in introducing specific kinds of integrated wholes or groups. More specifically, we argue that *yiqi* introduces the integrity via the temporal or spatial proximity in essence and induces a kind of the collective reading extended from the temporal and spatial proximity. The last one, the strict part-structure modifier *gongtong*, would only introduce groups and integrated wholes via property-overlapping or responsibility-sharing.

# TOWARDS AN INVENTORY OF SEMANTIC CLASSES FOR ABSTRACT NOUNS<sup>1</sup>

**Xavier Blanco**

*Universitat Autònoma de Barcelona*  
Xavier.Blanco@uab.es

## **Abstract**

We present a hierarchized list of Spanish semantic labels that could be used as genus in the analytic definitions of the FACTS described in the *Nuevo diccionario histórico de la lengua española*. We discuss the main linguistic notions underlying this hierarchy, as the actantial formulae and the typed semantic actants. The semantic labels of the first level of semantic intension are cited and commented. We mention some future work, namely the hierarchy of ENTITIES and the list of semantic fields.

## **1. Introduction**

This paper discusses the on-going construction of a hierarchized list of Spanish lexical units and nominal syntagms that would be used as genus in the analytic definitions of the abstract nouns (from now on, HECHOS: FACTS) described in the *Nuevo diccionario histórico de la lengua española* (NDHLE). We will call this list the Spanish Hierarchy of Semantic Labels of Facts (SHSL\_F).

The NDHLE (New Historical Dictionary of the Spanish Language) is a project of the *Fundación Instituto de Investigación Rafael Lapesa* (*Real Academia Española*) that will apply recent linguistic methodologies to a diachronic large coverage description of Spanish (Pascual & García, 2007).

---

<sup>1</sup> We wish to thank Igor Mel'čuk, Alain Polguère and Jasmina Milićević (Observatoire de linguistique Sens-Texte, Université de Montréal) for the help they provided during the construction of the SHSL\_F. We also thank José Antonio Pascual and Rafael García Pérez (Fundación Rafael Lapesa, RAE) for giving us the chance to work about semantic labels in the frame of the NDHLE project.

Our work is based on the theoretical and applied research performed in the frame of the *Lexique Active du Français* (LAF) (Mel'čuk & Polguère, 2007) and on the lexicological component of the Meaning-Text Theory (Mel'čuk & al. 1984-1999).

Let us precise that we will offer English equivalents for most of our examples. However, these English translations are only meant as a convenience for the reader. The linguistic description presented here is valid only for the Spanish lexical units, the English ones may not present at all the same semantic behaviour.

## 2. The Semantic Labels in Definitions

The semantic labels in the SHSL\_F are Spanish lexical units (lexems or phrasems) or Spanish nominal syntagms. These labels have to match the core semantic component of the dictionary headwords in which definition they are used.

The sketch of a formal definition for a FACT must contain at least:

- the semantic label of the SHSL\_F corresponding to the genus of the *definiendum*.  
As a typographical convention, we will use small capital letters for the semantic labels.
- the actantial formula of the FACT (see below).

Plus, eventually:

- the deep syntactic structures controlled by the headword for his different actants.
- a semantic field label.

Let's take two examples:

LADRIDO  
GRITO DE ANIMAL  
LADRIDO del perro X [*de* N, A<sub>pos</sub>]

LADRIDO (*bark*) is the headwork (headwords will be written in capital letters), GRITO DE ANIMAL (ANIMAL'S SHOUT) is the semantic label and *LADRIDO del perro X* is the actantial formula, where we can distinguish the argumental slot (variable X) and a

semantic restriction over the variable: *perro* (*dog*). Besides, we include the two deep syntactic structures [*de N y A<sub>pos</sub>*] (*el ladrido del pastor alemán, su ladrido; the bark of the German shepherd, his bark*). The semantic field label associated to this headword would be *animales* (*animals*).

#### DISPARO

LANZAMIENTO DE UN PROYECTIL O SONIDO QUE LO ACOMPAÑA

DISPARO del individuo X [*de N, A<sub>pos</sub>*] en dirección a Y [*a N, contra N, sobre N*] hecho con el arma de fuego Z [*de N*]

The semantic label of DISPARO is a complex one (it contains a disjunction) since both meanings (*lanzamiento/launching*) and (*sonido/sound*) admit the semantic criterion of compatible co-occurrence: *Sonó un disparo. Un disparo mató a Juan. Sonó un disparo que segó la vida de Juan. (A shot was heard. A shot killed Juan. A shot was heard that killed Juan)*. It is one and the same lexical unit with a meaning disjunction. Let's emphasize that the semantic label of ENTITY, ARMA DE FUEGO (FIREARM), applied over the Z variable, includes the meaning *projectile*, that does not appear directly in the actantial formula of DISPARO. The semantic field is *armas* (*weapons*).

Note that the headword DISPARO is a polysemous one or, to put it differently, there are several lexical units DISPARO. Consequently, DISPARO would have other definitions. For example, the normal interpretation of *El disparo del delantero holandés rozó el larguero (The shot of the Dutch forward grazed the crossbar)* does fortunately not include a firearm.

Observe that, since the actantial formula comprises the headword and his semantic actants, only semantic predicates will have an actantial formula (however, see 5). It is important to bear in mind that the *definiendum* of a lexical unit corresponding to a FACT is not only the form of the lexical unit in question, but the set formed by this form and its semantic actants with the typed variables and the relationships between actants coded by the means of prepositions and support verbs.

### 3. The Hierarchy of Semantic Labels

The set of semantic labels that conforms the SHSL\_F is hierarchically organized. The root is the label with the greater semantic extension: FACT. It is important to note that the current SHSL\_F is a relatively flat structure. It tends to develop horizontally rather than vertically. Actually, the maximum depth is seven (e.g. 2.9.3.1.1.1.1. ENUNCIADO O GESTO EXPRESIVO). We believe that this situation reflects the organization of the general lexicon, which would tend to favour quasi-synonymy relationships over hyponymy relationships, at least from a certain level of semantic intension. Of course, this can be different in axiomatically organized terminologies.

Sometimes, then, a branch of the hierarchy will attain considerable depth without splitting, e.g.:

- 2.9.3. MOVIMIENTO EFECTUADO (PERFORMED MOVEMENT)
  - 2.9.3.1. MOVIMIENTO DEL CUERPO (BODY'S MOVEMENT)
    - 2.9.3.1.1. GESTO (GESTURE)
      - 2.9.3.1.1.1. GESTO EXPRESIVO (EXPRESSIVE GESTURE)
        - 2.9.3.1.1.1.1. ENUNCIADO O GESTO EXPRESIVO  
(EXPRESSIVE STATEMENT OR GESTURE)

Even if the SHSL\_F may be (and probably still is) incomplete, this particular situation does not imply a lack of the hierarchy in this specific point. The SHSL\_F is not a taxonomy. Nothing forces us to respect the suitability conditions of a taxonomy. Moreover, it is important to resist the temptation to add fictitious nodes that would improve the symmetry of the hierarchy but will correspond neither to the genus nor reflect the lexical cooccurrence of any Spanish lexical unit.

The SHSL\_F has not only hyperonymical links, because it includes verbal, adjectival and adverbial labels too. Even if most labels are nominal (the grammatical category of designation), it is necessary to include labels of the other categories as well, in order to obtain a closed set of semantic labels for any FACT headword. Indeed, the genus of a definition must have the same grammatical category as its headword, since it has to respect the mutual substitutability principle of the definition well-formedness.

In this moment, we have a list of 352 semantic labels. As a simple presentation means, we have adopted the form of a numbered schema. However, the SHSL\_F is not formally a tree, because some labels have more than a superordinate taxon. For example, GRITO (SHOUT) as a SONIDO EXPRESIVO (EXPRESSIVE SOUND) is simultaneously under 2.2. ACTO DE COMUNICACIÓN (COMMUNICATION ACT) (which is a type of ACCIÓN, ACTION) and under 13.4. FENÓMENO FÍSICO (PHYSICAL PHENOMENON) (a subordinate of FENÓMENO, PHENOMENON). In the same way, CRIMEN DE SANGRE (BLOOD CRIME) is simultaneously under 2.10.1.1. DELITO (CRIME) and under 2.16.1. ACCIÓN DE MATAR (ACTION OF KILLING). Nevertheless, only thirty-one labels appear twice and only two appear three times. Redundancy is therefore limited.

The root label HECHO (FACT) has seventeen immediately subordinate labels: ACCIÓN (ACTION), ACONTECIMIENTO (EVENT), ACTITUD (ATTITUDE), ACTIVIDAD (ACTIVITY), CANTIDAD (QUANTITY), CARACTERÍSTICA (CHARACTERISTICS), COMPORTAMIENTO (BEHAVIOR), CONJUNTO DE HECHOS (SET OF FACTS), COSTUMBRE (HABIT), ESTADO (STATE), FENÓMENO (PHENOMENON), GRADO (DEGREE), PARÁMETRO (PARAMETER), PERÍODO (PERIOD), PROCESO (PROCESS), RELACIÓN FACTUAL (FACTUAL RELATIONSHIP) and SITUACIÓN (SITUATION).

It would be extremely interesting to have the formal definitions of these important sixteen Spanish lexical units (N.B.: CONJUNTO DE HECHOS is a syntagm). However this entails considerable difficulties, among them, the use of semantic primitives, cf. Wierzbicka (1996). Therefore, we will just give some elements of these definitions.

On the one hand, ACTOS, ACCIONES, ACTIVIDADES, COMPORTAMIENTOS and ACTITUDES are volitional FACTS. On the other hand, PROCESOS, ACONTECIMIENTOS, ESTADOS and CARACTERÍSTICAS are non-volitional FACTS. Except in some cases of non standard diathesis, the first semantic actant of a volitional FACT is always an agent. An agent includes the meanings *querer* (to want) y *causar* (to cause). A volitional FACT would be then any FACT whose first semantic actant *quiere causar* (wants to cause) something.

Furthermore, ACTOS and ACONTECIMIENTOS are punctual FACTS, since they do not have any internal temporal structure. On the contrary, ACCIONES, ACTIVIDADES,

COMPORTAMIENTOS, ACTITUDES, ESTADOS, PROCESOS and CARACTERÍSTICAS are non punctual.

We will not propose any diagnostic contexts or (tests) for the characterization of the labels directly subordinated to FACT. Some of these contexts are well know, others are only partially (or even not at all) useful. Classical references are Vendler (1967), Dowty (1979), Padučeva (1991)... From an operational point of view, we hope that an example for each class may suffice at the moment:

ACCIÓN:	<i>Juan ASESINÓ al Presidente.</i> <i>John ASSASSINATED the President.</i>
ACONTECIMIENTO:	<i>Juan ha sufrido un INFARTO.</i> <i>John has had a HEART ATTACK.</i>
ACTITUD:	<i>Juan hace gala de una ALTANERÍA increíble.</i> <i>John shows an unbelievable ARROGANCE.</i>
ACTIVIDAD:	<i>Juan ASESORA a una gran empresa.</i> <i>John ADVISE a big company.</i>
CANTIDAD:	<i>Juan tiene un MONTÓN de problemas.</i> <i>John has a LOAD of problems.</i>
CARACTERÍSTICA:	<i>Juan es FEO.</i> <i>John is UGLY.</i>
COMPORTAMIENTO:	<i>Juan es de una DESIDIA extrema.</i> <i>John shows an extreme INDOLENCE.</i>
CONJUNTO DE HECHOS:	<i>La VIDA de Juan es novelesca.</i> <i>John's LIFE is novelistic.</i>
COSTUMBRE:	<i>Juan FUMA.</i> <i>John SMOKES.</i>
ESTADO:	<i>Juan siente CANSANCIO.</i> <i>John feels TIREDNESS.</i>
FENÓMENO:	<i>Se oye un RUIDO insoportable.</i> <i>There is an unbearable NOISE.</i>
GRADO:	<i>Juan rinde al MÁXIMO de su capacidad.</i> <i>John performs to the MAXIMUM of his ability.</i>
PARÁMETRO:	<i>Juan ha llegado a una EDAD avanzada.</i> <i>John has reached an advanced AGE.</i>
PERÍODO:	<i>Juan ha disfrutado de dos SEMANAS de vacaciones.</i> <i>John has taken a two-WEEK holiday.</i>
PROCESO:	<i>La cerveza evita la OXIDACIÓN prematura de las células.</i> <i>Bier helps avoiding premature OXIDATION of the cells.</i>
RELACIÓN FACTUAL:	<i>Fumar PROVOCA cáncer.</i> <i>Smoking CAUSES cancer.</i>
SITUACIÓN:	<i>La institución atraviesa una grave CRISIS financiera.</i> <i>The institution is going through a serious financial CRISIS.</i>

#### 4. Actantial Formulae and Typed Semantic Variables

We are going to consider some cases of actantial formulae and typed semantic variables by way of examples. Let's take the label:

CONJUNTO DE SONIDOS EXPRESIVOS (SET OF EXPRESSIVE SOUNDS)

One example of predicate that can be described by this label is APLAUSO (APPLAUSE). Its actantial formula would be:

APLAUSO del individuo X al individuo Y por la acción Z (de Y)  
APPLAUSE of the individual X to the individual Y due to the (Y's) action Z

Other headwords that take the same label as genus are:

ACLAMACIÓN de los individuos X del individuo o acción Y  
ACCLAMATION of the individuals X to the individual or action Y

SILBIDOS (**pl**) del conjunto de individuos X al individuo o acción Y  
CATCALLS of the set of individuals X to the individual or action Y

As we can see, the actantial slots are represented by the variables X, Y, Z... They are typed with the semantic labels INDIVIDUO (INDIVIDUAL), CONJUNTO DE INDIVIDUOS (SET OF INDIVIDUALS) (which are ENTITIES) and ACCIÓN (ACTION). Sometimes, the typed variable presents a disjunction (INDIVIDUO o ACCIÓN). However, the SHSL\_F allows us to avoid artificial disjunctions. For instance, a high number of the Spanish nouns of statements APROBACIÓN (APPROVAL), DECLARACIÓN (DECLARATION), RECONOCIMIENTO (ACKNOWLEDGEMENT) admit as first semantic actant a human or a corporation, institution, etc. In order to represent this selection we do not need a disjunction between INDIVIDUO and ENTIDAD SOCIAL (SOCIAL ENTITY), because we are able to include both meanings under the label PERSONA (PERSON) (cf. *persona física, persona jurídica*...). It is to underline that the use of this label is not a mere technical means for compacting information, but it reflects accurately the selection restrictions of a Spanish noun. The noun *persona* is neither superordinate to INDIVIDUO nor to ENTIDAD SOCIAL, because it cannot be used as genus for any of this lexical units. The opposite, however, is true because some lexical units having the form *persona* have INDIVIDUO or ENTIDAD SOCIAL as genus. We use then a common subordinate label in

order to represent, in a natural way, the argumental selection of certain statement predicates.

Sometimes, the typing of the variable has to be so restrictive that we use not a semantic label, but a lexical unit with a much more restricted semantic extension (as we did with *perro* in the first example):

EMPASTE hecho por el individuo X sobre el diente Y del individuo Z  
FILLING performed by the individual X over the tooth Y of the individual Z

The Y variable is typed by *diente* (*tooth*) (note that *diente* has a bigger semantic extension than *muela* (*molar*) (cf. *diente molar*, *back tooth*).

In some cases, we have split semantic variables, as Z in:

FUNCIÓN SOCIAL O INDIVIDUO QUE EJERCE TAL FUNCIÓN  
El individuo X es MINISTRO responsable de Y en el gobierno de Z<sup>1</sup> de la entidad política Z<sup>2</sup>  
SOCIAL FUNCTION OR INDIVIDUAL THAT EXERCICES THIS FUNCTION  
The individual X is the MINISTER responsible for Y in the Z<sup>1</sup>'s government of the political entity Z<sup>2</sup>

This notation reflects that the variable can be saturated either with the designation of the government or with the designation of the head of the government (*el Ministro de Defensa del gobierno español*, *el Ministro de Defensa de Zapatero...*) but not both simultaneously (*\*el ministro de Defensa de Zapatero del gobierno español*) except if we add another predicate: *el ministro de Defensa del gobierno español ENCABEZADO por Zapatero*.

Besides the disjunctions in the typing of variables, which gives to the actantial formula the expression power of a regular grammar, the symbol <...> is used when we need to give the actantial formula the expressive power of a context-free grammar. At the moment, however, we have made a very limited use of this possibility:

EN CIERTA SITUACIÓN (IN A CERTAIN SITUATION)  
El hecho <el individuo> X tiene lugar <se encuentra> EN PRESENCIA DEL individuo Y  
The fact <the individual> X takes place <is> IN THE PRESENCE OF the individual Y

is equivalent to:

El hecho X tiene lugar EN PRESENCIA DEL individuo Y.  
The fact X takes place IN THE PRESENCE OF the individual Y.

El individuo X se encuentra EN PRESENCIA DEL individuo Y.  
The individual X is IN THE PRESENCE of the individual Y.

but block the sequences *\*El hecho X se encuentra en...* (*\*The fact is in...*) y *\*El individuo tiene lugar...* (*\*The individual takes place...*)

Most of the semantic labels are nominal, but we have at our disposal labels for other deep grammatical categories as well (verb, adjective, adverb and clausative). For the notion of deep grammatical category, see Mel'čuk (2006):

SENTIR UN DESEO SEXUAL (TO FEEL A SEXUAL DESIRE)  
El individuo X DESEA al individuo Y [= N **oblig**]  
The individual X DESIRES the individual Y [= N **oblig**]  
QUE ES UN CRIMEN DE SANGRE (THAT IS A BLOOD CRIME)  
Hecho X HOMICIDA  
Fact X HOMICIDAL

However, these labels are still not systematized. We still need to homogenize other important points, like the use of prepositions and some support verbs in the actantial formulae. In the same way, we must solve some ambiguities, for instance a same form, *hacer* (*do*), appears as predicate, as causative and as support verb, which is not optimal:

ACTO DE COMUNICACIÓN (ACT OF COMMUNICATION)  
ADVERTENCIA de la persona X a la persona Y de no hacer Z mediante el enunciado o la acción W  
WARNING of the person X to the person Y of not to do Z by the means of the statement or the action W  
ACCIÓN DE HACER DISMINUIR ALGO (ACTION OF CAUSE SOMETHING TO DECREASE)  
DESCUENTO por la persona X de la suma de dinero Y a la persona Z sobre W  
DISCOUNT from the person X of the sum of money Y to the person Z over W  
ACCIÓN BENÉFICA (BENEFICIAL ACTION)  
FAVOR de Z hecho por la persona X a la persona Y  
FAVOR of Z that the person X does to the person Y

## 5. Conclusion

The research described in this paper is still in progress. As well as the improving of the present FACTS hierarchy, we consider urgent the accomplishment of two complementary tasks.

On the one hand, we need a hierarchy of ENTITIES. Not only because entity labels have to be used in the actantial formulae of FACTS, but also because a big number of entities are not semantic objects. Indeed, most ENTITIES present argument slots inherited from prototypical predicates that apply over these ENTITIES. We have then quasi-predicates.

For example, TREN (TRAIN) has the semantic actants *materia X (material X)*, *del lugar Y (place Y) al lugar Z (place Z)* (e.g. *el tren de municiones; el tren de Barcelona a París; the ammunition train; the train from Barcelona to Paris*), which he takes from TRANSPORTAR (TRANSPORT). In the same way, ABOGADO (LAWYER) has the actantial formula:

Individuo X, que es el ABOGADO de la persona Y para Z  
Individual X, who is the LAWYER of the person Y for Z

which is inherited from REPRESENTAR (REPRESENT, in the juridical sense).

On the other hand, besides the genus and the actantial formula, it would be very interesting to systematically add the semantic field information, since, on the one hand, it can be very helpful for the future formulation of the complete lexicographical definitions and, on the other hand, it introduces another kind of partition in the lexicon, which can prove useful for several applications, among them the creation of specialized sublexicons.

We call semantic field a set of lexical units whose definitions share an important semantic component. For instance, the lexical units ANCLA (ANCHOR), BARCO (BOAT) y ESLORA (LENGTH) do not share at all the genus, but will have, in an explicit or an implicit way, the semantic component *navegación (navigation)* in their definitions.

Unlike the semantic labels hierarchy, the semantic fields list has to be elaborated in a rather intuitive way and will be a completely flat structure. A good example of one of

these lists, profusely used for large coverage lexicographic descriptions, is Mathieu-Colas & Buvet (1999). Another very interesting proposition is the list of semantic fields of the own LAF (Mel'čuk & Polguère, 2007: 493-513).

# Modelling ‘the perfect’, a category between tense and aspect

Anna Kibort

Surrey Morphology Group,  
University of Surrey, UK  
a.kibort@surrey.ac.uk

## Abstract

I demonstrate that a consistent interpretation of Reichenbach’s (1947) primitives and their configurations enables the construction of an intuitive and elegant semantic space for all logically possible tense meanings, independent of their mode of expression. I argue that the property which defines the perfect in absolute tense systems is the dissociation of the temporal location of the situation from the reference point from which it is viewed (i.e.  $R \neq E$ ). The analytical problems posed hitherto by the English Perfect are due to the fact that it neutralises the distinction between  $E < R$  and  $R < E$ . Although the semantic dimension of the perfect emerges from the system of temporal meanings, alternatively the perfect could be viewed as a category expressing meanings between canonical tense and canonical aspect, overlapping both.

**Keywords:** perfect tense, tense semantics, tense and aspect, grammatical features

## 1. The perfect and Reichenbach’s tense theory

### 1.1. Aims of the paper

This paper has two aims.<sup>1</sup> The first aim is to promote a new solution to the so-called ‘present perfect puzzle’ formulated by Klein (1992: 525):

In *Chris has left York*, it is clear that the event in question, Chris’s leaving York, has occurred in the past, for example yesterday at ten. Why is it impossible, then to make this event time more explicit by such an adverbial, as in *\*Yesterday at ten, Chris has left York?*

I demonstrate that the puzzle ceases to exist if the perfect is analysed as a semantic category which involves *any* dissociation of the temporal location of the situation from the reference point from which we choose to view the situation. I provide a simple model that is capable of representing this dissociation. In the proposed model, based on Reichenbach’s (1947) primitives E, S, and R, the perfect is represented as a dissociation of R and E ( $R \neq E$ ). The original idea promoted here is that, in tense systems with the primary deictic centre at the time of speech S, the dissociation of R and E may be grammaticalised as one category (a Perfect tense) regardless of the order of the two primitives along the time axis, thus neutralising the meaning distinction between  $E < R$  and  $R < E$ .

The second aim of the paper is to show the relationship between the perfect and the semantic tense distinctions that have been identified as logical possibilities for language. In the model proposed here, all logically possible tense meanings are captured with Reichenbach’s primitives. I demonstrate that resolving a hitherto

unnoticed inconsistency in Reichenbach's original interpretation of his system (see section 3.1) leads to a surprisingly clean and theoretically convincing system of tense meanings, that is, values of the tense feature. In the proposed system, the perfect can be regarded as a non-canonical tense, or alternatively it could be viewed as a semantic category between canonical tense and canonical aspect, overlapping both.

### *1.2. Reichenbach's 'relative tense theory'*

Reichenbach's (1947) framework is still used by many linguists, mostly descriptivists and some semanticists, to model grammaticalised tense values. It has been criticised over the years (recently for example by Vet 2007), and various influential attempts have been offered to improve it (e.g. Hornstein 1990).

Acknowledging the inadequacy of the traditional interpretation of Reichenbach's representations of tenses, I argue that Reichenbach's own interpretation of his system, repeated by most other researchers, was inconsistent (see section 3). Resolving the original errors of interpretation, however, reveals an elegant system, avoids the complications of other proposals, and provides a solution to the 'present perfect puzzle'. I argue, therefore, that Reichenbach's primitives *are* adequate to model tense meanings in natural language and provide a suitable foundation for a formal framework to model tense.

### *1.3. The perfect: preliminary observations*

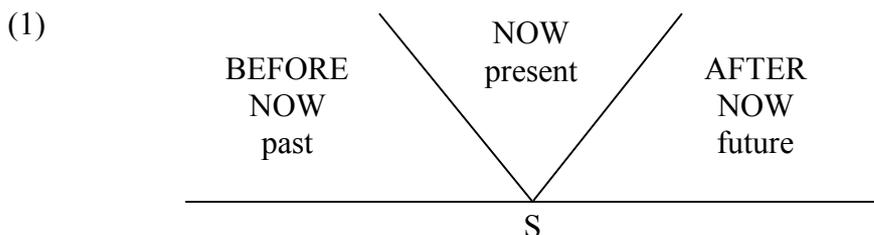

Although the perfect is often traditionally listed as an aspect, it cannot be viewed as a canonical aspect since it tells us nothing directly about the internal temporal organisation of the situation (Comrie 1976). If we take tense to be the grammaticalisation of location in time (Comrie 1985: vii), the perfect can be viewed as a tense. Specifically, we can first construct the semantic space of logical possibilities of expressing basic (non-perfect) tense meanings, that is all meanings where  $R = E$ , and then add the dimension of the perfect, that is all meanings where  $R \neq E$ , as a systematic extension of the basic tense meanings (see section 2.3).

Because it is possible to isolate the whole 'dimension' of the perfect within tense, and because its meaning is not purely deictic but captures a certain way of viewing a situation already located in time, the perfect could alternatively be viewed as a separate category, between tense and aspect. In other words, it could be argued that while the definition of tense has to include deixis, the distinction between  $R = E$  and  $R \neq E$  is independent of deixis. However, even in relative tense systems such as the one found in Yup'ik (Mithun 1999), which grammaticalise only the relation between R and E and always assume the deictic centre at R, the interpretation of tensed sentences is possible only when the deictic centre R is hooked either at the point of speech S (which can be regarded as the 'default' interpretation) or away from it (for example in narratives), depending on the context. Thus, relative tense systems arguably indicate that the perfect may be more appropriately analysed as a dimension within tense rather than as a separate category.

## 2. Modelling tense meanings

### 2.1. Time and tense

Following Comrie (1985: 2-3) and many other authors, I assume that time can be represented as a straight line, with the past represented conventionally to the left and the future to the right. The present moment is represented by a point on that line, labelled S (mnemonic for ‘speech time’):

Several things are intentionally left unspecified in diagram (1). One is whether the time line is bounded at either the left or the right (including whether it bends to form a circle; this might correspond to a different culture-specific conceptualisation of time, found on a limited scale in all cultures). Also unspecified is the representation of the flow of time, that is, whether S (or Ego) moves along a stationary time line, or time flows past a stationary reference point S (or Ego). These are important philosophical questions, but they don't seem to play a role in the analysis of tense as a grammatical category, even though they are metaphors that are important sources of time expressions across languages.

One of the extra-linguistic presuppositions for an utterance is constituted by the speaker's consciousness of the relation of the speech situation S to the reported situation/event (E) along the time axis. For temporal distinctions, the speech situation S projected onto the time axis serves at the basic orientation point. The distinction between absolute and relative tenses, however, results from the possibility of locating the deictic centre of the utterance either at the moment of speech (yielding absolute tenses, e.g. most tenses in English), or at any moment on the time line (yielding relative tenses, e.g. tenses in Yup'ik, Mithun 1999). An absolute tense system, with the primary deictic centre at S, can therefore be understood as a special case of a relative tense system.<sup>2</sup>

For temporal as opposed to aspectual distinctions the reported situation E (mnemonic for ‘event’) can be an event, state, process, or action, regardless of the internal temporal contour such as duration or iterativity, and is represented on the time line as a ‘point’. Similarly, S and R (see next section) also represent temporal locations relative to the other ‘points’ on the time line, while being neutral as to whether they are points or intervals of time longer than a point. As is conventional, the hyphen represents the relation ‘coincides/overlaps with’ (and therefore the order of the two

---

<sup>2</sup> Note that, although tenses in Yup'ik are all relative, very commonly the deictic centre of the utterance does fall at the moment of speech, which results in an ‘absolute’ interpretation. Furthermore, non-finite verb forms (which do not realise any absolute tense value) in languages such as English can be seen as realising relative tense (see e.g. Comrie 1985: 56-62).

coinciding points is irrelevant). Diagram (2) illustrates a naive view of a sample set of absolute tenses:

(2) past		E	S	
present			S-E	
future			S	E
past of the past	E <sub>2</sub>	(E <sub>1</sub> )	S	

On this view, a past situation E can be represented as occurring in the time before and not including the present moment (time ‘before’ S); a present situation E, whether continuing or repetitive, can be represented as occurring at the present moment (even though it may be encompassing a shorter or longer stretch of time) as long as it overlaps with the time which temporally or psychologically includes S; and a future situation E (a prediction, imposition or an instance of pre-planning) can be represented as occurring in the time after the present moment (time ‘after’ S).<sup>3</sup> Furthermore, it is possible that a single proposition (expressed in a simple clause) implies the occurrence of a second situation which is usually derivable from the context – as in, for example, the past of the past (or the pluperfect), which is a temporal relation that has been grammaticalised in many languages including English where it is expressed by one of the uses of the Past Perfect.

## 2.2. The R point

It is now widely accepted that the relative positions of just two points on the time line – the speech time S, and the event time E – are not sufficient to account for all the different tense meanings found in language. Therefore, since Reichenbach, most tense theories have used a third point in time, labelled R (mnemonic for ‘reference point’) to capture all possible tense distinctions. R indicates a psychological or imaginary temporal location which the speaker chooses to be the temporal reference point for the clause; it may, but does not have to, coincide with the basic orientation point S. The R point does not have to be expressed overtly through any lexical item in the clause, but may remain implied. It alters, in a systematic way, the viewing of the temporal location of a situation whose actual location represented by E remains constant with regard to S.

Diagram (3) represents the set of *absolute tenses* given earlier in (2), this time including the R point which is relevant to all tenses. Therefore, a non-naive representation of the absolute past, present, future, and past of the past all involve R coinciding with E:

(3) past		E-R	S	
present			S-E-R	
future			S	E-R
past of the past	E <sub>2</sub> -R <sub>2</sub>	(E <sub>1</sub> -R <sub>1</sub> )	S	

<sup>3</sup> It is assumed here that future time reference can, in principle, be subsumed under tense (see e.g. Comrie 1985: 43-48), even though some languages may not have a future tense or tenses and express future time reference with a modal category such as the irrealis.

Note that within the past of the past, the temporal relation of the reported event, labelled here as  $E_2$ , is absolute with regard to the deictic centre  $S$ , but relative with regard to the reference point which locates the occurrence of the implied event  $E_1$  (see also Comrie 1985: 65-68). Relative tenses in general are those which disregard the speech time  $S$ , but instead have a different temporal point as their deictic centre. The following is a sample set of *relative tenses*, illustrating different possible locations of  $E$  with respect to  $R$ , omitting the speech time  $S$ :

(4)	anterior	$E$	<b>R</b>	
	simultaneous		<b>R-E</b>	
	posterior		<b>R</b>	$E$
	anterior of anterior	$E_2$	$(E_1)$	<b>R</b>

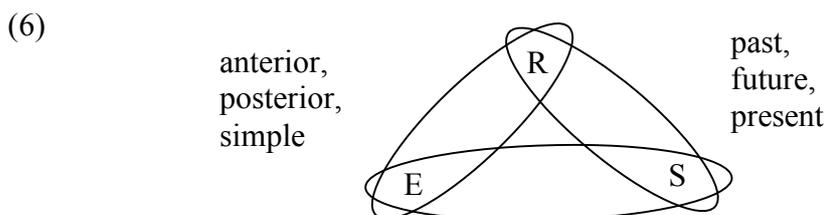

The tense meaning labelled here as ‘simultaneous’ is also referred to as ‘simple’, which is the label used originally by Reichenbach (1947).

Observe that the set of relative tenses in (4) parallels the set which illustrated the naive representation of absolute tenses in (2). However, I have now argued that the meanings of the absolute past, present, future, and past of the past have to include a reference point  $R$  which coincides with  $E$ , as in (3). In this way, all absolute tenses are correctly represented as a special case of relative tense: they are all a type of simultaneous/simple tense, that is, a tense where  $R = E$ .

Thus, in a post-Reichenbachian view of tense, it is not the position of  $E$  relative to  $S$  (the ‘naive view’), but the position of  $R$  relative to  $S$  which makes the speaker view the situation as ‘past’, ‘present’, or ‘future’. Furthermore, these temporal interpretations are expected to obtain regardless of the position of the reported event  $E$ . As was already shown in (4), the position of  $R$  with respect to  $E$  yields three possible tense meanings that have been labelled as ‘posterior’, ‘simple/simultaneous’, and ‘anterior’:

(5)	<b>R</b>	$S$		
		<b>R-S</b>		past
		$S$	<b>R</b>	present
				future
	<b>R</b>	$E$		posterior
		<b>R-E</b>		simple
		$E$	<b>R</b>	anterior

Understanding the meanings coded by the second set of relations is crucial for the interpretation of the perfect (section 2.4): ‘posterior’ can be understood as looking at  $E$  from an earlier point, or looking forward; ‘simple’ is best understood as ‘simultaneous’; and ‘anterior’ can be understood as looking at  $E$  from a later point, or looking backward. Diagram (6), which distills Reichenbach’s insights, is a visualisation of the relationships between all three primitives proposed by Reichenbach:

Note that the relation of  $E$  to  $S$  does not have a corresponding set of labels.

### 2.3. Tense meanings with one deictic centre (S)

Equipped with the three Reichenbachian primitives, we can map out the logical possibilities for tense meanings. I begin by illustrating the range of possibilities of coding the relation ‘E before S’ as different tenses. If the truth value of the proposition matched against the state of the world at the primary point of reference S yields the representation ‘E before S’, then the possible tense meanings incorporating the above relationship, that is, all possible ways of viewing the above situation, are:

(7)	<b>R</b>	E	S	posterior past
		<b>E-R</b>	S	simple past
		E	<b>R</b> S	anterior past
		E	<b>S-R</b>	anterior present
		E	S <b>R</b>	anterior future

All possible tense meanings that involve only one deictic centre (S) include three simple tense meanings (where R = E), five anterior tense meanings (where E < R), and five posterior tense meanings (where R < E). The three simple tense meanings, where R = E, are represented and illustrated from English in (8). The text in square brackets indicates the context for the temporal interpretation of the clause in question:

(8)	<b>R-E</b>	S	simple past
			<i>I saw him (yesterday)</i>
			<i>she was crying (for an hour)</i>
		<b>S-R-E</b>	simple present
			<i>the kettle is boiling</i>
			<i>I live here</i>
		S <b>R-E</b>	simple future
			<i>he will finish it (tomorrow)</i>
			<i>she will still be doing it (tomorrow)</i>
			<i>[I can see that] I am playing tennis</i>
			<i>(tomorrow at 5)</i>

It is important to reiterate that in this system tense meanings are conceived of as independent of aspectual meanings, even though there are interesting interactions between tenses and aspects. Hence, the English examples given in (8) illustrate expressions of temporal locations of events regardless of the internal temporal contours of the events and of any additional modal meanings conveyed. Also, as is now obvious, the names of tense meanings (‘simple past’, simple present’, etc.) do not necessarily correspond to particular grammatical tenses in a language (e.g. the English tenses labelled as Simple Past, or Simple Present). Thus, we can distinguish sentences such as *I saw him*, which is expressed with the Simple Past tense and has simple past temporal semantics, and *if I were you*, which is also expressed with the Simple Past tense but is typically understood as having simple present temporal semantics (and an additional modal meaning; see for example Patard 2008 on the modal uses of the English Simple Past).

To complete the account of the system of all possible tense meanings with one deictic centre (S), (9) lists representations of five anterior tense meanings, where E < R:

English (1947: 297; see also the Appendix), and most neo-Reichenbachian tense systems either propagate this exclusion or attempt to assign to it a future interpretation (e.g. Vet 2007: 9ff for French).

However, if the relation  $R < E$  ('posterior') is understood as looking at the event E from an earlier reference point R, and if the event E still holds at the point of speech (S-E), then the representation (R S-E) is precisely the one which captures the English 'universal perfect' or the 'perfect of extended now'. It is normally accepted that 'now' can be extended to express universal or timeless situations, as in diagram (1), and E can extend with it indefinitely, as in *spiders have eight legs*. By analogy, E can hold over a stretch of time which extends from an earlier reference point R (e.g. 'ten years ago') to the present (S), including 'now' (S-E), as in *I have lived here for ten years*.<sup>4</sup> Note, however, that the reference point R does not need to be expressed overtly through any particular lexical item, either in the perfect tenses or any other tense meanings. Hence, *I have always loved him* is still interpreted as (R S-E), with an 'understood' reference point R which provides the temporal bracket from which to view the situation. Placing the reference point before S-E, rather than together with S-E, means that the situation does not hold universally, but it has been holding for an overtly unexpressed period of time, e.g. *I have always loved him [since we first met / since he was born / etc.]*.

The examples in (13) and (14) are an illustration from English of all anterior and posterior tense meanings identified earlier in (9) and (10), respectively:

(13)	<b>E</b>	<b>R</b>	<b>S</b>		<i>I had met him before</i>
					<i>he will have finished it last week</i>
	<b>E</b>		<b>S-R</b>		<i>I have met him</i>
					<i>he will have finished it by now</i>
	<b>E</b>		<b>S</b>	<b>R</b>	<i>he will have finished it by tomorrow, [in fact, he has finished it already]</i>
					<i>[if it rains tomorrow,] we will have worked in vain yesterday (Comrie 1985: 73)</i>
			<b>S-E</b>	<b>R</b>	<i>he will have finished it by tomorrow, [he is finishing it now]</i>
			<b>S</b>	<b>E</b>	<b>R</b>
					<i>[he hasn't finished it yet, but] he will have finished it by tomorrow</i>
(14)	<b>R</b>	<b>E</b>	<b>S</b>		<i>I had known him for ten years</i>
	<b>R</b>		<b>S-E</b>		<i>I have known him for ten years</i>
	<b>R</b>		<b>S</b>	<b>E</b>	<i>next year we will have known each other for ten years</i>
			<b>S-R</b>	<b>E</b>	<i>[it's 1990, so] in the year 2000 we will have known each other for ten years</i>
			<b>S</b>	<b>R</b>	<b>E</b>
					<i>[if she gets married next year,] in the year 2000 she will have been married for ten years</i>

<sup>4</sup> Since E overlaps with 'now' (S) in this tense meaning, it is unsurprising that the universal perfect is most common with stative verbs when non-progressive; however, when progressive/iterative, it is found with dynamic and other non-stative verbs (e.g. punctual).

### 3. Tense meanings versus forms that realise them

#### 3.1. Reichenbach's (mis)interpretation of his system

I am now in a position to point out three critical errors in Reichenbach's original and others' later interpretations of his system.

First, both Reichenbach and many re-interpreters of his system assumed erroneously that any one logical tense meaning, defined as a particular configuration of the points {S, E, R}, must correspond to a particular grammaticalised tense in a language (see the Appendix for Reichenbach's original system of tenses and his suggestion of their corresponding English counterparts). However, languages typically combine two or more tense meanings into clusters which we recognise as grammaticalised tenses, and thus grammaticalise fewer temporal distinctions that are logically possible (note that, despite looking for one-to-one correspondences, Reichenbach did allow the Simple Future tense in English to have two different interpretations). Also, apart from the purely temporal meaning, grammaticalised tenses often include aspectual and modal meanings or other meanings expressing actionality distinctions, and can be employed for various pragmatic functions (e.g. polite questions, etc.). This is a key point, disregard of which leads to confusion of meaning and form and is bound to lead to an unsatisfactory account of tense regardless of which primitives, whether Reichenbachian or other, are used to model temporal meaning.

The second point treats an issue related to the cumulation of different meanings within individual grammatical tenses. Namely, Reichenbach's model is designed for tense, that is, to capture distinctions between different configurations of the 'points' (the primitives of the system) along the time line. Despite this, Reichenbach himself tried to force his system to express some aspectual or actionality distinctions that he encountered in English (specifically, durativity and iterativity). Both in Reichenbach's and in many neo-Reichenbachian systems, aspectual distinctions are added as various symbols (bars, boxes, zigzags, eyes, etc.) to representations expressing simple relative positioning of the three points on the time line. However, since it is assumed in such accounts that these aspectual distinctions belong to the system of tense oppositions, rather than being orthogonal to it, it is impossible to capture all distinctions consistently when they are scrutinised across such a tense/aspect system, and it is virtually meaningless to attempt comparisons of such concepts between languages, especially languages which are not closely related.

Reichenbach's attempt to include durativity in his model of tenses provides an instructive example (1947: 290). The English Simple Past sentence *I saw John* is represented as (R-E S). In order to represent *I was seeing John*, Reichenbach adds a short horizontal bar above the R-E in the Simple Past representation, to indicate that the event 'covers a certain stretch of time' ( $\overline{\text{R-E}}$  S). By analogy, while the Present Perfect sentence *I have seen John* is represented as (E S-R), in order to represent *I have known him for ten years* (the 'second usage' of the English Present Perfect) Reichenbach adds a long horizontal bar above the Present Perfect representation, stretching from before E until and including the moment of speech ( $\overline{\text{E S-R}}$ ). This is intended to indicate 'extended tense' of durativity, with the duration of the event reaching up to S. It is not clear, however, how continuing with this procedure would

allow Reichenbach to represent *I have been seeing John* or *I have been living here for a while*, and so on.

Although Reichenbach's key insight, for which he is acclaimed, was to interpret the relationship (E S-R) as expressing one type of the Present Perfect in English (the experiential/resultative perfect, as in *I have seen John*), it is clear that his account of the other type of the English Present Perfect (the universal perfect, as in *I have lived here for ten years*) is unsatisfactory, as it mixes up temporal and aspectual properties and thereby creates irresolvable problems for his tense system. Unfortunately, both Reichenbach and many others have tried to interpret the universal perfect as a variant of the experiential perfect. Having assigned the English Present Perfect tense to the (E S-R) representation, they failed to notice that there was already an appropriate model of the universal perfect in Reichenbach's system waiting to be used (R S-E). This shows that even Reichenbach himself did not apply his interpretation of the primitives and their configurations consistently throughout his system. In particular, he failed to interpret correctly the set of posterior tenses (R < E) and thought that four of them (out of five) could not be expressed through any particular grammatical tense in English. Unfortunately, this inconsistency has so far been repeated by all re-interpreters of his system.

Reichenbach's misinterpretation of the posterior relation (R < E) led him to suggest that one of the five posterior tenses, (S-R E), corresponded to the English Simple Future (note, however, that in Reichenbach's interpretation the English Simple Future also had an alternative representation, (S R-E), which indeed represents the simple future tense meaning). Furthermore, he incorrectly suggested that the representation (R E S), one of the three posterior past meanings, corresponded to *would* in *I did not expect that he would win the race*, *was going to* in *I did not expect that he was going to win the race*, and *was to* in *the king lavished his favour on the man who was to kill him* (1947: 297-298). This is because he failed to differentiate between absolute tense meanings in simple or main clauses, and relative tense meanings in subordinate clauses, as in the bi-clausal examples that he provided.

In the account offered here, the representation (R E S) is a temporal model of a simple clause expressing the 'universal perfect' (R < E) shifted into the past, before and not overlapping with the moment of speech, as in *I had known him for ten years* – see (14). On the other hand, the examples given by Reichenbach are bi-clausal and have to be represented with two pairs of points {E, R}. The pair of points {E<sub>1</sub>, R<sub>1</sub>}, representing the main clause, has its deictic centre at the point of speech S, while the pair {E<sub>2</sub>, R<sub>2</sub>}, representing the subordinate clause, has its deictic centre at R<sub>1</sub>:

(15) {*I did not expect*}<sub>E<sub>1</sub></sub> {*that he would win the race*}<sub>E<sub>2</sub></sub>      R<sub>1</sub>-E<sub>1</sub>    R<sub>2</sub>-E<sub>2</sub>    S

In the examples given by Reichenbach, there is no need to invoke the semantic category of the perfect which involves a stretch of time in either direction from event E<sub>2</sub>, hence the representation of the relative tense in these examples (R<sub>1</sub> R<sub>2</sub>-E<sub>2</sub>) is analogous to the representation of a simple future tense meaning (S R-E), except that it is shifted into the past by virtue of locating its deictic centre at R<sub>1</sub> which is before S. Another possible tense combination in which *would* expresses a relative tense meaning, which escaped Reichenbach's attention, is illustrated in (16):

(16) {*I did not expect*}<sub>E<sub>1</sub></sub> {*that he would be living here now*}<sub>E<sub>2</sub></sub>      R<sub>1</sub>-E<sub>1</sub>      S-R<sub>2</sub>-E<sub>2</sub>

Many more tense combinations are logically possible and expressible, involving both simple and perfect meanings. In section 3.3 I briefly mention them again, distinguishing between relative tenses in tense combinations and relative tenses which can function independently in main clauses by implying an event  $E_2$ .

### 3.2. *Tenses as grammaticalisations of tense distinctions*

I now return to the issue of tense meaning versus tense form. Despite the wide range of logical possibilities (which do not have an obvious limit if degrees of remoteness are additionally considered), not all of the possible tense meanings are found grammaticalised as tenses in any particular language. It is very common to find neutralisations of various temporal distinctions in one grammatical tense in a language. Furthermore, tense meanings are often grammaticalised in combination with other (aspectual, modal) distinctions. This is why grammaticalised tense-aspect-mood categories found in particular languages frequently do not correspond, despite often being labelled similarly.

English, for example, grammaticalises the whole semantic category of the perfect ( $R \neq E$ ) as a distinct tense, the Perfect. However, it neutralises the distinction between  $E < R$  and  $R < E$ . Hence, one Present Perfect tense is used in English for both meanings: *I have seen John* and *I have lived here for ten years*. Similarly, one Past Perfect tense is also used for both: *I had seen John before* and *I had lived there for ten years*. Furthermore, the Past Perfect in English also includes the ‘simple past + simple past’ tense meaning (see section 3.3). One Future Perfect tense neutralises numerous different temporal distinctions, as was exemplified in (13) and (14).

In the remaining part of this section, I give three more examples of grammaticalisation choices involving perfect meanings ( $R \neq E$ ), as found in three different languages other than English: Brazilian Portuguese, Polish, and Yup’ik.

A Northeastern variety of Brazilian Portuguese has a highly restrictive Present Perfect tense which grammaticalises exclusively the ‘universal perfect’ ( $R = S-E$ ) meaning (Laca, Cabredo-Hofherr & de Carvalho 2007), as in *Pedro tem dormido na varanda o inverno inteiro* ‘Pedro has been sleeping on the balcony all winter’. Therefore, apart from obeying other restrictions regarding the internal structure of the reported event, the Present Perfect tense cannot be used to express typical experiential/resultative meanings. For example, it cannot be used with ‘already’ or ‘still not’: *Ela (\*ja) tem escrito artigos* ‘She (\*already) has written articles’, *\*Ela ainda não tem chegado* ‘She still not has arrived’; it cannot express resultative or recent anteriority readings: *\*Acho que João tem matado o segurança* ‘I think that João has killed the guard’; and it cannot express certain future perfect meanings: *\*Quando a Ana regressar de Groningen, tu tens acabado a tese* ‘When Ana returns from Groningen, you [will] have finished your thesis’.

Polish does not have a distinct Perfect tense,<sup>5</sup> but grammaticalises the split within the Perfect ( $E < R$  versus  $R < E$ ) by using simple Past versus simple Present tense, respectively. For example: *Spotkałem ją tylko raz* ‘I [have] met her only once’, *Już to czytałem* ‘Already I [have] read this’, versus *Znam go od dziesięciu lat* ‘I know him

---

<sup>5</sup> Although there appears to be evidence that a new Polish Perfect, with the auxiliary *mieć* ‘have’, is emerging from the resultative (Björn Hansen, personal communication).

since ten years’, *Pisze tę książkę odkąd się poznali* ‘S/he writes this book since they met’ (see Kibort 1997 for more examples).

Finally, Central Alaskan Yup’ik has a relative tense system (Mithun 1999) and grammaticalises only the relation between R and E. Hence, it has distinct grammatical tenses to express the different relative positions of R and E:

- |                               |  |
|-------------------------------|--|
| (17) simultaneous:            | <i>nalkutaqa</i> ‘I am/was finding it’             |
| anterior:                     | <i>nalkutellruaqa</i> ‘I found/had found it’       |
| immediate/imminent posterior: | <i>nalkkutqataraga</i> ‘I am/was about to find it’ |
| distant posterior:            | <i>nalkuciiqaqa</i> ‘I will/would find it’         |

Furthermore, the deictic centre of the utterance is always assumed to be at R. Unlike languages with absolute tense systems, Yup’ik uses the relations  $E < R$  and  $R < E$  for ‘displaced experience’ rather than to indicate a stretch of time bounded by R and E. Hence, Yup’ik ( $E < R$ ) and ( $R < E$ ) temporal representations may correspond to ( $E-R < S$ ) and ( $S < E-R$ ), respectively, in absolute systems. Therefore, a stretch of time indicating ‘current relevance’ or ‘extended now’, such as the one expressed by perfect meanings in absolute tense systems, is expressed in Yup’ik by allowing the R-E point itself to be interpreted as extended forwards or backwards, as required (Mithun 1999: 31-33), like the ‘now’ in diagram (1).

### 3.3. Secondary tenses and tense combinations

Most tense meanings discussed so far locate an event E with respect to the primary deictic centre S. These may be called *primary* tense meanings. However, further (relative) tense meanings may locate an event  $E_2$  with respect to the deictic centre  $R_1$  which is the reference point for an implied event  $E_1$  (whose deictic centre is, in turn, S; see also (3) above). These may be called *secondary* tense meanings. Examples of such tense meanings grammaticalised as tenses are the following uses of the English Past Perfect (see also Squartini 1999 who argues for distinguishing this tense meaning as a grammaticalised tense in Germanic and Romance) and Future in the Past, illustrated in (18) and (19), respectively:

- |   |                                       |             |   |
|---|---------------------------------------|-------------|---|
| (18) [ <i>By then,</i> ] <i>they had moved in</i>                     | $R_2-E_2$                             | $(R_1-E_1)$ | S |
|   | simple past + simple past (‘earlier’) |             |   |
| (19) [ <i>John left for the front;</i> ] <i>he would never return</i> | $(R_1-E_1)$                           | $R_2-E_2$   | S |
| (Comrie 1985: 75)   | simple past + simple future (‘later’) |             |   |

In both representations above,  $E_1$  is an implied event, perhaps mentioned earlier in the discourse, and  $E_2$  is the dependent event which is expressed overtly.

Many more combinations of  $\{E_1, R_1, S\}$  and  $\{E_2, R_2, S\}$  are logically possible, where the deictic centre of  $E_2$  is  $R_1$ . However, if both events have to be expressed, the combination may not be grammaticalised as a separate tense.

## 4. Conclusions

When interpreted consistently throughout the system, Reichenbach’s primitives  $\{S, E, R\}$  are adequate to model all logically possible *tense meanings* in language. The range of logical possibilities for expressing the location of an event in time can be

argued to constitute the range of possible values of the grammatical feature ‘tense’. As with other grammatical features such as gender or number, out of the large range of possibilities languages grammaticalise different sets of values by neutralising some of the possible meaning distinctions. I have given examples of the different grammaticalisation choices by comparing briefly the category of the perfect in English, Brazilian Portuguese, Polish, and Central Alaskan Yup’ik. Therefore, as opposed to tense meanings, *forms of tenses* in languages result from grammaticalisation choices over possible tense values which may involve neutralisations of different temporal distinctions, often in combination with additional distinctions: aspectual, modal, and other.

As the approach outlined in this paper prioritises meaning (content) over mode of expression (form), it is compatible with realisational models of morphosyntax and capable of providing formal semantic input to such models. In an inferential-realisation approach to morphology (e.g. Stump 2001, 2002, 2006) feature values are identified by establishing a ‘form-paradigm’ correlating inflected stems with morphosyntactic or morphosemantic properties. The cells in a language’s form-paradigm are the basis for deducing the morphological realisation of the cells in that language’s content-paradigm. It is assumed that every lexeme in a language has an associated ‘content-paradigm’: a set of cells each of which consists of the pairing of the lexeme with a maximal consistent set of morphosyntactic or morphosemantic properties (for example, the values of the feature tense). The cells in a lexeme’s content-paradigm correspond to the different types of nodes into which forms of that lexeme may be inserted in syntactic structure. An inferential-realisation approach is particularly suitable for the study of tense which is frequently realised through periphrasis, portmanteau inflection (that is, cumulative exponence; for example, combination of tense exponence with aspect and mood), and extended exponence. On this view, periphrastic realisation of a tense value corresponds to one cell of a content-paradigm, which is advantageous both theoretically and practically in computational applications.

Feature values which have a morphological realisation are conceived of as units of linguistic description which are abstract enough to capture regularities across different components of grammar (morphology and syntax; morphology and semantics; morphology, syntax, and semantics) regardless of their mode of expression in a particular language or for a particular class of linguistic elements in a language. This means that, although they are proposed because they are initially recognised through morphology, the basis for their classification is content, not form. A content-based inventory of morphologically realised tense values, based on the meaning distinctions identified with Reichenbachian primitives, would be capable of enabling a systematic comparison of the temporal categories already found in different languages, as well as predicting which temporal categories may yet be found. The space of logical possibilities described by such an inventory could, therefore, be considered a ‘suitable framework in which different tense (...) systems can be compared’ (Dahl 2000: 3), a framework which we are currently still lacking.

As for the semantic category of the perfect in absolute tense systems, I have argued that it can be identified as a tense meaning which has the property  $R \neq E$ . If, as in English, grammaticalisation neutralises the distinction between  $E < R$  and  $R < E$ , it is possible to have one grammatical category of the Perfect that includes both the experiential/resultative perfect and the universal perfect. Finally, as for the starred

example from the ‘present perfect puzzle’ quotation in section 1.1 (*\*yesterday at ten, Chris has left York*), it can be understood straightforwardly as semantically incoherent, because it implies two reference points R located at different positions with respect to S: one is  $R < S$  (*yesterday at ten*), and the other is  $S-R$  (*Chris has left York*). Hence, the clausal modifier *yesterday at ten* involves a temporal concept which is semantically incompatible with the interpretation of the clause *Chris has left York* expressed in the Present Perfect, much like it would be incompatible with a clause in the Future Simple (*I will go*), even though it is not normally posited that *\*/#yesterday I will go* is a puzzle. Once the distinctive semantics of both the experiential/resultative perfect (E – S-R) and the universal perfect (R – S-E) in the system of tense meanings are properly recognised, it is possible to predict straightforwardly which temporal concepts will be (in)compatible with these tense meanings.

## Abstract

This paper discusses tense structure and temporal relations of Taiwan Sign Language (TSL), with the goal to find out how signers locate events in time and how events anchor the time in the discourse. Following Kuno (1975), Chafe (1984), Friedman (1975), and Sutton-Spence and Woll (1999), this study claims that temporal locating adverbs in TSL will evoke temporal frames for following events to anchor the time until a new temporal reference is made, and signers will conceptualize the temporal frames into the signing space. Segmented Discourse Representation Theory (SDRT) is employed to account for temporal relations between clauses.

**Keywords:** tense, sign languages, SDRT

## 1. Introduction

The expression of time is one of distinguished features of human languages. As to temporal system in languages, tense and aspect are two primary grammatical categories. Comrie (1976:1-3) defines tense as the ways to relate the time of the event referred to some other time, usually the moment of speaking, and aspect as different ways of viewing the internal temporal constituency of a situation. Put it into another way, tense allows speakers to locate events in time, while aspects reflect the speakers' different foci on internal constituency of an event. Following sentences (1a) and (1b) show the contrast in tense (i.e., past tense vs. non-past tense). However, sentences (2a) and (2b) exemplify a difference in aspects (i.e., non-progressive vs. progressive), even though both of them belong to the same tense (i.e., past tense). In this study, we will emphasize tense system of Taiwan Sign Language (hereafter TSL).

- (1) a. John walked to school.  
b. John walks to school.
  
- (2) a. Jean read the book.  
b. Jean was reading the book.

Tense is generally defined in terms of two perspectives. Strictly speaking, tense is defined as a grammaticalized expression to relate events to time and consistently reflects on inflectional morphemes (Comrie 1985; Binnick 1991; Smith 1997; Bhat1999; Mani et al. 2005). Broadly speaking, tense is defined as the strategies to locate events in time, and every human language has the concept of tense but may vary in expressions. This study adopts the broad definition of tense and agrees that all human languages have ways to locate events in time, and sign languages are without exception.

Studies on sign languages in the past 40 years have shown that human languages can be represented in two modalities: one is visual-gestural modality of sign languages and the other is oral-aural modality of spoken languages (Stokoe 1960, Stokoe et al. 1965, Kilma and Bellugi 1979, Lillo-Martin 1999, 2002; Meier 2002). TSL is widely used by deaf and hearing-impaired citizens of Taiwan. As noted by Smith (1989), TSL originates from two dialects of Japanese Sign Language, which leads to TSL having two mutually intelligible dialects: TSL of Taipei and TSL of Tainan. The grammatical structures of these two dialects are basically the same, whereas they mainly differ in lexicon (i.e., DRAGON, PINE APPLE, etc.) (Chang, Su and Tai 2005). In Taiwan, there is another signing system - Sign Chinese, so called *Wen Fa Shou Yu* 'grammatical sign language', which is created and manipulated for the instructional purpose in education system (Smith 1989). However, the grammatical system of Sign Chinese is based on the Chinese, whereas TSL has its own lexicon and grammar.

This study mainly explores three issues. First, the expression of tense in TSL will be investigated. Second, the functions of temporal adverbs in TSL discourse will be explored, including how signers structure the signing space to anchor the time, and how the temporal frames are established, allocated, and rearranged in signing space to create a coherent discourse. Third, Segmented Discourse Representation Theory (hereafter SDRT) is used to account for how rhetorical relations affect temporal relations.

The rest of this paper is divided into the following sections. Section 2 introduces the tense expression of TSL; Section 3 elucidates the tense structure within TSL discourse; in Section 4, temporal relations between clauses are illustrated, and Section 5 offers the concluding remarks.

## **2. Tense expression in TSL**

Hockett (1960) proposes a list of thirteen designed features of languages which

distinguish human languages from animal communication systems. One of design features is "displacement" which refers to human languages allow user to construct information about the past, present and future, and about the real world as well as imaginary world (Sutton-Spence and Woll 1999). That means sign languages are also able to express events in different time. Examples (3)-(5) examine whether the verb GO in TSL change its form along with different tense or not. (i.e., present time of (3), past time of (4) and future time of (5)). As shown in (3)-(5), the verb GO is articulated with moving the right hand in fist with extended index and middle fingers toward the left hand in flat with extended and together fingers which stands for classifier of SCHOOL.<sup>1</sup> The verb GO consistently remains the same form, even though it is involved in different time, as in Figure (1d), (2d), and (3d). In brief, TSL does not morphologically mark tense on verbs.

(3) HE<sub>i</sub> NOW SCHOOL<sub>j</sub> HE<sub>CL-i</sub>+SCHOOL<sub>CL-j</sub>+ GO

'He is going to school now.'

'He will go to school tomorrow.'

a.  $HE_i$

b. TOMORROW c. SCHOOL<sub>j</sub>

d.  $HE_{CL-i}+SCHOOL_{CL-j}+GO$

Figure (3)

Most of previous literatures agree that sign languages do not mark tense on verbs (Friedman 1975; Cogen 1977; Emmorey 2002 for American Sign Language; Bernnan 1983; Kyle and Woll 1985; Sutton-Spence and Woll 1999 for British Sign Language; Engberg-Pedresen 1993, 1999 for Danish Sign Language; Pereiro and Soneira 2004 for Spanish Sign Language; Meir and Sandler 2008 for Israeli Sign Language). However, there are few scholars hold different viewpoints about tense expression in sign languages. In the light of proving that sign languages are on a par with spoken languages, the earlier studies of sign languages aim at finding out parallel patterns with spoken languages. Jacobowitz and Stokoe (1988:36) claim that ASL reflects tense on verbs. The future tense in ASL is represented by an extension of the wrist, elbow, shoulder, or neck, and past tense is shown by a flexion of the same joints. Following Jacobowitz and Stokoe's study, Sutton-Spence and Woll (1999:117) also point out that certain sentences in British Sign Language (hereafter BSL) involve the inflection morpheme of tense. They mention that in BSL a forward movement of the head and shoulders may be used to show the future tense; conversely, a backward movement of head and shoulders indicates the past tense. Further, they also find out certain verbs in BSL have independent forms when they are in past tense (i.e., WIN, SEE and GO in BSL).

Engberg-Pedersen (1993:82-83) regards that Jacobowitz and Stokoe's study of tense in terms of extension and flexion of muscles and joints of articulators need more specific description in physical terms of possible articulators, modification of signs and a investigation of possible combination of muscle, but those are beyond the discussion

in linguistics. Likewise, Sutton-Spence and Woll (1999) agree that those non-manual features (i.e., backward or forward movement) cannot be regarded as consistent tense system, since these non-manual features may cover whole phrases or sentences rather than being limited on individual verbs. Further, those verbs with distinctive past tense forms are rare in BSL, so it is better to analyze them as independent lexical items.

As discussed above, some studies dedicate to prove that sign languages are parallel to spoken languages, while some studies accept the viewpoint that some distinctive features of sign languages are due to modality effects (Friedman 1975; Sutton-Spence and Woll 1999) or being Creole-like languages (Meier 2002; Tai 2005, 2006). Do sign languages involve tense inflection is a controversial issue in sign language studies. As mentioned by Friedman (1975:942-943), the reason for sign languages do not mark tense on verbs to maintain the awareness the present time is contributed to the physical aspect of visual language's constraints. Sutton-Spence and Woll (1999) also suggest that since the movement of verbs in sign languages has already been used to convey the grammatical relation or spatial relations between arguments, the verbs can not be marked no more for tense inflection. In addition, as noted by Aronoff, Meir, and Sandler (2005) and Tai (2006), sign languages share many commonalities with young Creole languages, and one of those similarities is no tense marking but a rich aspectual system. Accordingly, without marking tense on verbs in TSL maybe result from modality constraints or being a Creole-like language.

In fact, sign languages mainly resort to individual lexical items (i.e., temporal adverbs) to express the time reference. Like other sign languages, TSL relies on the temporal adverbs to indicate the time of clauses (i.e., NOW in (3), YESTERDAY in (4), and TOMORROW in (5).) However, it is worth clarifying that not all temporal adverbs are able to locate events in time. As mentioned by Smith (1997), temporal adverbs can be categorized as four types which signify different functions respectively, such as locating adverbs (i.e., now, last week), durative adverbs (i.e., for an hour), completive adverbs (i.e., in an hour), and frequency adverbs (i.e., never, sometimes, often). Smith suggests that only the locating adverbs can serve as locating events in time.

To sum up, TSL does not mark tense on verbs; instead, it resorts to temporal adverbs to locate events in time.

### **3. Tense structure in TSL**

Section 2 has indicated that TSL mainly relies on temporal locating adverbs to

express tense. However, not every clause in discourse has to cooccur with a temporal locating adverb. This section is going to investigate how the clauses anchor the time reference in the discourse. Before elucidating the tense structure, the concept and conventions of signing space will be introduced.

### 3.1 Signing space

The signing space is the space surrounding the signer and where the signs are articulated. Specifically, signing space is a three-dimensional space situating in front of the signer which extends vertically from above the signer's head to waist and horizontally from signer's body to an arm's length in front of and to the side of the signer, as demonstrated in Figure (4). While signing, signers employ the signing space to locate the arguments and to materialize their semantic relationships, and results in a coherent discourse.

#### (6) Signing space

Figure (4)

Engberg-Pedersen (1993:71-79) has summarized four conventions (i.e., semantic affinity, canonical location, and comparison as well as iconicity) related to structuring signing space in terms of semantic and pragmatic perspectives, and suggests that the choice of loci in signing space is not arbitrary. The first convention is semantic affinity which refers to referents with semantic affinity to each other are assigned to the same locus unless they need to be further distinguished for discourse reasons. The second is canonical location which indicates that referents tend to be assigned to loci where they are found typically, or a locus where a referent is conventionally associated with. Thirdly, the convention of comparison is related to how signers choose the left sideward locus for one referent and the right sideward locus for another referent when he/she wants to compare or contrast these two referents. Lastly, the convention of iconicity

states that the spatial relation between referents in signing space is a spatial layout of representations of referents as they really are, which is also known as the use of topographic space. However, Engberg-Pedersen reminds that these conventions are the tendencies, but do not serve as obligatory rules while structuring the signing space.

Engberg-Pedersen's (1993) conventions are formulated to predict the choice of loci for referents, but we regard that some of conventions can be extended applied to the expression of time. The convention of semantic affinity states that there is a tendency which referents with shared semantic properties will be assigned to the same locus. Analogically, the referents or events share the same temporal meaning tend to being articulated to the same locus in the signing space. Furthermore, while discussing the interaction between different tense, the convention of comparison will be employed to help structure the signing space. In the following subsection, how temporal frames are conceptualized into the signing space and how the signing space is organized to represent the tense structure will be discussed.

### *3.2 Tense structure*

Section 2 concluded that TSL mainly relies on temporal locating adverbs to express tense. This section will further discuss the functions of temporal locating adverbs in the discourse. In spoken languages discourse, temporal locating adverbs function as scene-setting (Kuno 1975), frame-setters (Chafe 1984), or discourse segment (Virtanen 1992), and they evoke conceptual temporal frames that serve as the time reference for following events, and block following events making time reference to the preceding event or temporal adverb.

Like spoken languages, Friedman (1975) proposes that in sign language discourse, temporal locating adverb will evoke a temporal frame which serves as a temporal reference for following events to anchor the time until new time reference is made. As suggested by Sutton-Spence and Woll (1999), topic-comment structure is commonly found in BSL, and they regard that temporal adverb acts like a topic which sets up a temporal frame and everything that follows is set in this frame. Likewise, temporal locating adverbs in TSL are able to evoke temporal frames for following events to anchor the time, as exemplified in (7).

This discourse describes the situation happening in the airport, and contains nine events, as shown in (7). This discourse only involves one temporal locating adverb (i.e., PAST in event 1), and all the following events are not marked by temporal adverbs. Even though there is no another temporal adverb, the entire following events can be

interpreted as past tense. Since the temporal adverb PAST occurring in the discourse initial position denotes a temporal frame of past tense, the entire following events are bound in this frame and are interpreted as past tense.

- (7) Event1: **PAST** HAVE ONE DAY I INDEX DEAF-MUTUAL-CLUB GO  
 Event2: INDEX<sup>→R</sup> TOUR^LEADER I GO AIRPLANE^LOCATION.  
 Event3: DEAF LINE UP.  
 Event4: DEAF<sub>CL</sub>+ENTER<sup>R→L</sup>  
 Event5: INDEX<sup>→R</sup> TOUR^LEADER INDEX^MALE SELF SIGN-  
 LANGUAGE DON'T-UNDERSTAND  
 Event6: INVITE HELP TRANSLATE PEOPLE<sub>CL</sub>+COME  
 Event7: TOUR^LEADER COME+++ COME +++ MICROPHONE  
<sub>CL</sub>+TALK  
 Event8: TOUR TELL GUIDE YOU CAREFUL  
 Event9: INDEX AIRPLANE CAREFUL LOCATION WHAT TELL  
 CAREFUL

In the past I took a trip with the deaf association. The tour guide and I went to the airport. The deaf people lined up and entered the airport. Since that male tour guide himself doesn't know sign language, he invited a translator to help him. The tour guide talked with microphone and said 'come here.' He required those deaf should be careful and instructed the locations and things which should pay attention to in the airplane.

As exemplified above, the temporal locating adverb will evoke a temporal frame for following events to anchor the time; in other words, it means that all those following events share the same semantic properties – time. Following the conventions of structuring the signing space, we regard that the events share the same time reference may be assigned to particular locus to associate with the temporal meaning. Due to visual-gestural modality, we further propose that signers will conceptualize the temporal frame into the signing space. These conceptualized temporal frames serve as "conceptual setting" (van Hoek 1992), and all the following events signed in the signing space will obtain the temporal meaning. For instance, as in (7), after PAST is signed, the entire signing space is conceptualized as corresponding to the temporal frame "past", and all the following events articulated in the signing space will associate with the temporal meaning "past".

Moreover, in some discourses, they may involve more than one temporal locating adverb, and the shift of temporal frame will occur. In such discourses, a temporal frame will be evoked by the early occurring temporal adverb, and then it will be shifted to another temporal frame when new temporal adverb is addressed, as TSL discourse shown in (8).

The discourse in (8) is a narrative discourse, and we identify the amount of events by the occurrence of verbs. This discourse involves seven events, and there are two temporal locating adverbs was employed in this discourse (i.e., YESTERDAY in the event 1, and TODAY in the event 2). This narrative discourse opens with a temporal locating adverb YESTERDAY, and the following events describe the situation that happened in yesterday until another temporal adverb TODAY-MORNING is made. In brief, the event 1 and the event 2 are within the coverage of the temporal frame "yesterday", and the event 3-7 are included in the temporal frame of "today morning"

- (8) Event 1: ZHU^QUANTIFIER^LEAF GIRL<sub>i</sub> **YESTERDAY** HOME GIRL<sub>CL-</sub>  
<sub>i</sub>+HOME<sub>CL-j</sub>+ GO (i moves away from j).  
 Event 2: SHE LIKE WHAT SING^GUITAR^BAND RECENTLY  
 PUBLISH SING^DISK BUY FINISH  
 Event 3: **TODAY-MORNING** RETURN HOME  
 Event 4: TAKE SING^DISK  
 Event 5: TEAR  
 Event 6: PUT  
 Event 7: STEREO<sub>CL</sub>+PLAY

'Yesterday Julie went out and bought the latest CD by her favorite band. She came home this morning, popped the CD out of its case and put it on the stereo.'<sup>2</sup>

In brief, in (8) the signing space is conceptualized as temporal frame "yesterday", when YESTERDAY is signed in the event 1, and later on the signing space is shifted and conceptualized as the temporal frame "today morning", when the new temporal adverb TODAY MORNING occurs in the event 3.

Moreover, certain discourse may involve comparison or interaction between referents and events in different times. The following discourse in (9) excerpted from a coherent discourse exemplifies how signers structure the signing space to express tense.

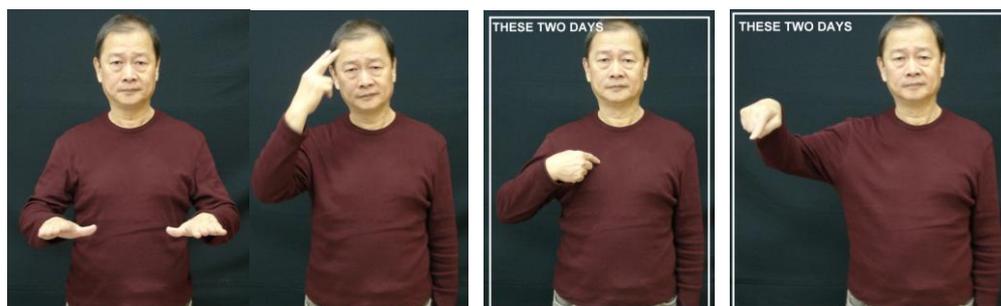

---

<sup>2</sup> This English discourse is adopted from Dickey (2001:152). The signer was required to paraphrase the same concept in TSL.

This discourse opens with a temporal locating adverb THESE-TWO-DAYS which evokes a major temporal frame for all the following events, as indicated by white square in Figure (5b). This temporal frame corresponds to the entire signing space, and the events (i.e., 'go to the supermarket' and 'buy things') which are expressed in the signing space obtain the temporal meaning 'these two days', as given in (9).

(9) THESE-TWO-DAYS I GO SUPERMARKET THING BUY

'These two days, I went to the supermarket to buy things.'

a. THESE TWO DAYS

b. I

c. GO

d. SUPERMARKET

e. THING

f. BUY

Figure (5)

In the second sentence, the author comments about the price of the fruits, one is the apple bought yesterday and the other is the banana bought today, as in (10). In this sentence, another temporal locating adverb YESTERDAY is addressed and evokes a sub-temporal frame which is embedded in the major temporal frame 'these two days', as shown in Figure (6c).<sup>3</sup> Further, another temporal locating adverb TODAY is mentioned, and also evokes a sub-temporal frame in the signing space. Since the signing space currently involves two independent temporal frames, the structure of signing space should be rearranged. The temporal frame 'today' is allocated in the left of signing space

<sup>3</sup> Wu (2002) suggests that in discourse some temporal adverbials will evoke sub-temporal frame which offer more specific information for the main temporal frame.

to distinguish from another temporal frame 'yesterday' which is conceptualized as in the right of the signing space, as demonstrated in Figure (6f). Hence, the following signs BANANA and BUY are signed toward the left of signing space to associate with the temporal meaning 'today' rather than being signed in the neutral space as usual, as shown in Figure (6g) and (6h). The following sign COMPARE is signed in both fist with extended index finger, and each of them stands for the fruits bought from different days, as in Figure (6i). The sign BETTER is signed with a leftward movement to indicate that yesterday's apple is better than today's banana, as shown in Figure (6j). Finally, the sign EXPENSIVE is signed at the left of the signing space to associate with the meaning of 'banana' and 'today', as in Figure (6k).

(10) I FIND YESTERDAY APPLE BUY TODAY BANANA BUY  
 COMPARE BETTER EXPENSIVE

'I found that the apple bought yesterday is cheaper than the banana bought today.'

a. I

b. FIND

c. YESTERDAY d. APPLE

e. BUY

f. TODAY

g. BANANA

h. BUY

i. COMPARE      j. BETTER      k. EXPENSIVE

Figure (6)

In the third sentence, the author continually compares the fruits bought from different time. It is worth to note that the identical temporal locating adverbs (i.e., YESTERDAY, and TODAY) are unnecessarily signed again, since the signing space has been already structured as 'yesterday' in the right and 'today' in the left. Thus, the signs are represented with different orientation and direction toward the left or right to associate the specific temporal meaning. The sign PINEAPPLE is signed at the right of signing space to indicate that it was bought yesterday, as in Figure (7a). The sign GRAPES is assigned at the left to associate with the temporal meaning 'today', as shown in Figure (7b). As for the following sign COMPARE, each extended index finger represents the fruits bought from different days, as in Figure (7c). The sign BETTER moves from the right to the left, which means that the yesterday's pineapple is better than today's grapes, as shown in Figure (9d). Lastly, the orientation of the sign EXPENSIVE is signed toward the left to indicate that today's grapes are expensive, as given in Figure (9e).

(11) PINEAPPLE GRAPES COMPARE BETTER CHEAP

'The pineapple bought yesterday is cheaper than the grapes bought today.'

a. PINEAPPLE      b. GRAPES      c. COMPARE      d. BETTER

e. EXPENSIVE

Figure (7)

Finally, after comparing the fruits bought from yesterday and today, the signer further states his opinion about the yesterday's female clerk. To maintain the cohesion of this discourse, the structure of signing space will be kept. The signer uses INDEX, which moves toward the right, to assign the locus for the following argument 'female clerk', as in Figure (8b). Then the sign MONEY^FEMALE 'female clerk' is signed with body leaning left-backward which lets the orientation of body and face more directly face toward the left to associate with temporal meaning 'yesterday', as in Figure (8c). Finally, the adjective PRETTY is also signed toward the right of signing space, as in Figure (8d).

(12) FURTHER INDEX MONEY^FEMALE PRETTY

'Further, yesterday's female clerk is pretty.'

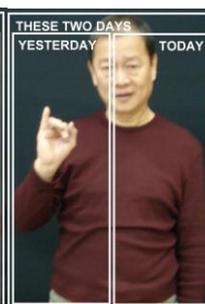

a. FURTHER

b. INDEX

c. MONEY^FEMALE

#### d. PRETTY

#### Figure (8)

To sum up, this section discusses the function of temporal locating adverbs in TSL discourse. We regard that temporal locating adverbs will evoke temporal frames serving as time reference for following events. Due to different modalities, we further propose that signers will conceptualize the temporal frame into the signing space. Once a temporal locating adverb is addressed, the signing space will be conceptualized as corresponding with this temporal frame, and all the following events signed in the signing space obtain the temporal meaning. As for interaction of two or more different time, signer will structure the signing space (i.e., to establish, allocate, and rearrange of temporal frames) to maintain temporal cohesion of discourse. After introducing temporal frames, section 4 will discuss about the interaction between rhetorical relations and temporal relations.

### 4. Temporal relations

#### 4.1 Segmented Discourse Representation Theory

Section 3 mentioned that TSL resorts to temporal locating adverbs to evoke temporal frames which are conceptualized into the signing space. This section further emphasizes in the temporal relations between clauses within a temporal frame. The argumentation proposed in section 3 may confront with some contradictory examples in discourse, and can not predict the tense structure precisely, as show in (13).

- (13) Event 1: TEACHER<sub>i</sub> TODAY UP^CLASS COME NOT-HAVE  
Event 2: HE YESTERDAY GO NIGHT-MARKET  
Event 3: WAY CAR+TEACHER<sub>CL-i</sub>+STRIKE  
Event 4: WOUND VERY  
Event 5: POLICE COME  
Event 6: TEACHER<sub>CL-i</sub>+CAR<sub>CL-i</sub> + PUT  
Event 7: AMBULANCE AMBULANCES<sub>CL-i</sub>+GO HOSPITAL  
Event 8: WE CLASS WORRY

'The teacher did not come to class today. He had a car accident on his way to the

night market yesterday. He was seriously wounded. He was taken to the hospital by the police officer. All our classmates are worried about him.'

In (13), the temporal locating adverb "TODAY" offers temporal reference for the event 1, and "YESTERDAY" evokes another temporal frame for following events to anchor the time. However, the interpretation of the event 8 does not fall within the temporal frame "YESTERDAY"; instead, it takes "TODAY" as its temporal reference. This example shows that our conclusion in section 3 needs to be adjusted or specified. Example (13) shows that the order of events does not obligatorily follow temporal sequence. Put it in another way, after evoking a temporal frame, the following events may not take this frame as temporal reference. To account the temporal relations within temporal frames, we adopt Segmented Discourse Representation Theory (SDRT) as the theoretical framework and take rhetorical relations into consideration.

SDRT is used to model discourse, and resorts to rhetorical relations to interpret discourse (Asher & Lascarides 2003). Rhetorical relation is also named as the discourse relations, (i.e., Narration, Contrast, Evaluation and so forth), which describe the rhetorical roles of utterances play in their discourse context (ibid. 3-4). Further, SDRT is developed to illustrate how rhetorical relations to capture the generalizations, such as temporal structure, individual anaphora, abstract entity anaphora, VP ellipsis, etc. In this paper, rhetorical relations will be adopted to illustrate the temporal relations. How do rhetorical relations correlate with temporal relations? As demonstrated in (14) and (15).

(14) Max fell. John helped him up.

(15) Max fell. John pushed him.

(Asher & Lascarides 2003:6)

In (14) and (15), these two examples have intuitively different temporal relations. In (14), the first event "Max fell" occurred before the second event "John helped him up"; in other words, the order of these two events obey temporal sequence. In (15), the first event "Max fell" happened after the literal preceding event "John pushed him"; that is, the second event signifies the cause of the literal first event. As far as rhetorical relations are concerned, sentence (14) belongs to narration, and sentence (15) is explanation. In brief, different rhetorical relations may involve different temporal relations which may result in events may not take closely preceding temporal adverb as temporal reference, as exemplified in (13).

SDRT is a kind of logical structure which is developed to formalize and represent

the rhetorical relations in the discourse. This theoretical framework contains two primary concepts. The first is the logic of informational content that refers to semantic structure is used to interpret discourse. The second is about the logic of information packaging which involves three concepts, i.e. the glue logic, discourse update, and discourse revision. In other words, the first concept refers to translate the clauses into semantic structure or so called glue language, and the second concept means that to establish the relations between clauses and package them together to interact with other events. To implement SDRT, we have to follow three steps: (1) to translate the clauses into the formula of glue language; (2) discourse update will attach the new information of a new clause to the current SDRS, and determines what kind of rhetorical relations link them together; (3) Maximize Discourse Coherence will be used to determine the best attachment site for the new coming information. To sum up, SDRT is a theory to model the discourse, and proposes several rhetorical relations to investigate the semantic interaction between clauses.

#### *4.2 Temporal relations in TSL*

This section selected one discourse to demonstrate how rhetorical relations affect temporal relation, as given in example (13). In (13), we find out that the event 8 does not take closely preceding temporal adverb "YESTERDAY" as temporal reference; instead, it takes "TODAY". Here, SDRT is employed to demonstrate the rhetorical relations between clauses of this discourse, and to figure out the reason, as given in (16) and (17).

In (16), the clauses are translated into semantic structures; further, the rhetorical relations between clauses are identified and packaged.<sup>4</sup> As indicated in (16), the event 3 and the event 4 have causality relations, and the events 5, 6, and 7 have narrative relations. Hence, the event 3-4 and the event 5-7 are packaged independently, and these two packaged units have narrative relations with each other. Furthermore, the information unit (event 3-7) offers the background information of the event 2; hence, they are packaged as an information unit (event 2-7) to have explaining relation with the event 1. Finally, the information unit (event 1-7) has causality relation with the event 8. The structure of rhetorical relation is demonstrated in (17). By indentifying the rhetorical relations of the clauses, we know that the temporal interpretation of the event 8 does not directly correlated to "YESTERDAY"; rather, the event 8 interact with the information unit (event1-7) and take "TODAY" as reference time.

---

<sup>4</sup> The symbol " $\pi$ " stands for event. The rhetorical relations are indicated by the terms in boldface.

(16)

$\pi_1$ : teacher'(x)  $\wedge$  school'(y)  $\wedge$  not\_go'(x, y)  $\subset$  today'

## 5. Concluding remarks

Like many other sign languages, TSL does not morphologically mark tense on verbs; instead, it mainly relies on temporal locating adverbs to express tense. Like spoken language, temporal locating adverbs will evoke temporal frames for following events to anchor the time until another new time reference is made. Unlike spoken language, TSL is significantly characterized by conceptualizing the temporal frame into the signing space. By structuring the signing space, signers are able to adjust direction or orientation of signs to associate with the locus where the temporal frame has been established instead of signing temporal adverbs repeatedly. Further, we demonstrate that the interaction between rhetorical relations, temporal relations and temporal relations, and prove that the rhetorical relations will affect time anchoring. The contribution of this study is to demonstrate the tense expression and the tense structure of visual-gestural languages, and points out some distinguished differences between oral-audio and visual-gestural languages. We hope those findings could assist the study of time in linguistics.

# Reported Speech in Russian and Italian: Verbs of Speech and Particles

Elizaveta Khachatryan

University of Oslo  
ILOS, PB1003 Blindern, 0315 Oslo, Norway  
elizaveta.khachatryan@ilos.uio.no

## Abstract

The present paper describes a well-known phenomenon: languages without a special grammatical category to transmit reported speech often do so by lexical means. The analysis focuses on the Russian particles *mol* and *deskat'*—formed from the Old Russian verbs of speech—and their Italian equivalents. Using the semantico-contextual approach, the description offered here helps to formulate the semantics of the two particles and to find their contextual equivalent in Italian: the verb *dire* (to say).

**Key-words:** semantic analysis, Russian particles, verbs of speech, Italian language.

## Introduction

In different languages there are various means of transmitting the words of others without assuming responsibility for what is said (Guentcheva 1996). Some languages have special grammatical categories for this; others use lexical means. This article focuses on Italian and Russian, neither of which has a special mood for this purpose. Grammars (in particular, Salvi & Vanelli 2004) point out that in Italian the conditional mood can be used with a reportative function. This is called the “journalistic” use, and it is widespread in the language of the mass media (see the first example below) and also appears in some expressions showing the disengagement of the speaker—i.e., *secondo lui* (in his opinion, according to someone [examples 2-4]).

- (1) Caduto l'aereo in Nuova Arizona. Il pilota sarebbe sopravvissuto.  
*A plane went down in New Arizona. The pilot [conditional mood, past tense] survived.*
- (2) E' stato trovato stamani in una zona impervia nei pressi del santuario delle Grazie, tra Zoagli e Chiavari, il corpo di Vincenzo Tagliasco, il docente di bioingegneria dell'università di Genova scomparso da venerdì. Secondo i primi rilievi dei carabinieri, il professore sarebbe morto per un colpo di arma da fuoco.  
*This morning in a solitary zone not far from the sanctuary delle Grazie, between Zoagli and Chiavari, the body of Vincenzo Tagliasco was found. The bioengineering professor of the University of Genoa has been missing since Friday. According to the first analysis of the carabinieri, the professor died [conditional mood, past tense] of a gunshot wound.*
- (3) Secondo una corrente teologica Maria si sarebbe addormentata.  
*According to one theological school Maria fell [conditional mood, past tense] asleep.*

- (4) Secondo il New York Times, sarebbe ormai guerra aperta tra USA ed Europa.  
*According to The New York Times, there is [conditional mood, past tense] an open war between the USA and Europe.*

In Russian there are two particles—*mol* and *deskat'*—that serve what could be defined as a reportative function. Dictionaries identify *mol* and *deskat'* as the textual markers of another speaker's words.

If the conditional mood in Italian and the Russian particles *mol* and *deskat'* have both the same (reportative) function, one can suppose that to translate the Russian particles one could use the conditional and vice versa. But in reality *mol* and *deskat'* never correspond to the Italian conditional.

The aim of the present article will be to discover the real role of *mol* and *deskat'* and the real equivalents of these two particles in Italian.

The methodology of this analysis is the semantico-contextual approach to the description of discourse markers elaborated by French and Russian linguists and based on Antoine Culioli's theory of enunciation (Culioli 1990).

Within the framework of this approach the particles considered as part of a larger group of discourse markers are described, like all linguistic units, across several regular formal properties that help to formulate their semantics. Among these regular properties there are the features of the scope, the position of the discourse marker, and the prosodic characteristics (Paillard 1999). In the present article we will analyze the features of the scope based upon which we can draw distinctions between two particles.

This approach is especially helpful for a contrastive analysis because it gives the same criteria for a description. The present analysis will offer a comparison of contexts of use of Russian particles *mol* and *deskat'*, and the contrastive description of Russian particles and their semantico-contextual counterpart(s) in Italian.

For this reason, the article is divided in two parts: the first part is dedicated to the analysis of the Russian particles *mol* and *deskat'*; in the second part, the Italian examples are analyzed.

## **1. Russian particles: *mol* and *deskat'***

### *1.1 Dictionary definitions*

Dictionaries usually define *mol* and *deskat'* as completely synonymous particles whose role is to transmit the discourse of another in the text or to mark words in the text as those of another speaker (Slovar' russkogo jazyka v 4 tomax, Bol'shoj slovar' russkogo jazyka).

But in spite of this similarity, a closer look reveals that the two particles are not interchangeable in all contexts. In general, it is easier to replace *deskat'* with *mol* than *vice versa*. (One reason for this could be the form itself of *mol*: it has properties of a clitic and is easier to connect with other words. However, we will see below that the other reason is the semantics of *mol*.) The use of *mol* is more widespread than that of *deskat'*, which is often considered by native speakers to be antiquated and inadequate for use in the modern language. An analysis of written journalistic language found a

more frequent use of *mol* than *deskat'*. At the same time in the corpus that we used (Russian Corpora in Tübingen) a large amount of occurrences of *deskat'* was found.<sup>1</sup> In examples (5) and (6) below, the particle *deskat'* is used, but it can not be replaced by *mol*.

- (5) “My predložili,-pišut oni,-real'no perevesti masterskuju na polnyj xozrassčet (poka on u nas bumažnyj, no podderžki tak i ne polučili. Vydvigaetsja somnitel'nyj argument : **deskat'** my k etomu ešče ne gotovy”.

*We proposed,-they write,-to put the enterprise on a self-supporting basis. But we didn't get any support. A doubtful argument is adduced: **deskat'**, we are not ready for it.*

- (6) Vosem'desjat pjat' funtov. Tanja odelila dva samyx zamygannyx pjatifuntovika, vložila obratno, usmexnulas'—**deskat'**, čto vy, nikakogo maroderstva ne imelo mesta.

*Eighty-five pounds. Tanja peeled off the two most bedraggled bills, put them back in the wallet, and grinned: **deskat'**, what are you talking about? There wasn't any looting.*

The difference between the two particles can be explained by their semantics, which can be formulated based upon formal features, and especially on the description of the scope, i.e., the part of the enunciation that changes its discourse status under the influence of a discourse marker or a particle.

For the present description it will be useful to distinguish between two positions: that of the first speaker (who describes the situation—we will call him the narrator)<sup>2</sup>—and that of the second speaker (who constructs the enunciation in a described situation—we will call him the speaker). The narrator can also be speaker if he transmits his own words that were said in the described situation.

## 1.2 Analysis of the scope

The scope of both particles has the form of a proposition P that can be an independent phrase or a part of a complex phrase (subordinated or juxtaposed). In both cases P as a scope of the particle (*mol* or *deskat'*) has the status of words that don't belong to the speaker: these are words of the other. In examples (7) and (8) the scope of both particles has the form of an independent phrase.

- (7) ... a novaja žena, Marta, samoljubivaja ženščina, Galočku znat' ne želaet i ee, Evdokiju Nilovnu videt' ne xočet , nikogda sjuda ne priedet , pis'ma ne prišlet i Nikolaju Demjanoviču priezžat' zapreščaet. Den'gi, **mol**, posylaj, a bol'se ničego.

*... and the new wife, Marta, a proud woman, doesn't want to know anything about Galočka, and doesn't want to see her, Evdokija Nilovna. She'll never come here or send a letter, and she forbids Nikolaj Demjanovič to come. Send, **mol**, the money, and nothing else.*

- (8) Teper' Mana svobodna ot splava. I ožila malost' rečenka. Xariusy objavilis'. No skol'ko ja iz-za togo vragov našil! Ot raboty, **deskat'**, odnosel'čan uvel. Rabota xorošim rukam zavsegda syščetsja. I čto za rabota, esli vsem vo vred ?!  
*Now the river Mana breaks free from the float and livens up a bit. The umbers turned back. But how many enemies I've made! You've caused, **deskat'**, the men from your village to lose their jobs. Those with good hands will always find work. And what is the sense of a job that's done at everyone else's expense?*

In example (7), *mol* P is inserted in a narrative that reports the account of Evdokija Nilovna: it is not a first person account from Evdokija Nilovna's perspective (cf. the use of the pronoun *ee*—her—to refer to Evdokija Nilovna); rather, P reproduces the words of the new wife (the speaker) transmitted by the narrator (Evdokija Nilovna). In example (8), *deskat'* introduces the words of the enemies of the narrator. The enemies constitute the speaker, and P is an argument against the actions of the narrator.

If P is part of a complex phrase, it has the form of a subordinate phrase (examples 13 and 14) or of a juxtaposed phrase (examples 9-12). Formally it can be considered indirect speech. In this case the particle and its scope can be preceded not only by verbs of speech (*verba dicendi*) (9) or by nouns describing the act of the communication or the process of thinking (*razgovory, ideja, mysl', argument*—conversation, idea, thought, argument, etc.) (12), but also by verbs of emotion or verbs describing gesture (10) and action (11).

- (9) Večerom volk i medved' prišli k izbuške lisy i sxoronilis'. /.../ Vdrug vidjat bežit zajats. Pozvali oni ego i govorjat : Ty, zajats, na nogu skor, sbegaj k lise, skaži, **mol**, medved' i volk uže prišli.  
*In the evening the wolf and the bear came to the fox's house and hid themselves. Suddenly, they saw a hare running past. They summoned him and said: You, hare, run as fast as you can to the fox and tell him, **mol**, the bear and the wolf have already arrived.*
- (10) - Vidiš' li, ja očen' staryj,-skazal Enen, ševelja vekoj. (Devočka kivnula: **mol**, vižu.)  
*You see, I am very old,—said Ehnen moving an eyelid. The girl nodded her head: **mol**, I see.*
- (11) A supruga ego, očen' počtennaja dama, prosto daže prirevnovala pirata k Korovjevu i daže ložečkoj postučala ... i čto ž eto, **deskat'**, nas zaderživajut ... Pora i moroženoe podavat'!  
*And his wife, a very respectable lady, was even jealous of Koroviev on account of the pirate and even banged a teaspoon... so what's the big idea, **deskat'**, what's holding us up? It's high time they served us our ice cream!*
- (12) “My predložili,-pišut oni,-real'no perevesti masterskuju na polnyj xozrasčet (poka on u nas bumažnyj), no podderžki tak i ne polučili. Vydvigaetsja somnitel'nyj argument: **deskat'** my k etomu ešče ne gotovy”.

*We proposed, –they write, –transferring the enterprise to a self-supporting basis. But we didn't get any support. A questionable argument is adduced: **deskat'**, we are not ready for it.*

In spite of the formal status of the indirect speech, the syntax (word order, syntactical constructions) and the vocabulary of the scope P are typical of the spoken language. From this point of view P can be characterized as direct speech.

- (13) *Vjalo pjaljus' na nego, on prinimaet moju len' za šok i krajne emotsional'no, sotrjasaja moi pleči, načinaet objasnjat', čto on, **deskat'**, ne možet vylovit' menja vtoroj den'.*

*I stare at him inertly, he takes my inertia for shock and very emotionally, shaking my shoulders, starts to explain to me, that he, **deskat'**, has been unable to fish me out for two days.*

- (14) *V svoe vremja bylo nemalo razgovorov po povodu togo, čto vot, **mol**, u amerikantsev est' "čelnoki", a u Sovetskogo Sojuza net. Značit, delalsja vyvod, amerikantsy vperedi v kosmičeskoj gonke.*

*Once there were many conversations to the effect that, **mol**, the Americans have space shuttles and the Soviet Union does not. In other words, it was inferred that the Americans are leading in the space race.*

In example (13), a spoken, emotionally colored verb (*vylovit'*–to fish out) is used; in (14), the whole construction (*vot u amerikantsev*–now in the case of the Americans; verbatim: there are the Americans) is typical of the spoken language: the demonstrative pronoun *vot* (there are) situates the phrase in the coordinate system of “hic et nunc,” in spite of the past tense of the principal phrase.

In particular, the deictic elements used in the scope P represent a distinct point of view. In example (10), the verb *vižu* (I see) has the form of the first person singular that corresponds to the subject of the phrase (*devočka*–a girl). The same thing can be observed in examples (11) and (12): the person presented in the scope–first person plural *nas* (us) in (11), and *my* (we) in (12)–indicates the subject of the phrase introduced before by a pronoun of the third person.

### *1.3 Semantic properties of mol and deskat'*

Based on the properties of the use of the deictic elements, we can formulate the differences between *mol* and *deskat'*.

*Mol* introduces the words of the speaker (or of the presumed speaker). In (9), the narrator (the bear and the wolf) are addressing the hare, and the phrase introduced by *mol* corresponds to the words that will be said by the hare. In (10), the narrator who describes the whole situation interprets the gesture of the girl nodding her head; *vižu* (I see) is the girl's reply. In the two examples below, we can see the same phenomenon: in (15), *on* (he) becomes *ja* (I) in the proposition introduced by *mol*; in (16), *firmy SŠA* (US firms) correspond to *my* (we).

- (15) I vot teper' v pis'me, po forme-objasnitel'noj zapiske na imja pervogo sekretarja obkoma, on sglazhival ugly: voobšče, **mol**, etu istoriju s Safronovym ja ploxo znaju.

*And now, in his letter, styled as an accusatory letter addressed to the first secretary of the regional committee, he was trying to tone things down: actually, **mol**, I don't know much about what's happened with Safronov.*

- (16) Firmy SŠA pytalis' v oblasti biotexnologii nekij čut' li ne diktat ustanovit': **mol**, my pervye vse otkryli /.../

*The US biotech firms were trying to pretty much take over: **mol**, we were the first to discover everything.*

The scope of *deskat'* does not always correspond to the words pronounced by the speaker. This is evident if we examine the use of pronouns more closely. In (12), a questionable argument is adduced by somebody else (the speaker is referred to in the passive voice), but in the proposition itself introduced by *deskat'*, the first person plural is used which corresponds to the person of the narrator (*my predložili*—we proposed): otherwise, *vy* (second person plural) would be used here. In (13), we find the same principle: *on* (he—third person masculine singular) indicates the speaker (*on* in the previous context: he starts to explain to me), while *menja* (me—first person singular) indicates the narrator. In (17), we can see the same phenomenon: the pronoun *mne* (to me—first person singular) in the scope of *deskat'* indicates the narrator who tells the story:

- (17) ...polučiv neprivyčnyj otpor, vosplamenilsja, oral, est', **deskat'**, v Permskoj oblasti kolhoz-millioner, tam by izbu mne dali besplatno...

*... after he had received an unexpected rebuff, he started to howl, there is, **deskat'**, in the region of Perm', a kolkhoz-millionaire, there they would give me a house for free...*

A hypothesis concerning the semantics of both particles was proposed by Denis Paillard (Paillard in press) and is based on these properties of the use of deictic elements, pronouns in particular. *Mol* shows that P is an almost exact reproduction of what was said by the speaker (Sx—in the terminology of Paillard). *Deskat'* shows that P is an interpretation-translation proposed by the narrator of what was said by the speaker. In this case, there is no guarantee that what is said coincides with the original message: P corresponds to the narrator's perspective.

This description could explain the stylistic differences between both particles. *Mol* is used in journalistic discourse; it often accompanies a quotation and is used with set expressions often introduced as a quotation. *Deskat'* marks a stronger link with the context: its scope is incorporated in the context (constructed by the narrator) and is presented as an argument within the development of the context. In (18), the scope of *deskat'* corresponds to the eventual words of the parents (the speaker) introduced by the narrator to clarify what has been said before: ... *told me, that they had spent a lot during holiday and that there would be little left for a birthday party for me.*

- (18) V kontse avgusta my vozvraščalis' s juga, i roditeli každyj raz čestno predupreždali, čto potratilis' na otdyxe i na prazdnovanie deneg počti ne ostalos'. **Deskat'**, osobyx raznosolov, Dima, ne budet.

*At the end of August we would usually return from the sea, and my parents would tell me that they had spent a lot during the holiday and that there would be little left for a birthday party for me. Deskat', there won't be any delicacies, Dima.*

These semantic differences can be explained by the semantics of the verbs that are the origin of both particles. *Mol* derives from the verb *molvit'* (to pronounce), and *deskat'* is the combination of two verbs: *deet'* (*дѣемь*)—the old equivalent of the modern *govorit'*—(to say) + *skazati* (*сказати*) (to say, to talk) (Vasmer, 1950-58).

These three verbs are the verbs of speech in the semantics of which the three components of the communication are included: the participants of the communication (speaker // hearer) that are trying to transmit their own representation of the world using the words.<sup>3</sup>

*Govorit'* (in Old Russian *deet'*) and *molvit'* describe the situation from the point of view of the speaker. The verb *molvit'* designs the speaking activity: a speaker uses words to present his own representation of the world. *Govorit'* describes the process of the addressed speech: the speaker exteriorizes his own representation of the world and transmits it to the hearer.

The semantics of *skazat'* is concentrated on the opposite side of this communication schema: on the hearer's possible interpretation based on the words pronounced by the speaker. *Skažu tebe neprijatnuju novost'* (I'll tell you the unpleasant news)—the news is called unpleasant from the point of view of the hearer (i.e., the news is unpleasant for the hearer). Another example: the expression *Skaži pravdu* (Tell me the truth) is often used during an interrogation where the speaker (who will become the hearer) is the person who knows the truth and is waiting for the confession. Otherwise the verb *govorit'* is used (*Govori pravdu*. —You have to say the truth).<sup>4</sup>

The semantics of both Russian particles reproduces the schema of the communication but involves different parts of it (speaker vs hearer), depending upon the semantics of the particular verb that forms the particle. A case in point is the above example illustrating an essential difference between *skazat'* and *govorit'*.

## 2. Italian equivalents

To create the collection of Italian examples used in this analysis, first of all the Russian words and constructions that generally precede the Russian particles were distinguished. All the constructions can be classified in different semantic groups: verbs of speech (e.g., *skazat'*, *rasskazyvat'*—to say, to talk, to narrate) and nouns describing communication in general (e.g., *razgovor*, *reč'*, *rasskaz*—conversation, discourse, account); words and expressions describing the emotional state of the speaker (e.g., *ulybat'sja*, *smejat'sja*—to smile, to laugh) or describing gestures and mimics (e.g., *pokazyvat'*, *kivat'*—to indicate, to nod). The common feature of all these groups is the presence of two participants (at least) in the situation that is described.

After that the Italian equivalents of Russian constructions were determined. In the created collection of examples<sup>5</sup> the phrases following the words and constructions that had been identified was then analyzed. Two main properties were discovered: the use of punctuation marks (dashes, inverted commas), and the use of the verb *dire* (to say).

- (1) Paola non risponde ; poi nota il mio stupore e sorride – Certo che no! Che domande!  
*Paola didn't respond, then she noticed my surprise and smiled–Of course not! What a question!*
- (2) Davvero? Tutti appassionati archeologi?! – Leila ride - Non lo so. Di sicuro, sono tipi un po' strani.  
*Really? All of them have a passion for archeology?!–Leila laughed–I don't know. But surely, they are strange people.*

In examples (1) and (2), the words introduced after the dash correspond to the interpretation, given by the narrator, of the smile (1) or of the laugh (2) of the other participant in the communication. In the context, nothing tells us that these are the speaker's real words.

In (3), the verb *telefonare* (to call), presupposes that somebody is speaking and indicates that these actual words, introduced by the expression *per dire* ([in order] to say), were pronounced. This case could correspond to the use of the particle *mol*. It is interesting to notice that with Italian verbs of speech the use of the verb *dire* is almost obligatory (Govorukho, 2006).

- (3) Operatori finanziari hanno telefonato alla Banca d'Italia per dire: “Avevate ragione voi e torto la Bundesbank.”  
*Finacial operators called the Bank of Italy to say: “You were right and the Bundesbank was wrong.”*

In examples (4) and (5), the expression *come per dire* (as if to say) marks the sentence that follows as a possible interpretation of the action (4) and of the gesture (5) of the other participant in the communication.

- (4) Ti fanno sentire un perdente e poi ti umiliano appena possono, quasi **come per dire**: dovete vivere la vostra adolescenza in modo brutale come noi.  
*They make you feel like a loser and then they humiliate as soon as they can, as if to say: you have to live your adolescence in a brutal way, as we did.*
- (5) Per proteggerti.–Indicando Eric con un cenno della testa, **come per dire**: per proteggerti da lui.  
*To protect you.–He indicated Eric with a nod, as if to say: to protect you from him.*

In (6) and (7), a correspondence between a gesture (a nod) and the words is created by the narrator: in other words, the gesture is interpreted by the narrator.

- (6) C'è una sosta in uno spiazzo con baracca ristorante. Il vecchio fa cenno **per dire** che posso scendere tranquillo.  
*There is a rest stop with a small restaurant. The old man made a sign to say that I didn't need to worry and I could go down.*
- (7) Fa un cenno al tipo atticciano **per dire** va bene.  
*He nodded to the stocky guy as if to say it's OK.*

The results of this analysis were checked against literary translations into Italian. Passages were chosen in which *mol* or *deskat'* appeared in the original Russian text. In the majority of cases the verb *dire* is used in the translation.

- (8) Berlioz totčas soobrazil, čto sleduet delat'. Otkinuvšis' na spinku skamji, on za spinoju professora zamigal Bezdnomnomu ne protivoreč', **mol**, emu, no rasterjavšijsja poet etix signalov ne ponjal.

*Berlioz understood immediately what was the best thing to do. Leaning back on the bench, behind the back of the professor he began winking at Bezdomyj: don't contradict him, mol, but the poet was confused and didn't understand him.*

Berlioz capì subito quello che conveniva fare. Addossandosi allo schienale della panchina, ammiccò a Bezdomyj dietro le spalle del professore, **come a dire**: non contraddirlo; ma il poeta, smarrito, non capì quei segnali.

Italian translation: *come a dire* (as if to say).

- (9) Publika volnovalas', no idti na stsenu poka nikto ne rešalsja. No nakonets kakaja-to brjunetka vyšla iz desjatogo rjada partera i, ulybajas' tak, čto ej, **mol**, rešitel'no vse ravno i v obščem naplevat', prošla i po bokovomu trapu podnjalas' na stsenu.

*The public was excited, but nobody dared to go out onto the stage. But finally a dark-haired woman emerged from the tenth row of the stalls and smiled: mol, it was really all the same to her and, in fact, she couldn't care less. Then she took the side stairs onto the stage.*

Il pubblico era emozionato, ma nessuno ancora si decideva a salire sul palcoscenico. Finalmente una brunetta uscì dalla decima fila di platea e, sorridendo, **quasi a dire** che a lei non importava niente e se ne fregava, avanzò e salì sul proscenio per la scaletta laterale.

Italian translation: *quasi a dire* (as if to say).

- (10) A supruga ego, očen' počtennaja dama, prosto daže prirevnovala pirata k Korovjevu i daže ložečkoj postučala ... i čto ž eto, **deskat'**, nas zaderživajut ... Pora i moroženoje podavat'!

*And his wife, a very respectable lady, was even jealous of Koroviev on account of the pirate and banged a teaspoon...so what's the big idea, deskat', what's holding us up...? It's high time they served us our ice cream!*

La sua consorte, una signora rispettabilissima, divenne addirittura gelosa delle premure che il pirata dimostrava per Koroviev, e picchiettò perfino col cucchiaino, **come a dire**: perché ci fanno aspettare?... Sarebbe ora di servire il gelato.

Italian translation: *come a dire* (as if to say).

In (8), the particle *mol* introduces the interpretation of the speaker's gesture (a wink); in (9), the emotional verb to smile is followed by the particle *mol* and its scope; in (10), an action (banging a teaspoon) is interpreted by a speech act. The Italian translation of all of these examples includes the verb *dire* (say).

## Conclusion

The Italian verb of speech *dire* can be considered the equivalent of the Russian particles of reported speech. It is possible to speak about a universal process of grammaticalization: the verbs of speech become marks of reported speech. The formal approach proposed here points to the particular (almost grammaticalized) use of the verb *dire* after words and expressions in which semantics presupposes the inclusion of two participants within the communicative situation.

---

<sup>1</sup> Since the present analysis describes the modern state of the language we used two parts of the Russian Corpora in Tübingen: the Contemporary Corpora which includes literary and press contents and the Corpus based on 20th century literature.

<sup>2</sup> Often there is also the real narrator—the voice of the author, as in (7), for example. But for this description of particles, his position is not important.

<sup>3</sup> The basis of this description is the vision of communication proposed by Culioli (Culioli 2002), in which, in contrast to pragmatic theories, the speaker does not have the decisive position in the communication. In the construction of the enunciation three elements collaborate: words - world - speaker. There is no direct link between an object of the world and the words. That is why there are different ways to say the same thing and the same word can be interpreted in different ways. The world is accessible through the words, but they transmit only the representation of the world that belongs to the speaker. The following schema represents the process of the communication: So (R') – words – S1 (R). So corresponds to the speaker and his representation (R') of the world which he tries to transmit by the words. S1 – the hearer – interprets the words and gets a representation (R) of the world which does not always correspond to the representation of the speaker.

<sup>4</sup> For a more detailed analysis, see Elizaveta Khachatryan (2006).

<sup>5</sup> For this purpose we used the Italian corpus (Coris/Codis) created at the University of Bologna which includes the texts of different genres of 20<sup>th</sup> century literature.

# On the Difference in Existential Meaning of Two Aspectual Markers in Modern Korean: the Relation between *-ko iss-*, *-e iss-* and the Existence verb *iss-*.

Kim, Kyung-Ae

Graduate School of Letters, Kyoto University

[kyungae@hotmail.co.jp](mailto:kyungae@hotmail.co.jp)

## Abstract

It has traditionally been assumed that Korean durative marker *-ko iss-* represents progressives in suffixing to durative verbs.<sup>1</sup> In addition to the aspectual meaning, however, *-ko iss-* also has the existential meaning. For example, the sequence '*nol-ko iss-*' (*nol-* 'to play') expresses action in progress in the aspectual type and the existence of the subject-in-the-act-of-playing in the existential type. These two types behave differently: the existential type has properties quite similar to the existential sentence of existence verb *iss-* i.e., the type of locative NPs, unmarked word orders, etc., while the aspectual type does not.

This existential *-ko iss-*, however, differs from the existential *-e iss-*, which is also an 'aspectual' marker, or from the existential verb *iss-* in the restrictions.

**Keyword:** durative marker *-ko iss-* and *-e iss-*, existential type, aspectual type, existential verb *iss-*

## 1. Introduction

Modern Korean has two durative markers, *-ko iss-* and *-e iss-*. The two forms consist of the nonfinite connective *-ko* and *-e*, plus the verb of existence *iss-*. It has generally been assumed that they represent various aspectual meaning depending on the aspectual properties of the verbs they are attached to: *-ko iss-* is attached to activity and accomplishment verbs and represents progressive meaning as in (1), and *-e iss-* is attached to achievement verbs and represents a resultant state as in (2).

(1) a. *yengi-ka talli-ko iss-ta.*

Yengi-Nom run-KO ISS-Decl

---

<sup>1</sup> Durative verbs such as *talli-* 'to run' or *cis-* 'to build'. And in fact it represents resultant states when it suffixes to state-maintenance verbs as *ip-* 'to wear'.

“Yengi (A person`s name) is running. ”

b. yengi-ka pap-ul mek-**ko iss-ta**.  
Yengi-Nom meal-Acc eat-KO ISS-Decl  
“Yengi is having a meal. ”

(2) a. kenmwul-i pwusecy-**e iss-ta**.  
construction-Nom collapse-E ISS-Decl  
“A/ The building in a collapsed state”  
b. kkochoyeng-i kkaycy-**e iss-ta**.  
Vase-Nom broke-E ISS-Decl  
“A/ The vase is broken”

In previous studies it has been said that the meaning of *-ko iss-* and *-e iss-*, i.e., progressive and resultant state, is fully determined by the inherent aspectual values of the verbs or verb phrases to which they are attached.

I show in this paper that it is the meaning of *iss-* that decides the interpretation of these forms. In the other words, regardless of the aspectual values of the VPs it is attached, *-ko iss-* is ambiguous between two kinds of sentence types, the aspectual type and the existential type, whereas for *-e iss-* only the existential type is possible.

For aspectual *-ko iss-*, its meaning is dependent on the inherent aspectual values of the verbs or verb phrases to which they are attached to, and they function as auxiliary verbs, representing progressive or resultant state. Existential *-ko iss-*, I argue represents the existence of subjects regardless of the aspectual properties of the preceding VPs and *iss-* in existential *-ko iss-* is functions as a main verb of the sentence. By contrast, the interpretation of *-e iss-* is existential regardless of the preceding verbs because *iss-* in *-e iss-* is always interpreted as the main verb for existential construction, and not as the aspectual auxiliary verb.

In the aspectual type (3a), *nol-* ‘to play’ is the main verb and *-ko iss-* functions as an aspectual auxiliary. In contrast, in the existential type (3b) *iss-* is the main verb and *-ko* modifies *iss-*, representing a kind of manner of existence. For *-e iss-*, as noted above, aspectual type (4a) is not permitted, so only the existential interpretation (4b) is possible.

(3) a. [ai-ka nol-][**ko iss-ta**.] ( the aspectual type)  
child-Nom play-KO ISS-Decl

“A/ The child is playing”

b. ai-ka [nol-ko] iss-ta. ( the existential type)

child-Nom play-KO ISS-Decl

“There is a child playing”

(4) a. \*[elum-i nok-][e iss-ta.] ( the existential type)

ice-Nom melt-E ISS-Decl

b. elum-i [nok-e] iss-ta.

ice-Nom melt-E ISS-Decl

“There is ice melted”

This paper is organized as follows. Section 2 offers a brief overview of the Korean *-ko iss-*, *-e iss-* and their grammatical meaning. In section 3, I will give evidence that supports the ‘Existential’ meaning of the Korean durative form *-ko iss-*, *-e iss-* and proposes a hypothesis as to how the ‘Existential’ meaning has arisen from durative and is currently on its way to full grammaticalization. Section 4 concludes the paper.

## 2. Previous Analyses

Here I review two studies that dealt with the meaning of <iss-> of <-ko iss-> and <-e iss->.

Lee (1998) deals with the syntactic and semantic functions of these two durative forms. She analyzes the functions of <-ko iss-> and <-e iss-> from their co-occurrence with *NP-ey* phrases. She observes that *-ko* and *iss-* used with transitive verbs of change-of-state, e.g. *ip-ta* ‘to wear’ and *sin-ta* ‘to wear’ can be separated by a locative phrase *NP-ey* (e.g. *VP-ko NP-ey iss-ta*), and claims that both V and *iss-* are functioning as main verbs, concatenated by a connective *-ko*, representing perfect meaning. <-ko iss-> with activity verbs cannot be separated by *NP-ey* phrase as (*chwum-ul*) *chwu-ta* ‘dance’ and (*pap-ul*) *mek-ta* ‘to eat meals’ (e.g. *pap-ul mek-ko NP-ey iss-ta*), and here *iss-*’s are the part of subsidiary verbs to represent progressive meaning.

Next she discusses <-e iss-> sentences. <-e iss->, which suffixes only to intransitive verbs of change -of-state, represents perfect meaning regardless of the separability.

Lee assumes like in previous studies, that the meanings of <-ko iss-> and <-e

iss-> are determined depending on the aspectual meaning of the verbs: when the main verb represents change of state, <-ko iss-> and <-e iss-> have a perfect interpretation, and when the main verb doesn't represent some change of state, <-ko iss-> has a progressive interpretation.

- V [+change] - ko iss-ta ----- separable with NP- ey ----- perfect meaning
- V [+change] - e iss-ta ----- ???-----perfective meaning
- V [-change] - ko iss-ta -----inseparable with NP-ey ---- progressive meaning
- V [-change] - e iss-ta -----ungrammatical

In this paper, I will show below that it is the meaning of <iss-> in <-ko iss-> and <-e iss-> and the two types of constructions it goes into that determines the interpretation of these forms, I argue that <-ko iss-> construction has two types, one is the existential type whose main verb is <iss->, and the other is the aspectual type, where <iss-> functions as an auxiliary verb, there are always two types of <-ko iss-> constructions regardless of the meaning of verbs. I show that activity verbs such as *talli-* 'to run' or (*pap-ul*) *mek-* 'to eat (meal)' can have two types of <-ko iss-> constructions contra Lee (ibid).

Ahn and Fukushima (2001) analyze <-ko iss-> and <-e iss-> constructions in terms of grammaticalization. They argue that for *-te iru* and *-te aru* at the end of Middle Japanese and <-ko iss->, <-e iss-> in Modern Korean, the meanings of the existential verb *iru, aru / iss-ta* affect them relatively strong and less grammatical comparing with *-te iru* in Modern Japanese. They argue for the existential <-ko iss-> and <-e iss-> in Korean, showing the following set evidences; (1) <-e iss-> always needs a *NP-ey* locative phrase as a semi-obligatory argument, (2) <-ko iss-> co-occurs with a *NP-ey* locative even when there is an *NP-eyse* locative, (3) verbs which do not take *NP-ey* locative arguments such as *po-* 'to see' or *masi-* 'to drink' can take them as arguments in the <-ko iss-> constructions.

Ahn and Fukushima (ibid.) don't discriminate between two types of <-ko iss-> constructions, which I will show in Section 3. Moreover, they don't give the detailed explanation about the interpretations of <-ko iss-> and <-e iss-> themselves, so it is not certain from Ahn and Fukushima (2001) about the relation with the meaning of progressive <-ko iss-> and resultant state <-e iss-> which earlier literatures mentioned, or about the differences between the interpretations with *NP-ey* and *NP-eyse* locatives.

### 3. Proposal: Two *-ko iss-* and one *-e iss-*

### 3.1 *-e iss-* expressing existence of entity

In this section, we will examine the properties of these two constructions, and show that the *-ko iss-* construction has two interpretations, aspectual type and existential type, whereas *-e iss-* has only one interpretation, the existential type.

Firstly, for *-e iss-* to be used the object referred to by the subject noun must exist in the context.

- (8) a. *cungke-ka epseci-ko iss-ta.*  
evidence-Nom disappear-KO ISS-Decl  
“The evidence is disappearing.”  
b. \**cungke-ka epseci-e iss-ta.*

( Kim 2006 : 24-25)

(8a) can be used, because *cungke* exists in the location of utterance, whereas (8b) cannot because the resultant state of *epseci-e iss* represents the absence of the subject in the location. *E iss-*, thus, cannot be used to express the absence of the subject as shown by the unacceptability of (8b). The fact *-e iss-* cannot express non-existence can also be seen in the following example.

- (9) ?? *nayngcangko-ey tulai-aisu-ka nok-a iss-ta.*  
refrigerator-Loc **dry\_ice** -Nom melt-E ISS-Decl  
“(Lit.) There is dry ice melted in the refrigerator”

- (10) *nayngcangko-eyse tulai-aisu-ka nok-ass-ta. (PAST)*  
refrigerator-Loc **dry\_ice** -Nom melt-PAST-Decl  
“(Lit.) Dry ice has melted in the refrigerator”

Dry ice disappears after evaporating (as its name suggests), so we cannot use *-e iss-*. The past form *-ess-* must be used in such a case. The constraint can be accounted for, as argued for in Kim (2006), if we assume that *iss-ta* denotes existence in *-e iss-*.

I will show that the *-ko iss-* construction expresses either the existential as well as the progressive (aspectual) meaning, as opposed to *-e iss-*. Korean has the two locative markers, that is *-ey* and *-eyse*. *-ey* expresses the location of an object and *-eyse* the location of an event as can be seen in (11) (cf. Sin 2002, Nam 1993, among others).

- (11) a. *chayksang-wi-[ey/\*eyse]*    *chayk-i*            **iss-ta.**  
           desk-on-Loc                    book-Nom            be-Decl  
           “There’s a book on the desk.”
- b. *hoyuysil-[eyse/\*ey]*            *hoyuy-ka*            **iss-ta.**  
           meeting\_room-Loc            meeting-Nom        be-Decl  
           “‘We have a meeting at the meeting room.’”

In (11a), *chayksang-wi-ey* ‘on the desk’ denotes the place of the subject *chayk* ‘book’, and in (11b), *hoyuysil-eyse* ‘at the conference room’ denotes the location where the subject event *hoyuy* ‘meeting’.

The fact that *-ko iss-* can co-occur both with *-ey* and *-eyse* shows that *iss-* in *-ko iss-* can refer to both the location of an event and that of an object. In (12), for example, *iss-ta* can express the existence of the event of a child playing or that of a child in the park.

- (12) a. *nolithe-an-[eyse/ ey]*    *elin ai-ka*    *honacase*            **nol-ko iss-ess-ta.**  
           playground-in-eyse/-ey child-Nom    alone            play-KO ISS-Past-Decl  
           “A/ The child was playing in the playground.”

In contrast, since *iss-ta* in *-e iss-ta* denotes existence of the subject NP and not that of an event *-eyse* is unacceptable, as shown in (13).

- b. *nayngcangko-[\*eyse/ ey]*    *aisukhulim-ka*    *nok-a iss-ta.*  
           refrigerator-eyse/ ey        ice\_cream-Nom    melt-E    ISS-Decl  
           “‘There’s a melted ice cream in the refrigerator.’”

Thirdly, as noted in Kim (2007) noted that interpretation of existence is related to word order in sentences with *-ko iss-*. Kuno (1973) assumes that LSV is the basic word order of existential sentences in Japanese. His assumption also applies to Korean, a fact that indicates that *-ko iss-ta* can be a locative sentence with *iss-ta* as an existential main verb.

- (13) a. (?) *nolithe-ey*            *ai-ka*            **nol-ko iss-ta.**  
           playground -ey            child-Nom        play-KO ISS-Decl  
           “‘There’s a child in playing at the playground.’”
- b. ?? *ai-ka*            *nolithe-ey*        **nol-ko iss-ta.**  
           child-Nom            playground -ey    play-KO ISS-Decl

“The nervous girl danced on the stage.”

c. hakkyo-kwunay siktang-an-[eyse /\*ey] yengi-ka honcase cemsim-ul  
 school-campus dining\_room- eyse/ey -Nom alone lunch-Acc  
 mek-  $\phi$  -ess-ta.  
 eat-  $\phi$  -Past-Decl

“At the dining hall Yengi had lunch alone.”

-eyse-, in contrast can be used regardless of whether -ko iss- is attached to the verb or not.

(16) a. kyosil-an-ey swuhak-sensayngnim-i

b. kyosil-an-ey haksayng-tul-i kongchayk-ey philki-ha-ko iss-ess-ta.

classroom-in-ey student-PI-Nom notebook-ey write-KO ISS-Past-Decl

“**In the classroom** the students were writing **on their notebooks.**”

(17) a. \*kyosil-an-ey swuhak-sensayngnim-i chilphan-ey

classroom-in-ey mathematic-taecher-Nom blackboard-ey

yensup-mwuncey-lul phwul-  $\phi$  -ess-ta.

exercise -Acc solve-  $\phi$  -Past-Decl

b. \*kyosil-an-ey haksayng-tul-i kongchayk-ey philki-lul ha-  $\phi$  -ess-ta.

classroom-in-ey student-PI-Nom notebook-ey write-KO ISS-Past-Decl

The fact indicates that NP-ey is licensed by iss- of -ko iss- and not by preceding verbs.

### 3. 3 Proposal: Existential type of -ko iss- and Existential verb iss-

In sentences with -ko iss-, the aspectual progressive interpretation is preferred to the existential interpretation. In fact, some restrictions are imposed only on the existential type of the -ko iss- construction. In this subsection, I will examine some restrictions on the existential type, and why such restrictions exist by showing its

- b. namwu-**eyse** swi-eyo.  
 tree rest-Decl “She’s taking a rest at the tree.”
- c. ?\*namwu-**ey** **iss**-eyo.  
 tree -ey be-Decl “She’s at the tree.”
- d. namwu-**aph-ey** iss-eyo.  
 -front-ey be-Decl “She’s in front of the tree.”

- (22) a. Question: yengi cikum eti-**ey** **iss**-ni? “Where is Yengi now?”
- b. hyenkwanmwun-**eyse** kitaly-eyo.  
 front\_door -eyse waite-Decl “She’s waiting at the front door.”
- c. ??hyenkwanmwun-**ey** iss-eyo.  
 front\_door-ey be-Decl “She’s at the front door.”
- d. hyenkwanmwun-**aph-ey** iss-eyo.  
 front\_door-front-ey be-Decl “She’s in front of the front door.”

The existential meaning of the *-ko iss-* construction appears ‘weaker’ in that it does not have the full-fledged distribution of existential *iss-* used independently.

- (23) a. kyosil-**ey** yengi-ka iss-eyo.  
 classroom-ey -Nom be-Decl  
 “Yengi is in the classroom.”
- b. ?kyosil-**ey** yengi-ka kongpwu-lul ha-**ko** **iss**-eyo.  
 study -Acc do-KO ISS-Decl
- c. kyosil **aph-cali-ey** yengi-ka kongpwu-lul ha-**ko** **iss**-eyo.  
 front-seat-ey -Nom study -Acc do-KO ISS-Decl

In (23a), a simple existential sentence is completely acceptable without location-specifying words such as *mith* or *aph*, (23b), an existential type of *-ko iss-*, sound a little odd, and must be reinforced by some location-specifying word.

Although *-ko iss-* sentences with *-ey* are not full-fledged existential sentences, they can be made more acceptable by adding more information about the subject and the location, i.e. emphasizing the existence of the subjects and the locations. Consider first, the example (24).

- (24) ?nolithe-ey ai-ka nol-**ko** **iss**-ta.

playground-ey child-nom play-KO ISS-Decl

“There’s a child in playing at the playground.”

In (25) and (26), modifiers are used to specify the location or the subject, respectively. In each case, the acceptability of the sentences improves.

(25) a. haksayng-tul-lo pwumpi-nun hakkyo-siktang-ey  
student-Pl-Inst crowd-Con school-dining room-ey

yengi-ka pap-ul mek-**ko iss-ta.**

“**At the dining room crowded with students,** yengi is having a meal.”

b. etwuketwukhayci-n hakkyo-yeph nolithe-ey

dark-Con school-next playground-ey

ai-ka nol-**ko iss-ta.**  
child-Nom play-KOISS-Decl

“**At the dark playground by the school** a child is playing.”

(26) a. hakkyo-siktang-ey sihem-ul machi-n yengi-ka  
school-dining room-ey test-Acc finish-Con -Nom

pap-ul mek-**ko iss-ta.**  
meal-Acc eat-KO ISS-Decl

“At the dining room, **Yengi, who has finished**

**his examination,** is having a meal.”

b. nolithe-ey ppalka-n moca-lul ssu-n

playground-ey red-Con hat-Acc wear-Con

ai-ka nol-**ko iss-ta.**  
child-Nom play-KOISS-Decl

“There’s **a playing child wearing a red hat.**”

In the case of (27), however, where the verbs are modified by adverbial phrases, the acceptability is not improved unlike (25)(26), but remains a little odd as (24). See (27).

(27) a. ?hakkyo-siktang-ey yengi-ka massiss-key pap-ul mek-**ko iss-ta.**  
school-dining room-ey -Nom relish meal-Acc eat-KO ISS-Decl

“At the dining room yengi is having a meal **with a relish.**”

#### 4. Conclusion

In this paper, I have discussed the difference in the existential meaning of two durative markers in modern Korean, *-ko iss-* and *-e iss-* as they relate to the verb of existence *iss-*. *-ko iss-* can be employed for the aspect type and the existential type, while *-e iss-* can be allowed only as an existential type.

# Perfect Versus Past in Korean

Kyung-Sook Chung

Pusan National University

[kchung@pusan.ac.kr](mailto:kchung@pusan.ac.kr)

## Abstract

This paper investigates two Korean suffixes—the simple form *-ess* and the double form *-essess*. Both have past time reference and are compatible with past-time adverbials. It is argued that only *-essess* is a true past tense, whereas *-ess* is a perfect, and that the meaning of discontinuity previously claimed to be associated with *-essess* should be treated as an implicature. It is also suggested that the cross-linguistic difference in the (in)compatibility of the perfect with past-time adverbials should be accounted for in relation to the meaning of the present tense (i.e. (im)perfectivity) in the language. Finally the proposed analysis provides an explanation for the analyses in which the English perfect is ambiguous between a universal and an existential reading.

**Keywords:** tense, aspect, perfect, current relevance, epistemic modality

## 1. Introduction

In this paper I investigate two Korean suffixes—the simple form *-ess* and the double form *-essess*. Both forms have past time reference and are compatible with past time adverbials, as shown in (1).

- (1) a. *Mary-ka cinan cwu-ey Seoul-ey o-ass-ta.*  
Mary-NOM last week-LOC Seoul-to come-PFCT-DEC  
'Mary came to Seoul last week.'
- b. *Mary-ka cinan cwu-ey Seoul-ey o-assess-ta.*  
Mary-NOM last week-LOC Seoul-to come-PAST-DEC  
'Mary came to Seoul last week.'

Both sentences in (1) describe past events, which are modified by the past time adverb *cinan cwu* 'last week'. The issue of this paper is whether or not the two Korean forms are the same past tense, and if they are not, what distinguishes the two. I argue that

---

\* I would like to thank the 18<sup>th</sup> CIL Tense, Aspect, and Modality Session audience for their comments. All shortcomings are my own.

only *-essess* is a true past tense, and that the meaning of discontinuity previously claimed to be associated with it should be treated as a pragmatic implicature of past (cf. Iatridou 2000). Thus, I argue that the difference between the simple form *-ess* and the double form *-essess* mirrors the difference between the perfect and the past manifested in most European languages.

## 2. Previous analyses

The simple form *-ess* has been analyzed as a perfective (Na 1971; Nam 1978, 1996), a (present) perfect (Choi 1983), an anterior (H.-S. Lee 1991; Han 1996), a past (C.-M. Lee 1985), or ambiguous between a perfect and a past (Suh 1996; Song 2003), whereas *-essess* has been analyzed as a pluperfect (H.-B. Choi 1983; Gim 1985; H.-M. Sohn 1994; E.-H. Lee 2007), an aspect of discontinuity (Nam 1978, 1996), or a past tense with the meaning of discontinuity (Kim 1975; C.-M. Lee 1987).<sup>1</sup> In this paper I only focus on *-ess* as past tense approaches and *-essess* as pluperfect approaches.<sup>2</sup>

### 2.1. *Is -ess a past tense?*

C.-M. Lee (1987:438-9) defines the simple form *-ess* as a past tense, which has not only the truth-conditional meaning of some event occurring in the past but also the pragmatically implicated meaning of the result state of the event continuing until the speech time. However, I show that the event referred to by *-ess* is not necessarily in the past and that rather *-ess* exhibits typical characteristics of present perfects in languages like English. First, as C.-M. Lee (1987) argues, the simple form and the double form can refer to past situations with the different status of result state. Compare the following set of data:

- (2) a. *Mary-ka*            *Seoul-ey*            *o-ass-ta.*  
       Mary-NOM        Seoul-to            come-PFCT-DEC  
       ‘Mary came to Seoul last week.’ [Mary is in Seoul]
- b. *Mary-ka*            *Seoul-ey*            *o-assess-ta.*  
       Mary-NOM        Seoul-to            come-PAST-DEC  
       ‘Mary came to Seoul last week.’ [Mary left Seoul]

<sup>1</sup> In fact, Kim (1975) defines *-essess* as a past tense with an ‘experiential-contrastive’ aspect. However, it seems to me that his notion of experiential-contrastive aspect meaning is almost the same as the notion of discontinuity claimed by other Korean linguists.

<sup>2</sup> For the discussion of the other approaches, see Chung (2005).

Although both sentences in (2) have past time reference, they express different situations: (2a) with *-ess* implies that there was a past event of Mary's coming to Seoul and its result state (i.e. Mary still staying in Seoul) holds at the present moment, whereas (2b) implies that the result state no longer holds (cf. Nam 1996:475).

Second, *-ess* is compatible with present-time adverbials such as *now*, although *-essess* is not, as shown in (3).

- (3) a. *cikum Mary-ka Seoul-ey o-ass-ta.*  
 Now Mary-NOM Seoul-to come-PFCT-DEC  
 'Mary has come to Seoul now.'
- b. *\*cikum Mary-ka Seoul-ey o-assess-ta.*  
 Now Mary-NOM Seoul-to come-PAST-DEC  
 '\*Mary came to Seoul now.'

This contrast also holds for the present perfect and the past tense in languages like English. Although present perfect is compatible with *now*, the past tense is not, as shown in the English present perfect and simple past sentences in (4) and the corresponding Italian sentences in (5) (Giorgi and Pianesi 1997:88).

- (4) a. Now I have eaten enough.  
 b. \*Now I ate enough.
- (5) a. Adesso ho mangiato abbastanza.  
 b. \*Adesso mangiai abbastanza.

Third, it has been noted that cross-linguistically past is not used for future or with future, although perfect (or perfective) can (Bybee et al. 1994:95; Giorgi and Pianesi 1997:89). That is, past only refers to situations in the past. Consider the Korean data in (6): *-ess* can co-occur with a future time-adverbial, while *-essess* cannot.

- (6) a. *ne nayil(-i-myen) cwuk-ess-ta.*  
 You tomorrow(-be-if) die-PFCT-DEC  
 'You are dead tomorrow.'
- b. *\*ne nayil(-i-myen) cwuk-essess-ta.*<sup>3</sup>  
 You tomorrow(-be-if) die-PAST-DEC  
 'You are dead tomorrow.'
- (7) *wuli-ka kuki tochakha-yss/\*??-yssess-ul-ttay-nun*  
 we-NOM there arrive-PFCT/ PAST-ATT-time-TOP  
*mary-ka ttena-ko eps-keyss-ta.*  
 Mary-nom leave-conj not.be-MOOD-DEC  
 'When we have arrived there, Mary will have left there.'

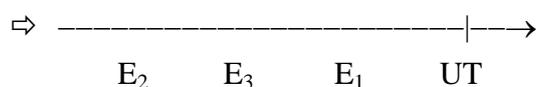

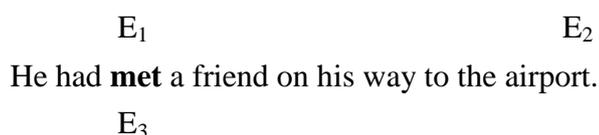

<sup>3</sup> Sentence (6a) is commonly used when the speaker wants to scare or tease the hearer.

In (7), the event of the embedded clause is in the future, and *-ess* is fine but *-essess* is not. So we see that *-ess* does not behave like a past tense but rather like a perfect. In what follows, I will argue that *-ess* is a perfect form with notions like current relevance.

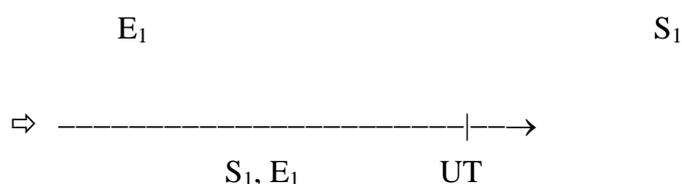

## 2.2. Is *-essess* a pluperfect?

In this section, after examining the double form *-essess* as pluperfect (or a past perfect) approaches, particularly E.-H. Lee's (2007) analysis, I will show problems with the approach and that the past tense approaches account for data with *-essess* better. It has been noted that the English pluperfect has two different readings—a temporal pluperfect (or preterit) reading and an aspectual pluperfect reading, as illustrated in (8a) and (8b) respectively:

- (8) a. John **arrived** at the airport at nine. He had **left** home two hours earlier.

- b. John **arrived** at the airport at nine. Mary had **already arrived** there.

The past perfects in (8a) simply locate the events earlier than the past-tensed event that provides the reference time and thus trigger a flashback effect; the past perfect in (8b) indicates that the result state of Mary's arriving at the airport, i.e., Mary's being at the airport, obtains at the time of John's arrival. The evidence for the ambiguity theory is that the past perfect of the preterit use can be substituted by a past tense (see (9a)), whereas that of the aspectual use cannot (see (9b)) (Ogihara 1996: 15).

- (9) a. John arrived at the airport at nine. He left home two hours earlier. He met a friend on his way to the airport.  
 b. John arrived at the airport at nine. #Mary already arrived there.

Based on this distinction, E.-H. Lee (2007:9) argues that *-essess* is a special kind of pluperfect that refers to an event preceding the given reference time but lacks an

aspectual interpretation (i.e. requires the absence of resultant state at the reference time), as illustrated in the following Korean examples corresponding to (9):

- (10)a. *John-i konghang-ey ahop-si-ey tochakha-yss-ta.*  
 John-NOM airport-LOC nine-o'clock-LOC arrive-PFCT-DEC  
 'John arrived at the airport at nine.'  
*ku-nun twu-sikan-cen-ey cip-ul nao-assess-ta.*  
 He-TOP two-hour-before-LOC house-ACC come.out-PAST-DEC  
 'He had left home two hours earlier.'  
*kuliko konghang-ey o-nun kil-ey chinkwu-lul mana-ssest-ta.*  
 and airport-to come-ATT way-LOC friend-ACC meet-PAST-DEC  
 'And he had met a friend on his way to the airport.'
- b. *John-i konghang-ey ahop-si-ey tochakha-yss-ta.*  
 John-NOM airport-LOC nine-time-LOC arrive-PFCT-DEC  
*Mary-nun pelsse \*/??tochakha-yssess-ta. /tochakha-y iss ess-ta/*  
 Mary-TOP already arrive-PAST-DEC /arrive-RESUL-PFCT-DEC  
 'John arrived at the airport at nine. Mary had already arrived there.'

In (10a), the *-ess* clause describes a past event and the *-essess* clause introduces an event that precedes the *-ess* event, triggering a flashback effect. In contrast, in (10b), we see that for the aspectual pluperfect reading, *-essess* is not acceptable although the resultative form *-e iss* is.

However, there are some problems with this pluperfect approach. First, as E.-H. Lee (2007) notes, *-essess* does not have an aspectual reading of the past perfect (see (10b)). If *-essess* is a true pluperfect, we need to explain why, unlike pluperfect forms in other languages, it only has the temporal (preterit) reading. Moreover, we also need to explain why *-essess* chooses the temporal reading instead of the aspectual reading, since the latter seems to be more intrinsic to the pluperfect than the former.

The second problem is, connected to the first problem, that pluperfects in languages like English and Italian allows two distinct time references, but *-essess* does not, as shown in (11)

- (11) a. Yesterday, Mary had left already/the day before.  
 b. *\*ecey(-nun) Mary-ka pelsse /ku cen-nal ttena-ssest-ta*  
 yesterday(-TOP) Mary-NOM already/that before-day leave-PAST-DEC  
 'Yesterday Mary had left already/the day before.'

While (11a) indicates that the pluperfect event of Mary's leaving is prior to (i.e. distinct from) the reference time, which is not the utterance time, (11b) indicates that *-essess*

does not allow a reference time that is distinct from the event time.<sup>4</sup>

Third, *-essess* is not even allowed in the typical pluperfect situations for the temporal reading, as in (12):

- (12) a. Mary made it to Boston on Thursday, and John had left on Wednesday  
/the day before.  
b. ??*Mary-nun Boston-ey mokyoil-ey ttuna-ss -ko*  
Mary- TOP Boston-to Thursday-LOC leave-PFCT-CONJ  
*John-un swuyoil-ey /ku cen-nal ttena-ssess-ta.*  
John- TOP Wednesday-LOC /that before-day leave-PAST-DEC  
'Mary made left for Boston on Thursday, and John had left on Wednesday  
/the day before.'

The pluperfect sentence in (12a) indicates that the event of John's leaving simply occurred on Wednesday, i.e. prior to Mary's leaving, not focusing on the result state of John's leaving. Still the corresponding Korean sentence with *-essess* in (12b) does not sound natural.

So far I have shown problems with the pluperfect approaches of *-essess*. In what follows I will show that the flashback effect associated with *-essess* can be accounted for by past tense approaches. The arguments come from some restrictions on the order between *-ess* and *-essess* in the time line, which parallel to those on the order between the perfect and the past in European languages. First, the past-tense marked event precedes the perfect-marked event in actual time in languages like English and Italian, but the perfect-marked event cannot be anterior to the past tense event, as shown in the following (Giorgi and Pianesi 1997:89).

- (13)a. Gianni emigro negli Stati Uniti, ma poi e tornato.  
'Gianni emigrated(PAST) to the States, but he has come(PFCT) back.'  
b. \*Gianni e emigrato negli Stati Uniti, ma poi torno.  
'\*Gianni has emigrated(PFCT) to the States, but then he came(PST) back.'

This difference also holds for *-ess* and *-essess*: the event referred to by *-ess* cannot be anterior to the event referred to by *-essess*, as in (14).

- (14) a. *mary-ka mikwuk-ey imin-ul ka-ssess-ta.*  
Mary-NOM USA-to emigration-ACC go-PAST-DC  
*kulentey tasi tolao-ass-ta.*  
but again return-PFCT-DC

<sup>4</sup> Actually E.-H. Lee uses this fact as an argument for her claim that *-essess* only has a preterit reading while the English pluperfect is ambiguous between an aspectual and a temporal reading. However, even if *-essess* only has a temporal reading, there is no reason why it cannot have a reference time distinct from the event time because it should denote a certain time (namely, the event time) prior to the reference time, as a pluperfect does. That is, *-essess*, as a pluperfect, should provide two distinct time intervals other than utterance time. If it only allows event time, then it should be, not a pluperfect, simply a past tense in which the event time is simultaneous with the reference time in the Reichenbach's (1949) scheme.

‘Mary emigrated to the USA. But she has come/came back.’

- b. \**mary-ka mikwuk-ey imin-ul ka-ss-ta.*  
 Mary-NOM USA-to emigration-ACC go-PFCT-DC  
*kulentey tasi tolao-assess-ta.*  
 but again return-PAST-DC

‘\*Mary has emigrated to the USA. But she came back.’

Second, when the linear order in which two clauses appear contradicts the actual temporal order of the events reported on, the English present perfect is often used in follow-ups of old news that is in the past tense, as illustrated in (15) (Inoue 1979:586):

- (15) All but one of the pieces in the epidemiological jigsaw puzzle **HAVE BEEN ASSEMBLED**, leaving little doubt in the investigator’s mind that the cook **spread** staphylococcal bacteria as he handled Danish canned ham. The meat **was eaten** in omelets served to 344 passengers as the 747 Jumbo jet approached Copenhagen for a refueling stop....

In (15), the clause containing the present perfect appears linearly before the clauses containing the simple past. In the real temporal order, the perfect event is more recent than the simple past event. The two Korean suffixes are also utilized to provide the same effect: in the text, the *-ess*-marked event can appear before the *-essess*-marked event but the former is posterior to the latter in the actual time line (see (10a)). Thus, the ordering between the simple form and the double form is summarized as follow:

- (16)a. When the actual temporal order of events is the same as the order of the text:

<u>Prior Event</u>	...	<u>Recent Event</u>
<i>-essess</i>	...	<i>-ess</i>
* <i>-ess</i>	...	<i>-essess</i>

- b. When the actual temporal order is contrary to the order of the text:

<u>Recent Event</u>	...	<u>Prior Event</u>
* <i>-essess</i>	...	<i>-ess</i>
<i>-ess</i>	...	<i>-essess</i>

However, the simple temporal ordering such as precedence or recency is not enough to account for the relationship between *-ess* and *-essess*. The two suffixes require a stronger meaning relationship as well as temporal ordering. Consider the following data:

- (17) *pwukhan-kwa mikwuk-un sip-il ceneba-eyse pwukhan*  
 North.Korea-and America-TOP ten-day Genoa-at North.Korea (NK)  
*hayk-mwunce-lul nonuyha-n-ta-ko hyenci oykyokwan-tul-i*  
 nuclear-issue-ACC discuss-PRES.IMPFCOMP local diplomat-PL-NOM

*PALKHI-ESS-ta. ... pwuk-mi sam-tankey kowuykup hoytam-un*  
 reveal-PFCT-DC. ... NK-America three-stage high.level talk-TOP  
*kim il-seng cwukek-uy samang-ulo cwungtantoy-ssest-ta.*  
 Kim il-sung resident-GEN death-with discontinue-PAST-DC.  
 (N.-S. Lee 1998:176)

‘The diplomats on the scene **ANNOUNCED** (or **HAVE ANNOUNCED**) that North Korea and the USA are to discuss the issue of the North Korean nuclear weapons in Genoa.... The three-stage high-official-level talks **had been** (or **were**) **discontinued** due to the death of the leader of the North Korea Kim, Il-sung.’<sup>5</sup>

In (17), the recent *-ess*-marked event (i.e. the local diplomats’ announcing the resumption of the US-North Korea summit talks) is on focus and the *-essess*-marked event (the discontinuance of the talks due of the former North Korea leader’s death) is the background information of the *-ess* event.<sup>6</sup> In other words, the *-ess*-marked event indicates foreground information whereas the *-essess*-marked event indicates the circumstances of what happened before, i.e. background information. This relationship also applies to data (10a) and (14).

I claim that in order to have *-ess* and *-essess*, the two events in questions must have a strong meaning relationship such as foreground-background relation or causal relation. This explains why data like (10b) and (12) are not natural: they are unacceptable not because *-essess* has no aspectual reading of the pluperfect reading but because of lack of this foreground-background relation between the sets of events. For example, (10b) and (12) are simply listing separate events (i.e. John’s arriving at the airport and Mary’s arriving at the airport in (10b), and Mary’s leaving for Boston on Thursday and John’s leaving on Wednesday/the day before in (12)). In contrast, in (10a), all the events are about the same person, John, and *-essess*-marked sentences provides the circumstance of what happened on his way to the airport. This means that in order to

<sup>5</sup> The translation is my own.

<sup>6</sup> E.-H. Lee (2007) provides many data with *-essess* in relation to *-ess*. All of them express that the *-essess* marked event is the background information of the *-ess* event. One of them is given in (i):

(i) *yengswuk-uy elkwul-ey cheumelo huymihan wusum-i penci-ess-ta.*  
 Yengswuk-GEN face-LOC first.time faint smile-NOM spread-PFCT-DEC

‘For the first time, a faint smile spread over Yengswuk’s face.’

*‘cal ha-yss-e. enni tekpwun-ey.’*

Well do-PECT-dec sister thanks-to

‘Thanks to you, sister. It went well’ [Yengswuk said]

*Tahee-nun apeci ceysa-ka iss-ki ithul ceney yengswuk-ul manna*  
 Tahee-TOP father memorial-NOM be-NOMI two.days before Yengswuk-ACC meeting

*ceysa-lul neknekhi chiluko-to namul ton-ul cwu-essess-ta.*

memorial-ACC sufficiently carry.out-even remain money-ACC give-PAST-DEC

‘Tahee had met Yengswuk two days before their father’s memorial service and had given her enough money to carry it out.’

have *-ess* and *-essess*, the two events must have a strong meaning relationship such as foreground-background relation as well as the temporal ordering. Thus I argue that *-essess* has a flashback effect, as E.-H. Lee (2007) notes, not because it is a pluperfect but because it is used to provide the background information for the more recent *-ess* event.

Before turning to my analysis of the two suffixes, I will examine the meaning of discontinuity previously claimed to be associated with *-essess*. According to Nam (1978, 1996), *-essess* is an aspect marker of discontinuity in that it indicates that the past event or the resulting state of the event no longer continues at the utterance time. C.-M. Lee (1985) defines *-essess* as a past tense with the truth-conditional meaning that the event or the result state of the event was discontinuous at some time between the event and the speech time. Thus (18) is not acceptable with adverbials like *cikum-kkaci* ‘until-now’ because *-essess* expresses that my loving my wife is discontinuous and no longer true.

- (18) ??*na-nun na-y anay-lul o-nyen-cen-pwuhe cikum-kkaci*  
 I- TOP I- GEN wife- ACC five-year-before-from now-until  
*kyeysokhayse salangha-yssess-ta.*  
 continuously love-PAST-DEC  
 ‘??I loved my wife continuously from five years ago until now.’

However, this meaning of discontinuity does not seem to be truth-conditional, namely, an entailment. Consider the following data:

- (19) *na-nun na-y anay-lul cengmal salangha-yssess-ko*  
 I- TOP I- GEN wife-ACC really love-PAST-CONJ  
*cikum-to salangha-n-ta.*  
 now-too love-PRES-DEC  
 ‘I really loved my wife and still do, too.’

If the meaning of discontinuity is an entailment, (19) should be a contradiction and unacceptable, but it is not. This means that the meaning of discontinuity associated with *-essess* is not an entailment but a pragmatic implicature because it is cancelable. Furthermore, this meaning of discontinuity as an implicature is automatically accounted for if *-essess* is a past tense.<sup>7</sup> This suggests that the reason that (18) is odd is not due to the continuity of the state, but due to the fact that past tense is not compatible with time adverbials like *now* (see (3))

### 3. Deictic versus non-deictic

I have shown that the simple form *-ess* as a past tense approaches and the double

<sup>7</sup> For the English past tense and its implicature, see Iatridou (2000).

form *-essess* as a pluperfect approaches are problematic. I have also shown that a simple temporal relation is not sufficient to account for the difference between *-ess* and *-essess*. In this section, I further investigate the two suffixes and show that the difference between the two can be accounted for by the difference between the deictic and the non-deictic.

As briefly discussed in section 2.1, while the reference time of *-essess* always in the past, *-ess* is not necessarily so, and it can be in the future or bound by modal operators, as illustrated in (20).

- (20)a. *John-un chocolate-lul mek-ess-ta.*  
 John-TOP chocolate-ACC eat-PFCT-DEC  
 ‘John has eaten chocolate’  
 Or ‘**If it is John, then he would/must have eaten chocolate.**’
- b. *John-un chocolate-lul mek-essess-ta.*  
 John-TOP chocolate-ACC eat-PAST-DEC  
 ‘John ate chocolate’ Or ‘**John used to eat chocolate.**’

The sentences in (20) are ambiguous between a particular event and a non-particular event reading. Especially with the non-particular event reading, (20b) with *-essess* refers to a certain past time period during which multiple events of John’s eating chocolate took place regardless of its regularity, indicating the existence of actual events. In contrast, propositions like *John likes sweets* are sufficient to utter (20a) with *-ess*, which expresses a general property of John’s, i.e., in any appropriate situation, John would/must have engaged in an event of eating chocolate prior to the reference time. In other words, (20a) is a generic sentence, whereas (20b) is a pure habitual sentence that requires actual events in the past.

Thus, *-ess* can induce a modal context, whereas *-essess* does not but requires a salient past time to refer to. This is also the case with the past and the present perfect in languages like Italian and German: the past only refers to a contextually salient past time but perfect can refer to a future situation or occur with modals (Giorgi and Pianesi 1997:89; Kratzer 1998). This difference becomes clear when they are negated, as shown in (21): (21a) simply means that there was no prior event at the utterance time, whereas (21b) means that at some past time there was no event of John’s chocolate eating, and thus the past time reference is not negated.

- (21)a. *John-un chocolate-lul an-mek-ess-ta.*  
 John- TOP chocolate-ACC not-eat-PFCT-DEC  
 ‘John has not eaten chocolate’
- b. *John-un chocolate-lul an-mek-essess-ta.*  
 John-top chocolate-acc not-eat-PAST-DEC

‘John used to not eat chocolate’

However, unlike the English present perfect, *-ess* can co-occur with past-time adverbials. Because of this compatibility with past-time adverbials, *-ess* has been analyzed as a past or as ambiguous between a perfect and a past. However, note that although *-ess* co-occurs with a past adverbial, it still saliently conveys the notion of a result state or current relevance, as illustrated in the following:

- (22) a. *han sikan-cen-ey pwul-i kke-ci-ess-ta.*  
 one hour-before-at light- NOM turn.off-PASSIVE-PFCT-DEC  
 ‘The light turned off an hour ago.’ [The light is off now.]  
 b. *han sikan-cen-ey pwul-i kke-ci-essess-ta.*  
 one hour-before-at light- NOM turn.off-PASSIVE-PAST-DEC  
 ‘The light turned off an hour ago.’ [The light is on now.]

Sentence (22a) indicates that the result state of an event of turning off the light has lasted for an hour and still holds at the speech time. This means that the past-time adverb not only refers to the time of the event but also sets the onset time of the result state. In contrast, (22b) with *-essess* only indicates that the event took place an hour ago but does not say anything about its result state except for the implication that the light is probably on now. Thus, I claim that (in)compatibility with past-time adverbials should not be the sole criterion for determining the perfect, even though it can be a criterion in some languages, and that the compatibility of *-ess* with past-time adverbials results from the imperfectivity of the Korean present tense, which will be discussed in the following section.

Following Inoue (1979) and Portner (2003), I argue that such notions as result state or current relevance should be understood in relation with topic in the discourse. Consider the conversation in (23)-(24):

- (23) A: *nay-ka stove-lul an-kku-n kes kath-a.*  
 I-NOM stove-ACC not-turn.off-ATT thing seem-DEC  
 ‘It seems that I did not turn/ have not turned off the stove.’ [The stove is on.]

- (24) B: *wuli-ka nao-l ttay mary-ka kk-ess-e/ ??kk-essess-e.*  
 we-NOM come.out-IR.ATT time mary-NOM turn.off-PFCT-DEC/??-PAST-DEC  
 ‘Mary turned it off when we went out.’ [The stove is off]

- (24') B: *wuli-ka nao-l ttay-nun mary-ka kk-essess-e /??kk-ess-e.*  
 we-NOM come.out-IR.ATT time-top mary-NOM turn.off-PAST-DEC/??-PFCT-DEC  
 ‘When we went out, Mary turned it off.’  
 (*nwu-ka tasi sutobu-lul khye-ess-nunci molu-ciman.*)  
 ‘I don’t know if somebody has turned it on again though.’

The current discourse topic of the conversation is the present state of the stove that the speaker thinks is still on. Sentence (23) with *-ess* is a possible answer to the topic,

whereas (23) with *-essess* is not. When the topic has shifted to the past time referred to by the *-nun*-marked adverbial, as in (24'), *-ess* is odd while *-essess* is fine because in (24') the speaker only gives information about that past time.

In addition, I argue that this result state implication is purely epistemic because in the actual world, the stove could be on if somebody else had turned it on later, i.e. only the speaker thinks that it is off, based on what (s)he knows about the actual world. Hence, the result state does not have to exist in the actual world, although the time interval in which the result state holds is actual. In this respect, I adopt Portner's (2003) modal theory of the perfect, in which the present perfect has a built-in epistemic necessity modal operator as its presupposition. This operates on the conversational background of the context plus the perfect proposition to yield its consequent state (CS), which is used to cover such notions as result state and current relevance. Thus *-ess* sentences like (24) yield the following inference scheme:

(25) Conversational Background = {p<sub>1</sub>, p<sub>2</sub>, p<sub>3</sub>,...}

Mary-ka stove-lul kke-ss-ta (24): Perfect Proposition

□ *The stove is off*: CS

To conclude, *-ess* is not a past but a perfect, which maps an event to a time interval through out which the CS of the event necessarily holds, whereas *-essess* is a simple past tense, as defined in (26).

(26)a. [[ *-ess* ]] =  $\lambda P. \lambda t. \exists e [P(e) \wedge \square \exists e' [CS(e', e) \wedge \tau(e') = t]]$ ,

where *e'* is a partial or complete answer to the discourse topic at the speech time.

b. [[ *-essess* ]]<sup>g,c</sup> is only defined if *c* provides an interval  $t < t_c$ ,  
if defined, [[ *-essess* ]]<sup>g,c</sup> = *t*. (cf. Kratzer 1998)  
*t<sub>c</sub>*: the speech time

In (26a), 'CS(*e'*, *e*)' means that *e'* is the consequent state of *e*; ' $\tau(e') = t$ ' means that the time of the event *e'* equals (or fully overlaps) the reference time (R). The CS of an event starts the moment the event ends, and it follows that the event is anterior to its CS, hence, to the R. Importantly, the CS is an answer to the discourse topic at the speech time and does not necessarily exist in the actual world.

#### 4. Perfect and past time adverbials

The question that remains to be answered is why the English perfect does not allow past-time adverbials but the Korean *-ess* does. I argue that (in)compatibility of the perfect with past-time adverbials should be understood in relation to the (im)perfectivity

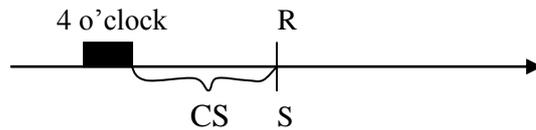

of the present tense in the language. In other words, the compatibility of *-ess* with past-time adverbials results from the imperfectivity of the Korean present tense, while the incompatibility of the English perfect with past-time adverbials results from the perfectivity of the English present tense.

Giorgi and Pianesi (1997) distinguish two different Present tenses—Simple Present (S-Present) and Imperfective Present (I-Present). The English present is an S-Present (R is instantaneous with the speech time S ( $S = R$ )), whereas the Italian present is an I-Present (R involves a long stretch of time that includes S ( $S \subseteq R$ )). Consequently, the two languages differ with respect to the co-occurrence of present tense with adverbials like *since*, as shown in (27a–b). The English present tense (S-Present) cannot co-occur with *since* (27a), whereas the Italian present (I-Present) can co-occur with the corresponding adverb (27b). Like the Italian present, the Korean present can co-occur with the corresponding adverb, indicating that the present tense is an I-Present (27c).

- (27) a. \*I love Mary since yesterday. — English  
 b. *Amo Mary da ieri.* — Italian  
 c. *na-nun ecey-pwute Mary-lul cohaha-n-ta.* — Korean  
 I- TOP yesterday-from Mary-ACC like-PRES-DEC

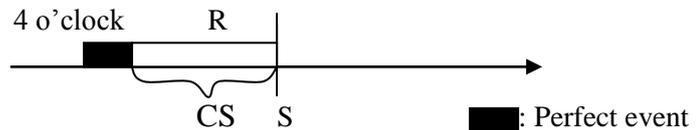

Now compare the English present perfect sentence in (28a) with the Korean counterpart in (29a).

- (28) a. \*John has left at 4:00:

- b.  $*\exists e [\text{leave}(\text{John}, e) \wedge 4 \text{ o'clock}(e) \wedge \square \exists e' [CS(e', e) \wedge \alpha(e') = t \wedge t = t_c]]$   
 $= \exists e [\text{leave}(\text{John}, e) \wedge 4 \text{ o'clock}(e) \wedge \square \exists e' [CS(e', e) \wedge \alpha(e') = t_c]]$

- (29) a. *John-i neysi-ey ttena-ss-ta:*

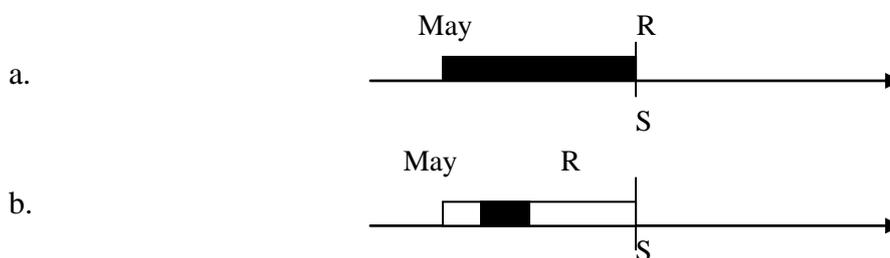

- b.  $\exists e [\text{leave}(\text{John}, e) \wedge 4 \text{ o'clock}(e) \wedge \square \exists e' [CS(e', e) \wedge \alpha(e') = t \wedge t \supseteq t_c]]$   
 $= \exists e [\text{leave}(\text{John}, e) \wedge 4 \text{ o'clock}(e) \wedge \square \exists e' [CS(e', e) \wedge \alpha(e') \supseteq t_c]]$

My definition in (26a) indicates that the time span of CS is exactly equivalent to the

time span of R, since the time when a perfect event ends is the time when its CS begins and R is the time when the CS exists. In (28a), the CS begins significantly before R, since R is instantaneous with S. This yields a time gap between the CS and R, which conflicts with the definition of the perfect. Formally, as illustrated in (28b), (28a) is contradictory because the time adverb indicates that the CS should begin at 4 o'clock and extend up to S, and at the same time the CS should be instantaneous with S. In contrast, in (29) with *-ess*, the CS and R completely overlap, which satisfies the denotation of the perfect.

In order to avoid the conflict, as in (28a), the English present perfect needs two strategies—either to make the perfect event continue up until S, whenever possible (see (30a)), or to modify R to extend from some past time up to S with temporal adverbials (see (30b)).

(30) John has been sick since May:

This explains why the English present perfect has been argued to be ambiguous between a universal (or continuative) reading and an existential reading (cf. Iatridou et al. 2003). In contrast, the Korean *-ess* only has an existential reading. This is also the case for the Italian present perfect (Giorgi and Pianesi 1997).

## 5. Conclusion

The proposed analysis suggests that the languages like Korean that do not have distinct forms for past opposed to perfect, as European languages do, still finds a way to make a distinction, i.e. by doubling the simple morpheme. It also suggests that the notion of current relevance is closely related to inferences associated with the asserted perfect event, and that perfect, as a presupposition, has a grammatical device for bringing in these inferences, while past can have the inferences as simple pragmatic implicatures. Although there are innumerable possible relevant propositions that could be inferred from the perfect event, only one is intended by the speaker. Thus, unlike McCoard (1978), I argue that finding a currently relevant proposition by using a perfect form cannot be arbitrary because the speaker makes use of the common ground and the logical inference process that other people share with the speaker. Under this analysis, the perfect across languages can be claimed to have the same property: a prior event yields a consequent state in the reference time immediately after its culmination. However, independent factors, such as the imperfectivity of the present tense can lead to a difference in behavior.

# On Tense-Aspect-Mood in Polar Interrogatives

Matti Miestamo

Helsinki Collegium for Advanced Studies  
P.O. Box 4, FI-00014 University of Helsinki, Finland  
matti.miestamo@helsinki.fi

## Abstract

The paper reports the preliminary results of a typological study of the marking of tense, aspect and mood (TAM) categories in polar interrogatives. The results are based on a pilot sample of 105 languages. Special attention is paid to how the marking of TAM categories in polar interrogatives differs from their marking in declaratives. The following types are found: the marking of polar interrogation is part of the mood system, interrogation is expressed by the absence of declarative marking, interrogation is expressed by an auxiliary construction, interrogatives require a non-finite form of the verb, TAM distinctions made in declaratives are lost in polar interrogatives. Finally, the results are compared with earlier results on the marking of TAM categories in negatives.

**Keywords:** polar interrogation, tense-aspect-mood, negation, typology, markedness, sampling.

## 1. Introduction

This paper is a typological study of the marking of tense, aspect and mood (TAM) categories in polar interrogatives. I will restrict my attention to polar interrogation in main clauses with verbal predicates and focus on interrogatives that are as neutral as possible in terms of focus or bias towards positive vs. negative reply. These conditions are satisfied by, e.g., the English polar interrogative sentence in (1a) but not by focused questions such as (1b,c), by tag questions such as in (1d), or by indirect questions such as the one in (1e).

### (1) English (constructed examples)

- a. *is King Arthur barking on the balcony ?*
- b. *is King Arthur barking on the **balcony** ?*
- c. *is it King Arthur that is barking on the balcony ?*
- d. *King Arthur is barking on the balcony, isn't he ?*

e. *I wonder whether King Arthur is barking on the balcony*

Typological studies of polar interrogatives (Moravcsik 1971; Ultan 1978; Sadock & Zwicky 1985; Siemund 2001; Dryer 2005a; König & Siemund 2007) have found the following types of marking polar interrogation: intonation, interrogative particles, interrogative verb morphology, order of constituents (verb fronting), disjunction (A-not-A), and absence of declarative morphemes. In an earlier study (Miestamo 2004, 2007), I have pointed out that interrogative (auxiliary) verbs should be regarded as a further type. In addition to the types of markers, attention has also been paid to their position (see Dryer 2005b). In my investigation of the marking of TAM categories in polar interrogatives, I will pay special attention to how their marking differs from their marking in declaratives. This question has not been previously addressed on the basis of extensive typological samples (Schmid 1980 examined co-occurrence restrictions in interrogatives, but without using an extensive and systematic sample). In my pilot study (2004, 2007), I have taken a preliminary look at the structural differences between polar interrogatives and declaratives, but with no special focus on TAM categories.

This study is part of a larger project examining structural similarities and differences between polar interrogatives and declaratives (and marked and unmarked categories more generally). In my earlier work (Miestamo 2005), I have examined structural differences between negatives and affirmatives, and proposed the following typological classification. Symmetric negatives differ from the corresponding affirmatives by the mere presence of the negative marker(s) whereas asymmetric negatives show some further structural differences vis-à-vis affirmatives. Symmetry and asymmetry can be observed in constructions and paradigms (what this means will become clearer in Section 3 below) and asymmetric negation can be divided into further subtypes according to the nature of the asymmetry. The different types of the classification can be accounted for by an analogy-based model of explanation where symmetric negation is explained by (language-internal) analogy to the structure of the affirmative and asymmetric negation by (language-external) analogy to functional properties of negation. In addition to negation, these principles of classification and explanation can be applied to other marked categories, e.g., polar interrogation. As I have shown in (Miestamo 2007), symmetric and asymmetric interrogative structures can be distinguished according to whether and how polar interrogatives differ from their unmarked declarative counterparts. In this paper, I will pursue this idea further, paying special attention to the marking of TAM categories.

This is a preliminary survey of the marking of TAM categories in polar interrogatives, and the conclusions will therefore remain preliminary. Furthermore,

focus will be on describing and classifying the data, and issues of explanation and other more theoretical questions will not be addressed in this paper. The structure of the paper is as follows: Section 2 introduces the language sample on which the study is based. Section 3 briefly introduces the distinction between symmetric and asymmetric polar interrogatives. Section 4 constitutes the central part of the study, focusing on the ways in which the marking of TAM categories can be affected in polar interrogatives in different languages. Section 5 compares the findings to what has been observed earlier about the marking of TAM categories in declarative negatives. Section 6 concludes the paper.

## 2. Sample

The sampling procedure follows the sampling principles introduced in Miestamo (2005). A variety sample containing at least one language from each of the 458 genera in Dryer's (2005c) WALS classification forms the basis of the study. The poorer availability of sources for the languages of some areas will introduce an areal-genealogical bias into the sample and therefore quantitative observations will be based on an areally balanced subsample of the overall variety sample. At this stage, only a part of the sample languages has been examined, and the results of this paper are based on this pilot sample of 105 languages (which is still to some extent areally biased). Table 1 lists the sample languages in each macroarea. In Figure 1, the sample languages are plotted on a world map.

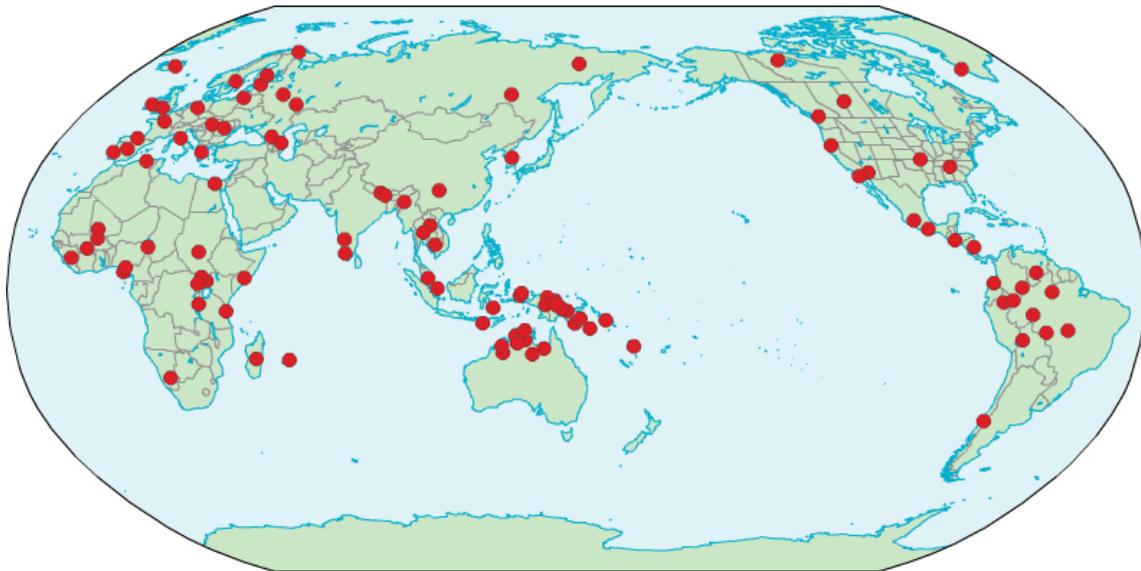

**Table 1.** Sample languages (n = 105)

Africa (17):	Arabic (Egyptian), Degema, Ha, Hdi, Igbo, Jamsay, Kabyle, Khoekhoe, Kisi, Koyra Chiini, Krongo, Lango, Ma'di, Ngiti, Somali, Supyire, Swahili
Eurasia (27):	Basque, Estonian, Evenki, Finnish, French, German, Greek (Modern), Hungarian, Icelandic, Irish, Italian, Kabardian, Kannada, Korean, Lezgian, Lithuanian, Malayalam, Mordvin (Erzya), Portuguese, Rājbanishi, Romanian, Russian, Saami (Skolt), Spanish, Swedish, Welsh, Yukaghir (Kolyma)
SE Asia and Oceania (13):	Hmong Njua, Indonesian, Kambara, Khmer, Kilivila, Lao, Malagasy, Meithei, Newari (Dolakha), Paamese, Semelai, Thai, Tukang Besi
Australia and New Guinea (23):	Alamblak, Arapesh, Daga, Gaagudju, Gooniyandi, Imonda, Inanwatan, Kayardild, Kobon, Lavukaleve, Malakmalak, Mangarrayi, Maung, Maybrat, Nabak, Sentani, Tauya, Una, Ungarinjin, Wambaya, Wardaman, Yelî Dnye, Yimas

---

North America (12):	Cree (Plains), Greenlandic (West), Halkomelem, Koasati, Maricopa, Mixtec (Chalcatongo), Osage, Pipil, Purépecha, Slave, Tiipay (Jamul), Wintu
South America (12):	Awa Pit, Hixkaryana, Hupda, Jarawara, Kwazá, Mapudungun, Mosestén, Rama, Sanuma, Trumai, Urarina, Yagua
Creoles (1):	Mauritian Creole

---

**Figure 1.** Sample languages (n = 105)

### 3. Symmetric and asymmetric polar interrogatives

We may observe symmetry and asymmetry in constructions and paradigms. In symmetric constructions, the presence of interrogative markers is the only difference as compared to the corresponding declaratives. This is the case, e.g., in Malayalam (2),<sup>1</sup> where the interrogative marker *-oo* appears clause-finally, and in Estonian (3), where the interrogative particle *kas* appear clause-initially.

---

<sup>1</sup> The following abbreviations are used in the glosses: 1 first person, 2 second person, 3 third person, ABS absolutive, ACC accusative, AFF affirmative, ALL allative, AOR aorist, ASS assertive, CNTMP contemporative, DAT dative, DECL declarative, DEF definite, ERG ergative, F feminine, FUT future, IMPF imperfective, IND indicative, INF infinitive, LCT locutor, LOC locative, NHYP nonhypothetical, NLCT non-locutor, NMLZ nominalizer, NPST nonpast, OBJ object, OBL oblique, PFV perfective, PL plural, POSS possessive, PRES present, PRT particle, PST past, PTCP participle, Q interrogative, REFL reflexive, SG singular, SOLCT solicitive, SS same subject, SUBJ subject, TOP topic, UNCERT uncertain, VN verbal noun.

(2) Malayalam (Asher and Kumari 1997: 8)

- |                              |                                   |
|------------------------------|-----------------------------------|
| a. <i>ava</i>   <i>varum</i> | b. <i>ava</i>   <i>varum-oo</i> ? |
| she come.FUT                 | she come.FUT-Q                    |
| ‘She will come.’             | ‘Will she come?’                  |

(3) Estonian (Erelt 2003: 108)

- |                                      |
|--------------------------------------|
| a. <i>sa tule-d täna meile</i>       |
| 2SG come-2SG today 2PL.ALL           |
| ‘You will come to visit us today.’   |
| b. <i>kas sa tule-d täna meile ?</i> |
| Q 2SG come-2SG today 2PL.ALL         |
| ‘Will you come to visit us today?’   |

In symmetric paradigms, the members of the paradigms used in declaratives and interrogatives show a one-to-one correspondence, and no grammatical distinctions are lost in the interrogative. This can be illustrated by the English paradigms in (4).

(4) English (constructed examples)

- |            |   |   |

| 3PL        | <i>they sing      do they sing ?</i>      | <i>they sang      did they sing ?</i>   |

Asymmetric interrogative constructions show structural differences as compared to the corresponding declaratives in addition to the presence of interrogative markers. In Halkomelem (5), the structure of the interrogative differs from the declarative in that interrogation is marked with an auxiliary and the lexical verb becomes less finite by losing its person marking to the auxiliary. In the Swedish interrogative construction (6) the asymmetry consists of a change in the position of the finite verb (verb fronting).

(5) Halkomelem (Galloway 1993: 238–239)

- a.  $k^w\acute{c}-l-\acute{x}^w-c\acute{a}l$   $t\acute{\theta}$   $x^w\acute{x}^w\acute{y}\acute{\theta}$

Asymmetric paradigms do not show a one-to-one correspondence between the members of the paradigms used in declaratives and interrogatives. In Awa Pit, declaratives can make a distinction between perfective and imperfective aspect (7a,b), but the past interrogative marker *-ma-* replaces these aspect markers (7c) and this distinction is lost in the interrogative paradigm. In fact, the appearance of the past interrogative suffix precludes the occurrence of all other suffixes between the root and the person marker and thus neutralizes the distinctions between the tense and aspect categories appearing in this position. Note that in addition to this paradigmatic asymmetry, the example also shows constructional asymmetry since the interrogative is not formed by simply adding an interrogative marker to a non-interrogative form, but the marking of tense-aspect is also affected.

(7) Awa Pit (Curnow 1997: 199, 221, 323)

- a.  $nu=na$   $juan=ta$   $pyan-t-zi$

'When Demetrio came, I was working.'
- c.  $anshik=na$   $a-ma-s?$   
yesterday=TOP come-Q.PST-LCT  
'Did you come yesterday?'

Asymmetric interrogatives – constructional or paradigmatic – may be further divided into subtypes according to the nature of the asymmetry, but this is not the main focus of the present study, where I will pay attention to how TAM categories behave in interrogatives. In symmetric interrogatives they are, by definition, expressed just like in declaratives. The cases that interest us are found within the asymmetric type. In other words, I will examine those cases of asymmetric interrogation where the asymmetry involves the marking of TAM categories. This will be the topic of the following section.

#### 4. The marking of tense, aspect and mood in polar interrogatives

This section discusses the different ways in which the marking of TAM categories in polar interrogatives has been found to differ from their marking in declaratives. For each type, at least one glossed example is discussed, and after the examples, some other languages are mentioned where TAM marking behaves in a similar manner. For lack of space, I cannot give examples of all the languages mentioned.

In Purépecha (8), polar interrogatives are marked by a polar interrogative marker that is part of the mood system of the language. The interrogative suffix *-(k)i* appears in the position where the declarative suffix *-ti* would appear in declaratives (except in the future where the interrogative marker is zero).<sup>2</sup> The other moods appearing in the same position are subjunctive, imperative and exclamative.

(8) Purépecha (Chamoreau 2000: 113)

- a. *'pedru i'se-š-ti-Ø 'pablu-ni*  
 pedro see-AOR-DECL-3SG pablo-OBJ  
 'Pedro saw Pablo.'
- b. *'pedru i'se-š-ki-Ø 'pablu-ni ?*  
 Pedro see-AOR-Q-3SG Pablo-OBJ  
 'Did Pedro see Pablo?'

---

<sup>2</sup> It is not entirely clear whether a case where the marker of the marked category (e.g., interrogative) simply replaces the marker of the unmarked category (e.g., declarative) and no other changes occur should be analysed as asymmetric at all (cf. the discussion in Miestamo 2007: 304–305). Nevertheless, strictly speaking, we are dealing with a difference in TAM marking between interrogatives and declaratives here, and this is thus clearly relevant to the present discussion.

In West Greenlandic (9), the interrogative mood is a member of the mood paradigm including declarative, interrogative, imperative/optative, contemporative, causative, conditional and participial moods. These mood distinctions are made in the inflectional suffix that also carries the marking of person and number of subject and object. The distinction between declarative and interrogative is not made in all person-number combinations. In (9a,b) we can see that with 2<sup>nd</sup> person singular intransitives the declarative and interrogative moods differ, but (9c,d) show that with transitives involving 3<sup>rd</sup> person singular subject and object the markers are identical. The marking of mood is thus affected in only a subset of the available person-number combinations. In West Greenlandic intonation takes part in the marking of polar interrogation and in the cases where there is no morphological difference between declaratives and interrogatives, only intonation marks the distinction.

| ‘Did Piitaq kill the stranger?’                     |                             |

The marking of polar interrogation is part of the mood system, the polar interrogative marker appearing in the place of a declarative marker, also in Korean, Kwazá, Somali and Tauya, and in some contexts in Maricopa as well. In Una, the interrogative marker also belongs to the paradigm of mood markers, but as declarative mood has no overt marking, the interrogative marker is simply added to the declarative.

In Welsh, polar interrogation is marked by a change in the form of the auxiliary in periphrastic tenses using *bod* ‘be’ as auxiliary. The present tense of this auxiliary, and to some extent also the past, has different forms for (affirmative) declaratives and interrogatives (as well as for negatives, which are irrelevant here). In (10a) the 3<sup>rd</sup> singular present declarative form of the auxiliary appears and in (10b) we find the corresponding interrogative form. It can be noted that, in the sense that we have a change in mood marking here as well, the Welsh construction is not that far from

constructions where interrogation is part of the mood system as in Purépecha – the main difference being that the marker that changes has the status of an auxiliary verb, and is therefore perhaps simply at an earlier stage on the cline of grammaticalization.

(10) Welsh (King 2003: 169)

- a. *mae- 'r*                      *dyn 'na- 'n*    *darllen*    *y*    *daily telegraph*  
 be.PRES.3SG.DECL-DEF man there-PRT read.VN    DEF Daily Telegraph  
 ‘That man is reading / reads the Daily Telegraph.’
- b. *ydy- 'r*                      *dyn 'na- 'n*    *darllen*    *y*    *daily telegraph ?*  
 be.PRES.3SG.Q-DEF man there-PRT read.VN    DEF Daily Telegraph  
 ‘Is that man reading / does that man read the Daily Telegraph?’

In Kabardian (11), polar interrogatives lack the affirmative mood suffix *-s* that occurs in affirmative declaratives (except for the present active tense where the suffix is not used in declaratives either). In most of the TAM categories polar interrogation is thus marked by the absence of the mood suffix. The mood suffix is also absent in negatives and in irrealis contexts.

(11) Kabardian (Colarusso 1992: 122, 126)

- a. *sə-λaaža-aγ-s*                      b. *ha-r*    *γəg<sup>y</sup>a-m*    *ø-y-a-g<sup>y</sup>-a-aγ ?*  
 1SG-work-PST-AFF                      3-ABS school-OBL 3-3-DAT-call-DAT-PST  
 ‘I worked.’                                      ‘Was (s)he attending school?’

In Khoekhoe, too, polar interrogation involves the loss of the declarative marker, but this is not the only segmental indication of polar interrogation since there are other structural differences between interrogatives and declaratives as well (and furthermore, an emphatic interrogative marker may appear in the position of the declarative marker). In Maricopa and Purépecha, the interrogative mood marker is zero in some persons or TAM categories, and in these cases we are also dealing with the loss of a declarative marker.

In addition to the construction exemplified in (7), Awa Pit has another interrogative construction, in which the auxiliary-like element *ki* (or *sa*) appears and the lexical verb is in a participial or infinitival form (12). This construction can distinguish between three tenses: the use of the infinitive conveys a future meaning (12a), the imperfective participle expresses the present (12b) and the perfective participle refers to the past (12c).

(12) Awa Pit (Curnow 1997: 324–325)

- a. *tilawa a-n ki-s ?*  
 tomorrow come-IMP PTCP Q-LCT  
 ‘Are you coming tomorrow?’
- b. *ashaŋpa mil ki-s ?*

 ‘Do you have a wife?’
- c. *nu=na ricaurte=mal i-t ki-s ?*  
 2SG=TOP Ricaurte=LOC go-PFV PTCP Q-LCT  
 ‘Did you go to Ricaurte?’

In the Halkomelem interrogative auxiliary construction (4), the marking of TAM categories is also affected in that the past and future markers occur on the auxiliary instead of the verb on which they would occur in the corresponding declaratives.

In Meithei (13), polar interrogatives are marked with the suffix *-lə*, which can only appear on nominalized verb forms. In (13d) *-lə* is preceded by the nominalizer *-pə*. Derivational TAM categories such as the perfective occur quite freely with the nominalizer, but inflectional categories such as the nonhypothetical or the assertive do not and TAM distinctions made by the inflectional categories are thus lost in the interrogative. Some derivational TAM suffixes, e.g. the potential and the non-potential, are inherently nominalizing, and the polar interrogative marker can thus be added to these forms.<sup>3</sup>

(13) Meithei (Chelliah 1997: 133, 140, 240)

In Hixkaryana (14) polar interrogation is marked by intonation. The language can make a distinction between nonpast and nonpast uncertain tenses, but in polar

---

<sup>3</sup> I am grateful to Shobhana Chelliah for confirming these facts in personal communication.

interrogatives only the latter category may be used (14b).<sup>4</sup> There is thus paradigmatic asymmetry between declaratives and interrogatives in that the certain-uncertain distinction is lost in nonpast interrogatives. Another case where TAM distinctions made in declaratives are lost in interrogatives was seen in Awa Pit (7) above. In Awa Pit, the loss of the distinctions is due to morphological incompatibility of the question marker and the markers of the categories expressing the TAM distinctions that are lost. In Hixkaryana this is not the case, and the loss of the distinction appears to be semantically motivated (a request for information involves lower certainty on the part of the speaker).

Loss of at least some TAM distinctions in polar interrogatives through mutual (morphological) incompatibility with the polar interrogative marker has also been found in West Greenlandic, Korean, Purépecha, Jamul Tiipay, Una, and more marginally in Basque and Imonda. The absence of mood marking in Kabardian also leads to the loss of some TAM distinctions. It should be noted that in West Greenlandic, Korean and Purépecha, the categories that are mutually exclusive with the interrogative marker are mood categories that are functionally incompatible with the interrogative to start with, e.g., declarative and imperative, and are thus, strictly speaking, irrelevant in a comparison between interrogatives and declaratives. In the other languages mentioned, as seen in the Awa Pit and Hixkaryana examples, at least some of the categories that are lost in interrogatives could, from a semantic point of view, be expressed in interrogatives. Lack of space precludes a more detailed discussion of these cases.

I have now discussed and exemplified the asymmetries concerning the marking of TAM in interrogatives vs. declaratives, i.e. the different ways in which the marking of TAM categories in polar interrogatives differs from their marking in declaratives in the sample languages. The following types were found: 1) interrogative marking is part of the mood system and replaces declarative mood marking in the same morphosyntactic position (e.g., in Purépecha, West Greenlandic and Welsh), 2) polar interrogation

---

<sup>4</sup> No example of a declarative with a nonpast uncertain tense verb, parallel with the examples in (14a), was found in the source. The translation in square brackets in (14b) shows what the meaning of the sentence without question intonation would be according to my reading of the source.

involves the loss of a declarative mood marker without the latter being replaced by an interrogative marker in the same morphosyntactic position (e.g., in Kabardian), 3) polar interrogation is expressed by an auxiliary construction that marks at least some TAM categories in a different way from how they are marked in declaratives (e.g., in Awa Pit), 4) the construction expressing polar interrogation requires the verb to be in a nominalized form which has an effect on the marking of least some TAM categories (e.g., in Meithei), 5) some or all TAM distinctions made in the declarative are lost in polar interrogatives (e.g., in Hixkaryana and Awa Pit). Note that this classification must be regarded as tentative at this pilot stage of the study.

In addition to the comparison between interrogative and declarative structure, we may also note that in a number of languages different interrogative constructions are used in different TAM categories. This is the case, e.g., in Awa Pit, where past tense interrogatives may use the suffixal construction (7) but other tenses must use the auxiliary construction (12), as well as in Halkomelem, Jarawara, and Welsh.

## **5. A comparison with negation**

The ways in which TAM categories behave in polar interrogatives (vs. declaratives) can be compared to earlier observations about their behaviour in declarative negatives (vs. affirmatives) made in (Miestamo 2005; Miestamo & van der Auwera, in press). First of all, we may observe that the loss of TAM distinctions is clearly less common in polar interrogation than in declarative negation; a preliminary count based on the pilot sample shows loss of TAM distinctions in polar interrogatives in 11 languages (including the three strictly speaking irrelevant cases mentioned above), whereas in negation this happens in 21 out of the 105 languages.<sup>5</sup> Furthermore, unlike in declarative negatives, the loss of TAM categories in polar interrogatives is almost always due to morphological incompatibility (occupying the same slot) with the question marker (naturally, semantics is partly responsible for which markers occur in the same slot). The only clear exception is found in Hixkaryana, where morphological incompatibility does not play a role, and the exclusion appears to be semantically motivated. In polar interrogatives, the loss of categories due to occupying the same slot most typically results in the loss of mood distinctions, and other categories are less

---

<sup>5</sup> The difference is interesting for the discussion on how the asymmetries observed between marked and unmarked categories can be explained (cf. Haspelmath 2006), see (Miestamo 2007) for discussion.

commonly affected. In negatives, tense, aspect and mood are equally often affected.

Another interesting difference between interrogatives and negatives can be observed in how they relate to irrealis marking. Both polar interrogatives and declarative negatives are prototypically about states of affairs that are either unrealized or whose reality status is not known to the speaker, and thus it could be expected that they behave similarly with respect to irrealis marking. My study shows, however, that irrealis marking is required in declarative negatives much more often than in polar interrogatives. In the 105-language pilot sample, there are 8 languages where declarative negatives require irrealis marking (at least in some TAM categories) but polar interrogatives can freely use realis as well (Alamblak, Arapesh, Halkomelem, Korean, Mangarrayi, Maung, Ungarinjin, and Wambaya), but there is only one language where the opposite is the case (Hixkaryana). In one language both polar interrogatives and declarative negatives must use an irrealis form (the non-declarative marked form in Kabardian), and in all the rest of the sample, realis can be freely used in both negatives and interrogatives. I do not have an explanation to offer for this difference at this point, but the line of explanation proposed by Mithun (1995), where the difference found in Caddo vs. Central Pomo is accounted for by scope differences, might be worth pursuing.

## **6. Conclusion**

In this paper, I have taken a preliminary look at TAM marking in polar interrogatives, paying special attention to how it differs from TAM marking in declaratives. The observations are based on a pilot sample of 105 languages. I first illustrated the distinction between symmetric and asymmetric interrogatives, then discussed the ways in which TAM marking was found to differ between interrogatives and declaratives, and then compared the findings to similar observations made on negatives (vs. affirmatives). In future work, these preliminary results must be re-examined with a much more extensive and representative sample, which will certainly reveal additional interesting phenomena concerning TAM in polar interrogatives and result in modifications of the preliminary typology proposed here. The issue of explaining the cross-linguistic findings can then also be addressed.

## Abstract

There is increasing recognition in typology that linguistic categories are language-specific and not universal, increasing the need for explicitness in language descriptions. In light of this development, I argue in this paper that pre-existing labels and descriptions for a set of subject-marking TAM prefixes in Eleme do not adequately characterise the distribution and use of these forms, which is conditioned by the complex interaction of person and number features, Aktionsart, epistemic modality and information structure. In response to the challenges raised by these data, I argue that when multiple analytical perspectives are required to understand the function of a grammatical form, fine-grained quantitative analyses with description give a complex but useful basis on which to compare languages.

**Keywords:** tense, aspect, modality, categories, discourse.

## 1. Introduction

There is increasing recognition in typology that linguistic categories are language-specific not universal (e.g. Croft 2001, Haspelmath 2007) and that the linguistic categories posited in a description are language-specific descriptive categories (cf. Haspelmath 2008). One way of indicating this viewpoint in descriptions is to use upper case labels such as English Past or Eleme Continuous to distinguish language-specific uses of these terms from some universal notion of ‘past’ or ‘continuous’. Given that, in principle, we are free to label a category with any language-specific term deemed appropriate, there is an onus on the language documenter to increase the transparency of the descriptive content of such terms, and not to assume the existence of pre-established categories (e.g. from the Latin tradition). Along with the augmented need for detail and clarity in language descriptions, the realization that categories are language-specific calls for a new honesty in assessing the scientific credentials of the methodologies typologists use in the pursuit of comparing grammatical categories cross-linguistically. In this paper I explore the consequences of Haspelmath’s (2007) proposal that ‘pre-established categories don’t exist’ in relation a set of verbal prefixes in Eleme (Ogonoid, Niger-Congo) that have proven ‘difficult’ to label transparently using traditional terminology. I demonstrate that if we rely on pre-conceived ideas about the properties pre-existing labels are assumed to have, previous analyses of this set of verbal prefixes based on evidence from elicited utterances - and even spontaneous data taken from discourse - do not correctly characterise their use. To understand their nature it is necessary to collate evidence on their *distribution* from discourse data (i.e. not just using spontaneous examples, but spontaneous examples in context). I argue that multiple analytical perspectives are required to adequately describe any grammatical

form that conflates or challenges pre-established grammatical categories. More specifically, I argue that when multiple analytical perspectives are required to understand the function of a grammatical form, fine-grained quantitative distributional analyses with description give a complex but potentially useful basis on which to compare languages. Access to data of this kind thus raises new challenges for how typologists might compare languages when a language-specific category can only be analysed successfully from multiple perspectives.

The paper begins with a brief introduction to Eleme and an outline of the problem for language description (§2); this is followed by an exploration of the TAM characteristics of the Eleme prefixes in question (§3) and a detailed examination of their subject marking properties with a high frequency verb in traditional narrative discourse (§4). The paper concludes with a summary (§5).

## 2. Background

Eleme is an Ogonoid (Benue-Congo, Niger-Congo) language spoken in Rivers State in south-eastern Nigeria. It is characterised typologically by nominative-accusative alignment, SVO word order and a rich verbal morphology including several productive reduplication strategies. Eleme also makes extensive use of lexical and grammatical tone. Multiple paradigms of participant reference affixes are evident in the language, including one set of subject-indexing prefixes that exhibit a range of semantic properties associated with TAM categories. This set of prefixes, exemplified in Table 1, has previously been described as marking the ‘Definite Past’ (Wolff 1964: 47, Williamson 1973: 10, Obele 1998: 212), with temporal characteristics taken to be primary in the attribution of a category label. For instance, Wolff (1964: 47) states “The Eleme prefix *a-* or *wa-* indicates recent past, but the form is also used in answer to the question ‘do/did you...’, hence perhaps the best gloss for the Eleme construction is ‘do/did...’”. Similarly, Williamson (1973: 10) only briefly describes the use of this form, by mentioning that “This verb form is used in reply to the question ‘Did you...’” Williamson contrasts the use of the Definite Past with the Simple Past (1973: 10), which is called the Aorist by Wolff (1964: 46), and referred to as the Perfective in the present study (§3). Obele (1998: 211-212) uses the same terminology as Williamson (1973) but does not discuss the use of either the Definite Past or the Simple Past in terms of their semantics or usage. Since the use of these forms is not explained any further, the reader must assume the properties of a pre-established category since otherwise constraints on the use of these forms remain opaque.

Table 1. Category X prefixes

	SINGULAR	PLURAL
1 <sup>st</sup>	<i>ma-</i>	<i>wa-</i>
2 <sup>nd</sup>	<i>wa-</i>	<i>wa-</i>
3 <sup>rd</sup>	<i>a-</i>	<i>ba-/a-(...-ri)</i>

In this paper I challenge the appropriateness of the label ‘Definite Past’ in terms of its descriptive adequacy, but also explore the notion of how much information – and

what type of information – is needed to characterise a category that is associated with a number of different meanings. First, I review the decisions made in the nomenclature of this ‘difficult’ category and therefore, for impartiality and clarity, I refer to them as Category X prefixes for the time being.

The Category X prefixes append directly to the verb root and are characterised by the phonological shape (C)a-. The first-person singular (*ma-*) and the third-person singular and plural (*a-* and *ba-*) are each uniquely distinguished in form while a typologically unusual conflation exists of the second-person marker with the first-person plural form *wa-*. The Category X prefixes typically occur alongside a restricted set of the Default Subject prefixes presented in Table 2 and, in the case of the second-person plural and third-person plural subjects, a set of subject suffixes, as in Table 3. The subject suffixes are not part of a discontinuous morpheme but rather have distinct distributional properties (Bond, to appear).

Table 2. Default subject prefixes

	SINGULAR	PLURAL
1 <sup>st</sup>	<i>m̃-/ñ-/ɲ-/ɳ</i>	<i>rɛ̃-/nɛ̃-</i>
2 <sup>nd</sup>	<i>ò-/ɔ̃-</i>	<i>ò-/ɔ̃-</i>
3 <sup>rd</sup>	<i>è-/ê-</i>	<i>è-/ê-</i>

Table 3. Subject suffixes

	SINGULAR	PLURAL
1 <sup>st</sup>		
2 <sup>nd</sup>	<i>-∅</i>	<i>-i</i>
3 <sup>rd</sup>	<i>-∅</i>	<i>-ri</i>

The paradigm in (1) exemplifies the distribution of the Category X prefixes with the verb *ʔà* ‘leave’.<sup>2</sup>

- (1)
- |   |  |
|---|--|
| <p>a. <i>ma-ʔà</i><br/>1SG.X-leave<br/>‘I left.’</p>              | <p>b. <i>nɛ-wa-ʔà</i><br/>1PL-X-leave<br/>‘We left.’</p>           |
| <p>c. <i>ɔ̃-wa-ʔà-∅</i><br/>2-X-leave-SG<br/>‘You (SG) left.’</p> | <p>d. <i>ɔ̃-wa-ʔà-i</i><br/>2-X-leave-2PL<br/>‘You (PL) left.’</p> |
| <p>e. <i>a-ʔà</i><br/>3.X-leave<br/>‘He left.’</p>                | <p>f. <i>ba-ʔà</i><br/>3PL.X-leave<br/>‘They left.’</p>            |

- g. *a-ʔà-ri*  
 3.X-leave-3PL  
 ‘They left.’

While previously described in terms of their temporal characteristics, spontaneous speech data reveal that constructions containing the Category X prefixes have a default reading of past time reference only if the predicate is not stative (2). In particular, if we take a fairly uncontroversial conception of what ‘past’ tense refers to, such as Bybee, Perkins and Pagliuca’s (1994: 316) definition that “the situation occurred before the moment of speech”, the implication of the use of this particular term for a category (rather than ‘non-future’ for example) is that it is not used for present or future situations. However, if the predicate is a stative one, as in (3), there is a present time reading, whereby the situation occurs simultaneously with the moment of speech and not before it (as the label ‘past’ suggests).

- (2)            *ɔwá*    *ɔkɔ́*    *a-sii*            *ɲkél-ɔ̀nʷi-yò*  
 wife    spirit    3.X-catch    small-child-SPF  
 ‘The spirit woman caught the boy.’

- (3)            *ɲɸɸé*            *a-bitá*            *ɔʔɔ̀ni*  
 mosquito    3.X-be.many    here  
 ‘There are many mosquitoes here.’

Conversely, perfective events in the past do not require a Category X affix, as in (4), suggesting that past time reference is simply a default characteristic of the form.

- (4)            *ɲgbaa*    *sii-ra*            *ɲna*            *dʒuá*  
 dog    catch-AGAIN    animals    bring  
 ‘Dog caught animals again (and) returned (with them).’

The type of contrast evident in these examples indicates that without further justification, a tense-based characterisation of the function of these affixes is misleading. In the discussion that follows, I show that the distribution of these prefixes is conditioned by the complex interaction of person and number features, Aktionsart, epistemic modality and information structure, challenging the usefulness of the labels applied to these forms in previous descriptions, but also raising more general concerns about the comparability of language-specific categories cross-linguistically.

### 3. A paradigm-by-paradigm approach

In Bond (2006a) it is argued that the morphologically unmarked default category in Eleme, referred to as the Perfective, is used in opposition to a number of morphologically marked aspectual/modal categories rather than absolute tenses. Perfectives mark a situation as temporally bounded, with the narration of events among

the typical functions of forms identified as perfective cross-linguistically. In narrative discourse, categories identified as ‘perfective’ tend to encode what Hopper (1979) calls foreground, while other categories – particularly those identified as imperfective – are used to encode the background. Foreground concerns “the parts of the narrative which relate events belonging to the skeletal structure of the discourse” (Hopper 1979:213), while background concerns supportive material that does not narrate the main events of the discourse.

In order to illustrate the relationship between foreground/background and aspect in Eleme, consider the personal narrative in (5). In personal narratives (where one of the main protagonists is the speaker), constructions that foreground information are commonly marked for subject using the default subject prefixes but are otherwise morphologically unmarked for aspect or tense.

- (5) a. *ba-dzú tfulá-mi tí-ga-dzí ðtðð nè*  
 3PL.X-come meet-1SG when.1SG-CONT-climb house give  
*ðtðð èbo ʒʔʒ nè ñ-tĩ-i*  
 house top place REL 1SG-stay-PRCL  
 ‘They came and met me when I was climbing the stairs to the place that I lived.’
- b. *wɛ wí-mi wí-mi kɔ́ ñ-titá-i*  
 and call-O1SG call-O1SG COMP 1SG.HORT-come.down-PRCL  
 And called to me, called to me that I should come down.’
- c. *wĩ-kpè ñn<sup>w</sup>ɛ dzú tfulá-ba dzú eke*  
 and.1SG-return back come meet-3PL come under  
 ‘And I came back down and met them.’
- d. *kí-ri-kɔ́ ñ-tĩ ʒʔʒni sé*  
 PROX-3PL-say 1SG-stay here Q  
 ‘Then they said do I live here?’

Foregrounded events in this sequence are first indicated in (5a) with the verbs *dzú* ‘come’ and *tfulá* ‘meet’. Note that the first of the verb stems in this Serial Verb Construction is marked with the Category X prefix *ba-* and not the third-person plural Default Subject affix complex *è-...-ri*. Participant reference marking aside, the subsequent verb forms used for the main sequence of events are morphologically unmarked. They are *wí* ‘call’ in (5b), and *kpè* (*ñn<sup>w</sup>ɛ*) ‘return’, *dzú* ‘come’ and *tfulá* ‘meet’ in (5c). Semantically, the unmarked forms have a default reading of perfective aspect and a secondary implication of past time reference. Finally, *kɔ́* ‘say’ in (5d) is also part of the foreground, but differs from the other foregrounded examples in that it is marked with the Proximative prefix *kí-*. This marker explicitly indicates the immediacy of the event in relation to the preceding one.

These forms used for foregrounding contrast with verb forms used for background information, which are encoded using a variety of other constructions. For instance, in (5a), some background information is indicated by a Continuous verb form. This clause is the only one that chronologically overlaps (i.e. is not sequential) with a foregrounded event in this sequence. It describes a situation necessary for understanding later foregrounded events, namely, why the protagonist was called to (i.e. because he was going up the stairs, in a direction away from the person calling out) and why he had to come down (because he was going upstairs and was therefore above the level of the caller). The relative clause in (5a) also provides background information necessary for understanding why the protagonist is asked if he lives in the house, but it is not part of the main sequence of events. The subsequent events are all sequential.

Despite the fact that all of the narrative (i.e. Perfective) verbs have past time reference in (5), there are a number of reasons why constructions of this type are best described in terms of perfective aspect and not past tense. Firstly, in Eleme, constructions containing a verb stem that is not marked by tense/aspect morphology contrast with constructions that are marked for imperfectivity using a Habitual aspect suffix or a Continuous aspect prefix. They do not contrast with constructions marked with present, future, or non-past tense. Secondly, the verb root has the same form and tone in both imperfective and perfective constructions, indicating that the only difference between an imperfective construction and a perfective construction is the presence of an aspectual affix (for a fuller account of this point see the arguments presented in Bond 2006a).

While constructions with morphologically unmarked verb stems are characterised as Perfective, achieving an adequate characterization of the Category X prefixes is much more complex. From a typological perspective, Category X has some of the characteristics of what Bybee, Perkins and Pagliuca (1994: 78-81) call an ‘old anterior’ - a category which is proposed to occupy some part of the middle ground on a grammaticalization chain between markers of anteriority at one end and markers of perfectivity at the other. While perfectives are used in the narration of events, anteriors (commonly referred to as ‘perfects’) mark a past situation as relevant to a situation at a reference time. Anteriors are used in narratives much more selectively than perfectives. The Eleme Anterior construction contains an Anterior auxiliary *bere* as well as a Category X prefix (6b), revealing a possible connection between the two in terms of meaning.

- |     |    |                       |              |    |                         |               |           |
|-----|----|-----------------------|--------------|----|-------------------------|---------------|-----------|
| (6) | a. | $\dot{\text{ɛ}}n^w i$ | Ø- <i>dò</i> | b. | $\dot{\text{ɛ}}n^w i$   | <i>a-bere</i> | <i>dò</i> |
|     |    | child                 | 3-fall       |    | child                   | 3.X-ANT       | fall      |
|     |    | ‘The child fell.’     |              |    | ‘The child has fallen.’ |               |           |

Old anteriors typically express one or more of the following meanings: resultative, completive, non-anterior past or perfective, ongoing states, commencing states or evidentiality. Of these, the Category X prefixes occur with resultant states, ongoing states, non-anterior perfectives and arguably indicate epistemic modality bearing some similarity to evidentiality in a broad sense, as discussed below.

As well as general states of the type expressed by verbs such as *ɲá* ‘know’ and *gbo* ‘have’ which are always inflected with a Category X prefix in affirmative constructions,

Perfective is coined to represent a category in Eleme that does not fit easily within the bounds of traditional terminology for grammatical categories, partly because the (language-specific) labels ‘Anterior’ and ‘Perfective’ are used more appropriately for other constructions in the language. Taking the stance that categories are language-specific means that we could just as well retain the name Category X for this paradigm of forms, because the use of a label with semantic association is simply a helpful mnemonic.

At what point then is a language-specific category adequately described to be useful to a typologist? Arguably, given the multiplicity of uses of the Anterior-Perfective prefixes, we still don’t have an adequate characterisation of this language-specific category because it has been characterised in a paradigmatic way, on the assumption that its primary use is that of a conflation of TAM categories. In the next section, I argue that fine-grained quantifiable evidence from frequency counts quickly reveals that an alternative less-intuitive analysis for the Eleme Anterior-Perfective is required.

#### **4. Quantitative analysis**

Corpus studies are well known for returning insightful results regarding phenomena that are otherwise undetected or misanalysed. This is particularly the case when the distribution of a form is not directly perceivable without quantitative analyses. Well-known studies of this type include Du Bois’s (1987) study into the discourse basis for ergativity, Fox and Thompson’s (1990) study of relative clauses in information flow and Bickel’s (2003) typological investigation of referential density.

In order to test the paradigm-centric analysis of the contrast between the use of the zero-marked perfective verb stems and the use of the Anterior-Perfective prefixes, a small corpus of Eleme traditional narratives was examined for the distribution and frequency of subject-indexing verbal affixes. The stance taken here is that valid linguistic analyses concerning language use should stand up to being tested by frequency counts in a spontaneous speech corpus and thus corpus analysis is an appropriate tool for checking the suitability of a linguistic description.<sup>3</sup> This paper reports preliminary analyses with a single lexical verb.

The frequency counts that form the basis for the observations in this paper come from a genre-stratified corpus of seven narratives told in a naturalistic setting in which each speaker had an audience of at least three people. The texts were chosen for inclusion in the corpus on the basis of (i) similarity of discourse style, (ii) spontaneity of speech, (iii) detailed level of analysis working directly with language consultants on the translations.

Table 4 details the number of verbs identified in each text in the corpus. For the purpose of the study a verb must be able to be the lexical head of a predicate without additional support material. Thus, while serial verb constructions containing two verbs count as two items in the frequency count, auxiliary verb constructions containing an auxiliary and a lexical verb count as only one verb. This is because auxiliaries in Eleme cannot form a predicate without a lexical verb, but lexical verbs can form a predicate without an auxiliary. Verbs that are morphologically marked for dependency on another verb are likewise not counted in the frequency count since they are always dependent on some other lexical verb acting as the head of the predicate. For a more detailed

exposition of the characteristics of verbs in Eleme, see Bond (2006a: 44-52). Within the corpus, a total of 779 verbs were counted that did not exhibit signs of morphological dependency.<sup>4</sup>

*Table 4.* Verb count within narrative discourse corpus

	TEXT NAME	NO. OF VERBS
1	Dog and his master	172
2	The child and the witch	144

4	Tortoise's belly	124
5	The rat baby	104
6	The flower pickers	65
7	Wuwu and the banana	40
	TOTAL	779

A total of 35 different subject-indexing strategies were identified within the corpus. This included five different zero strategies because in some cases, the selection of a particular TAM marker excluded the possibility of subjects with certain person or number features. For instance, a verb with the Continuous prefix *ka-* but no further subject marking morphology (i.e. the last case default marker for this category) excluded the possibility of a first-person singular subject (which would be marked with *ga-*) or a third-person plural subject (which would have the form *ka-ra-*). Across the corpus only three types of subject indexing strategy were found in every text: zero-marking (i.e. bare stems) with third-person singular subjects, Continuous-marked stems (*ka-*) with third-person singular subjects, and Anterior-Perfective marked stems (*a-*) with third-person singular subjects.

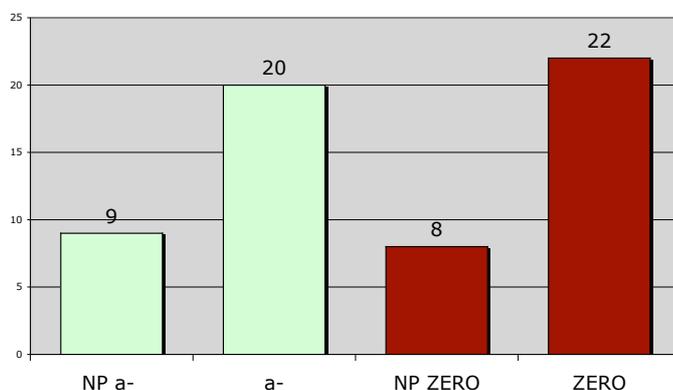

*Table 5.* Ten most frequent lexical verbs across the narrative corpus

VERB	FREQUENCY	NO. OF TEXTS
<i>kɔ</i> 'say'	62	7
<i>tfú</i> 'take'	49	7
<i>sí</i> 'go'	41	6
<i>ná</i> 'do'	37	6
<i>gwá</i> 'reach'	32	7
<i>mɔ</i> 'see'	32	7
<i>ʔà</i> 'leave'	22	7
<i>tfa</i> 'run'	19	5
<i>dʒú</i> 'come'	16	7
<i>ná</i> 'know'	17	4
<i>sii</i> 'catch'	16	4

Of the 779 verbs identified in the corpus, frequency counts were taken of each lexical item in order to identify those verbs for which the most convincing generalisations could be made. The ten most frequent lexical verbs are listed in Table 5. Of these ten verbs, only six were found in all seven texts, with *kɔ* ‘say’ found in all texts at high frequency due to the genre of the corpus. The only subject indexing strategy found with all of the high frequency words was the Anterior-Perfective *a-* and perfective stems with no overt marking, i.e. zero-marking. While high frequency verbs are well known for acquiring special grammatical functions and thus exhibiting specialised behaviour, in a relatively small corpus such as the one under discussion here, they are the only tokens with the high enough frequency to yield meaningful results. Furthermore, in an adequate account of the Anterior-Perfective category, it is not sufficient to consider the use of the prefixes in terms of generality (e.g. it behaves like X with most types of verb) without considering frequency (e.g. it occurs most frequently in X type constructions).

Focusing on the highest frequency verb ‘say’, all uses of the verb in the corpus with a third-person singular logical subject were investigated, resulting in a reduced total of 59 instances (out of 62) in total; of these, 29 instances (49%) were marked with the third-person Anterior-Perfective prefix while the remaining 30 verb stems (51%) were not morphologically marked for person or number. Of the stems marked with the Anterior-Perfective prefix, 9 (15% of all instances) were also preceded directly by an NP subject, while a comparable 8 unmarked stems (14% of all instances) were preceded by an NP subject, as indicated in Figure 1.

Figure 1. Distribution of Anterior-Perfective and zero marking subject strategies with 59 tokens of the verb *kɔ* ‘say’ with third-person singular subjects.

Within the 59 tokens, which have been controlled for speech genre, spontaneity, audience setting, verb type, person and number of subject, the degree of variation within the corpus for this verb is surprising. Given that *kɔ* ‘say’ is used in traditional narrative discourse to report the speech of others with omnipresent authority, the epistemic quality of the verb should not be expected to vary quite so much. Certainly, variation in the degree of epistemic authority the speaker has for each *kɔ* construction does not vary in the translations into English or perceivably in the structure of the story, suggesting this is not the motivation for the alternation. In order to pursue this issue, I investigated

four variables relating to discourse structure and the specific distributional properties of the verb *kɔ* ‘say’, namely:

1. Whether the speech introduced was direct or indirect.
2. Whether the subject referent for the token verb is different from the subject referent of the preceding verb (i.e. there is a *switch* of reference) or whether it is the same (i.e. there is *continuity* of reference).
3. Whether the speech predicate was preceded by another speech predicate or a non-speech predicate.
4. Whether the verb was the first verb in a predicate (V1) or a subsequent verb (V2).

Of these three variables only the final three revealed any correlations with the presence or absence of an NP subject and/or whether the token is a bare stem or marked with the Anterior-Perfective prefix *a-*, as detailed in Tables 6 and 7.

*Table 6. Correlations between three variables of discourse structure (NP subject).*

NP a-	SWITCH	CONTINUITY
SPEECH PREDICATE PRECEDES	2	0
NON-SPEECH PREDICATE PRECEDES	7	0

NP zero	SWITCH	CONTINUITY
SPEECH PREDICATE PRECEDES	3	0
NON-SPEECH PREDICATE PRECEDES	5	0

*Table 7. Correlations between three variables of discourse structure (no NP subject).*

a-	SWITCH		CONTINUITY	
SPEECH PREDICATE PRECEDES	8		0	
NON-SPEECH PREDICATE PRECEDES	2		10	

zero	SWITCH		CONTINUITY	
	V1	V2	V1	V2
SPEECH PREDICATE PRECEDES	3*	0	0	2†
NON-SPEECH PREDICATE PRECEDES	2**	0	10	5†

\* In all cases the answer is a response to a question or recognition of a statement.

\*\* Switch in subject but continuity of discourse topic; the preceding subject referent could not be interpreted as the subject referent of *kɔ* ‘say’ due to animacy constraints.

† Perhaps better analysed as a complementizer.

The figures in Table 6 indicate that when an NP subject precedes *kɔ* ‘say’ this is a consistent signal that there is a switch in the subject referent from the previous clause. The data in Table 7 suggest that when there is no subject NP a more complex situation prevails. If the token verb is marked by the Anterior-Perfective prefix and a speech predicate precedes the clause containing the token, there is always a switch in the reference of the subject. For instance, in the following example, a speech predicate (9a) precedes the token verb in (9b). The use of the Anterior-Perfective prefix in the second speech predicate indicates that the two speech verbs have different subject referents.

- (9) a. *a-kɔ é-ká-sí-ri m̀̀̀ti n-̀̀̀ne ké-ye*  
 3.AP-say 3-HORT-go-NEG lest one-person slaughter-O3SG  
 ‘She said he shouldn’t go lest someone slaughters him.’
- b. *a-kɔ m̀̀̀ ka-sí-ye*  
 3.AP-say COMP CONT-go-LOG  
 ‘He said that he will go.’

In contrast, when a non-speech predicate precedes a speech predicate headed by *kɔ* ‘say’ marked with *a-*, the prediction is that there will be continuity of reference, i.e. both predicate subjects have the same referent, as in (10), where the subject referents of *sii* ‘catch’ and *kɔ* ‘say’ are the same.

- (10) a. *̀̀̀w-̀̀̀k-a-sii-ye kwí*  
 woman-spirit-3.AP-catch-O3SG grabbing.noise  
 ‘The spirit woman grabbed him.’
- b. *a-kɔ b-̀̀̀-̀̀̀er-̀̀̀ni d-̀̀̀súri*  
 3.AP-say COP-2-stay-here eat-water.yam.porridge  
*̀̀̀t-̀̀̀-̀̀̀ra ñdʒe*  
 when-2-leave-AGAIN NEG.LOC  
 ‘She said “Since you stayed here and ate this porridge the time for you to leave will not come”.’

While the data is not exceptionless in this respect, variation of this kind should not be considered unusual since speakers make choices about reference, rather than follow hard and fast rules.

When the verb *kɔ* ‘say’ is a bare stem there is typically continuity of reference for the subject of the token verb from the preceding verb. The examples in (11) and (12) typify this type of construction in the corpus, in which the action of the preceding verb is a ‘preparatory action’ for the speech that follows (or is concurrent with the action of the subject marked verb).

- (11) *éméré́ a-kpa ènu kɔ́ kára b-àné re*  
 chief 3.AP-beat thing say just COP-person REL  
*ke a-má ð̃ñʷí á-bira òmú bira ð̃ñʷí-ye*  
 PR TCL 3.AP-give.birth child 3.HORT-bathe water bathe child-3SG.POSS  
 ‘The chief announced that anybody who gives birth to a child should bathe her baby.’

- (12) *a-tfú òge-ye kɔ́ àkà dzú òñʷé*  
 3.AP-take machet-3SG.POSS say mother come behind  
 ‘He took his machete (and) said mother should follow behind.’

In the two instances detailed in Table 7 where the token in question is preceded by a non-speech predicate, there is a switch in the reference but no overt marking of a pronominal form, the subject referent of the speech predicate is the topic, and the logical subject of the intervening preceding predicates could not be the speaker of the following speech since they are inanimates.

For instance, the examples in (13) come from a story in which a small child goes searching for a fire, which he forgets about when he is fed water yam porridge by a spirit woman. The topic of the discourse is *̀̀nkól-ð̃ñʷí* [̀̀nkól-ð̃ñʷí] ‘the small child’, which is followed by predicates that have *̀̀mp’o* [̀̀mpe, ̀̀mp’o] ‘heart’ and *̀̀nsá* ‘fire’ as their logical subjects. However, the topic is interpreted as the subject referent of the uninflected verb in the relative clause, and not *̀̀nsá* ‘fire’ (i.e. the subject of the preceding clause), indicating that this is a case of topic continuity.

- (13) a. *̀̀nkól-ð̃ñʷí, ̀̀mpe a-?oro*  
 small-child heart 3.AP-white  
 ‘The child, he was happy (lit. The child, his heart was white/pure).’
- b. *̀̀nsá kí-tã ̀̀mp’o, ̀̀nsá re kɔ́ ka-sí ?ó-m-èsaa*  
 fire PROX-desire heart fire REL say CONT-go roast-INS-yam  
*kí-tã ̀̀mp’o*  
 PROX-desire heart  
 ‘The fire was forgotten, the fire that he said he would go (and) roast the yams with was forgotten.’

There are some instances in the corpus where the verb is the second speech verb or verb of communication in a sequence, in which case it may be better analysed as a complementizer. This is the stance taken in (5b), and in similar examples in Bond (2006a, 2006b), since in examples like these, *kɔ́* has a perceptibly low tone and occupies a position consistent with another complementizer *mè*. For instance, in (9b), the lexical verb *kɔ́* is followed by *mè* (a complementizer that is never a verb), while in (14), *biná* ‘ask’ is followed by *kɔ́*. Conceivably, however, these could also be analysed as concurrent activities in a Serial Verb Construction in a similar way to those in (11).

- (14) *a-biná kɔ̀ àwiá be tʃá wɔ?*  
 3.AP-ask say/COMP sibling COP walk how  
 ‘He asked ‘How did your sister walk?’

The factors that underlie the distribution of NPs with and without the Anterior-Perfective prefix is less discernable from the available data about *kɔ̀* ‘say’ than the factors influencing the distribution of the prefixes when no NP subject precedes the token verb. However, there is some evidence to suggest that the use of the Anterior-Perfective prefixes with an NP subject may be conditioned by definiteness/specificity. For instance, in the corpus verbs with indefinite NP subjects marked with *nne* ‘one’ (11 in total) are never accompanied by Anterior-Perfective marking, and neither are those NPs which are morphologically indicated as being a highly specific identifiable referent, marked by the second position enclitic *=yo* (10 in total), suggesting that when NPs are morphologically marked in terms of their definiteness/specificity the Anterior-Perfective prefix is not used. This is an avenue that requires further investigation, across all verbs in the corpus. However, what I do not assume here is that the factors that influence the selection of the Anterior-Perfective prefix *a-* when an NP is present are necessarily identical to those that select *a-* when an NP subject is not present.

While the data provided here are somewhat impressionistic given the factors that interact with the selection of the Anterior-Perfective prefixes, they do indicate that reference tracking is a key feature of the prefixes, which have different distributional behaviour to verbs that are zero marked. Future work in this domain will involve extending the analyses across all the verbs within the corpus, and then across different genres of speech in order to consolidate or refute the observations made here as applicable across a wide spectrum of verbs.

## 5. Conclusions

Even the most earnest attempts to provide an accurate characterisation of a ‘difficult’ language-specific category are dogged by the absence of discourse-based distributional analyses because of the multiplicitous nature of factors affecting the use of forms. Such is the case in providing an adequate analysis of the Eleme Anterior-Perfective prefixes, which until now have been discussed in terms of their temporal characteristics, but not their referential characteristics.

The generalizations I make here hold for predicates containing the verb *kɔ̀*, within traditional narrative discourse. This is because the sample I have used is genre-specific, and the distribution pertains to the use of the third-person singular Anterior-Perfective prefix *a-* with only one lexical verb. Since not all members of a putative paradigm behave in the same way, one should not assume that the same characteristics hold for the first and second-person forms (or indeed the third-person plural forms), for which there is currently little data.

While paradigm-by-paradigm analyses of other verbs suggest that the distinction between the use of *a-* vs. zero-marking may be conditioned by the quality of evidence a speaker has for a proposition, this is not what underlies the use of *a-* vs. zero marking in the data investigated from this small corpus. Confirmative and anterior-like uses of

constructions containing the prefixes are neutralized in narrative discourse, where the story teller is an omni-present authority and thus all speech has the same evidential or ‘status’ properties. The data presented here suggests:

1. The presence or absence of an NP is an important factor in determining the referent of the subject marking prefix *a-*.
2. A token verb may be zero marked for subject and not directly preceded by an NP if the action of the preceding verb is either preparatory for or concurrent with the action of the token verb.
3. If a non-speech predicate precedes a token of *kɔ* marked with *a-* it will typically indicate continuity of reference, but if a non-speech predicate precedes it will trigger a switch in reference.
4. Selection of the Anterior-Perfective prefixes may be linked to definiteness/specificity or the morphological marking of such nominal categories.
5. In narrative discourse, recent past-ness is not an important characteristic of the meaning expressed by constructions containing the Anterior-Perfective prefix *a-*, nor can its presence be attributed to answering the question, ‘What did he do?’ since all perfectives answer this question in the narrative.

I argue that multiple analytical perspectives such as those examined in this paper are required to adequately describe any grammatical form that conflates or challenges pre-established grammatical categories. More specifically, when the function of a grammatical form is unclear, fine-grained quantitative distributional analyses with description give a complex but useful way to pursue analyses. Access to data of this kind raises new challenges for how typologists might compare languages when semantic characterizations are not adequate or not possible, or only relevant in certain discourse contexts. It is only by examining data in a fine-grained way (e.g. at the level of one lexical verb) that we begin to perceive the types of information that would otherwise go unnoticed using a non-quantifiable, non-discourse based model of data analysis.

## Notes

1. I gratefully acknowledge the role of the Endangered Languages Academic Programme (ELAP) at SOAS, ESRC (award no. PTA-026-27-0883) and AHRC (Doctoral Award) in providing the financial support necessary to carry out this research. It could not have been instigated without the invaluable support of my Eleme consultants who are too many to name individually, but all contributed to the corpus from which these conclusions are drawn, which was collected in Nigeria between February and June 2003. This paper has benefited from comments from audience members at versions presented at the MPI-EVA, Leipzig and CIL 18 in Seoul in July 2008, and at Special WOCAL 6 in São Paulo in August 2008. Attendance at Special WOCAL 6 was made possible through a British Academy Overseas Conference Grant. I would particularly like to thank Peter Austin, Mary Chambers, Kristine Hildebrandt and Dejan Matić for discussion and helpful comments on earlier drafts of this paper. All errors are, of course, my own.

2. The abbreviations used throughout this paper are: 1 = first-person, 2 = second-person, 3 = third-person, ANT = anterior, AP = anterior-perfective, COMP = complementizer, CONT = continuous, COP = copula, HORT = hortative, INS = instrumental, LOC = locative, LOG = logophor, NEG = negative, O = object, PL = plural, POSS = possessive, PROX = proximative, PRCLT = particle, Q = question particle, REL = relativizer, SG = singular, SPF = specific, X = category x (i.e. anterior-perfectives). Examples are presented in a phonemic orthography consistent with the IPA, with the exception of <r> used for [ɾ] and <y> used for [j].
3. There is of course a distinction between how speakers actually use language and their metalinguistic understanding of it, for instance the forms and structures that speakers use may not correspond directly to the types of grammaticality judgments they make. Each perspective on language use has its place in linguistics but this paper concerns how language is used in context.
4. This included the locative verb *do* ‘be located’ and the copula *be* which exhibit some of the properties of verbs, but have restricted potential in terms of their inflectional characteristics. While included in the total count of 779 verbs (amounting to 32 tokens and 34 tokens respectively), they do not ever occur with the Anterior-Perfective prefixes (or many other types of TAM and person/number marking) and are thus excluded from consideration on these grounds.

# **Irrealis and conditional structures: a temporal and/or aspectual issue?**

**Patrick Caudal\***

CNRS & Université Paris 7

UFRL, Université Paris 7, 30 rue du Château des Rentiers, 75013 Paris, FRANCE

pcaudal@linguist.jussieu.fr

## **Abstract**

Tense-aspect marking is known to play a central role in the interpretation of counterfactual (CF) conditional structures (CSs); it has thus often been claimed that their irrealis/CF content could be traced back to the past inflections often used to mark protases of CSs. The purpose of the present paper is to account for so far somewhat disregarded facts concerning the distribution and interpretation of tense-aspect inflections within CSs – notably the fact that (past) perfective viewpoint inflections (in the sense of Smith 1991) appear to be cross-linguistically ruled out from antecedent clauses of CSs. A comparison with other types of modal expressions (conditional and future inflections, modal auxiliaries) will provide additional evidence for the novel aspectuo-temporal account of CF CSs proposed here, and for a wider theory of the interaction of modality with tense-aspect.

**Keywords:** conditional structures, counterfactuals, modality, tense, aspect.

## **1. On the link between tense-aspect inflections and irrealis conditionals**

The possible existence of a link between past imperfective markers and conditional structures has received a good deal of attention in the recent (or not so recent) literature. A consensus seems to have emerged across both typological (see e.g. James 1982, Bybee & Fleischmann 1995) and theoretical works (Iatridou 2000, Ippolito 2004, Caudal & Roussarie 2005, Trnavac 2006, inter alia) that past imperfectives play a determining role with respect to the hypothetical/irrealis interpretation of conditional structure (CS) protases. Indeed, many languages use imperfective markers within protases, see e.g. Modern Greek (1) (Iatridou 2000) or Warlpiri (2) (Legate 2003:160).

---

\* Many thanks to Chris Reintges for his help with the Coptic data, and to Gerhard Schaden for fruitful discussions on modality in German. Any error or misconception is entirely mine, of course.

 ('If you come back without any meat, I will be angry with you.')

On top of the classical past vs. present CF CS distinction (cf. (3) vs.(4)-(7)), I will further divide past CF CSs between 'one-past' CF CSs as in (4)-(5) (which describe accessible possible worlds / open possibilities w.r.t. speech time and the actual world) vs. 'two-past' CF CSs as in (6)-(7) (which describe foreclosed possibilities / inaccessible possible worlds w.r.t. speech time and the actual world). French data will be widely used here, as French possesses a rich system of (past) tense-aspect inflections, which obligatorily mark CF CSs (PQP abbreviates the French *plus-que-parfait*, i.e. pluperfect; IMP abbreviates the French *imparfait*, i.e. past imperfective; COND the French (present) *conditionnel*).

 ('If Yann had been sick, Mona would have come.')

### 1.1. Goal of the present investigations

In contrast to the imperfective/CF typological link, (past) perfective markers can hardly appear within protases of CSs (Caudal & Roussarie 2005, Trnavac 2006), and certainly not with a CF reading.<sup>1</sup> Thus, the French *passé simple* is ruled out unless a CS receives a non-conditional, non CF reading, cf. (8) vs. (9). Accounting for the (4)/(8) contrast (and generally for the role of tense-aspect inflections w.r.t. CSs) will be the main goal of the present investigation.

- (8) \*Si Yann vint, Mona partirait.  
If Yann come-PS.3SG, Mona leave-COND.3SG.
- (9) Si Yann fut pieux en apparence, il fut en fait un vrai mécréant.  
If Yann be-PS.3SG pious apparently, he be-PS.3SG in fact a true heathen.  
(‘Though Yann seemed to be pious, he was in fact a true heathen’).

I will first clarify the contribution of tense-aspect inflections within CS protases in French, before assessing how such an analysis could carry over to other languages, i.e. German and Coptic, as well as to other modal forms cross-linguistically, notably conditional/future inflections and (semi-)auxiliaries. Crucially, instead of a mere ‘evaluation time’, I will argue that epistemic modal forms require a stative evaluation event; this move will prove fruitful to explain certain distributional and interpretative properties of tense-aspect inflections with CSs and other modal expressions.

### 1.2. Classifying existing approaches

Although the amount of available literature on CSs is too vast to contemplate a substantial review here, I will broadly categorise it in two main classes: *temporal* approaches (which take ‘pastness’ to play a major role in the constitution of irrealis meaning) vs. *aspectual* approaches (which regard aspectual meaning, and not just temporal meaning, as a major parameter in irrealis readings).

According to many influential *temporal* approaches to CSs (cf. e.g. Palmer (1986) and Iatridou (2000)), irrealis content is derived from the alleged ‘now excluded’ meaning of past imperfectives, so that a normally temporal operator/function ends up quantifying over (possible) worlds. Ippolito (2003) showed that such an approach could not account for e.g. (10), because past irrealis protases involve two past functions/operators, one of which should conflict with ‘tomorrow’. In addition to this, the ‘now-excluded’ approach must also explain why past imperfectives generally fail to

exhibit a modal reading within an ordinary matrix clause. Thus (11) does not have any hypothetical reading, contrary to what the ‘now-excluded’ approach would predict (it can report a past speech-act at most, and thereby have some volitional meaning).

- (10) If C. had taken his Italian test tomorrow, he would have passed.  
(11) #Jean partait demain.  
Jean leave-IMPF.3SG tomorrow

I will distinguish so-called temporal accounts from aspectual accounts of CSs. The latter fall into two broad classes, best illustrated by Arregui (2007) and Ippolito (2006): though both accounts claim that aspect plays a key role in construing CF meaning, Arregui argues that aspectuo-temporal functions associated with CSs protases take clause-internal scope, while Ippolito believes them to take clause-external scope (= over the protasis). Unfortunately, neither Arregui’s (2007) nor Ippolito’s (2006) account can explain why (8) is out, as will appear in section 1.3.

### *1.3. Existing approaches and the distribution of tense-aspect markers within CSs*

Arregui (2007) is a clause-internal aspectual account in that it assumes the aspectuo-temporal functions contributed by the antecedent clause verb to take clause-internal scope. Thus in (12), Arregui claims that some (allegedly) perfective function is contributed by the simple past inflection *-ed*, and that it bears on the event described by that verb, thereby contributing to the irrealis interpretation of the CS.

- (12) If your plants died next week, I would be very upset. (Arregui 2007)

In short, Arregui’s account involves three main points:

- (i) tense/aspect functions expressed by the protasis bear on its eventuality time; that is, they take clause-internal scope;
- (ii) the English simple past contributes a perfective function within (eventive) CSs, that is, sentences denoting a telic eventuality (I am making this (I believe sensible) assumption, because Arregui (2007) does not discuss in detail how the aspectual interpretation of sentences in the simple past is construed);
- (iii) the perfective function introduces a deictic (Lewis-event) pronoun, triggering the presupposition of some antecedent eventuality referent. In (12), the perfective-introduced pronoun being unable to pick up an appropriate eventuality referent in the current context, some pragmatic device is called in

to salvage the CS's interpretation (cf. Arregui's (2007) 'diagonalization').

Note first that (iii) is somewhat awkward because it leads us to view natural, unmarked sentences like (12) as semantically deviant; indeed, according to Arregui (2007), (12) requires to be salvaged by some pragmatic interpretative principle; a compositional semantic account would be preferable.

Second, Arregui's (2007) analysis (wrongly) predicts that (8) is correct, by salvaging it through the very means used to assign an interpretation to (12) (the French *passé simple* is clearly a perfective viewpoint tense, and contextual parameters are no different than in (12)).

And third, (iii) depends on (ii), which depends on (i); but unfortunately, (i) is problematic. This is obvious in a language like French, where the aspectual interpretation of an antecedent clause depends on the eventuality type described, and not on the inflectional tense-aspect marking of the protasis *per se*. For instance telic antecedent clauses in the *imparfait* yield 'perfective' readings (13), while atelic clauses yield 'imperfective' readings, (14) (I will argue below that the aspectual neutrality of e.g. the French *conditionnel* and *futur* reveals a parallel phenomenon; see section 3.1). This suggests that the antecedent clause's aspectual content cannot bear directly on the antecedent clause's eventuality time (*contra* (i)).

- (13) Si Luc partait ( $e_1$ ), Max viendrait ( $e_2$ ).  
 ('If Luc left-IMP, Max would come') ( $e_1 < e_2$ : 'perfective' protasis)
- (14) Si Luc était ivre ( $e_1$ ), Max viendrait ( $e_2$ ).  
 ('If Luc were-IMP drunk, Max would come'). ( $e_1 \sqsubseteq e_2$ : 'imperfective' protasis)

Let us now turn to Ippolito (2006). Ippolito assumes that irrealis meaning is not derived within CSs from an imperfective aspectual function, but from a 'universal' present perfect (UPP, cf. McCawley 1971) function which binds the evaluation time of the modal function<sup>2</sup> *WOLL* scoping over the propositional content of the protasis clause, cf. (15).  $\varphi / \psi$  stand for the antecedent / consequent propositions;  $\forall_{\sqsubseteq}$  captures the semantics of the 'extended now' (XNow) interval (McCoard 1978); *SIM* notes a similarity function *à la* Kratzer (1991), ranking worlds in terms of their similarity to the actual world; *HIST* notes an (historical) accessibility function between worlds.

- (15) PRES(PERF( $\forall_{\sqsubseteq}$ (WOLL(SIM(HIST( $\varphi$ )))( $\psi$ ))))

Therefore, it is unclear how Ippolito's account could handle (8)-(10), as it was devised

to account for imperfective tenses only. Moreover, turning again to (4)-(5) and (12), it is dubious why we should introduce a *PRES* and a *PERF* function to represent the contribution of a past, non-perfect tense, as Ippolito's account would have us do. Although Ippolito (2006) argues that "[CF] conditionals are marked by imperfective morphology, since in many languages standard occurrences of universal [present] perfect are marked by imperfective morphology", two important facts militates against this view:

- (i) imperfective tenses receive perfect-like readings only in (some) languages lacking a perfect; since perfects are widespread forms, this rules out the UPP as a plausible general component of meaning for imperfectives (and CSs);
- (ii) perfects are generally banned from 'one-past' CF CSs, cf. (16). How is that so, if the UPP is a key semantic component of 'one-past' CF CSs?

- (16) \*Si Yann a quitté son bureau, Mona partirait aussi.  
 If Yann leave-PC.3SG his office, Mona leave-COND.3SG too.  
 (\*'If Yann has left his office, Mona would leave too').

And more generally, it seems to me that if we take seriously the morpho-syntax/semantics interface, we cannot assume on the face of scant (and arguably debatable) evidence such an unlikely analysis as ascribing a perfect meaning to an imperfective marker. Occam's razor tells us that it is safer to assume that imperfective markers contribute imperfective meanings within CF CSs, rather an improbable 'perfect' meaning.

## 2. Towards a new analysis of the role of tense-aspect inflections within CF CSs

### 2.1. *The analysis in short: the role of past imperfective inflections*

I will now present an alternative analysis of CF CSs, hopefully able to account for the (4) vs. (8) contrast. I will here adopt Ippolito's (2006) idea that tense-aspect markers within protases of CSs take higher, clause-external scope. But unlike Ippolito, (i) I claim that past imperfective markers in protases contribute past imperfective functions (not some 'dummy' present perfect function); and (ii), I argue that an evaluation event (rather than a mere interval) is attached to the (conditional) modal contributed by the CS (there is an obvious parallelism with modal auxiliaries and their complement VPs, as

they often bear explicit aspectuo-temporal marking). Moreover, I will argue that for a CS to be well-formed, this event position should be stative, since modals express beliefs, i.e. private states.

If we combine this stative event position of CSs protases with a past imperfective viewpoint, then the state of belief is given as possibly valid at the utterance time, thus explaining the ‘present relevance’ of the speaker’s belief that Yann might come in (4) – this is a consequence of the so-called ‘open-ended readings’ of imperfective viewpoint tenses, illustrated in (17a)) and represented in (17b);  $\tau$  is the usual temporal trace function; modal operator  $\diamond$  marks the fact that the described event may or may not extend up to and include the utterance time event  $u$  ( $\tau(u)$  corresponding to the utterance time interval).

(17) a. Le bébé dormait cinq minutes plus tôt (et il dort encore peut-être).

The baby sleep-IMPF.3G five minutes more early (and he sleep-PRS.3SG still maybe).

(‘Five minutes ago, the baby was asleep (and maybe she still is)’).

b.  $\forall P, e [(PastImpf(P) \wedge P(e)) \rightarrow \diamond \tau(u) \subset (e)]$

For want of space, I will not provide here a detailed implementation of CF CSs (see Caudal, to appear). But if we adopt a Kratzer-style analysis of modality where *COND* is a ‘bare conditional’ modal treated as a generalized quantifier (GQ), while recycling Ippolito’s (2006) *SIM* and *HIST* functions, we can propose (15’a) as a ‘template’ representation for ‘one-past’ CF CSs in French, *PastImpf* being the past imperfective function associated with the *imparfait*; I take aspectuo-temporal functions to existentially bind some event variable. (15’b) gives some indication of a possible implementation for the *COND* modal GQ: it should crucially comprise an epistemic state event position – cf. (15’c). Finally, (15’d) gives a quick semantics for *PastImpf*, where *TopicTime* is the reference time interval, and *imperfective(e)* is an imperfective viewpoint operator, such that *TopicTime* must be included within the temporal trace of  $e$ .

(15’) a.  $PastImpf(COND(SIM(HIST(\varphi)))(\psi))$

b.  $[[COND]]^{c,g,t,w} =_{def} \lambda p \in D_{(st)}. \lambda q \in D_{(st)}. \lambda e. \forall w' [EpistemicState(e, [p(w')=1 \rightarrow q(w')=1])]$

c.  $[[EpistemicState(e, \varphi)]]^{c,g,t,w} =_{def} 1$  iff. Believe(Speaker,  $\varphi$ ) is true at  $\tau(e)$ , and state(e) holds.

d.  $[[PastImpf]]^{c,g,t,w} =_{def} \lambda P. \exists e [P(e) \wedge imperfective(e) \wedge TopicTime < \tau(u)]$

## 2.2. Why past perfective viewpoint inflections are ruled out

*Vice versa*, if we combine the event argument of the modal content of CSs (*COND* in (15')) with a perfective viewpoint as in (3), the analysis predicts that it should be aspectually shifted to some non-stative change-of-state event (perfective viewpoints being known to cause aspectual shifts on atelic predicates in general – or at least, this is arguably the case with the French *passé simple* (PS); cf. de Swart 1998 and Smith 1991)<sup>3</sup>.

I believe that this fact explains why (8) is agrammatical. First, irrealis readings of CSs clearly engage the speaker's belief in the degree of likelihood of a certain conditional, ranging from the possible (with present or 'one-past' protases) to the impossible (with 'two-past' protases). And interestingly, the only possible conditional-like, non-concessive reading of a protasis in the *passé simple* involves a complete lack of belief on the part of the speaker. Thus in (18), Speaker is totally agnostic w.r.t. to the actual likelihood or even impossibility of the protasis (and apodosis); it is simply unknown / unknowable to her. So it seems that even if we allowed the past perfective function to 'shift' the belief event to a non-open ended, transitional event, it would then conflict with the epistemic content inherent to CF CSs, which requires the speaker not to be agnostic about (im)possibilities.

- (18) Si Yann mangea, alors Mona mangea aussi.  
If Yann eat-PS.3SG, then Mona eat-PS.3SG too.  
(‘If Yann had lunch/dinner, then Mona had lunch/dinner too.’)

Note that parallel analysis will be proposed below for the meaning shifts observed with epistemic (semi-)auxiliaries in Romance and Germanic, cf. (32)-(34); but this time, no semantic type-clash arises, as the semantics of these auxiliaries can be shifted to a non-epistemic, 'effected action' reading, somewhat reminiscent of the meaning of *manage to*.

A probable additional cause for the agrammaticality of (8) is that the *passé simple* is aspectuo-temporally inconsistent with the *conditionnel présent* morphology in the consequent clause of (8): it would effectively prevent us from regarding as accessible at speech time worlds which the *conditionnel présent* requires to be accessible. Indeed the 'belief' event would then be given as past and perfective, i.e. as non-overlapping with speech time, thus leaving no room for presently valid beliefs.

Note that introducing a *conditionnel passé* ('past conditional') in the apodosis is

not sufficient to render (8) felicitous, cf. (19). This clearly shows that the aspectual clash between the perfective viewpoint and the epistemic state predicate is sufficient to cause (8) to be agrammatical.

- (19) \*Si Yann vint, on aurait mangé des crêpes.  
 If Yann come-PS.3SG, we eat-PST.COND.3SG PL.INDEF.DET pancakes.  
 ('If Yann came-PS, we would have eaten pancakes.')

In addition to the *passé simple*, a similar analysis can also be applied to the distribution of the *passé composé* with CSs (cf. (20)). This tense is known to have a hybrid aspectuo-temporal semantics; it is a perfect with past perfective features (cf. Caudal & Vettors 2007). But even if we take it to be aspectually underspecified between a past perfective and a perfect, it lacks an imperfective component of meaning; therefore, just like the *passé simple*, it is expected to 'shift' aspectually the belief state underlying the CS into a change-of-state, transitional event, therefore blocking a CF/irrealis reading.

- (20) \*Si Yann est venu, Mona partirait.  
 If Yann come-PC.3SG, Mona leave-COND.3SG.

Now assuming representation (21) for 'two-past' CF CSs, how do we ascertain that the belief event bound by the *plus-que-parfait* (pluperfect) function *PQP* cannot possibly hold at speech time, unlike with 'one-past' CF CSs?

- (21)  $PQP(COND(SIM(HIST(\psi)))(\varphi))$

(22) demonstrates that the *plus-que-parfait* does not exhibit any 'open-ended' reading, even when it has a resultative interpretation, and in spite of the fact that it comprises an *imparfait* marker. This is intuitively logical: the *plus-que-parfait* can only describe a past result state, i.e. one which lacks present relevance, and strictly precedes the utterance time interval  $\tau(u)$ , as shown by the sharp contrast between (23) and (24). Contrary to the *imparfait*, the *plus-que-parfait* can have past relevance, but not present relevance (it can describe events overlapping with some past reference interval, but not with the utterance time interval).

- (22) (Deux jours avant,) Marie avait été malade.  
 (Two days before), Marie be-PQP.3SG sick.  
 → Mary is not sick anymore.
- (23) Marie est encore au lit. \*Deux jours avant elle avait été malade.  
 Marie be-PRS.3SG still in bed. Two days before she be-PQP.3SG sick.
- (24) Marie était encore au lit. Deux jours avant elle avait été malade.  
 Marie be-IMPF.3SG still in bed. Two days before, she be-PQP.3SG sick.

Given that the semantics of the *plus-que-parfait* excludes present relevance (*PQP* lacks the entailment (17b) attached to the *imparfait*), then it naturally follows that in (6), Speaker cannot believe it possible at speech time that upon the (hypothetical) arrival of Yann, a pancake feast would take place. We have now explained the contrast between ‘one-past’ and ‘two-past’ CF CSs.

For want of space, the formal implementation of the *plus-que-parfait* will not be discussed here in detail (see Caudal (to appear) for such a development). Roughly speaking, though, if we assume an account of the *plus-que-parfait* along the lines of Higginbotham’s (2007) treatment of the pluperfect, we can propose the aspectuo-temporal representation (25) for sentences in the *plus-que-parfait*, where *P* is the verbal predicate, *TopicTime* the reference time interval, and *perf* the two-place perfect operator relating an event  $e_1$  to a result state  $e$ ; condition  $\tau(e_2) < \tau(u)$  captures the strictly past relevance of the *plus-que-parfait*.

- (25)  $[[PQP]]^{c.g.t.w} =_{\text{def}} \lambda P. \exists e_1, e_2 [P(e_1) \wedge \text{perf}(e_2, e_1) \wedge \tau(e_1) < \tau(e_2) \wedge \text{imperfective}(e_2) \wedge \tau(e_2) < \tau(u) \wedge \text{TopicTime} < \tau(u)]$

### 3. Other types of modal markers

The present analysis of the interaction between aspectual and modal meaning receives additional support from independently converging facts in at least two domains: (i) the aspectuo-temporal interpretation of ‘modal’ inflections (3.1) and (ii) the combination of modal (semi-)auxiliaries with tense-aspect markers (3.2).

#### 3.1. Modal inflections: on French and Coptic

Let us focus first on the well-known ‘aspectual neutrality’ of future and conditional morphemes (cf. Smith 1991, *inter alia*), such as the French *futur* and *conditionnel*. Indeed the aspectual interpretation of a verb thus inflected solely depends

on its lexical aspectual contribution (in combination with all its modifiers and adjuncts), cf. (26), which is clearly akin to (13)-(14) (i.e., telic verbs favour a ‘perfective’ reading, while atelic verbs favour an ‘imperfective’ reading in the case of both CSs and modal inflections). Yet these tenses respectively incorporate *présent* vs. *imparfait* endings, i.e. imperfective markers; I conclude from this fact that the aspectuo-temporal content of these endings bear on some modal expression conveyed by the *futur* and the *conditionnel*, rather than on the event described by the inflected verb.

- (26) a. Yann sera malade ( $e_1$ ) lorsque tu arriveras ( $e_2$ ).  
 Yann be-FUT.3SG sick when you arrive-FUT.2SG.  
 (‘imperfective’ protasis:  $e_2 \subseteq e_1$ )
- b. Yann mangera ( $e_1$ ) lorsque tu arriveras ( $e_2$ ).  
 Yann eat-FUT.3SG when you arrive-FUT.2SG.  
 (ambiguous protasis:  $e_2 < e_1$  or  $e_2 \subseteq e_1$ )
- c. Yann partira ( $e_1$ ) lorsque tu arriveras ( $e_2$ ).  
 Yann leave-FUT.3SG when you arrive-FUT.2SG.  
 (‘perfective’ protasis:  $e_2 < e_1$ )

Following Caudal & Veters (2007), I will argue that the French *conditionnel* is a (historically) morphologically complex item, construed by (i) forming a new verb stem and combining it with a former infinitive marking (*-r-*), and (ii) adding a final complex affix, which consists of an *imparfait* inflected form of the *avoir* (‘to have’) auxiliary. I will hypothesize that *-r-* has been reanalyzed as a future marker, i.e. as a modal marker (Caudal & Veters 2005). This gives us the following morphology to semantics mapping, clearly reminiscent of the above analysis of CSs:

- (27) Morphology: Verb.stem + modal marker *-r-* + *avoir*-*Imparfait*
- (28) Semantics: Tense(Aspect(Modal(Verbal-Predicate)))

In addition to the above French data, I would like to put forth additional evidence from Coptic Sahidic (Reintges 2004). Coptic verb stems have inherent aspectual marking; the language distinguishes between so-called ‘eventive’ stems (cf. *kôt*, ‘to build’; *ei*, ‘to go’) and so-called ‘stative’ stems (cf. *kêt*, ‘to be well-built’; *nêw*, ‘to have gone/been (somewhere)’). Note that stative stems have a resultative, almost perfect meaning, although an inflectional perfect exists; they are not intrinsically ‘open-ended’.

On top of this inherent aspectual marking, Coptic verbs receive inflectional aspectuo-

temporal marking – cf. the perfect inflection *a* in (29).

- (29) a-f-kôt  
PERF-3M.SG-build.EVT. ('He has built.')

Among these inflections, two are clearly modal, namely the future inflection *na* and the conditional inflection *šan*; and both have a constrained distribution with inherent aspectuo-temporal marking, as they reject stative verb stems (*šan* being restricted to protases of CSs), cf. (30) vs. (31), and (31) vs. (32).

- (30) \*er-šan-p-êi-kêt,  
REL.N-COND-DEF.ART-house-build.EVT,  
e-f-na-šôpe həm-f.  
REL.PRO-3M.SG-FUT-become.EVT in-3M.SG.  
(‘If the house is well-constructed, he will live in it’.)
- (31) e-f-šan-kôt am-p-êi,  
REL.PRO-3M.SG-COND-build.EVT PREP-DEF.ART-house,  
e-f-na-šôpe həm-f.  
REL.PRO-3M.SG-FUT-become.EVT in-3M.SG.  
(‘If he builds the house, he will live in it’.)
- (32) e-f-šan-kôt am-p-êi,  
REL.PRO-3M.SG-COND-build.EVT PREP-DEF.ART.-house,  
\*e-f-na-šoop həm-f.  
REL.PRO-3M.SG-FUT-become.STA in-3M.SG.  
(‘If he builds the house, he will live in it’.)

According to the present theory, modal inflections *na* and *šan* would be ascribed (i) an imperfective viewpoint meaning, and (ii) a (stative) epistemic semantic content. Now the fact that both *na* and *šan* reject stative stems seems to be indicative of some aspectual semantic incompatibility with (i)/(ii): the inherent aspectual content of verb stems must also take ‘higher scope’ than the modal content of inflections, and clash with (i) and/or (ii). Indeed, what could it mean for an imperfectively viewed epistemic state to receive a perfect/resultative meaning in addition?

### 3.2. Modal auxiliaries

The constrained distribution of tense-aspect markers with modal verbs/semi-

auxiliaries offers yet another source of additional parallel evidence for the present account of CF CSs. Thus example (33) suggests that the German modal *können* ('to be able (to)') shifts its meaning to a non-modal, factual interpretation when combined either with the *Perfekt* or the *Präteritum* (if a mere possibility was involved, we could deny it to have been realized through the 'aber...' continuation). This shifted reading demonstrates that the aspectuo-temporal content of verbal inflections outscope the modal content of the auxiliary they mark; note also that epistemic/deontic *müssen* behaves similarly (see Condoravdi 2002 for further evidence and a detailed discussion).

(33) a. Um 6 konnte Jens kommen, \*aber er ist nicht gekommen.

At 6 be-able-PRET.3SG Jens come-INF, but he not come-PRET.3SG.

b. Um 6 hat er kommen können, \*aber er ist nicht gekommen.

At 6 he be.able-PERF.3SG come-INF, but he not come-PERF.3SG.

French modal semi-auxiliary *pouvoir* exhibits similar semantic shifts with the *passé simple*: the epistemic reading is then ruled out, and an 'effected action' reading is triggered, cf. (34) (the effected event then cannot be negated). Note that in addition, another, non-epistemic reading seems to be available in (34); it refers to a non-verifiable, non-gradable possibility— whether Jean came or not does not belong to the speaker's set of beliefs, since the speaker is agnostic as to (i) whether this event actually took place or not (it is impossible to negate or validate this possibility; (34) sounds just as bad if we continue it with 'and Jean came indeed'; the speaker simply has no commitment w.r.t. its veridicality/accessibility), and (ii) whether the event of Jean coming is likely, unlikely or impossible, i.e. whether it should belong to a world deemed similar/dissimilar or accessible/inaccessible to the actual world. In contrast, events described by the propositional content of genuinely epistemic utterances such as (35) can be both negated or validated (this is an important characteristics of epistemic modal expressions), and are situated within worlds of varying accessibility and probability.

(34) Jean put venir à 6h, ??mais il ne vint pas.

Jean be.able-PS.3SG come-INF at 6, but he not come-PS.3sg.

(35) A 6 heures, Jean pouvait venir mais il n'est pas venu/et il est venu.

At 6 o'clock Jean be.able-IMP.3SG come-INF, but he not come-PC.3SG/and he come-PC.3SG.

I believe that all these facts concur in supporting the view that modal expressions

in general (CSs, modal auxiliaries or verbs, modal inflections...) involve some ‘higher’ modal predicate (i.e. a full clause or at least some part of a VP is subordinated to this predicate), over which the aspectuo-temporal content of verbal inflections takes scope – the semantic function of these modal predicates being to relativize an underlying bare conditional modal to an epistemic belief event ascribed to the speaker.

## Conclusion

Like Ippolito (2006) and unlike Arregui (2007), the present analysis has adopted a ‘clause-external’ approach to the role of tense and aspect within CSs. But against Ippolito (2006), past imperfective morphology is not here assumed to contribute a ‘universal present perfect’ meaning – it straightforwardly conveys a past imperfective meaning, with possible present relevance as a side effect of the ‘open-ended’, imperfective aspectual viewpoint it conveys (cf. (15’d), and its corollary, (17b)).

I have argued above that the real credit for CFs readings of CSs should be given to the fact that past imperfective operators/functions take scope over the (stative) belief/evaluation event argument associated with the modal meaning contributed by CF CSs, i.e. with a *conditionnel* consequent clause (this meaning arising from the association of a conditional *si P,Q* structure with a *conditionnel* marking of *Q*; although arguably compositional, this meaning seems to have been conventionalized).<sup>4</sup> The fact that this belief event is stative plays a crucial role in the present account (unlike any other existing account I am aware of), as it explains the impossibility of using perfective viewpoint tenses within antecedent clauses of CF CSs: indeed, perfective viewpoint tenses are aspect-sensitive (de Swart 1998), and ‘shift’ open-ended, stative event descriptions into transitional, bounded ones. My analysis also predicts the ‘lesser likelihood’ effects of (one) past imperfective vs. present marking, as well as the contrast between ‘one-past’ vs. ‘two-past’ CSs (cf. (21)-(25)).

I have suggested that additional support for the present theory can be found in the semantic behaviour of many different types of modal expressions with aspectuo-temporal markers – ranging from modal inflections to modal auxiliaries (the simple, partial implementation proposed here reflects this fact, for in a sense, it treats CSs on a par with modal/attitudinal verbs, as they all possess a stative event argument). And indeed, we have seen that modal expressions in general unproblematically combine with past (or present) imperfective markers, but not with perfective markers, which either rule out or block epistemic readings, cf. (33)-(35); again, such facts are best explained through the hypothesis that tense-aspect content can ‘outscope’ modal content. See also

Condoravdi (2002), who observed that the past morphological component of certain English modals did not affect the reference time of their complement verb. Incidentally, conditional/future inflections too are usually unproblematic in combination with modal expressions in general, including periphrastic modals, cf. (36)-(37). My analysis also predicts this fact, as I argued above that (French) modal inflections are endowed with imperfective viewpoints taking ‘complement verb-external’ scope, and bearing on their modal content.

- (36) Il se peut/pouvait que/pourrait/pourra que ...  
It Pro.Refl. be able-Impf./Cond/Fut.3sg.
- (37) \*Il s'était pu/#se put/#s'est pu que...  
It Pro.Refl. be able-PS./PC.3sg.

I have suggested that a parallelism should be drawn between all these aspect/modality interactions and the role of tense and aspect within the semantics of CSs, as they can all be explained through some sort of ‘out-scoping’ or ‘semantic subordination’ phenomenon causing some aspectuo-temporal function/operator to take higher scope than morpho-syntax seems to indicate.

Although I have mostly used French data to build up the present account, I believe it can be extended to other languages. Thus, one could take the English simple past to convey a past imperfective-like function when it bears on the stative modal predicate underlying CF CSs; since belief event predicates are arguably stative, there is no reason to assume that the English simple past would then convey a perfective meaning (*contra* Arregui 2007). The simple past would then trigger some entailment similar to (17b), and thereby license a ‘possibly valid at speech time’ interpretation of the epistemic belief event in (12).

Finally, this account has left many issues open for future discussion. In particular, for want of space, I have not attempted to define the temporal location and ordering of events described by the main verbs of antecedent vs. consequent clause of CF CSs. It crucially depends on two factors: (i) the present vs. ‘one-past’ vs. ‘two-past’ CF CS distinction (with its correlates on the inflectional marking of the consequent clause) and (ii) lexical aspectual information (e.g., within ‘one-past’ CSs, atelic sentences licence ‘present’ temporal reference, whereas telic ones favour or impose ‘future’ temporal reference), and other non-inflectional sources of aspectual meaning (including context). There is such a daunting amount of literature on the subject (see Schulz (2007) and Laca (2008) for a review of existing works and hypotheses) that it was impossible to consider

tackling this issue within the limits of the present paper. Finally, scope issues w.r.t. modal vs. aspectuo-temporal operators/functions are very complex in the case of modal auxiliaries, at least much more complex than what I have suggested above (see Condoravdi 2002 and Laca 2008 for a discussion). How these phenomena relate to the present account will remain a subject for further research.

---

## Notes

<sup>1</sup> Although some languages appear to license perfective markers within CS protases (cf. Trnavac 2006, Boogaart & Trnavac 2006), these markers seem to be derivational rather than inflectional, and/or to possess a more complex semantics and/or pragmatics than *bona fide* perfective inflections (see e.g. the Spanish *simple past*, which can receive conditional readings even in matrix clauses). I will leave aside such problematic data – arguably, derivational aspectual markers have a different semantic scope and play a different function at the semantics/pragmatics interface than tense-aspect inflections.

<sup>2</sup> Technically speaking, *WOLL* is a generalized quantifier over worlds; the antecedent proposition fills its restrictor, and the consequent proposition its nuclear scope (propositions denoting sets of worlds). Ippolito's (2006) treatment of modality is based on the central mechanism proposed in Kratzer (1991). I will also adopt this classical Kratzerian view of modality.

<sup>3</sup> Perfective viewpoint tenses allow us to aspectually 'view' the initial and final boundaries of whatever event they describe; therefore, when even combined with a state, the readings we get are clearly bounded, and not open-ended at all– that is, sentences in the PS always describe perfectly viewed changes-of-states, even when they describe 'durative' states. Thus, 'Jean aime Marie' (Jean love-PS.3sg Marie) can either mean (a) John started loving Marie or (b) John loved Marie (for a certain amount of time). In the (b) case, the described event comprises the initial and final boundaries of the loving state (so we get two changes-of-state, vs. one in the (a) case). Cf. Caudal (2008) for more on this issue.

<sup>4</sup> Evidence supporting this view can be found in the fact that concessive *si P,Q* clauses syntactically differ from 'temporal' indicative uses as well as CF uses of CSs in that they do not licence a reverse syntactic ordering, cf. *\*Il fut malheureux, s'il fut riche* (He be-PS.3SG. unhappy, if he be-PS.3SG. rich) vs. *Nous mangerions des crêpes, si tu venais* (We eat-COND.1PL pancakes, if you come-IMP.2SG). A concessive reading with reverse syntactic ordering requires the *si* clause to appear under the scope of an explicit concessive marker such as *même* ('even'). Since the left vs. right periphery positions are known to have different information structure properties, this contrast suggests that the concessive *si P,Q* can be regarded as an individually conventionalized construction at the syntax/semantics interface, to some extent. How concessive readings should be semantically represented will not be discussed here for want of space, though.

sfujii @ boz.c.u-tokyo.ac.jp

## Abstract

This paper examines predictive conditional constructions, paying particular attention to the constructional mechanisms for conveying the speaker's epistemic stance in Japanese conditional constructions, as compared to the corresponding English constructions. This paper shows: (1) Japanese makes a much less clear distinction than English regarding the speaker's epistemic stance; and (2) Japanese employs a variety of grammatical devices for encoding the speaker's epistemic stance, including not only tense/aspect/mood verbal morphology (which is also employed by English constructions) but also a variety of other grammatical devices. English and Japanese appeal to different grammatical devices (in addition to similar devices involving tense/aspect/mood and adverbs) which convey and manifest the speaker's epistemic stance in conditional constructions.

**Keywords:** conditionals, epistemic stance, modality, tense and aspect, Japanese.

## 1. Introduction

### *1.1. Main purpose*

This paper examines conditional constructions in Japanese, paying particular attention to the constructional mechanisms for conveying the speaker's epistemic stance in predictive conditionals, including modal expressions, tense and aspect morphology, and other grammatical devices used in Japanese. My examination of these aspects of Japanese conditional constructions is informed and guided by the analysis of English conditional constructions by Dancygier and Sweetser (2005). It compares the requirements (or preferences) of the linguistic manifestations of the epistemic stance of the speaker as identified in Japanese conditional constructions with those in the English counterparts.

## 1.2. Explanatory concepts and the focus of the present paper

Before focusing on the issue of epistemic stance in conditional constructions, this section briefly lists the major explanatory concepts that my research on conditionals has appealed to in the larger context of studying conditionals (Fujii 1990, 1993, etc.).

Explanatory concepts (issues and descriptive parameters):

- i) specificity (specific or non-specific events)
- ii) relative time
- iii) **the speaker's epistemic stance**
- iv) the domain in which conditionality is expressed (*a la* Sweetser 1990)
- v) **the speaker's valuation** (positive or negative) of the alternative situation in which P holds
- vi) pragmatic functions of conditionals and the speaker's communicative purposes

Among these aspects, the present paper focuses on the speaker's epistemic stance. In dealing with this issue in certain constructions, we will also be concerned with the speaker's valuation, as will be discussed in Sections 4.5 and 4.6.

With regard to (iv) in the above list, among the different types of conditionals in various domains in which conditionality is expressed, this paper focuses on predictive conditionals in the content domain (leaving out epistemic conditionals, speech-act conditionals, metalinguistic conditionals, etc.).

## 2. Predictive conditional constructions in English

### 2.1. Three construction types of predictive conditionals

**Predictive conditionals in English** normally involve three construction types requiring particular patterns of paired verb forms in the P- and Q-clauses.

- (1) a. **If P-present, Q-will-future**
  - b. **If P-past, Q-would**
  - c. **If P-pluperfect, Q-would have**

The speaker selects one of these constructions according to his or her epistemic stance

as well as temporal viewpoint. Combinations of these modal and tense morphologies in P and Q are required, if both P and Q appear, in English predictive conditional constructions.

## 2.2. *The speaker's epistemic stance and construction types*

People do not have the ability to see alternative futures, but we can talk about alternative worlds. In talking about alternative worlds, the speaker takes a certain epistemic stance toward the actuality of P (and certainty of P), and in some cases of Q as well. The speaker's epistemic stance is the speaker's assumption about the actuality of P, or the kind of commitment the speaker has to the proposition expressed (Fillmore 1990).

The epistemic stance that the speaker encodes can be one of the three kinds: neutral, positive, or negative, as explicated by Dancygier and Sweetser (2005). For neutral-stance conditionals, one basic pattern is (1-a) (illustrated in 1'-a), where 'backshifting' — i.e., the use of simple present forms with future reference — occurs in the background clauses for future predictions (Dancygier and Sweetser 2005).

### (1') **neutral stance**

#### **a. If P-present, Q-will-future**

If you ask him, he'll do it.                      Future predictive, hypothetical

### (1') **distanced, negative stance**

#### **b. If P-past, Q-would**

If you asked him, he'd do it.                      Future contrary-to-expectation

#### **c. If P-pluperfect, Q-would have**

If you had asked him, he would have done it.                      Past counterfactual

For distanced stance, (1-b) P-past paired with Q-*would* is used. Here, the speaker's negative epistemic stance is conveyed through the addition of another layer of past-tense morphology with no corresponding layer of temporal distance, which is regarded as 'distancing' by Dancygier and Sweetser (2005). For past-reference distanced stance (or an especially distanced stance), (1-c) P-pluperfect paired with Q-*would have* is used.

Combinations of these modal and tense morphologies in P and Q are required, if both P and Q appear, in English predictive conditional constructions. Fillmore's (1990) account of the selection of verbal forms and their pairings in protases and apodoses of

conditional sentences critically involves a notion of “**concord**”: in particular, Fillmore argued that the choice from among categories of epistemic stance must be identical in the two linked clauses of a conditional sentence. (This, however, is not the case for non-predictive conditionals, such as epistemic conditionals, which are not the concern of this paper.) Dancygier and Sweetser (2005) also explicate this point using the notion of ‘epistemic coherence’. What matters here is the combination of the grammatical codings on the antecedent and consequent. I thus take the same position as Dancygier and Sweetser (2005) and Fillmore (1990) that these combinatory requirements can best be described in terms of bi-clausal constructions.

By virtue of the specific tense/aspect/mood morphology and semantics associated with each construction, P alone (e.g., 2) or Q alone (e.g., 3) — by maintaining the same morphology — can evoke conditional mental spaces in the same manner as the bi-clausal version, by construing the single clause as part of a bi-clausal conditional.

(2) I can just imagine if it was my daughter. (Dancygier and Sweetser 2005)

(3) You are so lucky. My advisor wouldn't have been so patient. (Fujii 1996)

### **3. Potential ambiguity regarding the speaker's epistemic stance in Japanese predictive conditional constructions**

In **Japanese predictive conditionals**, by contrast, the uses of modality, tense and aspect are more variable, and not as fixed as in English conditionals. Of the several conditional clause-linking morphemes, all appearing at the end of the antecedent clause, most linkers construct either a tense-less non-finite clause or a clause that requires a fixed verb form and that has no tense discrimination. The inflectional verb ending -*(r)eba*, for example, does not contain its own tense within the P clause; its tense is governed by the main clause. The linking particle *to* requires the non-past (base) form of a verb and cannot take the past form. *-tara*, on the other hand, always comes in the past form of a verb, and cannot take a non-past form. *Nara* is an exception in that it can be preceded by either a past or non-past form of a verb in the antecedent. Thus whatever form the antecedent clause takes, the verbal morphology is not uniquely associated with a particular type of conditional construction. Furthermore, the use of epistemic modal auxiliaries (e.g., *daroo* ‘will’, ‘would’) is possible but not strictly required in the consequent clauses.

In what follows, Section 3 discusses potential ambiguity regarding the speaker's

epistemic stance in Japanese conditional constructions. Section 4 will then lay out grammatical devices for encoding the speaker's epistemic stance in Japanese.

### 3.1. *Neutral vs. positive epistemic stance*

#### 3.1.1. *Neutral vs. positive epistemic stance: Conditionals and temporals*

English regularly distinguishes between an irrealis antecedent and a realis antecedent by the choice of IF vs WHEN. For example, compare sentences (4) and (5):

- (4) If I come to Japan, I will call you.                      neutral stance  
(5) When I come to Japan, I will call you.                    positive stance

The use of the IF construction in (4) reveals that the speaker does not commit himself to the truth of the antecedent (neutral stance), whereas in (5) the use of WHEN reveals that the antecedent is taken for granted by the speaker (positive stance). As noted by Dancygier and Sweetser (2005), the 'backshifting' phenomenon occurs in the antecedent background clause in both constructions. But English uses a different clause-linker (that is, *when* vs. *if*) to reflect the difference in the speaker's epistemic stance: a WHEN temporal clause for a positive epistemic stance, and an IF conditional for a neutral stance.

In the Japanese equivalent (here, using *tara*), this epistemic distinction is not necessarily signaled by linguistic form, yielding potential ambiguity between the two interpretations manifested in (4) and (5).

- (6) *Nihon e ittara denwa simasu.*  
Japan to go-COND(if/when) (will) call (you)  
If/When (I) go to Japan, (I will) call (you).  
a) Conditional interpretation: (4) If I come to Japan, I will call you.  
b) Temporal interpretation: (5) When I come to Japan, I will call you.

TARA and TO clause-linking constructions, in general, can be used with a neutral stance in hypothetical conditionals, and can also serve as markers of temporal clauses with a positive stance, though there are certain other important semantic and pragmatic conditions on each construction. We note not only that the same clause-linking morphemes can be used for either neutral or positive stance, but also that both epistemic meanings can be expressed without making obligatory distinctions in the

tense/aspect/mood verbal morphology. As I will discuss in the next section, there ARE certain ways to encode this epistemic distinction in Japanese, but it is safe to say that the TARA and TO clause-linking constructions themselves do not specify the value of the speaker's epistemic stance and thus can accommodate either a neutral or positive epistemic stance.

### 3.1.2. Neutral vs. positive epistemic stance: Concessive conditionals and temporals

English regularly distinguishes between positive stance and negative stance, not only in the ordinary conditionals that we've just looked at, but also in concessive conditionals,, as illustrated in (7).

(7) Around here, even when spring comes, the snow does not start melting.

Exactly the same point as made in the previous section can, thus, be made with respect to concessive conditionals using the TEMO clause-linking construction.

(8) *Asu ame-ga huttemo ensoku ni ikimasu.*  
tomorrow rain-NOM fall(CcCd/EVEN IF) excursion DAT go-POL  
Even if it rains tomorrow, we will go on a picnic. (CcCd: concessive conditional)

(7') Around here, even when spring comes, the snow does not start melting.  
*Kono tihoo-de-wa haru-ni nattemo yuki-wa tokenai.*  
this area IN TOP spring-DAT become snow-TOP melt-NEG  
# Even if spring comes ...

In (8), the speaker's epistemic stance is most likely neutral. The speaker in (7'), on the other than, most likely takes a positive stance toward the antecedent event 'spring comes'. Here again, as will be discussed, there *are* certain ways to encode this epistemic distinction, but it is safe to conclude that the TEMO clause-linking construction itself does not specify the value of the speaker's epistemic stance and thus can accommodate either a neutral or positive epistemic stance.

### 3.2. Negative vs. positive stance: Past-reference

The second contrast to be considered is between negative and positive stance. This boundary is perhaps considered extremely clear-cut epistemologically, especially

for past specific events/states. At least in English, this distinction can never be obscured in linguistic manifestation; they are clearly manifested both with different clause connectives (if vs. when) and with different tense/aspect/mood verbal morphology on both the antecedent and consequent. Even this distinction, however, can sometimes be blurred in Japanese.

The TEMO can also be used in cases where the antecedent event is assumed to be true in the past. This creates ambiguity between past counterfactual concessives and past factual concessives. (9) can mean either “Although he had an operation, he did not recover,” (conveying the speaker’s positive stance), or when spoken with the right intonation or followed by some pragmatic particle such as *yo*: “Even if he had had an operation, he would not have recovered,” (conveying the speaker’s negative stance).

(9) *Syuzuyutu o sitemo naoranakatta.*  
 operation ACC do-CcCd(even though) recover-NEG-PAST  
 ‘Although he had an operation, he did not recover.’

-- or when spoken with the right intonation or followed by some pragmatic particle such as *yo*: ‘Even if he had had an operation, he would not have recovered.’

Similar potential ambiguities can also be observed in ordinary conditionals between past counterfactuals (negative) and past temporals (positive), though again there is always a way to disambiguate them in language use.

### 3.3. *Neutral vs. negative stance*

The preceding sections thus far have shown the potential ambiguity regarding the speaker’s epistemic stance in Japanese predictive conditional constructions, first, with respect to neutral versus positive stance and, second, with respect to positive versus negative stance.

As for the third distinction, the boundary between neutral (potential) and negative (unreal) stance has been noted as less clear-cut than the boundary between positive (real) and either neutral or negative (Harris 1986). This subtle contrast between a neutral and a negative stance is also less clearly manifested in Japanese than in English. This tendency seems to be widely accepted (or taken for granted) to the extent that many linguists working in Japanese linguistics even believe that this third distinction —between neutral and negative stance — can never be expressed in Japanese. However, I will show in Section 4 that there *is* a way to convey this subtle difference in Japanese as well.

#### 4. Grammatical devices for encoding the speaker's epistemic stance in predictive conditional constructions in Japanese

As mentioned earlier, in Japanese predictive conditionals the uses of modality, tense and aspect are more variable, and not as fixed as in English conditionals. How then can the various types of the speaker's epistemic stance be conveyed in Japanese conditionals? I will first show that, like in English but to a lesser extent, past tense and aspectual morphology can be used in Japanese for expressing distanced epistemic stances. Secondly, I will show that Japanese conditionals make use of a variety of other grammatical devices for expressing distanced epistemic stances.

##### 4.1. Tense, aspect

The first point, the use of tense and aspect, is illustrated in (10):

- (10) *zyuunen mae ni kono kusuri ga hakken-sarete-ireba,*  
10-year before in this medicine NOM discover-PAS-ASP-COND  
*musuko wa ima mo ikite-ita daroo*  
son TOP now too alive-ASP-PAST MOD

If this medicine had been discovered 10 year before, my son would still be alive now.

P	te-i-reba,	Q	-ta (daroo)
---	------------	---	-------------

The consequent clause shows the use of past tense for epistemic distancing. The son referred to in (10) is not alive in reality, but the utterance predicts in the distanced hypothetical space that he would be alive. The use of past tense in the consequent clause in (10) is not for past tense reference (its reference is present) but for distanced negative epistemic stance. The antecedent of (10) also shows that the perfective aspectual marker *te-iru* fits in past hypothetical conditionals, ensuring the effect of epistemic distancing. The perfective aspectual morphology *te-iru* is used here for encoding the speaker's negative stance toward the P event (i.e., this medicine was not discovered 10 years ago). This addition of the perfective aspectual marker for epistemic distancing is in a way analogous to two phenomena in English. First, in English there is the addition of another layer of past-tense morphology to the antecedent for epistemic distancing in future predictives (i.e., in the If P-past, Q-*would* construction). Second, it may also be analogous to the use of pluperfect for epistemic distancing toward a past reference (i.e., in the If P-pluperfect, Q-*would have* construction). But in this Japanese construction, because the linker (*r)eba* is used, tense morphology cannot be used for this epistemic encoding, as mentioned earlier, so the perfective aspectual marker is used in its place.

#### 4.2. Epistemic modal expressions on the consequent

(10) also shows the use of the epistemic modal auxiliary “daroo” on the consequent. It is typical to have this auxiliary “daroo” for predictive conditionals, but it is not required. As shown in (10-B) and (10-C), (10) can be easily interpreted in the same meaning without the auxiliary “daroo”, when it is spoken with the right intonation or followed by some pragmatic particle such as *yo*.

(10-B) *zyuunen mae ni kono kusuri ga hakken-sarete-ireba,*  
10-year before in this medicine NOM discover-PAS-ASP-COND  
*musuko wa ima mo ikite-ita*  
son TOP now too alive-ASP-PAST

If this medicine had been discovered 10 years ago, my son would still be alive now.

P te-I-reba,	Q -ta
--------------	-------

 (When spoken with the right intonation)

(10-C) *zyuunen mae ni kono kusuri ga hakken-sarete-ireba,*  
10-year before in this medicine NOM discover-PAS-ASP-COND  
*musuko wa ima mo ikite-ita yo*  
son TOP now too alive-ASP-PAST PART

If this medicine had been discovered 10 years ago, my son would still be alive now.

P te-I-reba,	Q -ta	yo
--------------	-------	----

 (When spoken with the right intonation)

Thus far we have seen the uses of tense and aspect morphology and the use of a modal auxiliary; these two devices are highly analogous to the devices regularly used in English. Japanese conditionals, however, make use of yet other grammatical devices for expressing distanced epistemic stances. The two major devices are (i) adverbs (Section 4.3.) and (ii) sentence-final connectives (4.4).

#### 4.3. Adverbs

The most straightforward device for encoding epistemic distancing is adverbs. There are certain adverbs dedicated to epistemic distancing — typically, *mosi* for ordinary conditionals (10-D), and *tatoe* for concessive conditionals (11).

(10-D) *mosi zyuunen mae ni kono kusuri ga hakken-sarete-ireba,*  
hypothetically 10-year before in this medicine NOM discover-PAS-ASP-COND  
*musuko wa ima mo ikite-ita daroo kedo*  
son TOP now too alive-ASP-PAST MOD though (concessive.linker)

If this medicine had been discovered 10 years ago, my son would still be alive now.

- (11) *tatoe*                    *syuzyutu o*                    *sitemo*                    *naoranakatta*                    *yo*.  
 hypothetically operation ACC do-CcCd(even though)recover-NEG-PAST PAST  
 b y any chance  
 Even if he had had an operation, he would not have recovered.

#### 4.4. Clause-linkers: consequent-clause-final connectives

(12) illustrates the fact that the addition of a concessive linker at the end of the consequent clause contributes to epistemic distancing and ensures that the speaker takes a negative stance toward the situation expressed in the antecedent and the consequent. Notice in (12), which contains neither the modal expression *daroo* ‘would’ or the adverb *mosi*, that the addition of *noni* ‘though’ to the Q clause clarifies the speaker’s negative stance toward the proposition. That is, the speaker takes it for granted that the son is not alive now in reality. This counterfactuality is clear even without the modal expression *daroo* ‘would’.

- (12) *zyuunen mae ni kono kusuri ga hakken-sarete-ireba,*  
 10-year before in this medicine NOM discover-PAS-ASP-COND  
  
*musuko wa ima mo ikite-ita noni*  
 son TOP now tooalive-ASP-PAST though (concessive.linker)

If this medicine had been discovered 10 years ago, my son would still be alive now.  
 Construal of (12): If this medicine had been discovered 10 years ago, my son would still be alive now, but since this medicine was not available then, my son is not alive now.

#### 4.5. Negative polarity items (or scalar expression) conveying negative valuation and in turn implicating epistemic distancing

Shown in (13) is an English example of future predictive conditional (one of the parade examples given by Fillmore 1990) with a distanced stance, using the construction type ‘if P-past, Q-would.’ Though English encodes the subjunctive notion less extensively compared to Romance and Slavic, English has retained this subjunctive construction for epistemic distancing for future reference.

- (13) Predictive conditional (Future reference): distanced stance  
 b. If she opened it, they’d escape. **If P-past, Q-would**  
 Cf. Predictive conditional (Future reference): neutral stance  
 a. If she opens it, they’ll escape. **If P-present, Q-will-future**

In Japanese, by contrast, it is normally assumed that the subtle difference between (a) and (b) regarding the degree of epistemic is not linguistically encoded (especially for future reference). I agree that this distinction is not as clear in Japanese as in English. The subjunctive notion in English often disappears in Japanese translations, and it tends to be more obscure in Japanese.

Nevertheless, I suggest that Japanese appeals to grammatical devices other than verbal mood to indicate epistemic distancing. There are certain devices other than tense/aspect/modality that can communicate the distanced epistemic stance in (b) in Japanese. One such example is shown in (14):

(14) Predictive conditional (future): distanced stance

b. (*Kanozyo ga*)    *ake*    *demo sitara*    *nigeru*    *daroo*  
          she    NOM    open    even    do    escape    MOD(will )

**verb-stem *demo suru* + conditional linker**

Lit. If she does even (the act of) opening it, ....

    If she just opens it, they'll escape.

This construction contains a verb-stem followed by *demo* ‘even’ and *suru* ‘do’, and establishes a negative polarity context. There is no exact translation natural in English, and the literal translation is “If she does even (the act of) opening it” or “If she just opens it”. But the functional equivalent that is natural in English discourse, I believe, is the subjunctive conditional (b) at issue.

As mentioned above, this construction establishes a negative polarity context. The property of negative polarity in this construction also reveals the speaker’s negative valuation toward the act of opening it: The speaker does not want it to happen. This phenomenon relates to one of the explanatory concepts mentioned in Section 1.2 – namely the speaker’s valuation (negative or positive valuation on the situation in which P holds). This parameter is different from the parameter of epistemic stance, and thus these two parameters must be kept apart. Nonetheless, their linguistic manifestations can sometimes be intertwined. In the construction illustrated in (14), the manifestation of the speaker’s negative valuation leads to the implication of the speaker’s epistemic distancing. This argues that, in modern Japanese, which does not have rich clear-cut verbal mood dedicated to distinguishing the speaker’s epistemic stance (between neutral and distanced negative stance), the constructional meaning of negative valuation (accomplished through the use of negative polarity items) serves to indicate epistemic distancing.

To be fair, we need to note here that past tense might also serve to indicate epistemic

distancing, when the past form happens to be an available option for the verbal form preceding the clause-linker in the antecedent. As mentioned earlier, the linker NARA is one such linker that allows either the past or non-past form of a verb. Thus, in (15), the use of the past form in the antecedent *aketa* ‘opened’ (as opposed to the non-past form) can be interpreted as conveying the speaker’s epistemic distancing.

- (15) Predictive conditional (future): distanced stance
- b. (*Kanozyo ga*) *aketa* *nara* *nigeru* *daroo*  
 she NOM open-PAST Cond(if) escape MOD(will )  
 b. If she opened it, they’d escape.
- a. (*Kanozyo ga*) *akeru* *nara* *nigeru* *daroo*  
 she NOM open Cond(if) escape MOD(will )  
 a. If she opens it, they’ll escape.

The problem, however, is that the simple past form appearing in the NARA antecedent, as in (15), might also serve to convey the speaker’s positive stance taking the antecedent event as ‘given’. (I.e., ‘If it is true that she opened it, I guess they will escape.’) Thus, the construction is not dedicated to the function of marking epistemic distancing, unlike the English If P-past, Q-*would* construction.

#### 4.6. Nominalized antecedent MONO nara

Another special subtle device for epistemic distancing is the NARA conditional antecedent taking the nominal MONO ‘thing’ (see Fujii 2000 for details).

As shown in (16), MONO (which is formally a noun, whose original prepositional meaning is “things”) can appear immediately preceding the conditional connective NARA ‘if’. This MONO construction serves to encode the speaker’s epistemic stance without changing the propositional content. Consider the following minimal pair (16) and (17):

- (16) *dekiru* ***mono*** *nara* *mooitido* *yarinaositai*.  
 do-POT MONO if (conditional linker) once again redo-want  
 ‘If it was possible, I wish I could do it all over again.’
- (17) *dekiru* ***nara*** *mooitido* *yarinaositai*.  
 do-POT if (conditional linker) once again redo-want  
 ‘If it is possible, I wish to do it all over again.’

In (16), the conditional connective NARA ‘if’ marks a conditional subordinate clause both semantically and syntactically. (17), using NARA only, is perfectly well-formed both syntactically and semantically, and is a sufficient expression of the conditional clause ‘if it

is possible' and the main clause 'I wish to do it all over again'. The addition of MONO to the conditional clause in (16), however, reveals the speaker's additional attitude toward the proposition — namely that the speaker considers the situation referred to by the proposition (expressed in the clause preceding MONO) very unlikely or even impossible. In the English translations contrasting (16) and (17), I have used the subjunctive mood (or past counterfactual conditional) for (16) containing MONO. Although such differences in propositional attitudes cannot easily be captured in translations, I believe that the difference at issue (i.e., the difference created by the addition of MONO to the conditional clause) is analogous to effects expressed by verbal mood in many other languages.

(18) also uses MONO to encode the same epistemic stance, a belief that the proposition in the MONO NARA clause cannot (possibly) be true.

- (18) 1905 M91: *iya da naa moo*  
'I hate it.'
- 1906 M91: *ikkagetu yasumi totte sutoraiki sityau*  
one-month take off go on strike  
'I'll take one month off and go on strike.'
- 1907 Y91: *yareru mono nara yatte mina.*  
do-POT MONO if do try (imperative)  
'If you could ever do it, why don't you do it? (I believe you cannot do it.)'

In the discourse context of (18), it is already clear to both speaker and addressee that the addressee cannot take one month off and go on strike. The speaker not only believes that the addressee could never do it, but wishes to highlight this impossibility by coming out with this rather unkind, ironic statement, "If you could ever do it, do it." Though not obligatory, potential expressions (glossed -POT, above) often accompany the verb in the subordinate clause in this use of MONO.

(19) involves a slightly different construal of the MONO NARA clause. In this use of MONO, the verb in the NARA conditional clause takes the volitional form (y)oo in *siyoo*. (With the volitional form on the verb, NARA alone cannot mark the conditional clause.)

- (19) ... *wagahai no hoo de sukosi demo tedasi o siyoo mono nara*  
'on my side' a little even meddle ACC do-VOL MONO NARA  
*kanai soogakari de oimawasite hakugai o kuwaeru*  
whole family together chase around harm ACC add  
'If I meddled in their business even a little bit, the whole family would get together to chase me around and do me harm.'

With the addition of MONO to the conditional clause in this use, the speaker's attitude is that the proposition expressed in the *consequent* clause (main clause) is undesirable. If the speaker thinks that the consequent is undesirable, the antecedent that leads to the

undesirable consequent must also be undesirable for the speaker.

In this construction, as mentioned earlier with another case, there seems to be a conceptual link between the speaker's epistemic stance for low probability (i.e. unlikelihood) and the speaker's subjective valuation for undesirability of the situation. What the speaker considers undesirable may as well be considered very unlikely to occur; or else it may be something that the speaker considers to be likely but with respect to which she displays her subjective desire that it should be unlikely. In either case, the use of the MONO NARA construction reveals that the speaker is subjectively putting herself at a psychological distance from the conditional proposition. This psychological distance and bias result in such specific attitudes as unlikelihood in the epistemic sense and undesirability in the subjective valuation sense. Though subtle, the addition of MONO seems to yield this modal nuance — that the speaker is subjectively putting psychological distance between herself and the conditional proposition.

The issue, again, is that this construction is not exclusively dedicated to this function of registering the speaker's epistemic distancing; though this construction can be used to convey it, we can find other uses of the MONO NARA construction that are not related to epistemic distancing.

#### 4.7. Other devices

The present paper has discussed the grammatical devices (1) through (6) below for encoding the speaker's epistemic stance, and briefly mentioned (8) and (9). Other devices related to the manifestation of the speaker's epistemic stance include (7) and (10).

1. tense, aspect on the antecedent and the consequent
2. epistemic modal expressions on the consequent
3. adverbs in the antecedent
4. clause-linkers: consequent-clause-final connectives
5. negative polarity items (scalar expression) conveying negative valuation and in turn implicating epistemic distancing <stem>-*demo sitara*
6. nominalized antecedent MONO: *mono nara*
7. nominalized antecedent NO: *no nara, no dattara*
8. final pragmatic particle such as *yo*
9. intonation
10. choice of clause-linker (for the antecedent)

## 5. Conclusion

This paper has explored constructional mechanisms for conveying the speaker's epistemic stance in predictive conditionals in Japanese as compared to English. It has shown first that Japanese makes a much less clear distinction than English regarding the speaker's epistemic stance. More significantly, this paper has shown that Japanese employs a variety of grammatical devices for encoding the speaker's epistemic stance, including not only tense/aspect/mood verbal morphology but also a variety of other grammatical devices. The analysis shows that English and Japanese appeal to different grammatical devices for conveying and manifesting the speaker's epistemic stance and other conditional meanings in conditional constructions.

# Global Applicability of *NURIGEUL* for Literacy Program and Multilingual Word-processing

김석연-金昔研-Sek Yen Kim-Cho, Ph.D.

Former Assistant Professor of Korean Language and Literature (up to 1976)

College of Liberal Arts and Sciences, Seoul National University

Professor Emeritus, State University of New York at Buffalo

(Major: Speech Science and Korean Studies)

Director of Sejong Studies Institute, Inc.

Address: 189 Crestwood Lane, Williamsville, NY 14221

E-mail address: [sykcho317@hotmail.com](mailto:sykcho317@hotmail.com)

## Abstract

The Korean alphabet known as *Hangeul* is truly one of the great achievements of human invention. It was invented by King Sejong (1397-1450) for the literacy program in 1443 and promulgated in 1446. The official title of this alphabet is “*Hwunmin Cengum*-(HC-訓民正音)”, or “The Correct Phonetic Alphabet-Education For All People”. This title coincides with UNESCO’s idea of “Education For All (EFA).” *Nurigeul* is a combination of the Korean word *nuri* (globe) and *geul* (script). *Nurigeul* is a globalized version of *Hwunmin Cengum* which I developed and extended to a universally applicable phonetic alphabet for the world wide literacy program and multilingual communication and word-processing. Since the graphic shapes of *Nurigeul* are designed by the depiction of articulatory-acoustic correlates, I call this script as ‘Visible Speech Sounds’.

**Keywords:** *Hwunmin Cengum*, Global Script *Nurigeul*, Universally Applicable Phonetic Alphabet, Global Literacy Program, Multilingual Wordprocessing, Visible Speech Sounds

File name: Kim-Cho Sek Yen: Global Applicability of *Nurigeul*.doc

## 1. Rationales for the Graphic Design of *Cengum-Nurigeul*

The rationales for designing the Correct Phonetic Alphabet-*Nurigeul* are clearly stated and exemplified in the original texts of *Hwunmin Cengum* (HC-translated: Correct Phonetic Alphabet-Education For All People) and *Hwunmin Cengum Haylyey* (HCH-translated: Explanations and Examples on the Text HC)

According to the original texts of HC and HCH, *Nurigeul* is created from the beginning for solving illiteracy problem by the originator of the alphabet in the mid 15<sup>th</sup> century. King Sejong, explained his purpose of inventing the HC (The Correct Phonetic Alphabet) as follows:

### 1.1. Sejong's Preface to the Text, HC

#### —Nurigeul is Designed for Literacy Program

“國之語音,異乎中國,與文字不相流通.故愚民,有所欲言,而終不得伸其情者,多矣.予爲此憫然,新制二十八字,欲使人易習,便於日用耳.” —世宗大王 序文  
“The speech sounds of our country's language are different from those of China and are not communicable with the Chinese characters. Therefore, when my beloved ignorant people want to say something, many of them are unable to express their wishes in writing. Feeling compassion for them, I have newly designed twenty-eight letters, only ardently hoping that **everyone learn them at ease** and readily practice and use them conveniently everyday.”

Besides King Sejong's Preface to the HC, the compilers of the Text of HCH (*Hwunmin Cengum Haylyey*) provided more on the rationale for the graphic design and functions of Nurigeul for its global applicability. Below are some of the remarkable statements justifying why Nurigeul is the best-fit script for global applications.

### 1.2. Characters are Designed in accordance with the Sound Pattern

“有天地自然之聲,則必有天地自然之文.所以古人因聲制字,以通萬物之情,以載三才之道,而後世不能易也.”

“If there is speech sound natural to Heaven and Earth, then there should certainly be a writing system natural to Heaven and Earth. Thus the people of antiquity, relying on speech sound [in accordance with both in produced sounds and perceived sounds] designed [Old Seal] characters, by depicting sounds and shapes of the objects, there through to communicate circumstances of the Myriad Things and to register the Way of the Three Germinants [Heaven, Earth and Man]; we of later generations cannot change this [design principle of the Old Seal characters].”

—Head compiler Ceng In-Ji's Postface to the Text HCH

### 1.3. Graphic Function as Universally Applicable Phonetic Alphabet

“以二十八字而轉換無窮,簡而要,精而通.故智者不終朝而會,愚者可浹旬而學.”

—Head compiler Ceng In-Ji's “Envoy of Postface” to the Text HCH

“Though only twenty-eight letters are used, their shifts and changes in function are endless. They are simple and succinct, reduced to the minimum of finite rule, yet **universally applicable**. Therefore, **an intelligent man can get acquainted with the script before the morning is over, and even a ignorant man can learn them in space of ten days.**” —Head-compiler Cheong's Envoy of the Tex of HCH

#### 1.4. The Creation of Ubiquitous Script, *Nurigeul* is not a man made thing

“殿下, 天縱之聖. 制度施爲超越百王. 正音之作, 無所祖述. 而成於自然. 豈以其理之無所不在, 而非人爲之私也.”

“Our Monarch, with his Heaven-endowed wisdom, the codes and measure that have been proclaimed and enacted, exceed and excel those of a hundred kings. The creation of the *Cengum-Nurigeul* is not something that has been transmitted by our ancestors; they have been perfected out of nature itself. Now since there is no place where the all-reaching Pattern is not found, this **ubiquitous script** certainly is not a man made, isolated thing.” —Head compiler Cheong’s Postface

#### 2.0. Graphic Design of the Correct Phonetic Alphabet, *Nurigeul*

What makes *Nurigeul* superior to all other writing systems is its design principle which takes into account significant physiological features of speech production and perception.

*Nurigeul* was developed by extending the design principle of the HC in terms of speech production and perception. Since there exists perfect correlation between the graphic shapes and graphic functions, letter shapes of the *Nurigeul* are designed by *visualizing* the places of articulation and the manner of articulation and its associated perceived sounds. Thus *Nurigeul* alphabet can be called “**Visible Speech Sounds.**”

#### 2.1. Graphic Design of the Five Basic Consonant Graphemes

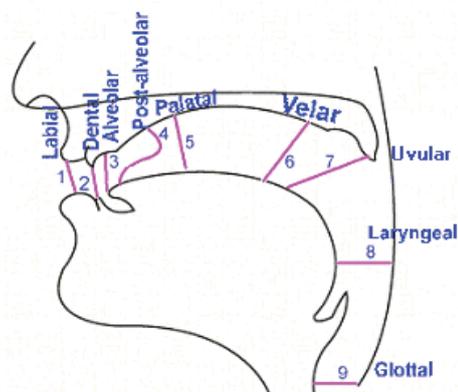

The design principle of *Nurigeul* is so simple and easy to learn that with only Five basic consonant letters, [○[0] or zero cipher] ▿[g<sup>h</sup>] ⊥[n] ^[s] and □[m], as building blocks, we can assemble and generate a whole new writing system according to increased and decreased sound energy.

The actual graphic shapes of the consonants were designed by depicting either the shapes of articulatory organs (i.e., the place of articulation: throat ○ and lips □) or the configurations of articulatory gestures (i.e., the manner of articulation: the velar ▿, the lingual ⊥ and the incisor ^).

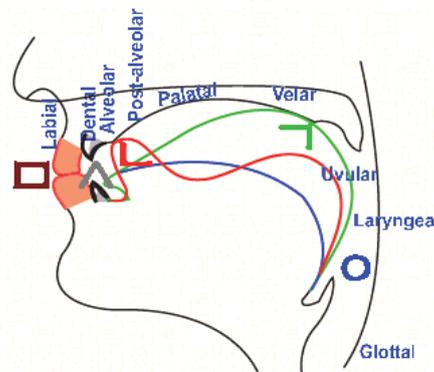

Speech sounds are produced in an order beginning in the **Throat** at the rear of the vocal tract and proceeding through the **Soft palate**, the **Tongue** and the **Incisors/Dentals** to the **Lips**.

A 35-year old male subject was fed thick valium liquid to enhance the outline of the soft tissue. From the filmstrip, one can see a corresponding relationship between the **Letter Shape** and the **Vocal tract Configuration** traced from cine-radiographic X-ray film.

- Diagram of the Left-lateral Head Orientation for the Depiction of the Five Basic Consonant Graphemes:  $\bigcirc$  [0]  $\neg$  [g<sup>h</sup>]  $\perp$  [n]  $\wedge$  [s]  $\square$  [m]

Target areas and Places of Articulation

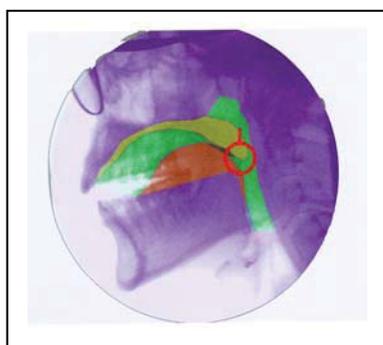

Articular Contours of The Five Basic Consonants

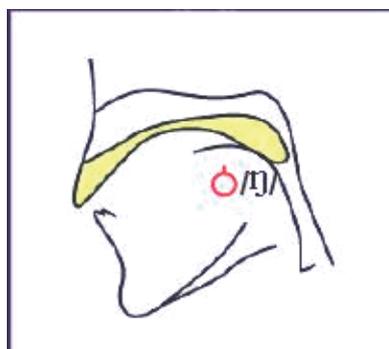

- Depiction of the Five Basic Consonant Graphemes

1. The basic shape of the throat sound  $\bigcirc$  [0] is a depiction of the outline of the laryngeal aperture from frontal observation. It looks like an opening of a pipe.
2. The basic shape of the velar sound  $\neg$  [g<sup>h</sup>] is a depiction of the outline of the back part of the tongue touching the velar region.
3. The basic shape of the lingual sound  $\perp$  [n] is a depiction of the tongue tip touching the alveolar ridge.
4. The basic shape of the dental sound  $\wedge$  [s] is a depiction of the jointed portion of the upper incisors “/” and lower incisors “\”.
5. The basic shape of the labial sound  $\square$  [m] is a depiction of the outline of the closed mouth from frontal observation.

## 2.2. Presentation of Frame Samples traced from the Cineradiographic Filmstrip

Frame A is a copy of the original X-ray frame of the vocal tract during the utterance of the nasal velar sound  $\bigcirc$  [ŋ].

In Frame B the soft palate region is blocked by the raising of the back of the tongue and lowered velar-uvula to produce the nasal velar sound  $\bigcirc$  [ŋ].

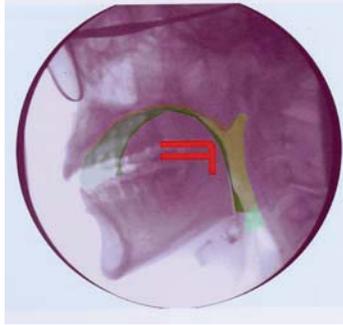

Fig. 2.2.1. The tracing of the mid-consonant structure for the utterance of /ha-k<sup>h</sup>-a/, (the letter **Ɵ**).

Fig. 2.2.2. The tracing of the mid-consonants structure for the utterance of [ha-**n**-a], (the letter **⊥**).

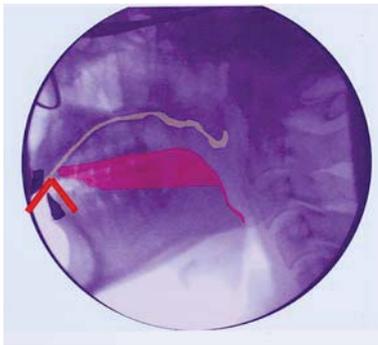

Fig. 2.2.3. The tracing of the mid-consonant structure for the utterance [ha-**s**-a], (the letter **^**).

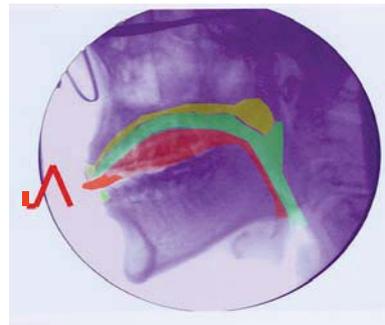

Fig. 2.2.4. The tracing of the mid-consonan structure for the utterance [ha-**θ**-a], (the letter **⋈**).

The aim of utilizing “cine-radiographic tracing” was to visually capture the structures of articulatory configurations. A systematic comparison of the shapes of the actual letters and the articulatory configurations in the Figures 2.2.1. through 2.2.4. show a complete correlation between the visualized configurations of the vocal tract activities and the consonant letters of Nurigeul. For example, the tongue-tip sticking out between the upper and lower incisors in order to produce English inter-dental sound [θ] is visible in the Fig. 2.2.4.

## 2.3. Overview of the Additive Stroke System of the Five Consonant Categories

### ⊙ Explanation of the ‘Additive Stroke System’

Besides the five basic consonant graphemes there are more letters that are either **Engraphed** or **Degraphed**.

- The “**Engraphed Graphemes**” are the letters with extra strokes added above the basic graphemes in order to portray “**increased harshness**”,  
e.g., ㄱ[ɡʰ] ㅋ ㆁ[ŋʰ], ㄷ[dʰ] ㅌ ㆁ[ŋʰ], ㅅ[s] ㅆ ㅈ[c]
- The “**Degraphed graphemes**” are the letters with extra strokes added below the basic graphemes in order to indicate “**decreased harshness**”,  
e.g., ㅅ[s] ㅆ ㅈ[c], ㄹ[r] ㄴ ㄷ[ɹ], ㅃ[bʰ] ㅅ ㅆ[β].
- There are also some letters that have the same letter written side by side,  
e.g., ㅎ[ħ] ㄱ[ʰ] ㄷ[ʰ] ㅅ[ʰ] ㅈ[ʰ] ㅊ[zʰ/zz] ㅍ[pʰ].  
These are called “**Diplograms**”, which typically involve tense sounds.

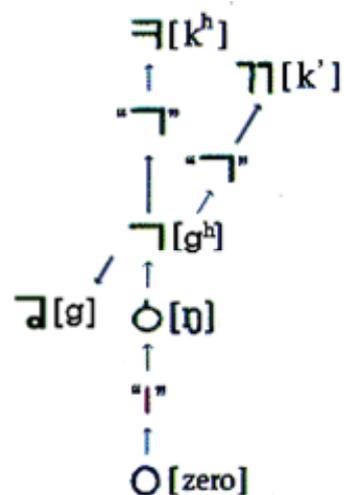

#### 2.3.1. Additive Stroke System of the Lanrymngal Graphemes: 〇[0] 〰[ʔ] ㅎ[h] ㅎ[ħ²]

1. The basic throat grapheme 〇 has no phonetic value as in the case of silent ‘h’ in ‘Hour’ it is a zero cipher.
2. When we add a horizontal stroke ‘—’ on top of the 〇, it is the engraphed throat sound [ʔ] as in ‘Hawaii’.
3. The engraphed throat grapheme ㅎ[h] as in ‘Hot’ is formed by adding an extra vertical stroke ‘|’ on top of the grapheme ‘〰’.
4. The throat diplogram ㅎ[ħ] is formed by writing ㅎ side-by-side. This sound is like the German word ‘Achtung’.

### 2.3.2. Additive Stroke System of the Velar Graphemes: 〇[n] ㄱ[g<sup>h</sup>] ㅋ[k<sup>h</sup>] ㆁ[k'] g[g]

1. The velar nasal 〇[n] as in '*sing*' is formed by engraving a vertical stroke " | " on top of the throat grapheme 〇. The protruding stroke is a symbol of the emission of sound energy through the nasal cavity.
2. The basic velar grapheme is ㄱ[g<sup>h</sup>]. This slightly aspirated sound is between [g] and [k].
3. The heavily aspirated sound ㅋ[k<sup>h</sup>] as in '*kid*' or '*cool*' is formed by engraving an extra grapheme "ㄱ" on top of the basic grapheme ㄱ.
4. The diplogram ㆁ[k'] as in '*sky*' is a tense velar sound.
5. The voiced velar stop ㄲ[g] as in '*God*' is formed by adding a symbol of voiced sound "ㅇ" to the lower left corner of the grapheme ㄱ.

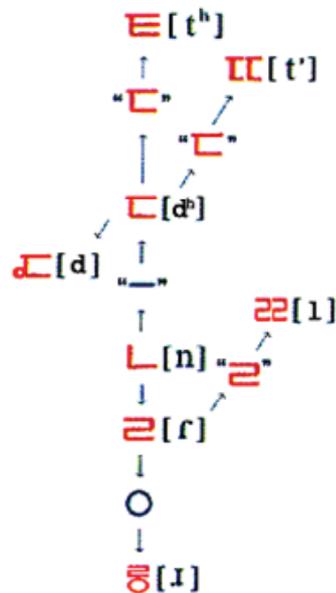

### 2.3.3. Additive Stroke System of the Lingual Graphemes:

ㄴ[n] ㄷ[d<sup>h</sup>] ㅌ[t<sup>h</sup>] ㄸ[t'] ㄹ[d] ㄺ[r] ㄻ[ɹ] ㄼ[l]

➤ Lingual-alveolar graphemes involve tongue and alveolar ridge.

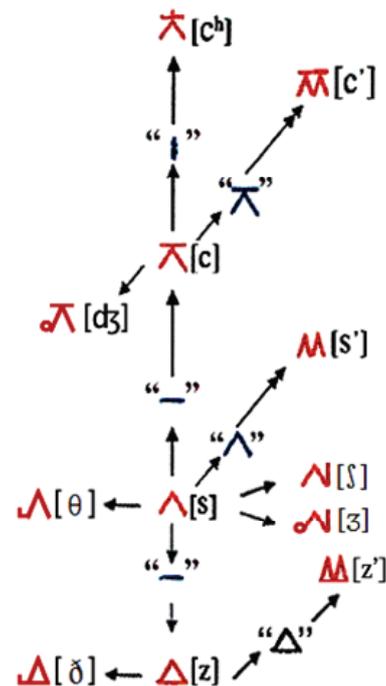

1. The basic lingual-alveolar nasal grapheme is ㄴ[n].
2. The engrahed grapheme ㄷ[d<sup>h</sup>] is formed by adding the horizontal stroke "—" on top of the basic grapheme ㄴ. This sound is between the English [d] and [t].
3. The heavily aspirated alveolar stop ㅌ[t<sup>h</sup>] as in English '*tool*' is formed by engraving the extra stroke "ㄷ" on top of the grapheme ㄷ.
4. The tense alveolar diplogram ㄸ[t'] as in '*still*' is formed by the same grapheme ㄷ written side by side.
5. The voiced lingual-alveolar stop ㄹ[d] as in '*dad*' is formed by adding a symbol of voiced sound "ㅇ" to the lower left corner of the basic grapheme ㄷ.
6. The lingual-alveolar grapheme ㄺ[r] as in '*throw*' is formed by the depiction of the tongue rolled up.
7. The degrahed lingual-alveolar grapheme ㄻ[ɹ] as in '*run*' and '*girl*' is generated by adding the symbol of voiced sound "ㅇ" below the grapheme ㄺ.
8. The lingual diplogram ㄼ[l] as in '*life*' is formed by the same grapheme ㄺ written side by side.

### 2.3.4-A. Additive Stroke System of the Dental-Palatal Graphemes:

$\wedge$ [s]  $\rceil$ [c]  $\text{A}$ [c<sup>h</sup>]  $\mathbb{M}$ [s']  $\mathbb{M}$ [c']  $\text{A}$ [dʒ]  $\Delta$ [z]  $\times$ [z']  $\text{A}$ [θ]  $\Delta$ [ð]  $\text{A}$ [ʃ]  $\text{A}$ [ʒ]

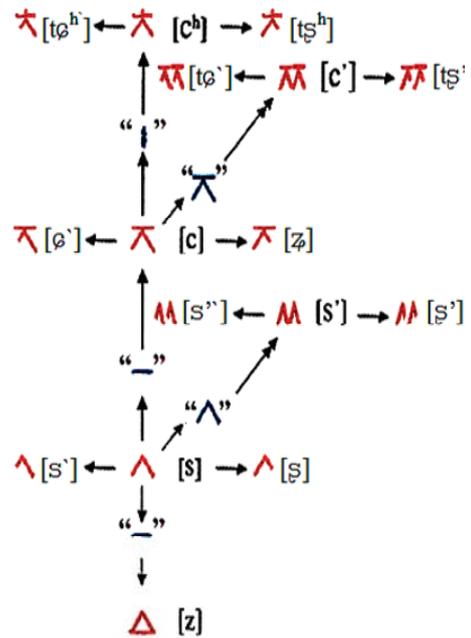

- Dental-Palatal graphemes involve dental-palatal area for production of dental-palatal sounds.
- 1. We have the basic incisor grapheme  $\wedge$  as in ‘Son’.
- 2. The engraphed grapheme  $\rceil$ [c] is formed by engraving the horizontal stroke “—” on top of the basic grapheme  $\wedge$ . This horizontal stroke represents the palatal area. This sound is between [dʒ] and [ch]. It is a typically pronounced affricate.
- 3. The heavily aspirated palatal sound  $\text{A}$  as in ‘Church’ is formed by engraving an extra vertical stroke “|” on top of the grapheme  $\rceil$ .
- 4. The tense diplogram  $\mathbb{M}$ [s'] as in ‘Seed’ is formed by the same letter  $\wedge$  written side by side.
- 5. The tense diplogram  $\mathbb{M}$ [c'] is formed by the same letter  $\rceil$  written side by side. This sound is as in ‘catchup’.
- 6. The voiced palatal stop  $\text{A}$ [dʒ] as in ‘juice’ is formed by adding a symbol of voiced sound “o” to the lower left corner of the letter  $\rceil$ .
- 7. The degraphed incisor grapheme  $\Delta$ [z] as in ‘visa’ is formed by adding the horizontal stroke “—” below the grapheme  $\wedge$ .
- 8. The tense diplogram  $\times$ [z'] as in ‘pizza’ is formed by the same letter  $\Delta$  written side by side.
- 9. The dental-lingual fricative  $\text{A}$ [θ] as in ‘think’ and  $\Delta$ [ð] as in ‘these’ are produced with the tongue tip sticking out between the upper and lower incisors. The letter shapes are formed by adding the lingual subscript ‘<sub>l</sub>’ to  $\wedge$  and  $\Delta$ .
- 10. The voiceless palatal fricative  $\text{A}$ [ʃ] as in ‘Sheet’ is formed by adding the vowel [ | ] to the grapheme  $\wedge$ .
- 11. The voiced palatal fricative  $\text{A}$ [ʒ] as in ‘viSion’ is formed by adding a ‘symbol of voiced sound “o” to the lower left corner of  $\text{A}$ .

2.3.4-B. Additive Stroke System of the Dental-Palatal Graphemes:

ㄣ[s] ㄣ[z] ㄣ[tʃʰ] ㄣ[tʃʰ'] ㄣ[s'] . ㄣ[s'] ㄣ[ʃ'] ㄣ[tʃʰ] ㄣ[tʃʰ'] ㄣ[s'] .

1. There are ten more unique dental-palatal fricatives generated in the mid 15<sup>th</sup> century for the accurate transcription of the Chinese language.  
Fricative refers to a sound produced by the friction of the breath issuing through a narrow opening of the speech organs as [f, v, s, z].
2. There is a category of retroflex fricative which involves the tongue tip curled back in the production of the sound.
3. There are five dental-palatal retroflex fricatives in the Chinese language. They are ㄣ[s] ㄣ[z] ㄣ[tʃʰ] ㄣ[tʃʰ'] ㄣ[s'].
4. There are five dental-palatal fricatives in the Chinese language. They are ㄣ[s'] ㄣ[ʃ'] ㄣ[tʃʰ] ㄣ[tʃʰ'] ㄣ[s']. These sounds are produced with the tongue tip between the lower lip and incisors.

### 3.0. Graphic Design of the *Nurigeul* Vowel Graphemes

The graphic design of the *Nurigeul* vowels is based on the two rationales. One was the traditional Yin-Yang cosmological features and the other is the Distinctive Features as the classificatory device. In the Yin-Yang rationale, Yin means dark and Yang means bright. This Yin-Yang concept involves the Three Great Powers: Heaven • [ʌ], Earth —[ɨ], and Man | [i].

Yang-Bright Vowels refer to Strong Vowels; Yin-Dark Vowels refer to Weak Vowels. Phonetically those three cardinal vowels • [ʌ], —[ɨ], and | [i] are Neutral Vowels. Based on these three neutral vowels, secondary and tertiary vowels are generated by the combination of three cardinal-neutral vowels. Thus, the rationale underlying the graphic depiction of the *Nurigeul* vowels has taken into account dual dichotomy. They are the Yin-Yang and Distinctive Features which are determined by the Amplitude of the vowels.

#### 3.1. The Three Cardinal Vowels: • [ʌ] —[ɨ] | [i]

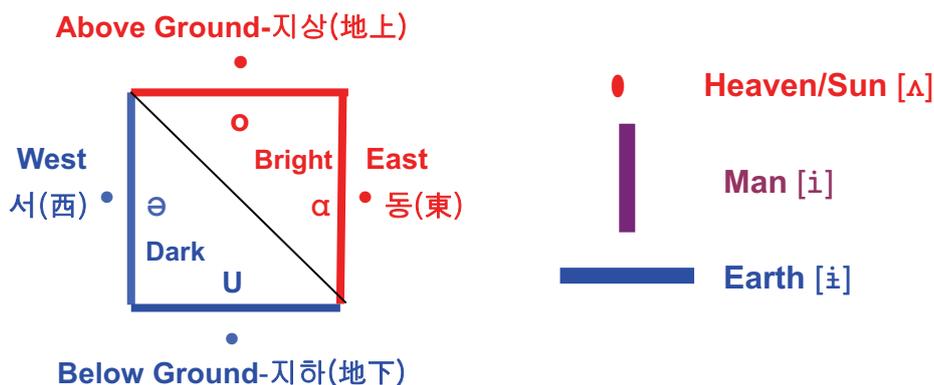

The three cardinal vowels • [ʌ] —[ɨ] and | [i] are designed by depicting Heaven/Sun (•), Earth (—) and Man (|) standing between heaven and earth. They are phonetically represented as Neutral Vowels. Since neutral vowels have no independent phonetic value they can be combined with any vowels.

The sound of neutral vowel • [ʌ] is as in ‘bus-bʌs’, ‘cut-kʌt’, ‘love-lʌv’.

The sound of neutral vowel —[ɨ] is produced when vowel [u] is uttered with the lip shape of vowel | [i].

The sound of neutral vowel | [i] is as in ‘sing-siŋ’, ‘sick-sik’ or ‘tear-tiə’.

#### 3.2. The Four Secondary Vowels: † [a] ⇄ [o] and † [ə] ⇄ [u]

The sound of the bright-strong vowel † [a/α] is as in ‘mama-mα : mə’.

The sound of the bright-strong vowel ⇄ [o] is as in ‘Ohio-Ouhaiou’.

The sound of the dark-weak vowel is † [ə] is as in ‘about-əbaut’, ‘earth-ə : rθ’

The sound of the dark-weak vowel is ⇄ [u] is as in ‘rude-ru : d’, ‘cool-ku : l’.

### 3.3. The Four Yodized Vowels: ㅟ [ya] ㅠ [yo] ㅡ [yø] ㅢ [yu]

Yodized vowels are vowels combined with the vowel ㅣ [i/y] pronounced with the ㅟ first. The four Yodized Vowels are generated by the conjugation of ㅣ and ㅏ → ㅟ; ㅣ and ㅑ → ㅠ; ㅣ and ㅓ → ㅡ; ㅣ and ㅕ → ㅢ.

The sound of ㅟ [ya] is as in ‘yacht-jɔt’, ‘YAHOO-jɔhu:’

The sound of ㅠ [yo] is in ‘yoga-jouŋø’, ‘yolk-jouk’

The sound of ㅡ [yø] is as in ‘yearn-jø:n’ or ‘shirt-ʃø:t’.

The sound of ㅢ [yu] is as in ‘news-nju:s’ or ‘shoes-ʃu:z’.

### 3.4. Other Complex Vowels Combined with Neutral Vowel ㅣ [i /y]

Complex vowels are generated by the combination of the neutral vowel ㅣ [i /y]

Note: All the Yodized vowels (vowels combined with ㅣ i /y) and the combination of simple vowels are called ‘diphthongs’.

	Other Complex Vowels combined with ㅣ [y]	IPA	Examples	Yin-Yang Features
*(8)	ㅏ + ㅣ → ㅟ	[ya]	as in ‘yacht’	bright/strong
(9)	ㅑ + ㅣ → ㅠ	[yo]	as in ‘york’	bright/strong
(10)	ㅓ + ㅣ → ㅡ	[yø]	as in ‘yearn’	dark/weak
(11)	ㅕ + ㅣ → ㅢ	[yu]	as in ‘news’	dark/weak
(12)	ㅏ + ㅏ → ㅝ	[æ]	as in ‘pan’	bright/strong
(13)	ㅓ + ㅏ → ㅞ	[e]	as in ‘pen’	dark/weak
(14)	ㅑ + ㅏ → ㅟ	[œ]	as in Goethe	bright/strong
(15)	ㅓ + ㅓ → ㅠ	[ü]	as in über	dark/weak
(16)	ㅡ + ㅏ → ㅡ	[Ø]	as in deux	dark/weak
(17)	ㅏ + ㅓ → ㅝ	[yæ]	as in ‘yet’	bright/strong
(18)	ㅓ + ㅓ → ㅞ	[ye]	as in ‘yes’	dark/weak
(19)	ㅑ + ㅏ → ㅟ	[wa]	as in ‘what’	bright/strong
(20)	ㅑ + ㅓ → ㅠ	[wæ]	as in ‘wagon’	bright/strong
(21)	ㅓ + ㅓ → ㅡ	[wø]	as in ‘work’	dark/weak
(22)	ㅕ + ㅓ → ㅢ	[we]	as in ‘wet’	dark/weak

⊙ Those 7 vowels ㅏ ㅑ ㅓ ㅕ ㅝ ㅞ ㅠ are simple vowels.

⊙ Position of Vowels in the Syllable: The vowels ㅏ ㅑ ㅓ ㅕ ㅝ ㅞ ㅠ are written just under the initial consonant/phoneme: e.g., 찻스교무교휴 while ㅏ ㅓ ㅕ ㅟ ㅡ ㅢ are written just to the right: e.g., 미가녀샤벼

#### 4. *Nurigeul* is the Only Solution!

In 1905, British phoneticians began collecting all the variable sounds of consonants and vowels used in world languages. In 1993, SIL (Summer Institute of Linguistics) finalized and promulgated IPA (International Phonetic Alphabet) as “SIL IPA 93.” There are 126 IPA symbols consisting of 98 consonants and 28 vowels. 126 IPA is the ultimate and complete collection of all the phonetic sounds classified according to the standardized ‘place of articulation’ and ‘manner of articulation’.

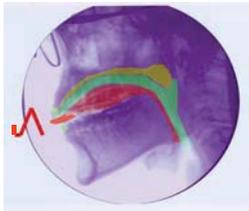

I have completed the Article entitled: **Nurigeul is the Only Solution!**  
 —**Let’s go with 126 Nurigeul Instead of 126 IPA.**

Shown below are some samples from the Comparative Chart of 126 IPA vs. 126 Nurigeul. Phonetic Description and Rationale for the Graphic Design are based completely on the Standard of IPA.

#### Let’s Go with 126 Global Script Nurigeul!

##### Pulmonic Consonants

IPA Nurigeul	A. Phonetic Description B. Rationale for the Graphic Depiction
[1] b <sup>h</sup> 𐄀	A. Voiceless bilabial stop. It is typically an aspirated sound. The phonetic value is between [p] and [b] produced with a complete closure of lips with no vocal fold vibration. B. The bilabial grapheme 𐄀 depicts and represents the increased harshness caused by the emission of labial pressure during the production of slightly aspirated voiceless labial stop 𐄀, as compared to the basic labial grapheme 𐄁. The engrahed <sup>3</sup> protruded stroke ‘! ’ added to the grapheme 𐄁 represents the emission of labial pressure from the lip opening.
[2] p <sup>h</sup> 𐄂	A. Voiceless aspirated bilabial stop, produced in the same manner as [p] but with a wide open glottis. B. The engrahed bilabial grapheme 𐄂 depicts and represents increased labial pressure discharge. The engrahed segmental stroke ‘= ’ refers to an indicator as an [h] superscript which represents the additional feature of ‘heavy aspiration’ and its pressure discharge.
[3] f 𐄃	A. Voiceless labio-dental fricative, as /f/ in forest, produced in the region between the lower lip and upper incisors without vocal fold vibration. B. The grapheme 𐄃 depicts the outline of the upper incisors sticking out from the lower lip to produce the labio-dental fricative /f/. The segmental stroke ‘^ ’ added to the lower left corner of the grapheme 𐄃 is an indicator of ‘incisors stuck out’ from the lower lip.
[4] v 𐄄	A. Voiced labio-dental fricative as /v/ in vine, produced in the region between lower lip and upper teeth with vocal fold vibration. B. The grapheme 𐄄 depicts the outline of the upper incisors sticking out from the lower lip to produce the labiodental fricative /v/. The segmental stroke ‘^ ’ added to the lower left corner of the grapheme 𐄄 is an indicator of ‘incisors stuck out’ from the lower lip.

<p>[5] θ ʌ</p>	<p>A. Voiceless interdental fricative as /th-θ/ in theory, with turbulence generated at the narrow region between the protruded tongue and incisors.</p> <p>B. The voiceless interdental fricative grapheme ʌ depicts the outline of the incisors and tongue tip (┘), required for the production of the interdental ʌ, as compared to the basic incisor grapheme ^.</p> <p>The segmental lingual stroke ‘┘’ is an indicator of a protruded tongue.</p> 
<p>[39] ð Δ</p>	<p>A. Voiced interdental fricative as /th-ð/ in thee, produced in the same manner as /θ/ but with vocal fold vibration.</p> <p>B. The voiced inter-dental fricative grapheme Δ depicts the outline of the incisors and tongue tip (┘) which represents decreased harshness as compared to the voiceless inter-dental ʌ. The segmental lingual stroke ‘┘’ added to the lower end of the upper incisor indicates the ‘protruded tongue’ for the production of the voiced interdental sound Δ.</p>
<p>[40] s ^</p>	<p>A. Voiceless incisor-alveolar fricative as /s/ in soap, produced through a narrow gap between the tongue tip and alveolar ridge, causing friction.</p> <p>B. The basic incisor grapheme ^ depicts the outline of the jointed portion of the upper ( / ) and lower ( \ ) incisors where the sibilant feature is produced.</p>

Note:

1. Each *Nurigeul* script was chosen from the Unicode-ISO 10646 except some scripts.
3. I used some exceptional *Nurigeul* scripts which, like J [v], consists of the combined letter like ʌ [v] that is listed in the ISO 10646. Other examples are as follows: K [f]←ʌ, A [θ]←ʌ, x [ð]←Δ

#### 4.1. Chinese Syllabary System as a Case Study of *Nurigeul*

Besides being a system of syllabic units, the Chinese characters are also ideographs, many of which tend to have the same pronunciation in spite of their widely different meanings. For example, ‘*tong*’ could be “East”, “Sameness”, “Winter”, “Frozen”, “Infant”, “Motion” and other homonyms. In order to differentiate their varying meanings, the Pinyin System is obliged to place one or the other of the Four Tone Markers. As shown in the following example, it is very simple to place the Tone Markers right after the *Nurigeul*’s syllabic units compare to Pinyin System.

Symbols of the Four Tones: /1<sup>st</sup> tone ' 2<sup>nd</sup> tone ;' 3<sup>rd</sup> tone ;4<sup>th</sup> tone

Ul;'Ekh 『x0/dk/aj'』 .	Tngn Ul;'EkhXj;RjEl;vk.	dkl, NñEkhVj..
请到 『天安門』	师傅, 请到这个地方.	哎, 知道了.
qǐngdào Tiānānmén .	shīfu, qǐngdào zhège dìfang.	ai, zhī dào le.

**Note:**

1. The 21 Initial Consonants currently in use in Chinese language have been established on the basis of the “Comparative Chart of Consonants in IPA vs. *Nurigeul* Graphemes”.
2. In order to transcribe the Pre-literate languages, a chart must be prepared as shown below. The chart which illustrates the difference between Pinyin/Romanization systems, IPA and Nurigeul for 21 Chinese Consonants.

4.2. Comparative Chart of Pinyin, IPA, Nurigeul for 21 Chinese Initial Consonants

Based on the following chart we can transcribe/transliterate the Chinese Mandarin pronunciation perfectly in Nurigeul script.

		Bilabial	Labio-dental	Dental	Retroflex	Palatal	Velar	Glottal
Plosives	Un-aspirated	(1) b[p'] ㅃ			(2) d[t'] ㄸ		(3) g[k'] ㄱ	
	Aspirated	(4) p[p <sup>h</sup> ] ㅍ			(5) t[t <sup>h</sup> ] ㅌ		(6) k[k <sup>h</sup> ] ㅋ	
Affricates	Un-aspirated				(7) z[ts] ㄷ	(8) zh[tʃ] ㅈ	(9) j[tʃ] ㅊ	
	Aspirated				(10) c[ts <sup>h</sup> ] ㄸ	(11) ch[tʃ <sup>h</sup> ] ㅈ	(12) q[tʃ <sup>h</sup> ] ㅊ	
Nasals		(13) m[m] ㅁ			(14) n[n] ㄴ			
Fricatives			(15) f[f] ㅍ	(16) s[s'] ㅍ	(17) sh[ʃ] ㅍ	(18) x[ç] ㅍ		(19) h[h <sup>2</sup> ] ㅎ
Voiced Continuant				(20) l[l] ㄹ	(21) r[z] ㄹ			

Notes:

1. The phonetic representation of the Chinese initial consonants is transcribed by IPA. The **IPA symbols written in red** indicate that that Pinyin System does not match the actual speech sounds of Mandarin Pronunciation. That means out of 21 Chinese initial consonants, 15 consonants represented by Pinyin are mismatches. Hence we are justified to adopt Nurigeul script for the correct phonetic representation of the Mandarin Chinese.
2. The actual phonetic features of the global language are represented by IPA. Without IPA symbols we can not evaluate the actual sound values.
3. The 21 Initial Consonants currently in use in Chinese language have been established also on the basis of IPA as the international standard. In order to transcribe languages without writing system, a chart must be prepared as shown above which illustrates the difference between Pinyin, IPA and Nurigeul for 21 Chinese Consonants.

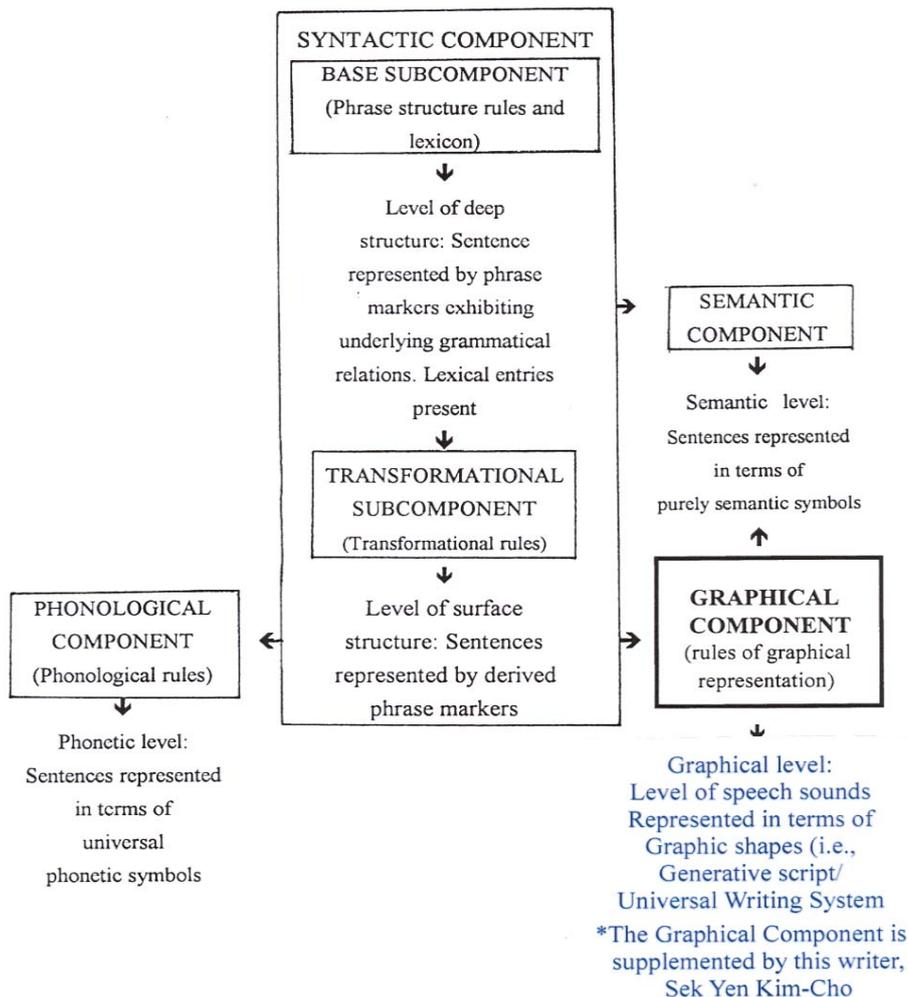

## 5. *Nurigeul* is A Generative Script—Generative Principle as the Common Denominator of Sejong and Chomsky

Justification for the rationale of designing of *Nurigeul* could be seen in the application of a “generative rule.” This means that as long as articulatory-physiological and acoustic-phonemic data are given, the graphic shapes can be generated infinitely by visualizing the related articulatory-acoustic information.

According to Chomsky, generative grammar is an outgrowth of a persistent concern with the “creative” aspect of language use. The Korean phonologists of the 15<sup>th</sup> century were just as deeply concerned with the creative use of script. In other words, the “generative script” was conceived as an “all-reaching Pattern” that could transcribe any sound that is linguistically significant. Consequently, the Correct Phonetic Alphabet of the consonant graphemes may be considered a Universally Applicable System of Writing. The goal of “Generative Graphic Universals” may be achieved by the pervasive portrayal of the “Sound Pattern of Speech.”

The following chart is taken from Chomsky’s *Syntactic Structure* (1965), to which I have added the “**Graphical Component**” in the belief that a complete **Organization of the Grammar** should include this level of “**Generative-Universal Script.**”

Organization of the grammar

The *Nurigeul* Script is intended to portray the correlation between the graphic shapes and their corresponding speech physiological data. Therefore, the verification of this correlation is tantamount to the identification of the “universal generative theory” implied by and used in the creation of *Nurigeul* that “any speech sound can be generated into a letter shape by graphically depicting the speech physiological data (which can be visualized by X-Ray tracing as well as the computerized visualization of the articulatory configurations)”. As such, the phonetic theorization of the generative rules in *Nurigeul* evolved into an applied theory of “Generative-Universal Transcribability of Speech Sounds,” and this points directly toward a conclusion that *Nurigeul* is a “**Universally Applicable Phonetic Alphabet.**”

Roman Jakobson’s (1969) theory of distinctive features can be interpreted as making an assertion about substantive universals with respect to the phonological component of generative grammar. It asserts that each output of this component consists of elements that are characterized in terms of a small number of *fixed, universal, phonetic* features. Each feature has substantive acoustic-articulatory correlates independent of any particular language.

It has been demonstrated that it was the search for the nature of universal phonetics that motivated the 15<sup>th</sup> century Korean linguists to adopt the **distinctive feature, generative script theory.**

The Korean phonologists of the 15<sup>th</sup> century conceived the graphic function as a phonetic symbol with a one-to-one correspondence between any kind of noise/sound and its correlated writing system.

Assume that a series of numbers, 1, 3, 6, 10, 15, 21 and 28, are given to two persons. They are instructed to deduce the number sequence and generate the subsequent components. One may generate the sequence 36, 45, 55, 66, 78, etc., in a minute, and the other may take twice as long, but the result would be identical.

It may be concluded that this reflects the difference in the learning ability of the two subjects. Regardless of the learning time, each subject had to have deduced the fundamental Pattern of sequencing by the iterative/infinite use of a finite rule. Thus they both understood the infinitely pre-existing Pattern of generative processes. A concrete idea of generating the “universal script” was suggested in the following quotation: “Though only twenty eight letters are used, their shifts and changes in function are endless. They are simple and succinct, reduced to the **minimum of finite rule, yet universally applicable.** Therefore, **an intelligent man can get acquainted with the script before the morning is over, and even a ignorant man can learn them in space of ten days.**” —Head-Compiler Cheong’s concluding remarks to the Commentary Text of HC

Thus, the main idea of the rationale is nothing other than the “Generative Pattern or Principle” which underlies the “Universally Applicable Script Function,” the Correct Phonic Alphabet-*Nurigeul*.

### **5.1. Originator’s Intent was to create “Universally Applicable Phonetic Alphabet”**

The originator’s intent in the 15<sup>th</sup> century was to determine precisely how this generative theory could exhaustively portray the “Nature of Sound Pattern” in human

speech sounds. The most explicit example could be found in the design of the labial graphemes. As for the design of the labial graphemes, the originator used different system of engraving from the other four homorganic categories.

In order to represent the class of labial sounds, the engraved strokes are assigned to reflect the labial pressure discharge. If the originator had not considered the relationship between the graphic shape and the associated physiological data, they would have designed labial graphemes as  $\square[m] \rightarrow \bar{\square}[b^h] \rightarrow \hat{\square}[p^h]$ , instead of  $\square[m] \rightarrow \sqcup[b^h] \rightarrow \amalg[p^h]$ . Those extra strokes “—” and “+” added to the basic labial grapheme  $\square$  do not have an associated physiological dimension in the vocal tract. This is because, the lips are located at the end of the vocal tract, and hence, no additional physiological dimensions, such as alveolar, palatal, etc. could be involved for the production of the harsher labial sounds.

Therefore, the originator of the Nurigeul script could not follow the same engraving system that was taken into account in the generation of the other four categories. Thus the originator has utilized different rationale for the additive stroke system for the Labial category.

As for the engraving system of the labial category, the amount of labial pressure discharge was taken into account for the generation of the harsher labial sounds. Thus the engraved segmental strokes ‘11’ and ‘::’ are added to the basic labial grapheme  $\square[m]$  as an indicator of  $[^h]$  superscript which represents the additional feature of ‘heavy aspiration’ and its pressure discharge. The additive stroke system for the labial graphemes are generated as follows:  $\square \uparrow 11 \rightarrow \sqcup$ ;  $\square \Rightarrow :: \Rightarrow \amalg$ .

## 5.2. Language, Script and Computer are the Tools to Facilitate Literacy Program, Multilingual Processing and Designing Scripts for Pre-literate People

I suggest the new metaphor that “If Language is the House of Being, then Script is the House of Language, and Computer is the House of Script.” The metaphor “house” is used to denote the sense of guarding, preserving and making accessible the vital function of those three elements, language, script and computer, which are in a dynamic, interdependent and mutually complementing relationship. We may envision a three-story house to make the metaphor complete.

Such sense of protection and guardianship may become apparent when we realize that those unreached people who have either no writing system or, even if they have one, it is so difficult that they cannot consider it practical to use it. In short, Endangered Languages will wither away and soon be lost unless they are “housed” and given a shelter.

Illiteracy inevitably implies computer illiteracy. But literacy itself is not a guarantee of computer literacy, if the script is so complex and hard to learn for ordinary people.

For the language processing of such cumbersome characters as Chinese and Mongolian Uigre script and Devanagari of Nepal language, an **inerlanguage** has to be made available in order **to bridge** between the spoken language and the written language. *Nurigeul* is uniquely fit to perform this role by word-processor.

In conclusion, Nurigeul is a global writing system that makes transparent language processing for all the languages in the world. Indeed a Standard Global Writing System should be recognized as the ubiquitous tool to solve the illiteracy problem in writing and multilingual word-processing for universal access to computer users.

## 6. Conclusions and Some Suggestions

1. In its graphic function and applicability, *Nurigeul* can hardly be surpassed. More and more experts recognize it as the best fit tool for “Global Literacy Program.”
2. The point has been raised that some people felt resistance at the fact that *Nurigeul* has its origin in a specific culture and geography. However, we all know that many great and universally recognized truths had a humble origin.
3. I, a humble linguist, am a living example. For no sooner I understood Sejong’s *Cengum*-Alphabet design principle, than I could expand it to the Global Script-*Nurigeul*. Moreover, no sooner I understood the principle of *Nurigeul*, than I was able to expand it as a vehicle for exiting from the darkness of illiteracy. A host of linguists from world’s leading universities has attested in one voice the remarkable scientific design principles that underlie Korean *Cengum-Nurigeul* Alphabet.
4. The Korean phonologists of the 15<sup>th</sup> century were just as deeply concerned with the creative use of script as Chomsky was in our time with the “creative” aspect of language use. The “generative script” was conceived as an “all-reaching Pattern” that could transcribe any sound that is linguistically significant. The goal of “Generative Graphic Universals” may be achieved by the pervasive portrayal of the “Sound Pattern of Speech.” It can be said that Roman Jakobson’s and Guna Fant’s distinctive features approach is also incorporated into the framework of the “generative script design.” The purpose of this generative theory is to find the most efficient strategy for swift language acquisition. Exactly the same intention was expressed by King Sejong well over five centuries ago. In fine, the system of rules that was adopted in Sejong’s *Nurigeul* script design was none other than the “Processes of Generative Pattern.”
5. Even though Inner Mongolians and Outer Mongolians have been speaking the same language, they were using two different writing systems. Therefore, they had no way of communicating with each other in writing. Also in India there are eight tribes living in the same area using the same language, but they use each different scripts, thus unable to correspond with each other. This sorry situation is still widespread in the 21<sup>st</sup> century. Since we have *Nurigeul* as the “Global Standard Writing System” already at hand and need only a public awakening to spread its remarkable efficiency, we must strive toward obtaining the support of UNESCO. For UNESCO has the exactly same goal to alleviate the illiteracy of today’s world citizens as when *Nurigeul* was first designed for its own time.
6. “SIL IPA 93” is the only writing system that had a single, internationally valid standard. For this reason, SIL IPA 93 ought to be recognized and adopted as the International Phonetic Alphabet. Unfortunately, IPA happened to be a phonetic symbol rather than a writing system. In this regard, IPA is similar to the musical notes that must be individually memorized, posing a heavy burden on our memory.
7. *Nurigeul* accomplished the feat of sidestepping this memory problem by transforming the phonetic symbol into a writing system. This transition was accomplished by the most efficient, ergonomic way, namely, by establishing correlation between sight and sound. Once the simple sense of correlation is

- captured, the 4 TN (Teaching Teachers To Teach *Nurigeul*) Workshop ideally recommends itself as the most effortless way of achieving illiteracy. In this respect, *Nurigeul* is comparable to Metric System, which proceeds by the simplest, additive scale known to us.
8. Graphic shapes of the *Nurigeul* script are designed by depicting the articulatory-acoustic correlates of speech sounds. There exists a direct correlation between the letter shape and its associated speech sounds. Therefore, *Nurigeul* is a script that can correctly transcribe the entire range of speech sounds.
  9. The *Nurigeul* script is the easiest and most efficient script to master from a learner's point of view. Sejong's statement that his Phonetic Alphabet can be mastered before one morning is over, means specifically that it can be learned even without a teacher. Moreover, as a universally applicable script, it is the optimal tool for Correct-transcription of speech sounds in a global sense.
  10. The biggest technological challenge in promoting multilingual processing and multilingual communication in cyberspace may be **digitization of writing systems**. It appears especially appropriate to recommend the **Use of *Nurigeul* as Uniscript** in the cyberspace. Reasons for favoring such a recommendation are very succinct and concrete; the graphic function of *Nurigeul* are visually captured by the cine-radiographic tracings and are identified as the Global Writing System at 2001 UNESCO Symposium on Language in Cyberspace, held in Seoul, Korea. At that symposium, the shape-function relationship of *Nurigeul* script has been verified.
  11. Dr. Victor Montviloff, Vice Chair of the Symposium, made the following comment: **"This *Nurigeul* is the best phonetic alphabet for the transliteration of entire range of human speech sounds."**
  12. Dr. Christian Galinski, Chair of the Symposium, also made the remark: **"This certainly is a universally applicable Phonetic Alphabet."** After hearing those comments, I told them "It was my ardent wish to see this *Nurigeul* adopted by the UNESCO as *Global Standard Writing System*." Thereupon both Dr. Galinski and Dr. Montviloff advised me to conduct case studies in the field of minority languages with the non-literate or pre-literate people, and submit the results. If the results were successful, they would consider adopting the "*Nurigeul*" as the "Global Script." Thus since April 2002, I have been giving 4TN Workshop for the literacy workers of unreached people and received enthusiastic responses.
  13. The Japanese computer specialist Dr. Kobayashi, who also took part in the Symposium, was a strong advocate of the Universal Writing System. He clearly saw the necessity of "One Simple Formula as a Universal Character Set" for the universal access to the database in the Cyberspace.
  14. The voice dictation system could use the *Nurigeul* script as it can portray and visualize the multi-dimensions of speech phenomena. Specifically, we can represent graphically places of articulation, manner of articulation and perceived discrete sounds. Thus, the *Nurigeul* was shown to be the most appropriate writing system for the Voice Dictation/Speech-to Text.
  15. Since *Nurigeul* script has two ways of spelling, i.e., in the syllabic level and the phonemic level, the best choice for the accurate transcription of the Chinese language is *Nurigeul* script which has one-to-one correspondence. If we choose Roman/Latin orthography for the linguistic representation of Chinese, we will end up in a similarly chaotic state again like the one Pinyin System had to go through.

# Modal, Temporal, and Evidential Aspects of Reduced Quotative Constructions in Korean

Suk-Jin Chang

Seoul National University

[sjchang@snu.ac.kr](mailto:sjchang@snu.ac.kr)

## Abstract

Sentence-final *S-ta-ko* and *S-ta-y* in spoken Korean are quotative constructions reduced from bi-clausal to mono-clausal sentences in the process of grammaticalization. These reduced quotative constructions (RQCs) and their variants including the retrospective *S-ta-te-la* are examined with focus on their formal (morphosyntactic and prosodic) constraints and modal-temporal-evidential functions. Multifarious meaning components pertinent to RQCs are presented as conjunctions of elementary predications in a neo-Davidsonian framework; they are situational, deictic, thematic, modal, temporal, aspectual, evidential, and illocutionary. Grams [QUOTE] (for quotative evidential) and [RETRO] (for retrospective modal) postulated in the syntax component interact with the TAM component of the grammar CUG (Constraint-based Unified Grammar), which is illustrated in an AVM (attribute-value matrix) in Appendix.

**Key words:** reduced quotative construction (RQC), gram, quotative evidential, retrospective modal

## 1. Introduction

This paper aims at describing two types of what is dubbed ‘reduced quotative construction (RQC)’ in spoken Korean: (1) *-ta-ko* and (2) *-ta-y* (and its subvariety *-ta-te-la*).<sup>1</sup> They are the outgrowth of grammaticalization through the process of deleting the main subject and its verb of saying (in the *ta-ko* RQC) or the complementizer *ko* and the verb of saying *ha* (in the *-ta-y/-ta-te-la* RQC).<sup>2</sup> It is proposed that these RQCs, which are bivalent with respect to clausality, get a quotative evidential [QUOTE] posited at the deletion site and are interpreted as bi-clausal with an additional subject.<sup>3</sup> The *-ta-te-la* RQC, containing the retrospective modal *-te*, gets a separate treatment along with the non-quotative retrospective *-te-la* and the retrospective quotative *-te-la-y* constructions.

In section 2, formal (morphosyntactic and prosodic) constraints of the RQCs and their temporal, modal, and evidential functions are examined along with the bivalent trait of mono- and bi-clausal constructions. In section 3, diverse meanings of RQCs are represented in a neo-Davidsonian framework: situational, deictic, thematic, temporal, modal, evidential, mirative, and illocutionary. Section 4 is summing-up and conclusion. A CUG-based AVM of a reduced quotative sentence is provided in Appendix.<sup>4</sup>

## 2. Form and function

To begin with, let us briefly look into regular quotative constructions. There are two types: direct and indirect. A direct quotation (DQ), flanked by quotation marks in writing, is in the form of a sentence or a sentence fragment. It is positioned either after the matrix subject as in (1a), or sentence-initially before the matrix subject as in (1b). Normally, a complementizer (COMP) (or quotative marker), *lako*, *hako*, or *ko is* appended to the direct quotation. By contrast, an indirect quotation (IQ) is in the form of a finite clause marked with *ko* (not *lako*, *hako*) and followed by a verb of saying. It is placed, as in the case of the direct quotation, either after the subject as in (2a), or sentence-initially as in (2b).

### (1) Direct quotation

- a. NP - “DQ” - *lako/hako/ko* - V  
     |                                    |  
     SUBJ                                COMP
- b. “DQ” - *lako/hako/ko* - NP - V  
                                   |            |  
                                   COMP       SUBJ

### (2) Indirect quotation

- a. NP - IQ - *ko* - V  
     |            |  
     SUBJ        COMP
- b. IQ - *ko* - NP - V  
       |        |  
       COMP   SUBJ

In the *-ta-ko* construction, *ha* 'say' and its tense and sentence-type morphemes are left out, and the construction is marked only with a terminal contour (TC) or a punctuation mark---period (.), question mark (?), or exclamation mark (!). The fusion of COMP and the verb of saying is widely attested cross-linguistically: e.g., the Japanese *-tte* (← *to iu* 'say that'; Martin 1988:559) and *diz.que* 'say that' in

the Sejong Corpus (2007) of 12,500,000 words.

(6) a. *-ta-ko* (728), *-ta-ko-yo* (80), *-ta-kwu* (318), *-ta-kwu-yo* (252), *-nya-ko* (176), *-nya-ko-yo* (40), *-nya-kwu* (89), *-nya-kwu-yo* (93), *-la-ko* (744(88-656)),<sup>7</sup> *-la-ko-yo* (185), *-la-kwu* (615), *-la-kwu-yo* (335), *-ca-ko* (58), *-ca-ko-yo* (81), *-ca-kwu* (81), *-ca-kwu-yo* (11)

b. *-ta-y* and its variants:

*-ta-y* (433), *-ta-y-yo* (363), *-ta-n.ta* (748), *-ta-p.ni.ta* (574), *-ta-p.ni.kka* (34), *-la-y* (478), *-la-y-yo* (232), *-ca-y* (4), *-ca-y-yo* (1)

+ PAST:<sup>8</sup>

*-ta-y-ss-e* (1), *-ta-y-ss-e-yo* (1), *-ta-y-ss-ta* (1), *-ta-y-ss-p.ni.ta* (0), *-ta-y-ss-p.ni.kka?* (0), *-la-y-ss-e* (3), *-la-y-ss-e-yo* (2), *-la-y-ss-ta* (2), *-la-y-ss-p.ni.ta* (2), *-la-y-ss-p.ni.kka?* (0)

c. *-ta-te-la* and its variants:

*-ta-te-la* (74), *-ta-te-nya?* (15), *-ta-te-y* (6), *-ta-te-y-yo* (0), *-ta-p.ti.ta* (17), *-ta-p.ti.kka?* (10), *-la-te-la* (11), *-la-te-nya?* (6), *-la-te-y* (2), *-la-te-y-yo* (0), *-la-p.ti.ta* (7) *-la-p.ti.kka?* (4)

Let us now take up three RQCs one by one and look into their temporal, modal and evidential functions.

### 2.1. RQC *-ta-ko*

This RQC is commonly used in a dialogue exchange as an echo utterance (Chang 1982) – an echo question with a rising TC (↗), or an echo statement with a falling TC (↘) in response to a prior utterance. The echoic question is also called ‘reprise’ (Bolinger 1957, Ginzburg and Sag 2000) or ‘question raised to the second power’ (Jespersen 1924:304). Jespersen notes that most languages use the same form as in indirect questions with a much more marked rising of the interrogative tone. It is here called a high rising TC (↗), carrying mirative overtones. The listing in (7) illustrates, as observed in many languages, constructional traits of echo questions in contrast to those of yes-no questions.<sup>9</sup>

(7) Echo questions

Echo Q	Yes-No Q	Remark
E: <i>Is that true?</i> ↗	<i>Is that true?</i>	high-rising TC
F: <i>Si c'est vrai?</i>	<i>Est ce que c'est vrai?</i> (or <i>Est ce vrai?</i> )	<i>si</i> added; word order

G:	<i>Ob</i>	<i>das wahr ist?</i>	<i>Ist das wahr?</i>	<i>ob</i> added; word order
D:	<i>Om</i>	<i>det er sandt?</i>	<i>Er det sandt?</i>	<i>om</i> added; word order
K:	<i>Cengmal-i-nya-ko?</i>	<i>Cengmal-i-ya?</i>		<i>ko</i> added
	(정말이냐고?)	(정말이야?)		
J:	<i>Hontoo-ka-tte?</i>	<i>Hontoo-ka?</i>		<i>tte</i> added
	(本当かって?)	(本当か?)		
C:	<i>Ni shuo</i>	<i>zhen de ma?</i>	<i>Zhen de ma?</i>	<i>ni shuo</i> ‘you say’ added
	(你说真的嗎?)	(真的嗎?)		

C=Chinese D=Danish E=English F=French G=German J=Japanese  
K=Korean

In the European languages, except English,<sup>10</sup> the echo question is morphosyntactically distinct from the normal yes-no question. It has an additional word—a complementizer (or a subordinate conjunction) and word order is not inverted. Chinese has an additional clause *ni shuo* ‘you say’, similar to the periphrastic expressions ‘you say.’ and ‘did you say?’ in English. Japanese, similar to Korean, has *-to* (complementizer ‘that’, corresponding to *-ko*) or colloquial *-tte*. With a high rising TC, the speaker expresses his/her mirative overtones—surprise, joy, irony, and the like.

Let us now consider the following dialogue exchange between Yong and Tol and see how the *-ta-ko* RQC functions: (8a) is Yong’s statement about Mia; (8b) is Tol’s echo question, which is either to verify what Yong said by a rising TC or to show his mirative overtone by a high rising TC;<sup>11</sup> (8c) is Yong’s echo statement, which is to reaffirm his earlier statement (8a).

(8) a. Yong: Mia-ka o-ko iss-e-yo.<sup>12</sup>

SM come-PROG-POL.DEC

“Mia is coming.”

b. Tol: Mia-ka o-ko iss-ta-ko? ↗ / ↗

SM come-PROG-DEC-COMP-QUOT-INT/EXL

“Mia is coming--did you say?” (or “Mia is coming! --Unbelievable!”)

c. Yong. Yey, Mia-ka o-ko iss-ta-ko-yo. ↘

yes SM come-PROG-DEC-COMP-QUOT-POL.DEC

“Yes, Mia is coming--I said.”

Notice that in the English rendition a parenthetical phrase ‘did you say?’ or ‘I said’ is added like a tag, to give a quotative meaning. The tense is past. English has no gram corresponding to the Korean *-ta-ko* construction (or the Japanese *-to/-tte*). In echo utterances the intonational

contour of falling, rising, or high rising is essential in determining the type of speech act since there is no morphological distinction among declarative, interrogative and exclamatory. A high rising terminal contour denotes various mirative overtones. In the context of dialogue exchange, the unspecified quoter/reporter is the speaker in declaratives or the hearer in interrogatives; that is, the speaker or the hearer is the direct source of quoted information. This is the primary function of the *-ta-ko* constructions. However, as a secondary function, the *-ta-ko* RQC is also used to inquire (with a rising TC) or reaffirm (with a falling TC) an indirect source of information by a third person, either definite or indefinite, or hearsay.<sup>13</sup> See examples in (9).

(9) a. Yong: Nayil pi-ka o-n.ta-kwu? ↗  
 tomorrow rain-SM come-DEC-COMP-QUOTE-INT  
 “It’s going to rain tomorrow--did (s)he/they say?”

b. Yong: Nayil Mia-ka o-n.ta-kwu-yo. ↘  
 tomorrow rain-SM come-DEC-COMP-QUOTE-DEC  
 “Mia is coming tomorrow--(s)he/they told me/I was told.”

The direct or indirect auditory evidential coming from the speaker-hearer (by default), or a third person or hearsay is phrased in English as a tag, thus resembling a bi-clausal construction.<sup>14</sup> In the *-ta-ko* RQC, the parenthetical clause is implicated, not expressed, thus presented as mono-clausal construction on the surface but interpreted as bi-clausal.

## 2.2. RQC *-ta-y*

The *-ta-y* RQC, unlike the *-ta-ko* RQC, has tense and S-level variants, as we saw in (6b). Some of the variants are given in (10), each marked with the quotative evidential [QUOT] after the clausal ending in the morpheme sequence.

(10) a. <i>-ta-y</i> .	b. <i>-ta-y-ss-e</i> .	c. <i>-ta-y-ss-ta</i> .
DEC-QUOT-IMT.DEC	DEC-QUOT-PST-IMT.DEC	DEC-QUOT-PST-PLN.DEC
d. <i>-ta-y-ss-sup.ni.ta</i> .	e. <i>-la-y-ss-e.yo?</i>	f. <i>-la-y-ss-sup.ni.kka?</i>
DEC-QUOT-PST-DEF.DEC	IMP-QUOT-PST-POL.INT	IMP-QUOT-PST-DEF.INT

Normally, the quoter/reporter in a *-ta-y* sentence is a third person, not a direct discourse participant (the speaker or the hearer), and the third-person subject is unspecified as given in (11a). However, the quoter-subject may show up overtly as in (11b); thus the *-ta-y* RQC is a bona fide bi-clausal construction.<sup>15</sup> This reveals the constructional trait of the *-ta-y* RQC—

bivalent clausality.

(11) a. Mia-ka cikum o-ko-iss-ta-y-ss-e.yo

SM now come-PROG-DEC-QUOT-PST-POL.DEC

“Mia is coming now—(s)he/ they said.”

b. Yong-i Mia-ka cikum o-ko iss-ta-y-ss-e.

SM SM now come-PROG-DEC-QUOT-PST-POL.DEC

“Yong said Mia is coming now.”

Consider now examples in (12), which are modifications of (11b) with temporal expressions.

(12) a. Ecey Yong-i Mia-ka nayil o-n.ta-y-ss-e.yo.

yesterday SM SM tomorrow come-DEC-QUOT-PST-POL.DEC

“Yesterday Yong said Mia will come tomorrow.”

b. Ku cennal Yong-i Mia-ka taum.nal o-n.ta-y.ss-e.

the prior.day SM SM next.day come-DEC-QUOT-PST-IMT.DEC

“On the previous day Yong said Mia would come next day.”

c. Ecey Yong-i Mia-ka kucekkey/ku cennal wa-ss/\*o-n -ta-y-ss-e.yo.

yesterday SM SM day-before-yesterday come-PST/come -DEC-QUOT-PST-POL.DEC

“Yesterday Yong said Mia came the day before yesterday/on the previous day.”

The time reference *cikum* ‘now’ in (11) is concurrent to the speaker’s speech time, not to Yong’s quoting time; likewise, *ecey* ‘yesterday’, *kucekkey* ‘the day before yesterday’ and *nayil* ‘tomorrow’ are relative to the speech time ‘now’. If the temporal reference were to be relative to the Yong’s speech time (that is, quoting time), *ku cennal* ‘the previous day’ and *taum.nal* ‘next day’ should be used as in (12b). The quoted clause of (12c) contains the past reference *kucekkey* ‘the day before yesterday’; thus the verb form is marked past--*wa.ss* ‘came’. The same holds in English. In English, however, the tense in the reported clause may vary between present (*is*) and past (*was*) or future (*will/would*), which is due to the sequence-of-tenses constraint and also to the speaker’s temporal vantage point.

The speech act involved in the *-ta-y* RQC is the speaker’s stating (or the hearer’s questioning) what a third person quoted; it is not the act of the speaker’s asserting (or the hearer’s questioning) the propositional content of the situation itself. The speaker/hearer is not committed to the truth value of the proposition.<sup>16</sup>

### 2.3. RQC *-ta-te-la*

The RQC *-ta-te-la* is a subvariety of *-ta-y* and involves the retrospective modal *-te*.<sup>17</sup> It

expresses the speaker's (in declaratives) or the hearer's (in interrogatives) recalling of his/her auditory perception of what was quoted by a third person or hearsay. It has two S-types: declarative and interrogative. Some of its S-level variants are given in (13); the structural meanings of its declarative and interrogative constructions are given in periphrastic form in (14).

- (13) a. *S-ta-te-la.* ↘ (DEC-QUOT-RETRO-PLN.DEC)  
 b. *S-ta-te-nya?* ↗ (DEC-QUOT-RETRO-PLN.INT)  
 c. *S-ta-te-y* ↘ (DEC-QUOT-RETRO-IMT.DEC)  
 d. *S-ta-te-y* ↗ (DEC-QUOT-RETRO-IMT.INT)  
 e. *S-ta-te-yo* ↘ (DEC-QUOT-RETRO-POL.DEC)  
 f. *S-ta-te-y.yo?* ↗ (DEC-QUOT-RETRO-POL.INT)  
 g. *S-ta-p-ti-ta.* ↘ (DEC-QUOT-DEF-RETRO-DEC)<sup>18</sup>  
 h. *S-ta-p-ti-kka?* ↗ (DEC-QUOT-DEF-RETRO-INT)

- (14) a. S--y said, x perceived, x recall. (=13a) (x = I; y = third person)  
 b. S--did y say, did x perceive, do x recall? (=13b) (x = you; y = third person)

One who quotes a situation is a third person normally unspecified as in (15a,b) but the quoter-subject may show up as in (15c). And one who recalls someone's quoting is the speaker in a declarative sentence (15a) or the hearer in an interrogative sentence (15b).

- (15a) a. *Mia-ka o-ko iss-ta-te-la.*  
 SM come- PROG-DEC-QUOT-RETRO-PLN.DEC  
 "Mia is coming—(s)he/they said, I heard, I recall."  
 b. *Mia-ka o-ko iss-ta-te-nya?*  
 SM come-PROG-DEC-QUOTE-RETRO-PLN.INT  
 "Mia is coming—did (s)he/they say, did you hear, do you recall?"  
 c. *Yong-i Mia-ka o-ko iss-ta-te-la.*  
 SM SM come-PROG-DEC-QUOT-RETRO-PLN.DEC  
 "Yong said Mia is coming—I heard, I recall."

In addition to the sentence-external RQC (form: *-ta-te-la*), the retrospective morpheme *-te* normally occurs sentence-internally in a non-quotative construction (form: *-te-la*) and also in a sentence-internal RQC (form: *-te-la-y*). See the three retrospective constructions in (16a-c).

- (16) a. *-te-la* (S-internal retrospective)  
*Mia-ka o-ko iss-te-la.*  
 SM come PROG-RETRO-PLN.DEC  
 "Mia is coming--I saw, I recall."  
 (More natural: "I saw Mia coming--I recall.")

b. *-te-la-y* (S-internal retrospective-quotative)

Mia-ka o-ko iss-te-la-y.

SM come PROG-RETRO-QUOT-IMT.DEC

“Mia is coming--they saw, they recalled, they say.”

(More natural: “They saw Mia coming--they recalled, they say.”)

c. *-ta-te-la* (S-external quotative-retrospective)

Mia-ka o-ko iss-ta-te-la.

SM come PROG-DEC-QUOTE-RETRO-PLN.DEC

“Mia is coming—they said, I heard, I recall.”

The retrospective *-te* induces perceptual (visual or auditory) evidential: (16a) denotes the speaker’s recollection (at speech time) of his/her direct perceptual (visual) act in the past; (16b) denotes a third person’s quoting (at speech time) of his/her recollection of his/her perceptual act in the past; (16c) denotes the speaker’s recollection (at speech time) of his/her auditory act (in the past) of a third person’s quoting of a situation. The primary function of *-te* is a speech participant’s recollection of his/her sensory perception; it denotes not a simple perceptual evidence but its recollection.<sup>19</sup>

Let us consider the issue of what is negated in the negative answer to a retrospective quotative question *-ta-te-nya*. Four negative replies (17b.i-iv) are all possible, with preferred interpretation in the given order (i-iv).

(17) a. Mia-ka o-ko iss-ta-te-nya?

SM come-PROG-DEC-QUOT-RETRO-PLN.INT

“Mia is coming--did they say, did you hear, do you recall?”

b. Ani-yo.

“No.”

i. An o-ko iss-ta-tey-yo.

no come-PROG-DEC-QUOT-POL.DEC

“Mia is not coming--they said, I heard, I recall.”

ii. O-ko iss-ta -ko ha-ci anh-tey-yo.

PROG-DEC-COMP say-CONN NEG-RETRO-POL.DEC

“They didn’t say Mia is coming—I heard, I recall.”

iii. Kulen mal mos tul-ess-e.yo.

such saying not hear-PST-POL-DEC

“I haven’t heard such a thing.”

iv. Sayngkak an na-yo.

thought not come.out-POL.DEC

“I don’t remember.”

Negation of the eventuality described (that is ‘Mia is not coming’) may come up first of all, followed by negation of quoting, auditory perception and lastly, negation of the speaker’s recollection of his/her past perceptual act. It may be that a reduced quotative-retrospective question almost presupposes, or takes for granted, the respondent’s mental recollection of his/her past perceptual act.

### 3. Meaning Representation

Meanings of reduced quotative constructions described in section 2 are represented, as laid out in (18), by unifying multifarious meaning components in a discourse. A unified meaning of a sentence is the conjunctions of the relevant meaningful elements enumerated in (20). They are represented in a new-Davidsonian framework, augmented with event (e) and time (t) arguments in elementary predications.

(18) Meaning components

- a. Situation: e.g., come(x,e,t)
- b. Thematic-role: e.g., agent(x,e), theme(x,e), agent-theme(x,e)<sup>20</sup>
- c. Discourse participant: e.g., named(x,Mia), named(x,Yong)
- d. Speech-act:
  - i. Deictic:<sup>21</sup> speaker(a), hearer(b), utterance-time(t<sub>U</sub>).
  - ii. Illocutionary:<sup>22</sup> e.g., state(a,b,e<sub>RETRO</sub>,e<sub>U</sub>,t<sub>U</sub>), ask(a,b,e<sub>RETRO</sub>,e<sub>U</sub>,t<sub>U</sub>)
  - iii. Manner of speaking:<sup>23</sup> e.g., plain(a,b,e<sub>U</sub>,t<sub>U</sub>), polite(a,b,e<sub>U</sub>,t<sub>U</sub>)
  - iv. Mirative:<sup>24</sup> e.g., surprising(e,t), incredulous(e,t)
- v. TAM:<sup>25</sup>
  - (a) Temporal:
    - Relational: overlap(t<sub>i</sub>,t<sub>j</sub>), precede(t<sub>i</sub>,t<sub>j</sub>)
    - Referential: e.g., event-time(t<sub>E</sub>), retrospection-time(t<sub>RETRO</sub>), perception-time(t<sub>PER</sub>), quoting-time(t<sub>Q</sub>)

(b) Aspectual:<sup>26</sup> e.g., in-progress(e,t), culminate(e,t), hold(s,t)

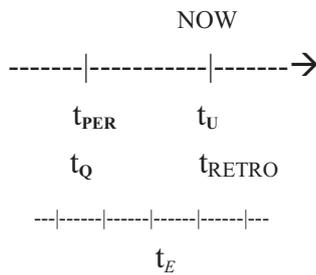

(c) Modal:<sup>27</sup> e.g., recall(x,e,t<sub>RETRO</sub>), intend(x,e,t), infer(x.e.t)

(d) Evidential: e.g., perceive(x,e,t<sub>PER</sub>),<sup>28</sup> quote/report(x,e,t<sub>Q</sub>)

Before presenting a unified meaning of a retrospective quotative sentence, let us look into the temporal relations pertinent to the *-ta-te-la* RQC. They are indicated by temporal overlapping (=) and preceding (<) relations as in (19a), or graphically as in (19b).

(19) a.  $t_U = t_{RETRO}$ ,  $t_{PER} = t_Q$ ,  $t_{PER} < t_U$ .

b.

Note: the event time  $t_E$  can be located anywhere on the timeline.

A *-ta-te-la* quotative sentence (15a), repeated below as (20), is paraphrased roughly as in (21a); its unified meaning is given in (21b)

(20) Mia-ka o-ko iss-ta-te-la. (=15a)

(21) a. Paraphrase:

I say to you in a plain manner of speaking that I recall that I heard that (s)he/they quoted that Mia was coming.

b. Unified meaning:

$come(x,e,t_E) \wedge agent(x,e) \wedge named(x,Mia) \wedge speaker(a,t_U) \wedge hearer(b,t_U) \wedge$   
 $plain(a,b,t_U) \wedge say(a,b,e_{RETRO},t_U) \wedge recall(a,e_{PER},e_{RETRO},t_{RETRO}) \wedge$   
 $perceive(a,e_Q,e_{PER},t_{PER}) \wedge quote(x,e,e_Q,t_Q) \wedge overlap(t_{RETRO},t_U) \wedge overlap(t_E,t_Q) \wedge$   
 $overlap(t_Q,t_{PER},) \wedge precede(t_Q,t_U) \wedge in-progress(e,t_E)=s \wedge hold(s,t_E)$

#### 4. Summary and Conclusion

Reduced quotative constructions *-ta-ko*, *-ta-y* and *-ta-te-la* retain a bivalent trait with respect to clausality and they are analyzed and interpreted as bi-clausal constructions. The postulated quotative gram [QUOT] interacts with a quotative evidential in the TAM component of the

---

grammar CUG.

The *-ta-ko* RQC is typically echoic or repetitive and its reduced tense is past. Its high rising TC denotes the speaker's mirative overtones, its rising TC the speaker's inquiry about what was said or hearsay, and its falling TC the speaker's reaffirmation of what he/she said earlier or hearsay. The *-ta-y* RQC, in which normally the quoter/reporter is a third person, denotes a quotative speech act; the speaker/hearer is not committed to the truth of the proposition quoted. The *-ta-te-la* RQC, marked with the retrospective modal [RETRO] in addition to the quotative evidential [QUOT], denotes the speaker/hearer's recollection of his/her past auditory perception of what was quoted by a third person or hearsay.

## Acknowledgments

I am grateful to Jae-Woong Choe, Kiyong Lee and Jae-Mog Song for their comments and suggestions on a previous draft.

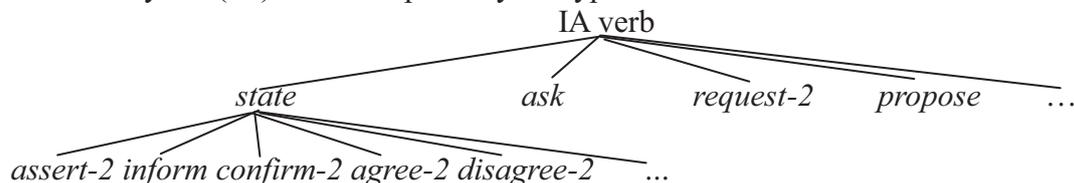

## Notes

1. For ease of reference I use the forms *-ta-ko* and *-ta-y* as representative of the two types of RQCs, which have each a number of S(entence)-level and S-type variants.
2. A similar, and widespread, pattern of grammaticalization is that of dependent-clause connectives (e.g., *-ketun*, 'if', *-nikka* 'as' and *-myense* 'while') functioning as sentence-final grammatical morphemes with main clauses left out. (See Rhee 2008 and works cited therein).
3. 'Quotative' is kept apart from 'reported' by Aikehenvald (2004:177): if the authorship of the evidence is known, it is 'quotative; if not, it is 'reported'. The two terms are interchangeably used here; the former is preferred, though, since 'direct/ indirect/reduced quotation' is used throughout. Explicating Korean reportative evidentials, Kim (2000:24) distinguishes 'quotative' from 'reportative' on the basis of the syntactic reduction of the complementizer *ko* and the verb *ha*, and their morphological fusion after the reduction. The category 'quotative' is regarded primarily as modal by Dahl (1985:149) and he cites the Japanese *soo da*, which is treated as inferential evidential by Aoki (1986:231-235) along with *yoo-da* and *rasi-i*.
4. CUG (Constraint-based Unified Grammar; cf. Chang 2005, 2007), an offshoot of HPSG (Pollard and Sag 1994, Sag et al. 2003), is designed to be an all-embracing grammar encompassing prosody, phonetics, orthography, and pragmatics on top of the usual tripartite components of phonology, syntax, and semantics.
5. Korean has half a dozen S-levels, each showing a distinct manner of speaking: plain (PLN), polite (POL), deferential (DEF), intimate (IMT), blunt (BLT) and familiar (FML). S-level and S-type are fused to form a sentence/clause ender: e.g. *-ta* (PLN.DEC), *-p.ni.kka*

- (DEF.INT). Of these S-levels only the plain (PLN) is admitted to form a quotative clause. The S-level terms are from Chang (1996).
6. See (6b) for other S-type variants (e.g., *-ta-n.ta*, *-ta-p.ni.kka*) or past tense variants (e.g., *-ta-y-ss-e*, *-ta-y-ss-ta*).
  7. The form *-la* (in *-la-ko*), which is an imperative ending, is also an allomorph of the declarative ending *-ta*, when used with the copula *i/ani* ‘be/be not’. Notice that its imperative use (88 tokens) is scanty in comparison to its declarative use (656 tokens).
  8. Those marked ‘0’ are possible forms but not found in the Corpus.
  9. European examples are taken from Jespersen (1924:304).
  10. In Chaucerian English, a retorted wh-question had the quotative marker *that* inserted after a wh-word: e.g., ‘But wherefore **that** I speke al this?’ (Jespersen 1924:304).
  11. For a mirative reading the punctuation mark (! or !!) may be used with a gloss EXL (exclamatory) or MIR(ative).
  12. The form *V-ko iss* ‘be V-ing’ is termed PROG (progressive aspect), corresponding to the Japanese *-te iru* ‘be V-ing’. The Japanese *-te i-ru* gram also functions as resultative (Nakau 1976:430), corresponding to the Korean *-e iss* ‘be V-en’ construction. The particle *ko* (or the Japanese *te*) in these constructions is a connective (CONN) (or a continuative called ‘gerund’ by Martin (1988, 1992)).
  13. Indirect evidence can be divided into quoted/reported and inferred: the former into second-hand evidence and evidence from hearsay or folklore; the latter into inference from results and inference from reasoning (Bybee et al. 1994:323-4).
  14. The English sentence (9a), repeated below as (i), is a pseudo-bi-clausal sentence, whereas (ii) is a genuine one.
 

i. (9a) It’s going to rain tomorrow—did they say?	(pseudo)
ii. Did they say it’s going to rain tomorrow?	(genuine)
  15. In the framework of CUG an additional NP argument (i.e. subject) is placed on the ARG-STR (argument structure) list.
  16. This type of speech act is termed ‘presentative’, which is distinct from the assertive type (Faller 1994, Chung 2005).
  17. The grammatical status of *-te* has been described variously: tense (Choe 1937), aspect (Martin 1954), tense-aspect (Lee 1991), mood (Sohn 1975, Chang 1996, Suh 1996, Ko 2004), spatial deictic tense (Chung 2005), evidential (Song 1998, 2002; Kim 2000).  
A Japanese dialect, spoken in Goshogawara, north of Aomori, is described to have a verbal construction (V-) *te-ra*, which like the Korean (V-) *te-la* denotes ‘direct evidential’ (Urushibara (2008), presented at CIL-18). The following are from her examples:
    - i. *Mina-ga hon-o yon-de-ra*. ‘Mina is reading a book.’ (direct evidential) or ‘Mina has read a book.’
    - ii. *Mina-ka chayk-ul ilk-te-la*. ‘Mina read/has read a book.’ (direct evidential).
 We may render (ii) as: ‘I saw Mina read(ing) a book, I recall.’ Or ‘Mina read/was reading a book—I saw, I recall.’
  18. The morpheme sequence of *-p-ti-ta* (in *S-ta-p-ti-ta*) is DEF-RETRO-DEC; likewise, *-p-ti-kka* is DEF-RETRO-INT. Notice RETRO is posited between S-level *-p-* and S-type *-ta/kka*.
  19. Note the modal and evidential difference between (i) and (ii). The Korean *-te-la* sentence (16a) is better rendered as (ii) rather than as (i).
    - i. I saw Mia coming.
    - ii. I saw Mia coming, I recall.
  20. The hyphenated role (e.g. agent-theme ‘both agent and theme’) is from Parson (1990:81).

21. Speaker and hearer indices are assigned variables a and b, respectively.
22. Illocutionary-act (IA) verbs are partially subtyped as:

The type *state*, which is unmarked, that is sense-1 in WordNet (v. 2.1), forms a synset (synonym set) with *say* and *tell*. Reference to WordNet (and its sense specification) is meant to provide a precise sense of each of IA verbs. The type *state/say/tell*, together with its subtypes, roughly corresponds with Austin's (1962) expositives, Searle's (1979) assertives and Bach and Harnish's (1979) constatives. These verbs are used performatively.

23. Manner of speaking, which is labeled 'DL (discourse level)' in CUG, may well be included in the TAM component; it is represented with discourse-level predicates--plain, polite, intimate, deferential, familiar, and blunt, which correspond to the identically termed syntactic S-levels. See Note 5.
24. Mirativity (cf. DeLancey 2001), like manner of speaking, may well be treated under TAM as interacting with TC in prosody and punctuation in orthography.
25. In CUG, TAM is a component of SA (speech act) in PRA(gmatics) as it is essentially deictic-centered or speaker/hearer-oriented. Evidentiality, as information source (Willett 1988:53), is included in TAM as its extended feature.
26. Aspectual predicates 'culminate' and 'hold' are taken from Parsons (1990): hold(s,t)--a state holds at t (that is, a resultant state).
27. Modal is delimited to mood: *-te* 'retrospective', *-keyss* 'volitive, inferential' and *-n/nun* 'indicative'. The indicative mood is not marked and glossed as such in this paper.
28. Subtypes of *perceive* include *observe*, *see*, *hear*, and *feel-3*. (WordNet defines *feel-3* (sense-3 of *feel*) as 'perceive by physical sensation'; sense-1 as 'undergo an emotional sensation').

staniaksylwia@ling.bun.kyoto-u.ac.jp

## Abstract

In Japanese the notions of obligation and advice are expressed in a form of conditionals, which literally translate as *eIf not p, not goodf* and *eIf p, goodf* respectively. In this paper we analyze both constructions with special focus on the role the speaker's attitude plays in determining both meanings. We propose that in the case of obligation the conditional construction represents a cause result relation. In the case of advice, on the other hand, the conditional construction serves to mark the proposition of the antecedent as potential and to provide propositional attitudes in the consequent. We argue that such approach leads to a more natural and precise descriptions of the phenomena involved in the comprehension of these conditional expressions.

## 1 Introduction

In Japanese, constructions involving conditional clause markers are used for expressing the notions of obligation (1) and advice (2).

- (1) yoyaku si-naker-eba nara-nai  
reservation do-NEG-COND become-NEG  
'You have to make a reservation.'  
(lit.: 'If you don't do reservation, it won't be good.')

- (2) tyotto yasun-dara ii  
little rest-COND good  
'You should rest a bit.'  
(lit.: 'If you rest a bit, it'll be good.')

The obligation construction translates literally as *'If not p, not good'*, and the one of advice as *'If p, good'*. Both constructions look alike, and have been treated in linguistic literature as grammaticalization of the speaker's positive or negative attitude toward the proposition, i.e., as realizations of the same logical structure.

IF  $p$ ,  $q$  where  $q$  is the speaker's evaluative judgement GOOD/BAD, towards the realization of  $p$ . (Akatsuka 1992, 4)

There is however, a crucial difference between obligation and advice. To express advice, positive attitude of the speaker toward the proposition is indispensable ((Searle 1969), (Vanderveken 1990)). However, no particular attitude of the speaker toward a proposition is required for expressing obligation. The main claim of the paper is that despite the overt resemblance the two expressions are interpreted in different ways.

We argue that adopting a clear distinction between modality as a content category and illocutionary force as a pragmatic category with respect to the structure '*IF p q*' gives a valuable insight into the comprehension of both obligation and advice.

The argumentation of the paper is organised as follows. In section 2, we will see that in contrast to advice, obligation is not performed with the speaker's attitude but it is propositional in the sense that it is capable of being true or false. Obligation depends on the relevant rules that also determine the consequences for being not obedient. Thus, we will propose that the '*If not p, not good*' construction represents a causal relation between the antecedent and the consequent.

In section 3 we will be paying attention to the fact that the structure '*IF p q*' yields advice not only when ' $q$ ' represents the speaker's positive attitude, but also when ' $q$ ' represents a question like 'how about?'. We adopt the relevance theoretic idea that illocutionary force is not encoded in a sentence, but the hearer recognises the speaker's intention within an inference process based on a sentence mood. We will show that also the '*If p good*' construction initiates an online inference process through which the hearer recognises the speaker's intention, cf., (Wilson and Sperber 1988) and (Lenci 1994).

## 2 Obligation

### 2.1 Obligation and the speaker's attitude

The speaker can express obligation and simultaneously either her/his positive (3) or negative (4) attitude towards it. Thus the attitude itself does not constitute the meaning of obligation.

- (3) asita-wa sooru-e ika-naker-eba ikenai ga  
 tomorrow-TOP Seoul-DIR go-NEG-COND go.well-NEG but  
 tanosimitai-to omou  
 enjoy.want-COMP hope  
 ‘I have to go to Seoul tomorrow, still I want to enjoy it.’
- (4) yara-naker-eba nara-nai keredo ima-wa yaritaku-nai  
 do-NEG-COND become-NEG however now-TOP do.want-NEG  
 ‘Although I have to do it, I don’t want to do it now.’

The speaker’s attitude, once expressed, cannot be judged as false. Obligation, on the other hand, can be rejected as false. In other words, obligation is part of the message conveyed by the proposition.

- (5) A: repooto-wa asita madeni kaka-naker-eba  
 report-TOP tomorrow until write-NEG-COND  
 nara-nai darou.  
 become-NEG guess  
 ‘The report has to be written by tomorrow, I guess.’
- B: iya, simekiri-ga nobita-yo  
 no deadline-NOM extend.PERF-PART  
 ‘No, the deadline has been extended.’

Therefore the ‘consequent’ in the ‘If not p, not good’ construction can not be treated as expression of the speaker’s negative attitude.

The construction indeed is not frozen, but revels quite high productivity, i.e. several conditional connectives and several negative expressions in the consequent are being used.

<i>p</i> naker-eba	<b>nara-nai</b>
<i>p</i> NEG-COND	become-NEG
<i>p</i> nai-to	<b>ike-nai</b>
<i>p</i> NEG-COND	go.well-NEG
<i>p</i> naku-tewa	<b>dame</b>
<i>p</i> NEG-COND	bad

Thus, the construction reflects an inference, which leads the addressee to the conclusion that ‘p’ is indispensable. Determining the sense of the consequent is crucial for describing the inference process.

Note that by uttering an obligation, the speaker informs the addressee that not executing the action in question will break some rules.

It can be natural laws, legal, moral, prudence rules etc. For example, saying that ‘*According to the law, you have to ask the author’s permission to copy his book*’ means that *Coping a book without the author’s permission violates the rules defined by the law*. The *If not p, not good* constructions sound odd in a context, where one does not know the rules an event applies to.

- (6) ? asita-wa ame-ga hura-naker-eba nara-nai  
 tomorrow-TOP rain-NOM fall-NEG-COND become-NEG  
 (int.: ‘It must rain tomorrow.’)

Note also that violating rules or laws does not always bring about real consequences. One could e.g. manage to copy a book without the author’s permission without any punishment for it. Thus, in our view, the construction does not convey the idea that not executing ‘p’ will bring about some negative consequences for the addressee, but that the negative expressions *nara-nai*, *ike-nai*, *dame* etc. refer to inconsistency with rules/laws the speaker is referring to. That is, the construction encodes the message that not executing *p* will result in violating the relevant rules.

## 2.2 Obligation and causation

The above analysis can be supported by the fact that similarly to obligation interpreting a cause-result relation requires considering some rules governing such relation. For example, interpreting fine as a result of crossing a street against red light requires considering the traffic laws. Feeling hungry as a consequence of skipping a meal is determined by natural laws, etc.

Let us examine here the conditional connectives used in the obligation construction. Japanese has several conditional connectives. In the obligation constructions *-(e)ba*, *to*, *tewa* are used.

- (7) yoyaku si-naker-eba ike-nai  
 reservation do-NEG-COND go.well-NEG
- (8) yoyaku si-nai-to ike-nai  
 reservation do-NEG-COND go.well-NEG
- (9) yoyaku si-naku-tewa ike-nai  
 reservation do-NEG-COND go.well-NEG  
 ‘I have to make a reservation.’

The conditional connective *-tara* is often used in advice constructions but never in obligations. This connective is used i.a. in future, non-causal contexts in which *-(e)ba*, *-to*, *tewa* are not acceptable.

- (10) kono repooto-wo kai-**tara** sensei-ni  
 this report-ACC write-COND professor-DAT  
 teisyutu-si-masu  
 submit-do-POLITE  
 ‘After I finish the report, I’ll submit it to the professor.’
- (11) a \*repooto-wo kak-**eba**/-**uto** sensei-ni  
 report-ACC write-COND professor-DAT  
 teisyutu-si-masu  
 submit-do-POLITE  
 ‘If I write the report, I’ll submit it to the professor.’
- b repooto-wo kak-**eba**/kaku-**to tan’i-ga moraeru**  
 report-ACC write-COND credits-NOM can.get  
 ‘If I write the report I will can the credits.’

In (10) there is no causal relation between the antecedent and consequent, here the *-tara* connective is perfectly acceptable. In the same context the *-(e)ba* and *-to* connectives are unacceptable (11a), but if the consequent is changed so that it refers to the result of the action described in the antecedent, both *-(e)ba* and *-to* are attested (11b). The connective *-tewa* is different from *-(e)ba* and *-to* in that it is used only with negative consequents. In the case of future events it is, however, the same as *-(e)ba* and *-to*, used only to mark causal relation (See (Arita 2004, 171) for more details).

- (12) taroo-ga ki-**tewa minna-ga komaru**  
 Taroo-NOM come-COND everybody-NOM be.trouble  
 ‘If Taroo comes everybody will be troubled.’ (Arita 2004, 171)

To summarise, we showed in this section that the speaker’s attitude toward the proposition does not influence the meaning of obligation as such and that like causality, obligation emerges from rules/laws.

Moreover, we saw that although obligation in Japanese is conveyed through conditional construction, the conditional connective *-tara* that marks relation between single events is not accepted in the obligation construction. Thus, we propose that the ‘*If not p, not good*’ construction should be analysed as a cause-result relation.

It is important to note also that the ‘*If not p, not good*’ constructions never convey the meaning of epistemic necessity, and we argue that it is this overtly marked cause-result relation that prevents the ‘*If not p, not good*’ construction from being extended into epistemic domain<sup>1</sup>.

### 3 Advice

#### 3.1 Advice and the speaker’s attitude

The speaker’s positive attitude is a sincerity condition for expressing suggestion (Searle 1969). However the speaker can express advice through the ‘*If p q*’ construction not only by filling it with her/his positive attitude towards the proposition, but also by embedding the proposition in e.g. an interrogative mood.

- (13)      mou sukosi yasun-dara dou-desu-ka  
           more little rest-COND how.about-POLITE-Q  
           ‘Why don’t you rest a little more.’

This fact is not surprising, if one considers speech acts as a purely pragmatic category as it has been proposed in Wilson and Sperber (1988). We adopt here the idea that illocutionary force is not encoded in a sentence, but the hearer recognises the speaker’s intention within an inferential process based on the information encoded in a sentence mood (c.f. also (Lenci 1994)).

To present the inference process in some more detail, let us first look at the definition of directives by Lenci (1994, 120)

Directives “Given the utterance  $\varphi$ , the hearer  $H$  identifies the intention of the speaker  $S$  to communicate a directive illocution with  $\varphi$  iff  $H$  recognizes a motive or reason for her/him to do an action  $e$  as belonging to the set of assumptions  $\{I\}$  that is consistent with the presumption of relevance of  $\varphi$ .” (Lenci 1994, 120)

---

<sup>1</sup>Compare Sweetser (1990), Bybee et. all (1994) argument that the deontic notions were primary and developed into epistemic ones.

The additional condition for the hearer to recognise advice is that she/he understands that the action in question will bring her/him some benefits:

- “a suggestion can be recognized if the hearer understands that the reason for her/him to do the action derives from the fact that such an action can bring positive effects for the hearer her/himself (Lenci 1994, 120)”

### 3.2 *If p, good: optative mood*

In the case the proposition in ‘IF p q’ is embodied in an optative mood (13), the addressee’s inference could be as follows:

- (14) tyotto yasun-dara ii  
 little rest-COND good  
 ‘You should rest a bit.’ (lit.: ‘If you rest a bit it’ll be good.’)

(14) is a declarative sentence, with a lexical optative mood marker ‘ii’. That is, the addressee can decode from it the information that:

- (14a) ‘you rest’ is a desirable action.  
 (14a) activates other assumptions that belong to the hearer’s cognitive environment, e.g.:  
 (14b) The speaker knows I am tired.  
 (14c) Resting is crucial to muscle repair / allows for proper healing.  
 (14d) If resting helps me to regenerate then I have a REASON to do it.

The hearer recognises during the inference process, that the action can bring her/him some benefits, thus she/he interprets it as advice.

In some contexts *If p, good* is interpreted as hope or regret. Consider the following examples.

- HOPE.

- (15) asita hare-tara ii na  
 tomorrow be.sunny-COND good EMOT.  
 ‘I hope it will be sunny tomorrow.’

- REGRET

- (16) kono ko-ga otoko-dat-tara yoi noni  
 this child-NOM boy-COP-COND good EMOT  
 ‘I regret the child is not a boy.’ (Takeda 2004, 206)

In this case, the information encoded by the optative mood can be described as follows:

The propositions (15) and (16) represent a desirable event.

Note that (15) represents a future event, (16) a past event but neither of them can be controlled by the speaker or the addressee, thus both utterances can be interpreted only as expressions of the speaker's desire.

### 3.3 *If p, how about?: interrogative mood*

When the proposition in 'IF p q' is embodied in an interrogative mood, the addressee's inference could be as in the following:

- (17)      mou sukosi yasun-dara dou-desu-ka  
            more little rest-COND how.about-POLITE-Q  
            'Why don't you rest a little more.'

As (17) is an interrogative sentence, the speaker communicates with it that there is some completion of the thought represented by the proposition that is desirable (Wilson and Sperber 1988). Thus, the information decoded by the addressee is

(17a) my opinion about taking rest is desirable.

(17a) activates other assumptions that belong to the addressee's cognitive environment, e.g.:

(17b) I am tired now.

(17c) Resting is crucial to muscle repair / allow for proper healing.

(17d) If resting will help me to regenerate then I have a REASON to do it.

The above analysis shows that in the case of advice the '*IF p q*' structure should be considered not as a grammaticalization of the speaker's positive attitude towards the proposition 'p', but as a means to mark a proposition as potential (conditional) and embody it into a sentence mood.

The inference process based on the '*IF p q*' construction, where 'q' refers to an optative or interrogative mood can be summarised as follows. When 'p' refers to past, or future that the interlocutors do not have influence on, the 'IFp good' construction conveys a regret (past) or hope (future). When 'p' refers to an action that is controllable by the addressee, both *If p, good* and *If p, how about?* initiate

an inference that leads the hearer to the conclusion that executing the action described in the proposition may bring him/her some profits.

the sort of circumstances expressed in the antecedent	mood	result of the inference
uncontrollable by the hearer / past	optative	regret
uncontrollable by the hearer / future	optative	hope
controllable by the hearer	optative	advice
controllable by the hearer	interrogative	advice

## 4 Conclusions

In conclusion, we presented several lines of evidence that despite the overt resemblance the expressions of obligation and advice represent distinct structures. That is, obligation constructions represent a cause-result relation. Whereas, the advice constructions represent a proposition embedded in an optative or interrogative mood.

This approach allows us to account for (i) ellipsis and (ii) the usages of the *-to* connective in counterfactual contexts.

(i) Ellipsis:

Consider (18-19) where [e] indicates the ellipsis site.

- (18) kekkon si-naker-eba [e]  
 marriage do-NEG-COND  
 ‘I have to get married.’ or  
 ‘If I had not get married’ (When the speaker is married already).

- (19) hutatabi siken-ni oti-tara [e] na  
 again exam-DAT fail-COND EMOT  
 ‘I hope he will fail the exam again.’ or  
 ‘I am terrified of failing the exam again.’

Unless (18) refers to a counterfactual situation, and the rules the speaker is referring to are unclear to the addressee (i.e. when the addressee recognises that not getting married will violate the relevant rules) the sentence is interpreted as obligation. (19) on the other hand, can be interpreted as hope or regret depending on the intonation of the particle ‘na’, i.e. depending on the speaker’s attitude.

(ii) *-to* usages in counterfactual contexts.

The connective *-to* cannot mark counterfactual conditionals, therefore (20) has only one interpretation.

- (20) kekkon si-nai-**to**  
marriage do-NEG-COND  
'I have to get married.'

However *-to* can be followed by an optative mood marker expressing an attitude toward counterfactual event.

- (21) (It was very nice trip.)

anata-mo kuru-**to** yokat-ta-noni  
you-also go-COND good-PAST-EMOT.  
'It's a pity you didn't go with us.' (Sunakawa 1998, 295)  
(lit.: 'If you came, it would be good.')

In our view, such usage of '-to' is accepted, because the conditional connectives in the hope/advice construction do not function to mark a conditional relation between the antecedent and consequent but just to mark the event described in the antecedent as potential.

# Similarity and Dissimilarity in Treebank Grammars

Markus Dickinson

Indiana University

## *Abstract*

To uncover rules in a treebank grammar which are of dubious quality, we investigate two methods for detecting problematic structures, both based on the same notion of similarity. The first is based on the notion that similar rules should receive the same annotation. The second is based on the idea that rules which are dissimilar to other rules are likely problematic. We show these two methods to be effective in detecting erroneous rules, rules used for ungrammatical or otherwise non-standard constructions, and rules which reveal non-uniform decisions made in the annotation scheme.

## 1 Introduction and Motivation

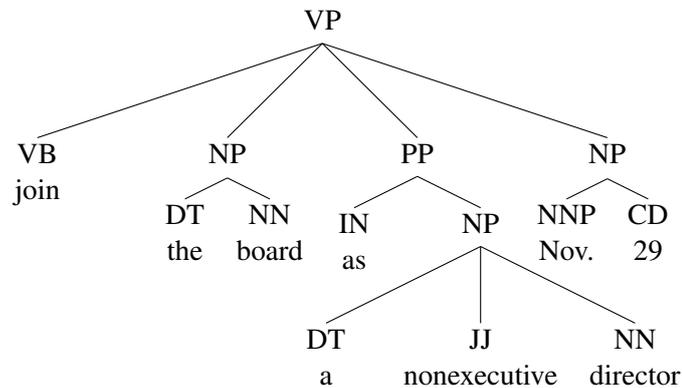

While annotated corpora are commonly used for both natural language processing (NLP) and for linguistic searching, there is a need to investigate the quality of such annotation. Corpora can be viewed as large repositories of language data, useful for the construction and validation of linguistic theories. As such, there is an increasing number of linguistically-annotated corpora, presenting information on a wide range of linguistic properties, such as morphological distinctions (e.g., Leech, 1997), syntactic distinctions (e.g., Sampson, 1995), semantic distinctions (e.g., Kingsbury et al., 2002), and discourse distinctions (e.g., Allen and Core, 1996). This annotation present in a corpus is the result of applying an annotation scheme to the data, capturing the desired distinctions. In other words, annotation encodes a linguistic description of the data, and in order for this to be useful, it must be of high quality.

When we speak of a theory being encoded in a treebank, of course, it is not that simple. There are competing factors in what kind of (descriptive) linguistic theory is encoded. On the one hand, corpus annotation is guided by external criteria: do the distinctions capture linguistic properties needed for certain corpus uses, such as parsing or linguistic searching? On the other hand, we have internal criteria: can the distinctions can be annotated easily and automatically (cf. Elworthy, 1995; Déjean, 2000)?

Syntactically-annotated corpora, or treebanks, tend to emphasize broad coverage and these so-called internal criteria, making sure that the annotation can be done consistently, with high inter-annotator agreement (e.g., Voutilainen and Järvinen, 1995). This is often at the expense of true grammar development, however. While the treebank is annotated quickly and in a way which lends itself to parsing, it is not clear what the properties are of the encoded grammar. Does it match anything resembling linguistic theory, or was it annotated consistently at the cost of being theoretically desirable?

As one example, consider the partial tree from the Wall Street Journal (WSJ) corpus portion of the Penn Treebank (PTB, Marcus et al., 1993) shown in 1. To avoid disagreements between annotators, the trees are given flat structures; in this case, no one has to decide where the *as* phrase attaches, instead including it simply as a daughter of the VP. Thus, we wind up with rules like  $VP \rightarrow VB\ NP\ PP\ NP$ , which do not correspond to theories distinguishing arguments from adjuncts in the syntactic structure.

(1)

Although such treebanks have served to advance the state-of-the-art in computational linguistics, there are still problems with using grammars extracted from them, regardless of whether we intend to extract a grammar for parsing or for linguistic analysis. First, as illustrated above, treebanks commonly contain rather flat structures and coarse categories. This means that there are missing linguistic decisions, which would have to be recovered for linguistic searching. Indeed, these distinctions are often useful to use in parser models and must be recovered for parser training (cf. Petrov et al., 2006). Furthermore, the distinctions may not only be missing, but may be incompatible with a linguistic theory. Secondly, there is the sheer number of rules to contend with. The WSJ, for example, has over 17,000 rules for 50,000 sentences. Grammar compaction methods can reduce the size of the rule set (Krotov et al., 1998; Hepple and van Genabith, 2000), but there is still a need to sort useful rare constructions from unhelpful ones (Foth and Menzel, 2006; Daelemans et al., 1999). Finally, there is the problem of annotation errors, which arise in the process of creating a large corpus. These errors have a detrimental effect on the training and evaluation of natural language processing (NLP) systems (cf. Dickinson and Meurers, 2005a; Hogan, 2007) and also on the precision and recall for finding desired linguistic constructions (cf. Meurers, 2005). For example, Padro and Marquez (1998) show that, for many current comparative evaluation situations, one cannot truly tell which technology is better.

These three problems are related, in that they deal with the quality of corpus annotation. To attack these problems, we set out to investigate and automatically identify problematic treebank rules, which reveal different quality issues with the treebank. Namely, problematic rules might be erroneous, cover ungrammatical constructions, or reveal the quirks of an annotation scheme, that is, where it needs feedback.

But how can one investigate rule quality in an automatic way? How can one rule be better or worse than another? To answer this, we use properties of the whole grammar itself as a guide to how rules should generally be organized. Specifically, we focus on finding similarities and dissimilarities among rules, and we make two hypotheses, which

we show to be effective. The first hypothesis is that similar rules should receive the same annotation, as discussed in section 3. The more similar two rules are, the more we expect them to be categorized in the same way. The second hypothesis is that rules which are dissimilar to every other rule are likely problematic, as outlined in section 4. If a rule behaves like nothing else, there should be a good reason for it; if there is no reason, there is likely a problem. For both approaches, the same definition of similarity can be used.

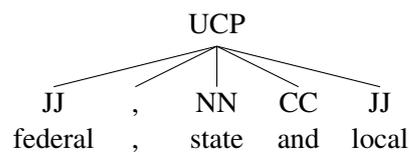

While we only investigate problematic rules, finding commonalities between rules provides insights into an appropriate syntactic model for treebank grammars. This is an important step for tasks such as recovering latent annotation, grammar compaction, and annotation scheme revision.

## 2 Background

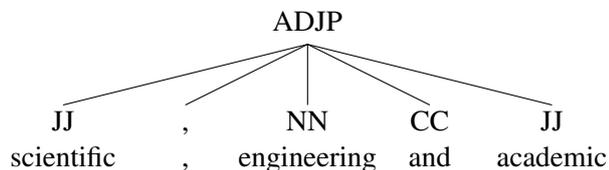

To motivate the need for a definition of similarity across treebank rules, we start with an error detection method that searches for inconsistency of labeling within local trees (Dickinson and Meurers, 2005b). The insight is that one can generally determine the syntactic category of the mother of a rule based on the categories of its daughters. In other words, linguistic phrase structure rules tend to be endocentric (cf. X-bar syntax, Jackendoff, 1977). If the same daughters list has more than one mother, this might indicate a violation of endocentricity. Thus, Dickinson and Meurers (2005b) search for variation in mother categories which dominate the same daughters; daughters lists with more than one mother are flagged as potential errors. This method turns out to be quite successful at detecting errors, as 74% of variations in the WSJ contain errors.

As an example, consider the daughters list JJ , NN CC JJ, which varies between unlike coordinated phrase (UCP) and adjective phrase (ADJP), as in (2). Here, we successfully flag an error, as there is no need for variation: the guidelines indicate that ADJP is erroneous Bies et al. (1995, p. 120).

- (2) a. [<sub>UCP</sub> federal/JJ ,/, state/NN and/CC local/JJ] public officials

- b. [<sub>ADJP</sub> scientific/JJ ,/, engineering/NN and/CC academic/JJ] communities

A limitation of the method is its lack of generality, in that a rule occurring once cannot vary with any other rule (Dickinson, 2006). Furthermore, it is not only identical daughters lists which must share the same mother, but also very similar daughters lists. In order to increase recall, we note that many rare rules are actually quite similar to other rules. Currently, for example, the daughters lists ADVP RB ADVP and ADVP , RB ADVP, as shown in (3), are treated distinctly. If they are treated as the same daughters list, then

there are two different mothers, PP (prepositional phrase) and ADVP (adverbial phrase), and this variation points to the presence of an error, in PP in this case. What is needed is a way to say that these rules are behaving in the same way.

- (3) a. to slash its work force in the U.S. , [*PP* [*ADVP* as] soon/*RB* [*ADVP* as next month]]
- b. to report their purchases and sales [*ADVP* [*ADVP* immediately] ,/, not/*RB* [*ADVP* a month later]]

### 3 Similarity

To increase the number of errors found, therefore, we relax the identity requirement between daughters lists. Namely, we automatically create equivalence classes of daughters lists to assist in error detection, where the defining property of making equivalences is that the mother of each rule is still predicted to be the same by all daughters list in the class. To create such equivalences, we can use the insight that anything not contributing to prediction can be ignored. Grouping rules based on the predictive information of daughters will result in better recall of errors.

#### 3.1 Equivalence criteria

Based on this notion of predictability, we can use fairly simple properties of rules in order to establish equivalences between them. For each daughters list, the steps we employ are the following (Dickinson, 2006):

1. Remove daughter categories that are always non-predictive to phrase categorization.
2. Group head-equivalent lexical categories.
3. Model adjacent identical elements as a single element.

In the first step, we remove daughter categories that are always non-predictive to phrase categorization, and these are categories which are always adjuncts. Clearly, we need to keep the head in a list of daughters, as head information generally percolates up to the mother. We also need to keep all arguments, as arguments can distinguish one rule from another. For example, *SINV* (inverted sentence) is the mother for the daughters list *VP NP PP* because the head (*VP*, verb phrase) precedes the argument (*NP*, noun phrase). We thus want to remove adjuncts, but this has to be done in such a way that it generalizes across all rules. Thus, we focus on eliminating “inherent” adjuncts, which come in a few different forms in the PTB. First, there is punctuation, which is not involved in the predicate-argument structure (cf. Hollingshead et al., 2005), and is often not included in treebank rules (cf. Brants et al., 2002). Secondly, parentheticals (*PRN*) refer to solely parenthetical material and thus are always adjuncts when they occur in a daughters list. Finally, empty elements (i.e., *-NONE-*) can refer to any category, and thus they are uninformative with respect to the mother category.<sup>1</sup>

---

<sup>1</sup>Note that empty elements are generally a problem for error detection (Dickinson and Meurers, 2003).

The second step is to group what we call *head-equivalent* lexical categories, or categories which are the same in predicting the mother. The intuition here is that phrases headed by, for example, either singular common noun (NN) or plural common noun (NNS) are generally NP, and this distinction does not add any information in predicting the mother. The full set of mappings is given in table 1, which is similar to mapping #2 in Hepple and van Genabith (2000). All other lexical tags (i.e., not in the table) are not grouped with any other tags: there are 13 such tags only equivalent to themselves.

Base category	Head Equivalence Classes
Determiners	{DT, PDT, PRP\$}
Adjectives	{JJ, JJR, JJS}
Nouns	{NN, NNS, PRP}
Proper nouns	{NNP, NNPS}
Adverbs	{RB, RBR, RBS}
Verbs	{MD, VB, VBD, VBG, VBN, VBP, VBZ}
<i>Wh</i> -determiners	{WDT, WP\$}

Table 1: Head-equivalence classes in the WSJ

The final step is to model adjacent identical elements as a single element. This is akin to modeling a flat series of identical categories with the Kleene + operator (XP+), and we do this for arbitrarily long sequences. For instance, for the daughters list NN IN NP IN NP, the second IN NP says nothing more about predicting mother category, and so this is mapped to NN IN NP. All repetitious sequences are mapped into the shortest possible sequence that is still predictive. For JJ NN NN JJ NN, for example, we first reduce it to JJ NN JJ NN, and then to JJ NN. This Kleene reduction step bears much in spirit to the correcting of illegal syntactic structures for the Penn Korean Treebank in Han et al. (2002), where legitimate right-hand sides of rules are hand-encoded as regular expressions, in order to detect and correct illegal syntactic structures.

## 3.2 Results

**Evaluation of equivalence criteria** Before testing the effect of grouping rules into equivalence classes for error detection, we first want to ensure that the equivalence criteria are not eliminating anything essential to phrase categorization. In other words, do we lose any predictive information by using equivalence classes? To gauge this, we sampled 100 equivalence classes from section 00 of the WSJ and examined them by hand. It turns out that in 98 cases, nothing predictive has been removed. In fact, in 24 of those cases, the mapping is complete; that is, nothing more should have been removed.

The two unsuccessful mappings involve the label NAC (not a constituent), as illustrated in (4). The daughters list NNP , NNP , reduces to NNP, but NNP by itself does not predict NAC. In fact, Bies et al. (1995, p. 208) mention that the presence of a comma partially determines NAC here. In the future, one could consider being more careful with punctuation, but the results are effective enough for us to continue.

- (4) [<sub>NAC</sub> Albuquerque/NNP ,/, N.M./NNP ,/,]

**Results for rule similarity** Turning to the results for the rule similarity error detection method, by grouping daughters lists into equivalence class, we map 15,989 daughters lists to 3783 equivalence classes. From these 3783 classes, 546 have variation in their labeling. While 546 is less than the original 844 varying daughters lists, each class is much bigger. In fact, since all instances of an original rule are within the same class, we are guaranteed to find at least as many varying rules as before.

We sampled 100 of these 546 variations and marked for each whether it contained an error, and we thus estimate 71% error detection precision. Significantly, this is on a par with the original error detection precision (74%), which means that we are increasing recall without sacrificing precision.

Indeed, this method points to nearly a thousand erroneous rule types, and these are a superset of the cases in Dickinson and Meurers (2005b). As one example, consider the equivalence class JJ VB, as shown in examples (5) and (6). Here, we have four different daughter lists all mapping to JJ VB, with variation between ADJP and NP. Crucially, without equivalence classes, the list JJR VBN, with ADJP as its mother category, would not have been found to be in variation with NP when using daughters lists.

- (5) a. [<sub>NP</sub> personal-income/JJ growth/VB]
- b. [<sub>NP</sub> other/JJ high-yield/JJ deals/VBZ]
- c. [<sub>NP</sub> last/JJ May/MD]
- (6) [<sub>ADJP</sub> lesser/JJR developed/VBN]

Thus, we successfully increase error detection recall, without sacrificing precision, and we do so with only a small amount of manual work.

While this is successful for the WSJ, new criteria would have to be hand-written for other treebanks and languages. The same general principles apply, namely maintaining the predictability of the mother category. The only caveat is that one must be careful about which abstractions to make; for example, case distinctions important for subcategorization should not be conflated.

**Annotation scheme issues** Detecting errors is not all that these method allows us to do. This method of using rule similarity also reveals various issues with the annotation scheme. We provide a few brief examples here, as a way to illustrate the types of cases that such methods uncover.

First, as before, we are able to turn up cases of acceptable non-endocentricity, as in example (7), where a PP is headed by a verb. We also find more subtle cases where the annotators had difficulty in deciding what type of phrase a sequence should be categorized as. For example, we find nominal constructions functioning adverbially, as in (8), with ADVPs apparently headed by nominals, apparent violations of endocentricity whose annotation is not entirely clear. Finally, we find inconsistent treatment of undocumented constructions, for instance, *due to* phrases.

- (7) [<sub>PP</sub> not/RB including/VBG [<sub>NP</sub> the Soviet Union]]
- (8) a. [<sub>ADVP</sub> way/NN sky/RB] high
- b. [<sub>ADVP</sub> [<sub>NP</sub> a week] ago/RB [<sub>NP</sub> Friday]]

## 4 Dissimilarity

Using equivalence classes allows us to compare the similarity of rules, but looking at the comparability of treebank rules has a broader effect. So far, equivalence classes provide a way to talk about rule similarity; the other side is to talk about rule dissimilarity. Equivalence classes can be used to provide support for the validity of a rule: the more rules that are within a class, the more evidence that the annotation scheme legitimately licenses that sequence.

Or, to view this from the opposite direction, a rule which does not have any equivalents in the grammar is more likely to be covering a non-linguistic construction. This is indeed worth investigating, as 2141 of the 3783 equivalence classes in the WSJ have only one unique daughters list. Consider an example like (9): here, the daughters list RB TO JJ NNS has no similar rules in the treebank, and it indeed is erroneous (Bies et al., 1995, p. 179).

(9) [NP close/RB to/TO wholesale/JJ prices/NNS]

From a random sample of 100 of the 2141 unique rules, we find that 39 of them are errors. Thus, we estimate 835 errors, with a 95% confidence interval of 630 to 1040 errors. Additionally, we find four rules which cover ungrammatical sentences.<sup>2</sup>

This 39% precision is rather low, but recall that we essentially get these dissimilar cases for free, in that the same notion of similarity is used here as in the endocentricity-based method. Furthermore, as we will see below, there are interesting reasons other than errors for rules being anomalous.

Additionally, we can identify a subset of cases which is more likely to contain errors. The notion of dissimilarity is based on the notion that daughters lists can and should vary (e.g., by having more or less adjuncts), but this is not always the case. Some rules correctly allow for no fluctuation; for example, the rule NP → EX for the existential use of *there* (with 1075 occurrences) cannot be modified in any way. It turns out that 777 of the 2141 unique rules map to themselves; that is, nothing was changed in creating the equivalence class. But the other 1364 rules did change, more strongly indicating that they could potentially fluctuate: they map to something that could have been comparable but does not exist in the treebank. Sampling 100 of these 1364 cases turns up 49 errors and 6 rules for ungrammatical sentences. In the future, one could experiment with more carefully identifying daughters lists which are rightfully incomparable to other rules.

We can finally note that the errors we detect overlap very little with the errors detected in the similarity method. Of the 1364 cases, only five have more than one mother. Furthermore, because we are looking at unlikely sequences of daughters, we tend to find more bracketing errors than in the first method. So, even though the methods share the same notion of equivalence, they lead to finding different types of errors because they look for different types of anomalies.

---

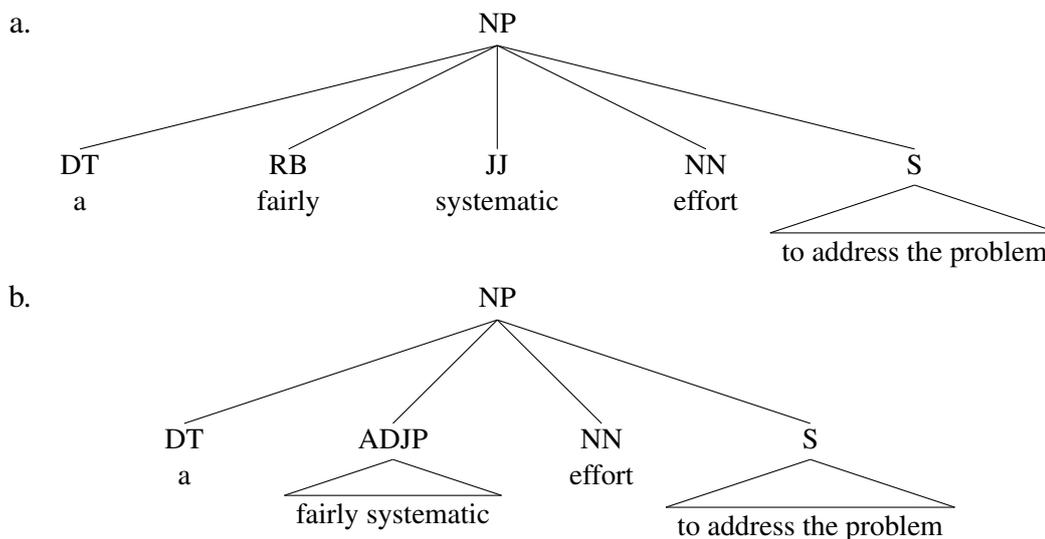

<sup>2</sup>While the term “ungrammatical” can be debatable, we use it in instances where the sentence is simply non-English; see, e.g., Foster (2007) for more discussion of grammaticality and the need to distinguish it in natural language parsing.

## 4.1 Analyzing the cases

To understand what this method does, it is instructive to walk through the different kinds of cases that the method turns up, both for dissimilarities which highlight errors or cover ungrammatical sentences and for those which are correct, as they reveal interesting properties of the annotation scheme. We thus outline the three kinds of cases here.

**Errors** We have established that there are errors in the treebank, but a major question is, why are there errors? As it turns out in this case, one of the major sources of errors is the overapplication of flat structures in the treebank. In the WSJ, many constructions are supposed to be left flat, such as nominal modifiers which are themselves nouns, but this does not apply to all cases. In (10), for example, the RB JJ sequence annotated as in (10a) should be bracketed as an ADJP, as in (10b). We find these cases because the sequence is more anomalous without that extra layer of structure.

(10) there seems \* to be [<sub>NP</sub> a/DT fairly/RB systematic/JJ effort/NN [<sub>S</sub> \* to address the problem]]

Likewise, the dissimilarity method finds categories which appear in the wrong context. In (11), for instance, the category DT (determiner) appears in the daughters list DT ADJP CC PP, which should be CC ADJP CC PP. Finding a DT next to an ADJP is normally not a problem, but given the context of the whole rule (where CC [coordinating conjunction] is present), we are able to detect a misplaced category.

(11) [<sub>UCP</sub> both/DT [<sub>ADJP</sub> prudent] and/CC [<sub>PP</sub> in the best long-term interest of the shareholders]]

Finally, we even detect some non-endocentric structures with the dissimilarity method, as in (12), where the POS (possessive ending) category appears to be heading a VP. The reason we detect these cases is that these are also categories in the wrong context. POS NP SBAR is not a normal sequence, irrespective of its mother category, which in this case does not match.

- (12) It [<sub>VP</sub> 's/**POS** [<sub>NP</sub> that last set of numbers ,] [<sub>S<sub>BAR</sub></sub> as much as anything else , that \*T\* gives the Giants hope in the Series games 0 \*T\* to come]] .

**Ungrammatical constructions** In addition to errors, this method uncovers constructions which are for ungrammatical language, or non-standard English. For example, in (13), we see rules such as QP → RB JJ \$ CD, which are the best analyses given the annotation scheme, but which are clearly for ill-formed constructions (e.g., *as little \$ 3* should be *as little as \$ 3*). Likewise, as shown in (14), there are rules which are used to cover “financialspeak.” In either case, it is not clear that these types of rules should be annotated in the same fashion as grammatical rules.

- (13) a. Now , they 're charging [<sub>QP</sub> as/RB little/JJ \$/\$ 3/CD] \*U\* a day .  
 b. Chemical earnings [<sub>VP</sub> declined/VBD [<sub>PP</sub> by one-third] [<sub>PP</sub> to \$ 120 million \*U\*] [<sub>X</sub> last year 's robust levels]]
- (14) a. [<sub>NP</sub> [<sub>NP</sub> Net income] [<sub>X</sub> \*] :/ : [<sub>NP</sub> \$ 599.9 million \*U\* ; or \$ 20.20 \*U\* a share] ]  
 b. [<sub>FRAG</sub> [<sub>NP</sub> Call] [<sub>PP</sub> at par] [<sub>PP</sub> after two years] and/CC [<sub>ADVP</sub> thereafter] [<sub>PP</sub> at par] [<sub>NP</sub> every six months] ./.]

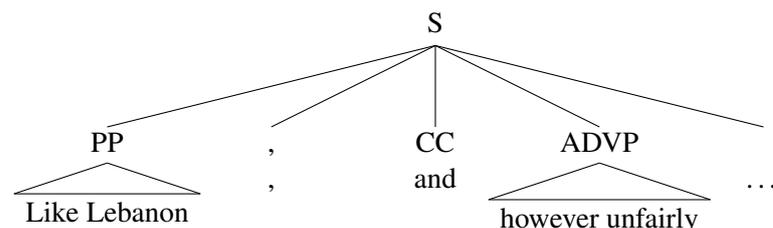

**Annotation scheme & guidelines** Finally, we turn to some correct corpus examples, where the method uncovers properties of the annotation scheme and the guidelines which seems to be reflective of non-uniform practices. For treebanking purposes, this is perhaps the most useful aspect of the dissimilarity method: it reveals properties of the annotation which need to be revisited. We present only a few examples here, although there are more which are discovered.

First, we find issues with the category QP (quantifier phrase), used for complex numerical determiners. According to the guidelines, both *as little as* and ranges of dollar amounts are annotated as flat QPs (Bies et al., 1995, p. 194-202). Crucially, though, there is no guidance on what to do when they are together, and so we find flat QP structures, as in (15).

- (15) [<sub>QP</sub> as/RB little/JJ as/IN \$/\$ 89/CD to/TO \$/\$ 109/CD]

Secondly, we have cases like (16) which arguably contains a parenthetical, namely the string *and however unfairly*. Since parentheticals (PRN) are “determined ultimately by individual annotator intuition” (Bies et al., 1995, p. 50), we cannot say that this analysis is incorrect. We can note, however, that with a parenthetical analysis, the daughters list PP PRN NP VP would reduce to the frequent PP NP VP.

- (16) [<sub>S</sub> [<sub>PP</sub> Like Lebanon] ./, and/CC [<sub>ADVP</sub> however unfairly] ./, [<sub>NP</sub> Israel] [<sub>VP</sub> is regarded \* by the Arab world as a colonial aberration] ./.]

Relatedly, sometimes one analysis is not the absolutely correct one, but only preferred over another analysis. For example, VP gapping is the preferred analysis in some structures, but variability is explicitly allowed for (Bies et al., 1995, p. 125). Thus, we find odd rules such as  $NP \rightarrow NP$ ,  $ADVP RB NN$ , which could also have been analyzed as having a gapped verb.

(17) they do not serve [<sub>NP</sub> [<sub>NP</sub> the people] ,/, and/CC [<sub>ADVP</sub> particularly] not/RB consumers/NN]] .

## 5 Possible extensions

The methods we have described are clearly effective for detecting errors and other anomalous rules in a flat treebank, but they can be generalized for work on this and other treebanks.

### 5.1 Generalizing the search for anomalous rules

We have treated the dissimilarity method essentially as a side effect of the similarity one, using only strict equivalences. The problem is that using strict equivalence misses some generalizations between rules. Consider, for example, the one occurrence of the correct rule in (18).

(18) [<sub>NP</sub> the/DT 100/CD largest/JJS Nasdaq/NNP financial/JJ stocks/NNS ]

While DT CD JJS NNP JJ NNS may be the only daughters list of its kind, i.e., it has no equivalents, we can infer its correctness from similar rules in the treebank. For example, there are three instances of  $NP \rightarrow DT CD JJ NNP NNS$  in the WSJ, which are not strictly equivalent, but which are similar.

Thus, the search for dissimilar rules can be broadened, and this is what is done in Dickinson (2008). Namely, one can search for similar rules by using edit distance between rules; the principle put forth here that rules with few similar rules are the most anomalous is still true. Putting the idea of dissimilarity more directly in the task, one can also examine anomalous subsequences of daughters (e.g., bigrams) to find those which are the most problematic.

### 5.2 Portability

We here also sketch out ways in which the notion of similarity can be broadened to include richer treebank formalisms. The method we have used is based on a simple notion of rule similarity; thus, to apply it to treebanks with relatively flat context-free rules, one need only write a small set of treebank-specific adjunct categories and category mappings. The method faces challenges in extending to other types of treebanks, however, and we outline those challenges here, offering some pointers to solutions.

First, there are treebanks which contain discontinuous constituents, that is, constituents which are not contiguous. In example (19) from the TIGER treebank (Brants et al., 2002),

for instance, the noun phrase *Ein Mann det lacht* ('a man who laughs') is a complete constituent with material intervening.

- (19) **Ein Mann** kommt , **der lacht**  
 a man comes , who laughs  
 'A man who laughs comes.'

We have assumed contiguous context-free rules in our definitions of rule similarity and dissimilarity, as categories are strictly ordered with respect to each other. In this new situation, we need a way to map discontinuous trees to context-free rules. Following work on context-free parsing with discontinuous treebanks (cf. Boyd, 2007), one possible solution is to split each constituent into its component parts. For example, with a split NP, we might have  $S \rightarrow NP-d \text{ VMFIN} , NP-d$  as a rule, where *-d* marks one part of a discontinuous element. This would allow the NP elements to be compared with other NPs, while at the same time not making any assumptions about free word order.

Secondly, there are treebanks, which employ less flat structures, often only binary-branching trees (e.g., CCGbank (Hockenmaier and Steedman, 2007)). Obviously, this results in much fewer rule possibilities. The question for our method is: what information still highlights inconsistency?

Consider what happens when flat trees are binarized. In (20), for instance, we have an endocentricity violation. Here, it does not matter whether we have binary-branching or flatter trees; the fact that VP is the mother of POS is generally sufficient to indicate a problem. That is to say, endocentricity violations are in principle detectable with binary trees.

- (20) a. It [<sub>VP</sub> 's/**POS** [<sub>NP</sub> ... ] [<sub>SBAR</sub> ... ]]  
 b. It [<sub>VP</sub> 's/**POS** [<sub>NP</sub> [<sub>NP</sub> ... ] [<sub>SBAR</sub>] ... ]]

Consider now how we would detect the overapplication of a flat structure, as shown in (21). To detect that RB JJ in (21b) should be ADJP, we either need to move beyond local trees, or we somehow need to flatten them. It seems that we need to examine trees which contain only maximal projections (e.g., NP in (21b)) and pre-terminal categories (e.g., RB, JJ, NN), skipping over intermediate levels.

- (21) a. [<sub>NP</sub> a/DT fairly/**RB** systematic/**JJ** effort/NN ... ]  
 b. [<sub>NP</sub> a/DT [<sub>N'</sub> fairly/**RB** [<sub>N'</sub> systematic/**JJ** [<sub>N'</sub> effort/NN [<sub>SBAR</sub> ... ] ]]]]

Finally, we can consider richer linguistic annotation, such as treebanks with head-driven phrase grammar (HPSG) and lexical-functional grammar (LFG) annotation, such as the kind used to convert treebanks into more deeply annotated resources (e.g., Miyao et al., 2004; O'Donovan et al., 2005). As the conversion process typically involves hand-written grammatical constraints, these treebanks can be expected to have a greater amount of consistency.

But the question remains: since nonterminal elements are now complex bundles of features instead of a simple category, how does one compare rules in this context? For our methods, the main questions to answer are: which features of the daughters predict the mother's category, and which sequences can be seen to be anomalous? For

example, in an HPSG feature structure, one would likely want to use the value of the `SYNSEM|LOC|CAT|HEAD` path to determine the POS or category of each unit.

In this context, we can note that a potential benefit of our method is that it can assist in preprocessing of treebanks. That is, we can detect structures which lead to a failure of “grammar acquisition” (Miyao et al., 2004), and this requires very little work in extracting problematic constructions.

## 6 Summary and Outlook

We have shown how one can use basic linguistic abstractions to group treebank rules into equivalence classes. These equivalence classes of rules can be used, in the first place, to assist in detecting non-endocentric structures, by finding classes of rules which should have the same mother category, and, in the second place, to detect anomalous structures by finding rules which do not fit into an equivalence class with any other rules. This is done by using only a few simple, highly precise properties that maintain the predictive information of the daughters.

There are a variety of ways in which this work can be taken in the future. First, to validate the methods further, it needs to be applied to other treebanks and languages. Elucidating which properties of a treebank are predictive can provide further insights into general grammar compaction methods. In particular, applying equivalence mappings to treebanks with discontinuous and binary-branching representations (see section 5.2) will further the connections between flat context-free representations and other formalisms employing approximately the same amount of category information, but with different structural requirements.

Finally, one can use the insights of equivalence classes to explore regularities in the grammar. This could take the form of adding latent annotation (cf., e.g., Petrov et al., 2006) to subclasses of rules which have much in common, or this could involve generalizing the treebank grammar to predict new rules which did appear in the original data set.

## Acknowledgments

I would like to thank Adriane Boyd and Detmar Meurers for their useful and insightful comments on earlier versions of this work, as well as the participants of the *Fifth Workshop on Treebanks and Linguistic Theories* for feedback on the rule similarity method. This material is based upon work supported by the National Science Foundation under Grant No. IIS-0623837.

# Linearization of Syntactic Dependency Graphs in terms of Traversal Algorithms

Miyoko Yasui

Dokkyo University  
1-1 Gakuencho, Soka, Saitama 340-0043 JAPAN  
myasui@dokkyo.ac.jp

## Abstract

Assuming dependency graphs as syntactic representations instead of phrase structure trees, this study attempts to derive the major word orders, SVO, SOV and VOS, via the set of three tree traversal algorithms common in graph theory and computer science, and to explain their correlations with some of the syntactic differences: (i) clause-internal scrambling in V-peripheral languages and its absence in SVO languages, (ii) obligatory *wh*-movement in SVO languages and its absence in V-peripheral languages; and (iii) pseudo-cleft *wh*-questions in V-initial languages besides in-situ *wh*-phrases. The proposed word order parameter is three-valued in contrast to the more familiar two-valued one, offering finer distinctions between SVO and VSO languages, which are both head-initial.

**Keywords:** Dependency Graph, Traversal Algorithms, Scrambling, *Wh*-movement, Word Order

## 1. Dependency Graphs with Bound Morphemes as Independent Nodes

We can identify two kinds of syntactic representations in the current theories of syntax: phrase structure tree adopted in Chomsky (1957) and subsequent work, and dependency tree employed under various frameworks (e.g., Hudson (1984), Mel'čuk (1988), Debusmann & Kuhlmann (2008), and Joshi (1985)). Formally, they are both trees, with a root node dominating all the other nodes and each non-root being immediately dominated by exactly one node (see Diestel 1997). Their PF interpretations, however, are totally different; only the terminal nodes of a phrase structure tree are pronounced, whereas every node is relevant to PF interpretation in a dependency tree. The contrast is illustrated by a pair of subtrees in (1a,b).

(1a) is a phrase structure of the generative tradition. Its non-terminal nodes are not pronounced, whether they are reanalyzed according to the bare phrase structure theory of Chomsky (1995) or not. On the other hand, the two nodes of the dependency tree in (1b) are to be pronounced.

Another related difference is that a phrase structure tree like (1a), if the order of sister nodes is specified by phrase structure rules or a particular value of the head parameter, is mapped into a single word ordering via a very simple algorithm: pronouncing the terminal nodes from left to right. A dependency tree like (1b), in contrast, is not associated with any self-evident ordering algorithm. In fact, drawing on the idea in Gazdar et al. (1985), a dependency tree is decomposed into two parts: immediate domination (ID) and linear precedence (LP) trees. Of course, their correspondence should not be totally free, and a number of formal constraints have been proposed such as projectivity and nestedness.<sup>i</sup>

A tree is a kind of data structure and its properties have been extensively studied in graph theory and computer science, where several algorithms have been formulated and used widely to traverse all the nodes. The left-to-right PF interpretation mentioned above appears to be taken for granted among linguists, but it has almost no resemblance to the common traversal algorithms on trees. Following Yasui (2003, 2004), I will adopt one set of standard graph-theoretic traversal algorithms and apply them to dependency-based syntactic representations.<sup>ii</sup> The key syntactic assumption taken from the generative tradition is that tenses, which are bound morphemes in many languages, constitute independent syntactic nodes. This is not adopted in most dependency-based studies and explicitly denied by Hudson (1984) and Sugiyama & Hudson (2006). I will show that the morphological properties of tenses and other bound morphemes in a dependency structure are crucial in causing displaced phenomena in its PF realization, which include scrambling, *wh*-movement and verb-second.

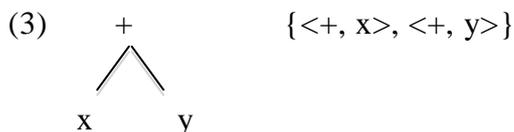

## 2. A Dependency Graph and its Traversals

An infix arithmetic expression like (2a) has the prefix and postfix variants in

(2b,c).

- (2) a. x+y
- b. +xy
- c. xy+

(2a-c) can be associated with the single hierarchical structure in (3), where the operator + immediately dominates its operands.

The graphical configuration in (3) can be defined by the set of two edges or ordered pairs on its right; the set-theoretic notation will be adopted below. (2a-c) can be derived from (3) in terms of the well-known recursive algorithms on trees, i.e., by starting a depth-first traversal from the root and pronouncing each node between, before, and after visiting its child nodes, respectively (cf. Knuth (1997:318-320)). They are called inorder, preorder, and postorder traversals. If the right child is traversed before its left child, the three more orderings given in (4a-c) are obtained.

- (4) a. y+x
- b. +yx
- c. yx+

(2a-c) and (4a-c) have the same value if '+' is taken as addition.

It is reasonable to extend this line of analysis to word order variation found in natural languages exemplified in (5a-c).

- (5) a. He scolded her.
- b. *Kare-ga kanozyo-o sikatta.*  
      he-NOM she-ACC scolded  
      'He scolded her.'
- c. *Ha-fahan si Maria i bistidu-ña gi tenda.*  
      3S-buy Maria the dress-3S LOC store  
      'Maria bought her dress at the sore.' (Chung 1990: 562)

The inorder and postorder traversal algorithms mentioned above derive (5a, b) from the common dependency structure defined in (6), which is given in English for ease of illustration.

- (6) {<scolded, he>, <scolded, her>}

(5c) can be derived analogously with irrelevant details set aside. As in (4), the child nodes of the verb are commutative in Japanese and Chamorro but are not in English.

- (7) a. \*Her scolded he.

The local syntactic relations listed above are directional; (8) defines a directed graph with the matrix tense as its root. It is, however, not a tree since the subject is directly governed by more than one element (i.e., the tense and the verb). The standard traversal algorithms take trees as inputs but also work properly with rooted acyclic directed graphs like (8) if formulated as in (9):

- (9) Given a node A in a graph G *and A has not been pronounced*,
- i. traverse A's child 2,
  - ii. pronounce A, and
  - iii. traverse A's child 1.<sup>vii</sup>

The order of the three components in (9) is inorder; the preorder and postorder traversals are (ii)-(i)-(iii), and (i)-(iii)-(ii), respectively. The italicized proviso prevents a doubly-connected node from being pronounced twice.

The inorder, postorder and preorder traversals of (8) yield (10a-c), where child 2 is traversed before child 1.

- (10) Child 2 of [past] and child 2 of *scold* traversed first
- a. INORDER: [past]-he-[past]-scold-(he)-scold-her-scold-[past]  
=> he [past] scold her (SVO)
  - b. POSTORDER: [past]-he-[past]-scold-(he)-scold-her-scold-[past]  
=> he her scold [past] (SOV)
  - c. PREORDER: [past]-he-[past]-scold-(he)-scold-her-scold-[past]  
=> \*[past] he scold her

Each node is to be pronounced where it is underlined in (10a-c); the occurrence of *he* after it has been pronounced is parenthesized. The resultant sequences are given after the arrows. If we make a reasonable assumption that a tense morpheme must be adjacent to the verb it is affixed to in the output of traversal, (10a,b) satisfy it but (10c) does not. The output of (10c) is asterisked in this sense.

If traversals are relaxed so as to let either child be traversed first at the two branching nodes, three more sets of outputs are obtained.

- (11) Child 1 of [past] and child 2 of *scold* traversed first
- a. INORDER: [past]-scold-he-scold-her-scold-[past]-(he)-[past]  
=> \*he scold her [past]
  - b. POSTORDER: [past]-scold-he-scold-her-scold-[past]-(he)-[past]  
=> he her scold [past] (SOV)
  - c. PREORDER: [past]-scold-he-scold-her-scold-[past]-(he)-[past]  
=> [past] scold he her (VSO)

- (12) Child 1 of [past] and child 1 of *scold* traversed first

- a. INORDER: [past]-scold-her-scold-he-scold-[past]-(he)-[past]  
=> \*her scold he [past]
- b. POSTORDER: [past]-scold-her-scold-he-scold-[past]-(he)-[past]  
=> her he scold [past] (OSV)
- c. PREORDER: [past]-scold-her-scold-he-scold-[past]-(he)-[past]  
=> [past] scold her he (VOS)

(13) Child 2 of [past] and child 1 of *scold* traversed first

- a. INORDER: [past]-he-[past]-scold-her-scold-(he)-scold-[past]  
=> \*he [past] her scold
- b. POSTORDER: [past]-he-[past]-scold-her-scold-(he)-scold-[past]  
=> he her scold [past] (SOV)
- c. PREORDER: [past]-he-[past]-scold-her-scold-(he)-scold-[past]  
=> \*[past] he scold her

The asterisked outputs in (10)-(13) violate the verb-tense adjacency. Note, first, that all the four outputs of postorder traversal satisfy the condition, resulting in SOV and OSV. In postorder traversals, heads are pronounced after all their child nodes regardless of which child is traversed first; so they appear adjacent to each other in clause-final position. As for inorder traversal, of the four outputs, only (10a) is allowed, which yields SVO.<sup>viii</sup> In this way, the present theory predicts the correlation between the possibility of clause-internal scrambling and the position of heads in SOV and SVO languages, which is confirmed by data from Japanese and English

Of the four outputs of preorder traversal, (11c) and (12c) are morphologically well-formed, yielding VSO and VOS. Thus, with respect to the S-O reversal, Chamorro is correctly predicted to behave on a par with postorder languages rather than inorder languages. On closer examination, however, preorder traversals are more restricted than postorder traversals. In particular, while the postorder traversal of (8) can visit either child of the root first, the preorder traversal necessarily chooses the edge between the tense and the verb, skipping the other edge with the subject; otherwise, the verb-tense adjacency would be disrupted. Suppose that a given word order counts as basic or unmarked if derived by a consistent traversal: either child is given priority throughout. Then, the basic order obtained in inorder is SVO, with each node traversed as in (10a), whereas the preorder traversal should proceed as in (12c), in which child 1 is traversed first and VOS results. This accords with the observation that V-initial languages like Malagasy and Palauan, unlike Chamorro, have the rigid VOS order, though the syntactic status of the so-

called ‘subject’ has attracted much controversy (see Chung (2005a) and Pearson (2005) among others). I reserve my conclusion on this issue.

#### 4. Moved and In-Situ *Wh*-phrases

##### 4.1 Overt *Wh*-movement in Inorder Languages

The S-V-O order in tensed declarative clauses can be generalized into specifier-head-complement, which subsumes *wh*-movement. It is worth examining how much of its parametric differences can be deducible from the theory advocated here.

First, English moves a *wh*-phrase obligatorily into the specifier of CP, whereas Japanese and Chamorro do not. Take (14) as an example, with its dependency graph defined in (15).

(14) What did John buy?

(15) {<[WH], what, 2>, <[WH], [past], 1>, <[past], John, 2>, <[past], buy, 1>, <buy, John, 2>, <buy, what, 1>}

It has been proved that within the subgraph rooted by a tense, the edges marked with 2 (i.e., specifiers) need to be traversed first in English. Let us suppose that on the CP level headed by [WH], edge 2 is traversed first, which results in (16):

(16) [WH]-what-[WH]-[past]-John-[past]-buy-(John)-buy-(what)-buy-[past]-[WH] ==> what [WH] John [past] buy

Traversing edge 1 first on the CP level yields (17).

(17) [WH]-[past]-John-[past]-buy-(John)-buy-what-buy-[past]-[WH]-(what)-[WH] ==> John [past] buy what [WH]

[WH] is adjacent to *what* in both (16) and (17), but in neither is [WH] adjacent to [past]. Of the two outputs, (16) appears to be the more plausible for (14). As a first approximation, suppose that [WH] needs to be adjacent to a tense just like a verb is. Then, this morphological condition can be met in (16) if [past] moves to COMP followed by *Do*-support, which are well-justified processes.<sup>ix</sup> The traversal output in (17), on the other hand, does not seem to be salvaged by any known syntactic operation. Syntactic *wh*-movement is captured in the present theory as obligatory traversal of the edge between the interrogative marker and the *wh*-phrase. I will assume that this line of analysis can be extended to overt *wh*-movement in other SVO languages as well as the so-called verb second property in Germanic languages.

Note that the subject-auxiliary inversion does not apply if the matrix subject is a *wh*-phrase as in (18), with its dependency graph defined in (19a).

(18) Who brought it?

(19) a. {<[WH], who, 2>, <[WH], [past], 1>, <,[past], who, 2>, <[past], buy, 1>, <buy, who, 2>, <buy, it, 1 >}

b. [WH]-who-[WH]-[past]-(who)-[past]-buy-(who)-buy-it-buy-[past]-[WH]  
 ==> who [WH] [past] buy it

Traversing (19a) in order with child 2 always first will yield (19b), where [WH], [past] and the verb are not interrupted by the initial *wh*-phrase; hence, the inversion is unnecessary. It remains to explain why the inversion is absent entirely in the embedded context. I will assume that selection of [WH] by a higher interrogative predicate somehow remedies its morphologically dependent status.

#### 4.2 *In-situ Wh-phrases in Postorder and Preorder Languages*

Second, Japanese and Korean do not obligatorily front a *wh*-phrase. For instance, Japanese allows the two orderings corresponding to (14).

(20) a. *John-ga nani-o kaw-ta ka/no?*

NOM what-ACC buy-PAST Q

b. *Nani-o John-ga kaw-ta ka/no?*

what-ACC NOM buy-PAST Q

'What did John buy?'

Suppose that (20a,b) share the configuration in (15), apart from the phonetic content of each element. It is easy to verify that (20a, b) are obtained in postorder by giving priority to child 1 and child 2 at each branching node, respectively. In either case, the interrogative marker, tense and verb are pronounced clause-finally due to the head-last nature of the postorder traversal. Note that unlike in English, <[WH], what, 2> in (15) can but need not be traversed in Japanese. In this sense, Japanese lacks syntactic *wh*-movement, and (20b) is an instance of clause-internal scrambling discussed in Section 3.

As for V-initial languages, Georgopoulos (1991), Potsdam (2006), and the references cited therein show that quite a few of them allow a *wh*-phrase in situ. Consider the Malagasy example in (21a), which is assumed here to have the configuration defined in (15) apart from irrelevant details.

(21) a. *nividy inona i Bao?*

buy.ACT what Bao

'What did Bao buy?' (Potsdam 2006: 2158 with a slight modification)

- b. [WH]-[past]-buy-what-buy-Bao-buy-[past]-(Bao)-[past]-[WH]-(what)-  
[WH] ==> [WH] [past] buy what Bao

The in-situ ordering is obtained from (15) by consistently giving priority to child 1 as in (21b).

So far, Malagasy apparently behaves on a par with Japanese, which is V-final. If the counterpart of (20b) is considered, some crucial differences arise. If child 2 of the root is traversed first (and the rest is analogous to (21b)), (22) is obtained.

- (22) [WH]-what-[WH]-[past]-buy-(what)-buy-Bao-buy-[past]-(Bao)-[WH]  
==> [WH] what [past] buy Bao

If (22) were to surface, the *wh*-object *inona* in (21a) would simply be fronted. In fact, the construction with the clause-initial *wh*-object should be (23).

- (23) *inona no novidin' i Bao?*  
what PRT buy.PASS Bao

'What was bought by Bao?' (Potsdam 2006: 2159)

While the Japanese scrambled *wh*-question in (20b) does not differ from (20a) apart from the word order, (23) differs from (21a) in two respects: the verbal morphology is changed and the particle *no* is required. Setting aside the first point, much evidence has been offered that (23) is a kind of pseudocleft on a par with (24); both involve the particle *no*.

- (24) *ny mofo [ no novidin-dRasoa ]*  
the bread PRT buy.PASS-Rasoa

'It was the bread that was bought by Rasoa.' (Potsdam 2006: 2169)

The pseudocleft strategy for clause-initial *wh*-phrases and focused phrases is attested in other Austro-onesian languages.<sup>x</sup> It differs from scrambling of a *wh*-phrase in V-final languages and overt *wh*-movement in SVO languages.

Before going into the pseudocleft analysis of (23) in more detail, it should be noted that (22) violates the morphological condition on an interrogative marker tentatively proposed for the English *wh*-question in (14): [WH] needs to be adjacent to the tense. Presumably, the clause-initial position is by far the most salient perceptually in languages of any word order, and it should be able to host a semantically special expression like a *wh*-phrase and topic. English meets this need with its child 2-first in-order traversal, while Japanese employs scrambling permissible in its postorder traversal. I will claim that as (22) is unavailable, Malagasy and some

other Austronesian languages resort to the pseudocleft strategy.

#### 4.3 Clause-initial *Wh*-phrases in Preorder Languages

If (23) is a kind of pseudocleft, the verb is part of the headless relative rather than the matrix element. In other words, (23) lacks a matrix tense and a copula just as predicative constructions like (25a-c).

- (25) a. [NP *vorona ratsy feo*] *ny goaika*.  
bird bad voice the crow  
'The crow is a bird with an ugly voice.'
- b. [AP *faly amin' ny zanany*] *Rasoa*.  
proud PREP the child.3SG Raso 'Raso is proud of her children.'
- c. [PP *any an-tsenà*] *aho*.  
PREP ACC-market 1SG.NOM 'I am at the market.'

(Potsdam 2006: 2157)

Predicative constructions without a finite copula are not uncommon in natural languages. Then, it is necessary to reconsider the morphological conditions on a tense and an interrogative marker assumed for English.

If a clause contains a bound tense morpheme, it must be affixed on some appropriate free morpheme: a verbal in English and an adjective as well in Japanese, for instance. If a language allows a tenseless clause, the adjacency condition is vacuously satisfied.

As for an interrogative marker, Chung's (1991) clausal typing theory crucially depends on the assumption that languages like English lack it; they are forced to front a *wh*-phrase to type a clause as interrogative. In contrast, I have been assuming that an interrogative marker exists in all questions, including a covert one in English. Languages with overt *wh*-movement typically exhibit the verb-second property, which I have claimed to be deducible from the adjacency condition between a phonetically empty interrogative marker and a tense. I thus need to claim that tenseless questions like (23) contain a phonetically empty interrogative marker. Since (23) is well-formed, the abstract interrogative marker should be morphologically innocuous without the presence of tense.

Note that the interrogative marker *ka* in Japanese can follow not only verbs and adjectives but also nouns and prepositions in their predicative usages:

- (26) *Kore-wa nani ka/dare-kara ka?*  
this-TOP what Q who from Q

'What is this/Who is this from?'

(26) are tenseless clauses with the *wh*-phrases in situ. If Malagasy is strictly head-initial, (23) can be analyzed as containing the abstract interrogative marker initially as the head of the entire sentence, followed by the *wh*-phrase in-situ, which, as Potsdam (2006) and others argue, is the focus predicate of a pseudocleft, with the *no*-marked constituent as the complex subject. This is an instance of the unmarked head-initial order and is the mirror image of the head-final Japanese word order: subject-predicate-*ka*.

If an interrogative bound morpheme in general needs to attach to a predicative constituent rather than a tense, the morphological condition on the English abstract interrogative marker proposed earlier should be revised accordingly; it should be adjacent to a predicate in the matrix context, which is a constituent headed by a finite verbal element including the copula *be*.

In summary, to place a semantically special expression like a *wh*-phrase clause-initially, natural languages employ different strategies depending on their basic word order or traversal mode: overt *wh*-movement as an instance of in-order traversal, clause-internal scrambling inherently available in postorder traversal, and the pseudocleft strategy in pre-order languages.

#### 4.4 *In-situ Wh-phrases in Chinese and Indonesian*

Potential counterexamples to the present theory in favor of Chung's (1991) clausal typing theory are Chinese and Indonesian, which are SVO like English but allow a *wh*-phrase in-situ like Japanese. As is well-known, Chinese is head-final in N projections. If the interrogative marker is under C, as Chung (1991: 26) and others assume, C projections are also head-final at least on the surface level. Some Germanic languages are mixed as to the position of head across categories. Then, it is necessary to specify the mode of traversal for each category in these languages rather than for an entire language once. Any typological study would be burdened with this much of complication. If Chinese is head-final within C projections, its in-situ strategy for *wh*-phrases is not surprising.

As for Indonesian, Chung (1991) analyzes in-situ and fronted *wh*-phrases on a par with those in other V-initial Austronesian languages like Palauan. Moreover, Cole et al. (2005) argue that the clause-initial 'subject' in verbal sentences of Standard Indonesian is like the clause-final 'subject' in other Austronesian languages in disallowing a *wh*-phrase; a pseudocleft construction needs to be adopted instead. If

Indonesian exhibits typical syntactic properties as V-initial languages, one possibility in my theory is to claim that its surface SVO order derives from some V-initial structure. In fact, the Indonesian existential construction with the verb *ada* is V-initial. As for *apa(kah)*, which marks yes/no questions in Indonesian, it is clearly a free morpheme, and its presence in clause-initial position is not problematic (see Sneddon (1996)). Needless to say, much is to be worked out especially on what is often referred to as subject in Indonesian as well as in V-initial languages.

## 5. Two-valued and Three-valued Parameters on Word Order

My approach is quite similar to Fukui (1993), Saito & Fukui (1998) and Haider & Rosengren (2003) in that it rests on the correlation between the position of head and word order freedom. They share the idea that scrambling is possible if its output accords with the head parameter value of a language in question; for example, Japanese allows leftward scrambling since it does not disturb its right-headed or head-final structure, while the opposite holds in English. I will concentrate on Fukui (1993) as it mentions V-initial languages while the other two do not. He cites Chamorro data as examples of rightward scrambling in a V-initial language in parallel with leftward scrambling in Japanese, which is V-final. If Palauan and Malagasy are strictly VOS as mentioned in Section 3, however, they do not straightforwardly fit into Fukui's theory. As for leftward movement to the other side of V, V-initial languages are predicted to behave on a par with SVO languages. If the pseudocleft analysis of clause-initial *wh*-phrases in the former is correct, it is totally different from overt *wh*-movement in the latter.

Moreover, Fukui (1993) mentions extraposition and heavy NP shift as instances of rightward scrambling in English.

(27) a. I read a review  $t_i$  last week [of John's book]<sub>i</sub>. (Fukui 1993: 410)

b. They brought  $t_i$  into my room [the beautiful pink dress]<sub>i</sub>.

Constituents to be moved rightward need to be heavy; so (28a, b) are not acceptable.

(28) a. ?\*I read a review  $t_i$  last week [of it]<sub>i</sub>.

b. ?\*They brought  $t_i$  into my room [that]<sub>i</sub>.

The heaviness does not govern leftward scrambling in Japanese or rightward scrambling in Chamorro. Fukui and the other two studies mentioned above assume a familiar two-valued head parameter. The differences exemplified in (28) and initial *wh*-phrases would favor the present approach with a three-valued parameter.

---

<sup>i</sup> According to Debusmann & Kuhlmann (2008) and others, projectivity disallows discontinuous dependency, and nestedness forbids cross-serial dependency. Since discontinuous dependency is amply attested, while cross-serial dependency is rare, projectivity needs to be relaxed but in a restricted manner, by limiting the number of discontinuities in a subtree. The mainstream dependency-based studies focus on mathematical aspects of dependency trees and pay little interest to parametric differences as to word order. Specifically, ID and LP trees are integrated into order-annotated trees to which tree traversal algorithms are applied but for purposes totally different from mine.

<sup>ii</sup> Kural (2005) adopts the same traversal algorithms but apply them to standard tree notations, whereby only terminal nodes are PF-interpreted. Brody (2000) adopts a dependency-like structure to derive the linear order of tense, light verb and main verb but his motivation is quite different from mine.

<sup>iii</sup> It follows from the present theory that long-distance scrambling should be treated differently. This conclusion is supported by data involving A-binding, but I will not go any further here.

<sup>iv</sup> Quite a few researchers claim to derive some instances of V-initial order from SVO, adopting Kayne's (1994) LCA.

<sup>v</sup> Layered structures proposed by Hale and Kayser (1993) and others can be adopted here, but the choice does not affect the overall argument in this paper.

<sup>vi</sup> If each directed edge is expressed as an (annotated) ordered pair, and such pairs are stacked as the structure is built up, the priority of specifier over complement corresponds to the last-in first-out mode in all the three word order types. See Fukui and Takano (1998) for a related but distinct approach.

<sup>vii</sup> Given a set of ordered triplet of the form  $\langle x, y, n \rangle$  (i.e., the edge  $x$ - $y$  with the annotation  $n$  on it), to traverse  $A$ 's child 2 is to find a node in the second slot of the triplet where  $x=A$  and  $n=2$ , and go on to another triplet with the obtained node in its first slot.

<sup>viii</sup> English modal auxiliaries are often assumed to be base-generated under  $T$ . I assume that the existence of bound tense morpheme as an independent syntactic node limits their traversal choice to be consistently child 2-first.

<sup>ix</sup> Head movement can be defined as an operation on graphs called edge contraction

---

(Diestel 1997: 16).

<sup>x</sup> Clause-initial *wh*-phrases in Chamorro can be analysed analogously, but see Chung (2005b).

# Geographic Information Systems (GIS) in Linguistic Research. Studies, Data and Future Perspectives

Oliver Streiter

National University of Kaohsiung,  
Nanzi, Kaohsiung, Taiwan  
ostreiter@nuk.edu.tw

## Abstract

In the context of worldwide efforts to document endangered languages (Aristar Dry 2002, Crystal 2002), we discuss Language GIS, a possible corner-stone methodology for future language studies and the management and coordination of documentation and preservation projects. We will give a panoramic of possible applications, and focus on the problem of the nature and availability of data for Language GIS. We show how computational linguistics can contribute to the development of Language GIS. The newly developed technology and resources should be reinvested into the support of documentation and preservation projects.

**Keywords:** GIS, Language death, documentation, computational linguistics, language mapping

## 1. Introduction to GIS

GIS (Geographic Information System) is software to capture, store, manage and analyze structured data that consist mainly of geographically referenced information. With GIS, for example, one can assign a measure of elevation (the *geospatial information*) to the points of the earth (the *geospatial references*). This elevation model, then, can be mathematically processed or visualized dynamically in maps.

The exploration of a scientific question with GIS begins usually with the inspection of maps generated from the data. A researcher might, for example, add different information layers, each of them describing the flora and fauna of the region onto the elevation model and observe possible interdependences. Does the habitat of an animal depend on the height or the plants or other animals living in that region? How strong are the border lines of habitats and do animals cut across the border lines?

If an observation fits into a scientific framework, the generality of the observation can be tested statistically, using the formal data in the GIS. The data view might, for example, suggest that carnivorous animals cut more easily across habitats, this could be tested not only for the region observed, but for all available data, potentially all known animals of the globe. GIS, like a coin, has two sides. One can look at the data through maps for inspection and process the raw data for testing. It is this double possibility that makes GIS an epistemologically sound and mighty research tool.

## 2. From GIS to Language GIS

### 2.1. From Language to Space

In terms of a linguist, with GIS, one creates and manages a corpus of data that can be used for developing and testing spatial theories (Wright et. al 1997) or theories that rely on data that can be stitched together through spatial and temporal references. Lan-

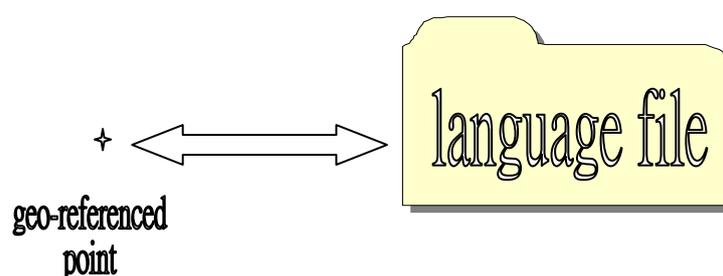

guage data might be thought of being of both types, either directly or indirectly linked to space. But any closer inspection will reveal that space and languages are always indirectly linked, mediated at least through time and the activities of the speaker community

Working on the spatial distribution of whistled languages (Gartner & Streiter 2006, 2007), one would explore the hypothesized link between features of languages, e.g. to be whistled, and spatial features, e.g. to be rough and remote, as suggested in literature. But one cannot understand the origin of whistled languages without reference to the activity of people, e.g. shepherding for El Silbo (Classe 1957) and hunting for Mura Pirahã (Everett 2005). In addition, the whistling of Pirahã might come from a time when the Pirahãs lived in more mountainous regions (c.f. Morris 2007). Time, like the activity are thus an almost indispensable features for language mapping.

The grammaticalization of notions like 'uphill' and 'downhill' (Brown & Levinson 1993) is conditioned by the physical features of the environment and relevant activities in that environment like climbing or descending. Inherent links between a language as such and space do thus not exist, while the tuple language, time and activity might be meaningfully mapped onto space.

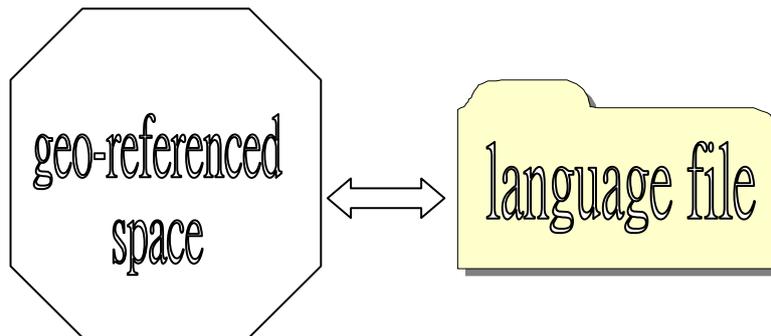

## 2.2. Language Mapping

Language Mapping refers to the modelling of a relation between language related features and geospatial references, as well as compiling data into the model. What characterizes different approaches to language mapping is the way that language features, including language names, are linked directly or indirectly to different types of mathematically defined regions. Technically, languages can be mapped to a point, a line or a polygon. Using a point to map a language, one might take, e.g. for the language French, the centre of Paris as localization, c.f. Figure 1. This model, as everyone understands, might be interesting for a Martian. For a linguist it is only sub-optimal.

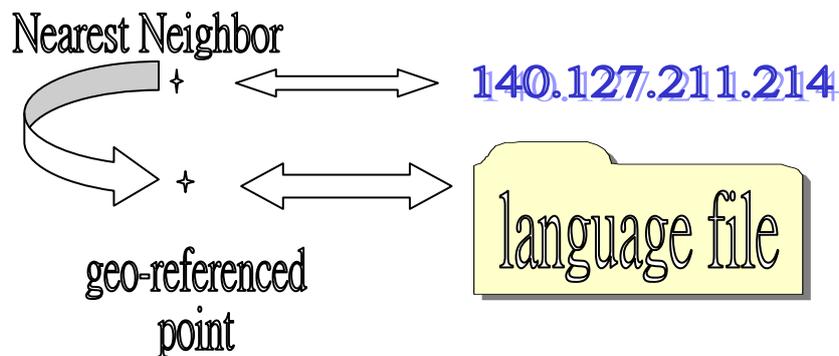

**Figure 1:** *Point-based, direct language mapping: A folder of language-related data is mapped directly onto a point in space and time.*

Lines can be used to represent, for example, migration paths of language communities, or to represent derived, hypothesized language data, such as isoglosses. Most widely used is the polygon and, in the case of French, a multi-polygon. Since a point might always be calculated from the polygon, e.g. in PostGIS as 'update language set gps\_point=centroid(gps\_polygone)', the polygon mapping is to be preferred over the point representation.

**Figure 2:** Polygon based, direct language mapping: A folder of language-related data is mapped onto space and time. A simplified and suboptimal model.

Actually one might find applications where the direct mapping as point or polygon might seem sufficient. The point method, for example, might seem sufficient if one want to map the IP of a web-client to its geospatial references and these to the nearest language, to generate automatically a web-site in the clients language, cf. Figure 3. The polygon might be sufficient for drawing automatically webs, provided that there are reasonably clear border lines.

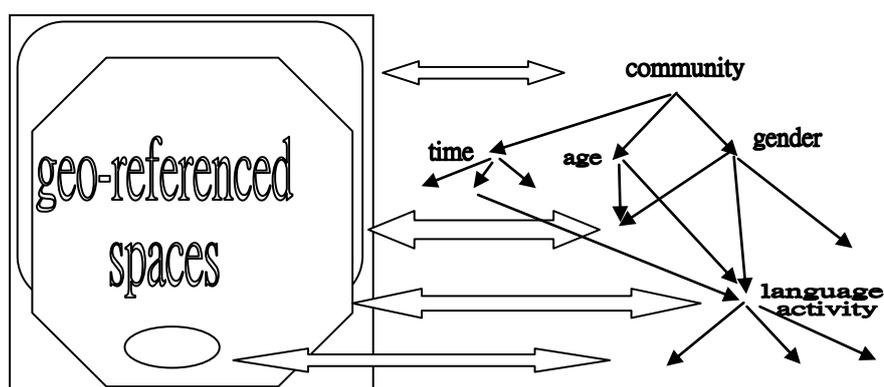

**Figure 3:** Point-based, direct language mapping, a possible application: Mapping IP-addresses to languages files.

Both methods, however, more often than not, map to irrelevant spaces in plain nature or to places where other languages are spoken instead of or in addition to the indicated language. In addition, all types of direct language mapping can quite easily be abused for ideologies, as the relation between language and space is not represented as mediated by time, activities, sub-populations etc, but as somehow supernaturally been given.

Instead, using a community as a basic unit, as suggested by Dahl and Veselinova (2006), one might obtain much richer, more precise and more relevant data. In addition, we suggest that a community can be modelled in the form of a lattice where sub-branches describe gender, activities, age, professions or other factors. These communities can be mapped through time onto a space in the form of a polygon. Nomadic groups, for example, that have different pastures in different times of the year might be mapped

onto different space in time. The hunters of a community are mapped for the time of hunting to another space than the non-hunting part of the community. The tuple of community or sub-community defined through age, activity, gender etc., the place and the time can than be mapped through language activities like ‘reading Arabic’, or ‘writing Mongolian with Cyrillic characters’ onto space and time. As this model is fully functional even if partially underspecified in the absence of data, it is not more difficult to implement and enrich with data. Actually, census data can be easily converted in to a basic language maps if the locations of the communities have been geo-referenced. E.g. for Taiwan, cities and villages are mapped in National Statistics, Republic of China (Taiwan), <http://eng.stat.gov.tw> (2008.10.14). The provided data, available also through XNLRDF map ethnic groups onto cities and villages. Using known percentages of language skill of ethnic groups might be sufficient to create a first model that can be refined step by step, as long as interpolated values are distinguished from hard data.

**Figure 4:** Polygon based, language mapping through communities and language activities.

The benefits of this approach are obvious. Maps can be drawn for different sub-groups or different times of the day or the year. The encounter of language communities can be described or predicted through space and time. Not languages are mapped but language activities, giving a much richer image of the state of a language.

For this model or any other model for language mapping, common standards, however, are crucial, e.g. for the naming of languages, ethnicities, localities, writing systems, language activities or religions. In addition, such standards have to be built on consensus and be publicly available so that data can be mapped. We thus hypothesize that the understanding of the importance of common standards and data sharing, which matured in computational linguistics over many years, will help Language GIS from the ground. Our personal contribution in this light is the development of unambiguous mappings among names of languages, scripts, writing standards, orthographies, ethnicities or other social groups, religions, localities and practices in the framework of XNLRDF. Unambiguous naming is achieved at the cost of longer, sometimes arbitrary names, such as 'Eton (Vanuatu)', 'Eton (Cameroon)', 'Eton (Berkshire)', 'Eton (Georgia, U.S. State)'.

### 2.3. *Obstacles to Language GIS*

Although GIS has become a standard tool in many areas such as conflict management, biology, archeology, the management of heritage sites, journalism and economy, language related research has, with a few noticeable exceptions, yet failed to grasp the implications of this technology, although discussed in linguistic literature already in Williams (1996). As early as 1990, the Linguasphere Project, cited in Williams (1996), tried to map the languages of the world, but the data have not been made available to the community and are probably lost.<sup>1</sup>

A few language studies have since then made use of the map-drawing facility of GIS, e.g. for the creation of language atlases (Crissman 2002) or the mapping of linguistic bibliographic entries (Blundell et al. 2007). GIS has also been used in Language Archiving Projects, e.g. the Formosan Language Archive, for browsing and as a source of meta-data for lexical entries, grammatical structures, language distribution etc. (Weng et al. 2003). GIS has also been used to understand linguistic, cultural and biological diversity on the globe, c.f. (Maffi 2005).

In a maybe first systematic investigation of language mapping for GIS (Dahl & Veselinova, 2006), the question how languages can be linked to geospatial and temporal references is raised. Dahl and Veselinova examine the suitability of the traditional polygon-based, direct language mapping, where a certain space is directly linked to a language. According to the authors, this model is suboptimal, especially for smaller languages, languages in multilingual regions and languages occurring in more than one place (Dahl & Veselinova, 2006). A language name is thus a suboptimal geospatial information to be linked to a geospatial reference. As suggested above, language activities of sub-communities are more informative and maybe less ideological.

Very recently, the need of systematic investigations of Language GIS seems to have been recognized as it is apparent from the set-up of the LL-Map project (<http://www.llmap.org>) and of the Colloquium on Geography and GIS in Language Documentation, scheduled to take place at the University of Hawai'i on March 12-14, 2009.

In spite of these promising steps in Language GIS, it is worth to look at the reasons why linguists have ignored GIS for 20 years. The first reason might related to the research paradigm. Under the influence of generative linguistics many linguists turned away from the study of languages as social phenomenon to a functional study of the human genome. Ignoring GIS helps to stabilize this paradigm that stresses unity instead of diversity. The point-based or polygon-based direct mapping of languages, as used for example in typological studies as in (Haspelmath et al. 2005, 2008), can be seen as minimal commitment to language as a social phenomenon and the variations that result from that.

Another aspect adding to the cold reception of GIS as linguistic tool by linguists might have been the limited acquaintance with now omnipresent technologies like Internet, GPS and XML. But even for those eager to try GIS for language studies, there have been and still are a number of obstacles. First, there is the lack of available data, in addition the linguistic information needed might not be available and the mapping might be suboptimal. Therefore data have to be created before research can start. This however is more a psychological argument than a principled argument, as corpus linguists neither wait for corpora to be sent from heaven. Instead they develop corpora, together with

---

<sup>1</sup> For a discussion about the relation of sharing and preserving data cf. (Streiter, Scannell & Stuflesser 2006).

guidelines of how corpora have to be constructed. In the same line, we have to recognize that proposing models of how languages are mapped to space and time and how such data can be obtained is a linguistic question that merits time and support. Once this space is academically and institutionally granted, the development of data for Language GIS may start.

Second, GIS technology is conceptually and technically more complex than, for example, concordancers. Thus, small projects are less likely to engage in Language GIS. Instead, Language GIS will be started most likely by heterogeneous teams of linguists, information scientists and GIS-experts, mediated, possibly, by computational linguists as the latter have the communicative competence to engage with linguists and computational scientist, two groups which sometimes are difficult to bring together.

### **3. Getting Language GIS from the Ground**

We foresee three possible directions that studies in Language GIS might take. We suggest that computational linguists contribute in these three directions to get Language GIS from the ground, gaining at the same time expertise and resources which position computational linguistics in this new field that otherwise might be contested by information scientists, GIS-experts, linguists or corpus linguists. But any of these groups in isolation might not be in state to tackle the complex question of language mapping.

#### *3.1. Language GIS for Linguists*

One branch in the development of Language GIS will use data as they become available by and by to explore their potential for language-related research. We have argued elsewhere (Streiter 2007), that Language GIS-based studies are scientifically sound through the double nature of the data. One view on the data consists of automatically drawn maps which either focus on a subset of the available data or, as an alternative, compress data for visualization in a map. Thus data can be seen only distorted, filtered or in a zoom and only these visible data can be used for theory formation. Theory testing then can be done using statistics on the entire data set. As the entire data, luckily, can neither be understood nor memorized by a human brain, the research method, from a statistical point of view, is sound. Computational linguistics could help in the process of setting up tools and resources, contributing with their collaborative esprit, their knowledge of open standards and their computational infrastructure, sharpening the understanding of the potentials, needs and problems in this field. A fundamental problem for the development of Language GIS relates to data.

#### *3.2. Language GIS Data*

The second branch of Language GIS research will be concerned with the creation of Language GIS data, for all parts of the world, for modern and historical languages and for an ever growing set of linguistic features (typological features, socio-linguistic features, features describing writing systems etc). Thus, beside the problem of specifying where a language is spoken, Language GIS might include data showing where languages are written, with which writing system, where a language can be reached through radio or television, how street signs are written, where and how languages are taught etc.

In contrast to many GIS data, e.g. on elevation, crops, natural vegetation, population etc, which are freely or easily available (c.f. Decker 2001), Language GIS data are difficult to get or put into usage. Some Language GIS data are either available under a commercial license which impedes further development, as for example the data published by Global Mapping International (2006). Although one might use these data to offer services over the Internet, the usefulness of the data would be limited to the functions provided in the interface. The LL-Map project sets out to create data for Language GIS, but as data are based on the data provided by Global Mapping International, the question remains how these data can be distributed. All available information on the LL-Map project seems to indicate that only services and no data are made available, e.g. the project states a commitment to “An argument for the web services model” (Max Planck Institute, Leipzig 2007). In addition, the data of Global Mapping International are based on the potentially suboptimal polygon-base direct language mapping, shown in Figure 2. None of the LL-Map relevant documents seems to tackle these problems, c.f. <http://www.lmap.org/>.

The ECAI Pacific Language Mapping Project at the Electronic Cultural Atlas Initiative (<http://ecai.org>) aims at the electronic mapping of the languages of the Pacific, South Asia and Madagascar. Data can be freely downloaded and used. However, due to the way the data have been acquired, the naming of languages is unusual and unclear. Language names overlap, for example, only for a small part with the language names used by Ethnologue (<http://www.ethnologue.com>). In addition, names are distorted by spelling errors or, potentially, OCR. As a consequence, hundreds of languages names have to be manually mapped onto more frequently used and unambiguous language names, a work that is done by the author and made available within the XNLRDF-downloads.<sup>2</sup> A varied set of language data and maps is distributed by Ljuba Veselinova at <http://www.ling.su.se/staff/ljuba/maps.html>.

Overall, a situation in which a few research centres have access to GIS data of languages and just provide other researchers with services or tools that allow accessing the data only through an interface is to be avoided as that would impede the growth of science. Imagine, for example, the huge amount of research that would not have been done if corpora like the Penn Treebank (Marcus et al. 1994) would have been accessible through a Web-based interface only, or if Google would not have made its API for Google Maps or Google Web available. The LL-Map project is thus not well conceived and divides the linguistic community into those who have Language GIS data and those who haven't. An API solution, similar to those offered by Google might allow to compromise between ownership of data and promoting research.

By making available as many Language GIS data as possible, even if incomplete or in a suboptimal model, the interested community might limit the respective advantage of retaining Language GIS data, till the point where retaining and not sharing Language GIS data turns into a disadvantage (cf. Streiter, Scannell & Stuflesser 2006).

As for the involvement of computational linguists, we foresee a situation, similar to corpus linguistics, where computational linguists became more and more involved in the creation of corpora, especially of rich corpora, once the potential of corpora had been realized. GIS-data share with corpora a multi-functional potential and will go a similar way. In addition, GIS data conform to concerns of computational linguists with portability. Data are not encapsulated and not compressed, or at least, encapsulated and

---

<sup>2</sup> For more information on XNLRDF cf. (Streiter & Stuflesser 2006) and <http://140.127.211.214/research/nlrdf.html>.

compressed GIS data can be compiled for backup and distribution, e.g., into XML. Although different formats can be transformed and merged in popular GIS tools, incompatibilities or data-loss might occur if the same phenomenon is modeled differently e.g. once as a polygon, e.g. a language distributed over a specific area, or as point, where each speaker or each community would be a distinctive data point (c.f. Galton 2005, Dahl & Veselinova 2006). It is here where standardization efforts might start, extending then to the naming of languages, writing standards, scripts or ethnicities etc within GIS systems.

### *3.3. Language GIS and Computational Linguistics*

The third branch of development will be concerned with conceiving and implementing new applications in language research, Computational Linguistics, Information Retrieval and the simulation of language development. Merging corpora, dictionaries, CALL-systems and NLP-tools with GIS will create new perspectives and new qualities. Before achieving complete merges of GIS data, GIS applications, linguistic data and linguistic applications, one might compile either GIS data into computational linguistic data and applications, or integrate computational linguistic functionalities into a GIS.

This might result in the first case in geospatial references in a computational lexicon, in corpora, in termbanks, giving access to spatial world knowledge, e.g. for anaphora resolution, in extracting geospatial information from text, in creating dynamic web-pages according to the cultural background mapped from the IP address through the geospatial references, text generation, question answering from GIS (translating spatial predicates into NL-predicates), in mapping language communities through IP addresses and much more. An immense research field is basically unexplored.

The integration of computational linguistic applications into GIS might result in geo-referenced dictionaries, dictionary entries, corpora, textual entries from corpora, syntactic structures derived from geo-referenced texts or Optimality Theory (OT) parameters, creating computational models that can calculate over languages, time and space. Technically speaking, GIS can access all kind of computational linguistic data, e.g. through interfaces to databases such as PostgreSQL/PostGIS (<http://www.postgresql.org>, <http://postgis.refractions.net>). For spatial calculations over the maybe precompiled computational linguistic data, GIS provides predefined functions for borders, overlaps, inclusions, densities, distances etc. In addition, phenomena like syntactic structures or lexicon entries can be mapped onto different layers to represent contact and borrowing,

Other research directions might relate to the simulation and prediction of language development in order to predict the endangerment of languages and identify critical zones and constellations for the survival of languages. GIS might also be used as a monitor for the development of languages on the one hand and revitalization or documentation efforts on the other, to manage and coordinate such efforts for an optimal usage of available resources.

## **4. Summary and Conclusion**

To sum up, the overall purpose of this paper is to stimulate the linguistic community to reflect about, experiment with and set up an infrastructure for GIS, a powerful tool, which has entered many sciences (c.f. Lang 2003, WHO 2006) but has passed, with a few exceptions (Crissman 2002, UNESCO 2005, Lin 2006) almost unobserved

by a discipline which cannot deny its relation to space and time. The combination of GIS and languages goes far beyond the drawing of maps and the range of possible applications can barely be overseen at the moment. While showing the principal problems that might interfere with the promotion of Language GIS, we discuss the potential contribution of Computational Linguists in getting Language GIS from the ground. Finally we encourage linguist to reinvest the newly developed technologies and data into the urgent problem of language documentation and language maintenance. While the reformation of linguistics through Language GIS is needed and will happen, the mapping of vanishing languages cannot wait.

## Abstract

TimeML is a specification language for annotating temporal information in text. Since it was developed based on English, it tends to reflect the specificity of English constructions. English is an isolating language, which makes porting TimeML to typologically different languages (e.g., agglutinative ones) challenging. In this paper, we analyze some of these issues based on Korean, an agglutinative language, and suggest possible solutions. We address two general situations. First, cases in which English conveys information by means of two independent events (e.g., quotative and evidential constructions), while Korean employs a single event together with bound morphemes. Second, constructions of verbal periphrasis in English (e.g., involving modal or aspectual auxiliaries) which in Korean correspond to verbal clusters with two separate events.

**Keywords:** TimeML, temporal information, event representation, isolating languages, agglutinative languages, corpus annotation.

## 1. Introduction

The past decade has seen a renewed interest in temporal and event-based reasoning in natural language, applied to a number of tasks, from information extraction to reasoning systems (cf. Allen and Ferguson 1997; Mani and Wilson 2000; Harper et al. 2001; Setzer 2001; Ferro et al. 2005). The most basic issues concern the identification and representation of temporal data in discourse. TimeML, a specification language aiming at capturing the richness of temporal information in natural language, has been created within this context (Pustejovsky et al., 2005) and has recently been adopted as an ISO standard (ISO WD 24617-1:2007).

TimeML was conceived as a surface-based annotation scheme. That is, it does not encode the actual interpretation of the constructions it marks up, but their grammatical features. For example, the *leaving* event in the sentence *We are leaving tomorrow* is not annotated as expressing a future tense, but as expressed by means of a present tense form. Several considerations motivate this surface-based approach. As an annotation language, it must guarantee the marking up of corpora in an efficient and consistent way, ensuring high

inter-annotator agreement. As a representation scheme, it needs to be used for training and evaluating algorithms for both temporal information extraction and temporal reasoning.

A surface-oriented approach is the suitable option for meeting such requirements. Nevertheless, it poses a challenge at the representation level, since it encodes information mainly based on the structure of the target language, and thus content equivalences among different languages are hard to establish. For example, aspectual information is annotated by means of a relation between two event entities, which parallels the syntax of aspectual constructions in English, involving an aspectual predicate (e.g., *begin*) and the event expressed by its subordinated clause. Nonetheless, this representation (i.e., two events linked by a relation) is not adequate for languages conveying aspectual information at the morphological level, such as Slavic ones.

Constructions of indirect quotation in Korean offer a further example of mismatch of linguistic devices employed in different languages to express the same. Where English (and most other Indo-European languages) uses specific verbs (e.g., *say*, *tell*) syntactically scoping over the reported event, in Korean the reported event is generally marked by the mood morpheme *-ko*. As in the previous case, English quotative constructions are annotated using a link between the two events. But because of the morphological nature of the phenomenon in Korean, this is not a satisfactory solution for that language.

The goal of the present research is to establish equivalent TimeML representations for phenomena expressed by different constructions across languages, which can reflect the grammatical specificity of each construction (morphologic vs. syntactic) and at the same time ensure a semantic correspondence. We work with some of the Korean constructions that are realized in different ways than their English counterparts, due to the different typology (agglutinative vs. isolating) of these two languages.

Next section summarizes TimeML, paying specific attention to the elements that will be needed in what follows. Then, section 3 delves into the correspondence between English and Korean TimeML representations of temporal- and event-related constructions. Two general situations are addressed. First, English conveys information by means of two independent event expressions (e.g., quotative and evidential constructions), while Korean employs a single event together with one or more morphemes (section 3.1). Second, those structures realized with a verbal periphrasis in English (e.g., constructions with modal and aspectual auxiliaries) but with a verbal cluster in Korean, composed of two distinguished event-tagable expressions (section 3.2).

## 2. TimeML in a Nutshell

TimeML features four major data structures: EVENT, TIMEX3, SIGNAL, and LINK. EVENT, TIMEX3 and SIGNAL are text-consuming tags. The **EVENT** tag encodes event-denoting expressions, which can be expressed by different predicative elements; mainly, verbs (e.g., *dance*, *play*), nouns (*embargo*, *election*), adjectives (*willing*, *expectant*), and prepositional phrases (e.g., *on board*). The **TIMEX3** tag annotates temporal expressions of different sorts: fully specified dates, times, and durations (respectively: *Tuesday*, *October*

28, 2008; *midnight of January 1, 1994*; and *4 months*), or just partially specified dates, times, and durations (*two days ago*; *some time tomorrow*, and *few months*). Finally, the **SIGNAL** tag annotates elements that indicate how temporal objects are related among them (e.g., subordinating connectors such as *when* or *after*).

On the other hand, the LINK tag is non-text consuming as it relates temporal objects to one another. It splits into three main types: (a) **TLINK**, which encodes temporal relations among EVENTS and TIMEX3s; (b) **ALINK**, representing aspectual information as expressed between an aspectual predicate and its embedded event; and (c) **SLINK**, encoding subordination relations conveying evidentiality (e.g. *Mary **said** [she bought some wine]*), factivity (*John **regretted** [Mary bought wine]*), or intensionality (*Kate **thought** [Mary bought beer]*).

Information relevant to each tag is characterized by means of attribute-value pairs. The current research concerns the tags EVENT, SLINK, ALINK, and TLINK, so here we only introduce the attributes that are relevant to these tags. EVENT attributes are: event ID (*eid*), event instance ID (*eiid*), class (e.g., perception, reporting, aspectual, state, etc.), tense (present, past, future), aspect (perfective, progressive, etc.), pos (part-of-speech), vform (form of non-finite verbs, such as infinitive, gerundive, etc.), polarity, modality, and mood.

On the other hand, SLINKs are characterized by the attributes: link ID (*lid*), eventInstanceID (which points to the subordinating event), subordinatedEventInstance (pointing to the subordinated event), and *reltype*, with possible values: *factive*, *counter-factive*, *evidential*, *negative-evidential*, *modal*, and *conditional*.

Finally, ALINKs and TLINKs have the attributes: link ID (*lid*), eventInstanceID and *relatedToEventInstance* (both of them taking event IDs as their values), and *reltype*. This later attribute has different values for TLINKs and ALINKs. For the former, these are: *before*, *after*, *ibefore*, *iafter*, *including*, *is\_included*, *during*, *during\_inv*, *begins*, *ends*, *begun\_by*, *ended\_by*, *simultaneous*, *identity*. And for the later: *initiates*, *culminates*, *terminates*, *continues*, *reinitiates*. As an example, (1) illustrates the use of these tags:

(1) John said<sub>e1</sub> that Mary began<sub>e2</sub> to work<sub>e3</sub>

*John*

```
<EVENT eid="e1" class="REPORTING" tense="PAST" aspect="NONE"
  polarity="POS">
```

*said* </EVENT>

*that Mary*

```
<EVENT eid="e2" class="ASPECTUAL" tense="PAST" aspect="NONE"
  polarity="POS">
```

*began* </EVENT>

*to*

```
<EVENT eid="e3" class="OCCURRENCE" tense="NONE" aspect="NONE"
  polarity="POS">
```

*work* </EVENT>

```
<TLINK eventID="e1" relatedToEventInstance="e2" relType="AFTER"/>
```

```
<SLINK eventID="e1" subordinatedEventInstance="e2"  
  relType="EVIDENTIAL"/>  
<ALINK eventID="e2" relatedToEventInstance="e3"  
  relType="INITIATES"/>
```

Sentence (1) presents three EVENT expressions (*said*, *began*, and *work*), an SLINK conveying a relation of type evidential between events *e1* (*said*) and *e2* (*began*), a temporal relation between these two same events (*e1* took place after *e2*), which is annotated by means of a TLINK, and an aspectual construction (*began to work*), encoded with an ALINK of type *initiates*. Due to space limitations, some EVENT attributes are obviated.

### 3. Porting TimeML to Korean

In the past years, there has been much research carried out within the field of Natural Language Processing (NLP) which has targeted Asian languages, including Korean. Nonetheless, there are still clearly identifiable gaps when comparing the NLP state-of-art NLP between most Asian languages and English. For example, it does not exist yet any system for identifying temporal information and applying temporal reasoning, which is specifically focused on the Korean language. Temporal systems are fundamental components of several NLP applications, such as information extraction, question answering, or narrative understanding (cf. Pustejovsky et al. 2005). Porting TimeML to Korean is therefore a fundamental step towards the advancement of several fields within Korean NLP.

TimeML has recently become an ISO standard markup language for time-related information. Among other languages, the ISO-TimeML spec includes Korean, although a fully-fledged version addressing all the specificities of this language has not been completed yet. Currently, the Korean part of ISO-TimeML, written by Kiyong Lee, mainly reflects a conceptual analysis of how temporal information is conveyed in Korean. The next step is thus finding out what problems there are in porting TimeML to Korean regarding forms rather than interpretational level, and subsequently setting the subset of TimeML that is suitable for representing Korean, as well as its corresponding annotation guidelines. In what follows, we identify some of these issues and consider what could be adequate solutions to them.

#### 3.1. Information Expressed by a Single Morpheme

### 3.1.1. Quotative Construction

The main issues in porting TimeML to Korean are due to the typological differences between Korean and English.<sup>1</sup> TimeML was developed using English as the reference language, and given that it was conceived as a highly surface-based annotation scheme, the structure of English is often reflected in the choices made regarding its tags and attributes.

English is a rather isolating language, and therefore many levels of linguistic distinctions are expressed in a periphrastic manner. On the other hand, an agglutinative language such as Korean tends to use morphological combinations to express its grammatical distinctions (e.g. markers of evidentiality, sentence mood morpheme, etc.). For example, quotation constructions in English use two predicates, the reporting and the reported one, which TimeML marks up as independent EVENTS:

(2) John said<sub>e1</sub> that he bought<sub>e2</sub> some wine.

```
John
<EVENT eid="e1" class="REPORTING" tense="PAST" aspect="NONE"
  polarity="POS">
said
</EVENT>
that he
<EVENT eid="e2" class="OCCURRENCE" tense="PAST" aspect="NONE"
  polarity="POS">
bought
</EVENT>
some wine.

<SLINK eventInstanceID="e1" subordinatedEventInstance="e2"
  relType="EVIDENTIAL" />
```

TimeML uses a subordination link (SLINK) in order to convey the evidentiality feature that the reporting predicate projects to the event expressed by its subordinated argument.

On the other hand, Korean quotative constructions, such as that in (3), consists of only one verb stem, which corresponds to the subordinated predicate in English. Note that there is no reporting predicate such as *say* in English. Nevertheless, the sentence has a reporting interpretation.

(3) 존-이 그가 와인-을 사-쓰-다-ㄴ-다<sup>2</sup>  
John-i ku-ka wine-ul sa-ss-ta-n-ta  
J-Nom he-Nom wine-Acc buy-Past-Dec.Quo-Pres-Dec

<sup>1</sup> From the morphological point of view, languages can be classified as isolating (also known as analytic) or agglutinative. Isolating languages are those in which words are composed of a single morpheme. By contrast, words in agglutinative languages tend to consist of several morphemes. Korean is an agglutinative language whereas English is an isolating one.

<sup>2</sup> This sentence has ambiguity brought by anaphora. But because this issue is not related to the topic of this paper, we will not address it here, choosing only one of the possible readings.

‘John said that he bought some wine’

The quotative expression *-ta-n-ta* above is a contracted form of *-ta-ko malha-n-ta* ‘Dec-Quo say-Pres-Dec’. Even though example (3) is a simple sentence involving no subordination at the syntactic level, the two distinguished tense markers, ‘-ss-’ and ‘-n-’, are evidence of the existence of an implicit reporting event. Specifically, the past tense marker ‘-ss-’ applies to the main event here (buying), while the present tense marker ‘-n-’ is understood as applying to an implicit reporting event. As additional evidence in favor of two independent events, there are also two different sentence mood markers.

The sentences in (4) and (5) show that each of the two tense markers is related with one event separately.

- (4) a. 존-이 그-가 와인을 사-ㄴ-다-ㄴ-다  
John-i ku-ka wine-ul sa-n-ta-n-ta  
J-Nom he-Nom wine-Acc buy-Pres-Dec.Quo-Pres-Dec  
‘John says that he will buy some wine’  
b. reporting time < speaking time < buying time

- (5) a. 존-이 그-가 와인을 사-ㅅ-대-ㅅ-다  
John-i ku-ka wine-ul sa-ss-tay-ss-ta  
J-Nom he-Nom wine-Acc buy-Past-Dec.Quo-Past-Dec  
‘John said that he bought a wine’  
b. buying time < reporting time < speaking time

In (4a), the sentence has two present tense markers, one of which applies to the reporting event and the other to the buying event, separately. The resulting temporal order among events and speaking time is shown in (4b). On the other hand, the sentence in (5a) has two past tense markers, which results in the temporal order among events that is shown in (5b).

Constructions like these presented above pose problems for the standard TimeML treatment of quotative constructions. Although they are just simple sentences, the relationship between the reporting and reported events is expressed morphologically, and thus the SLINK mechanism employed in English to relate both (surface-expressed) events does not seem to apply here. On the other hand, the reported nature of the main event in Korean sentences (corresponding here to the buying event) cannot be marked by means of an EVENT attribute because it actually stems from a relation between two events (one of them implicit), which are both characterized with specific tense and mood values.

Nevertheless, the evidence of an implicit reporting event argues in favor of marking two independent EVENTS, each of which with different tense and sentence mood values. But because there is no surface predicate for the implicit reporting event, it needs to be annotated as a non-text consuming EVENT, as shown in (6):

- (6) 존-이 그-가 와인-을 사-ㅅ-다-ㄴ-다  
John-i ku-ka wine-ul sa-ss-ta-n-ta

J-Nom he-Nom wine-Acc buy-Past-Dec.Quo-Pres-Dec  
 ‘John says that he bought some wine’

*John-i wine-ul ku-ka*

```
<EVENT eid="e1" class="OCCURRENCE" tense="PAST"
  sentenceMood="DEC" yaleRomanization="sa-ss-ta-n-ta">
sa-ss-ta-n-ta </EVENT>
```

```
<EVENT eid="e2" class="REPORTING" tense="PRESENT"
  sentenceMood="DEC"/>
```

```
<SLINK eventInstanceID="e2" subordinatedEventInstance="e1"
  relType="EVIDENTIAL"/>
```

```
<TLINK eventInstanceID="e1" relatedToEventID="e2"
  relType="BEFORE" />
```

As can be seen, the semantic and grammatical features of the implicit event (i.e., event class, tense, and mood) are annotated as attribute values in that empty EVENT tag, and then the adequate SLINK and TLINK relating the (explicit) reported event and the (implicit) reporting event can be introduced.

To sum up, tense and sentence mood markers in Korean quotative constructions provide grammatical evidence for the existence of two different events. Based on that, TimeML can annotate these constructions by means of two EVENT tags together with the appropriate links relating them (SLINK and TLINK). Because the construction has only one verb form at the surface, TimeML needs to appeal to a non-text consuming EVENT tag.

### 3.1.2. Evidential Constructions

In contrast to quotative constructions, there are other structures in Korean that do not present morphological evidence in favor of the existence of implicit events, which nevertheless need to be interpreted as involving two (or even more) events. This is for instance the case of evidential constructions in Korean.

Broadly speaking, evidentiality is concerned with the way the information that is conveyed in statements was acquired by the speaker. As such, it concerns distinctions like: direct perception, hearsay, inference, assumption, etc. In Korean, there are many evidential morphemes. Here are some examples.

- (7) a. 존-이 와인-을 사-더-라  
 John-i wine-ul sa-**te**-ra  
 J-Nom wine-Acc buy-**Retro**-Dec  
 ‘I saw that John was buying some wine’
- b. 아이-가 참 예쁘-네  
 ai-ka cham yeppu-**ney**  
 child-Nom really pretty-**Evi**  
 ‘(Now I see) the child is really pretty’
- c. 존-이 와인-을 사-리 가-쓰-구나

- John-i wine-ul sa-re ka-ss-**kwuna**  
 J-Nom wine-Acc buy-to go-Past-**Evi**  
 ‘(I guess) John went to buy some wine’
- d. 메리-는 참 착하-지  
 Mary-nun cham chakha-**ci**  
 M-Top really kind-**Evi**  
 ‘(I already know) Mary is really kind’

The final endings ‘-ney’, ‘-kwuna,’ and ‘-ci’ are all evidential markers in Korean: ‘-ney’ expresses the speaker’s realization of some information by perception at the present time; ‘-kwuna’ is usually considered to express knowledge by inference; and ‘-ci’ denotes previously acquired knowledge. The morpheme ‘-te-’, a marker of retrospective mood, is also considered an evidential marker, since it has comparable behavior both conceptually and grammatically. In spite that there is no predicate denoting a seeing event, ‘-te-’ conveys it and temporally locates before the speaking time.

On the other hand, being an isolating language, English expresses evidentiality in a periphrastic manner. Hence, the TimeML treatment of these constructions consists in marking the two involved predicates as EVENTS, and introducing an SLINK between them:

(8) I saw<sub>e1</sub> that John bought<sub>e2</sub> some wine

```

I
<EVENT eid="e1" class="PERCEPTION" tense="PAST" aspect="NONE"
  polarity="POS">
saw </EVENT>
that John
<EVENT eid="e2" class="OCCURRENCE" tense="PAST" aspect="NONE"
  polarity="POS">
bought </EVENT>
some wine

<SLINK eventInstanceID="e1" subordinatedEventInstance="e2"
  relType="EVIDENTIAL"/>

```

Let us now consider the Korean counterparts:

(9) a. Periphrastic

존-이 와인-을 사-는 것-을 내-가 보-았-다  
 John-i wine-ul sa-nun kes-ul nay-ka po-ass-ta  
 J-Nom wine-Acc buy-rel.ending thing-Acc I-Nom see-Past-Dec  
 ‘I saw that John bought some wine’

b. Morphological

존-이 와인-을 사-더-라

John-i wine-ul sa-te-ra  
 J-Nom wine-Acc buy-Ret-Dec  
 ‘(as I saw) John bought some wine’

Korean has both a periphrastic and a morphological way for expressing evidentiality. Annotating the periphrastic version (9a) with the standard TimeML treatment poses no problem because it has two predicates denoting events like English counterpart.

(10) *John-i wine-ul*

```
<EVENT eid="e1" content="BUY" class="OCCURRENCE"
  tense="PRESENT" aspect="NONE" polarity="POS">
sa-nun </EVENT>
Kes-ul nay-ka
<EVENT eid="e2" content="SEE" class="PERCEPTION" tense="PAST"
  aspect="NONE" polarity="POS" >
po-ass-ta </EVENT>

<SLINK eventInstanceID="e2" subordinatedEventInstance="e1"
  relType="EVIDENTIAL" />
```

Morphological constructions, however, are harder to handle (9b). They are similar to quotative constructions in the sense that, although there is only one predicate expressed at the surface, the sentence refers to more than one event. For instance, in the case of (9b), there is the implicit reference to a seeing event, brought about by the retrospective mood morpheme ‘-te-’. Unlike quotative constructions, however, there is no morphological evidence of the implicit event; e.g., tense or sentence mood markers independent of those applied to the only verbal predicate in the sentence. The issue to consider is therefore whether to treat these evidential constructions in the same way as quotative constructions (namely, introducing a non-text consuming EVENT --refer to example 6), or to handle them by specifying the evidential value of the main predicate at the mood attribute of its EVENT tag, as illustrated in (11).

(11) 베트남-은 참 덥-더-라  
 Vietnam-un cham tep-te-la  
 Vietnam-Top really hot-Ret-Dec  
 ‘(as I saw) Vietnam was really hot’

```
Vietnam-un cham
<EVENT eid="e1" content="HOT" class="STATE" pos="ADJECTIVE"
  tense="NONE" mood="RETROSPECTIVE" >
tep-te-ra </EVENT>
```

ISO-TimeML uses the mood attribute for retrospective mood, thus not introducing any non-consuming tag and respecting, in this way, the surface-based philosophy of TimeML. This is, however, different than the English counterpart, which presents two EVENTS related

with a TLINK signaling their relative temporal order. But besides the mismatch between the English and the proposed Korean treatment, the main drawbacks of treating evidential markers by means of the mood attribute are two. First, by not annotating the implicit event, the representation loses information concerning the temporal relation between this and the explicit event. And second, there is the practical issue of how to annotate sentences with more than two mood markers. Consider (12):

- (12) 내일        비-가    오-ㄴ-다-더-라  
 nayil       pi-ka    o-n-ta-te-la  
 tomorrow rain-Nom come-Pres-Dec.Quo-Ret-Dec  
 ‘(as I heard) (someone said that) it will rain tomorrow’

The above sentence has two mood morphemes: quotative ‘-ta-’ and retrospective ‘-te-’. Data like this favor to the use of a non-text consuming EVENT tag which can be related to the explicit EVENT by means of an SLINK, very much as it is done for evidential constructions in English.

- (13) 존-이 와인-을 사-더-라

*John-i wine-ul*

```
<EVENT eid="e1" yaleRomanization="sa-te-la" class="OCCURRENCE"
  tense="PRESENT" aspect="NONE" polarity="POS">
```

```
sa-te-ra </EVENT>
```

```
<EVENT eid="e2" class="PERCEPTION" tense="PAST"
  polarity="POS"/>
```

```
<SLINK eventInstanceID="e2" subordinatedEventInstance="e1"
  relType="EVIDENTIAL"/>
```

```
<TLINK eventInstanceID="e2" relatedToEventInstance="e1"
  relType="OVERLAP"/>
```

The use of non-text consuming EVENT tag is not compliant with the surface-based annotation philosophy followed in TimeML. However, it makes it possible to recover information regarding implicit events in discourse and seems closer to the conceptual level.

### 3.2. Information expressed at the Verbal Cluster

In the previous section, we analyzed some problems regarding the TimeML annotation of linguistic information realized at the morphological level in Korean. Here, we show a different kind of problem in porting TimeML to morphological languages.

Korean has many kinds of verbal clusters consisting of two verbs and their associated morphemes. These constructions are devices to represent grammatical elements such as aspect, voice, modality, etc. Consider the following examples:

- (14) a. 메리-가 울-고        있-다  
 Mary-ka wul-ko        iss-ta

M-Nom cry-ending exist-Dec

‘Mary is crying’

b. 메리-는 존-이 와인-을 사-게 하-였-다

Mary-nun John-i wine-ul sa-key ha-ess-ta

M-Top J-Nom wine-Acc buy-ending do-Past-Dec

‘Mary caused John to buy some wine’

c. 메리-가 와인-을 사-야 하-ㄴ-다

Mary-ka wine-ul sa-ya ha-n-ta

M-Nom wine-Acc buy-ending do-Pres-Dec

‘Mary should buy some wine’

In (14a), ‘-ko iss-’ is a progressive aspect marker composed of the connection ending ‘-ko’ and the verb ‘iss-’, which means *exist* or *be*. In (14b), ‘-key ha-’ is a causative construction. Finally, ‘-ya ha-’ in (14c) is a modality expression which denotes necessity. The fact that these constructions use both morphemes and verbs makes it difficult for them to be annotated in TimeML. Next, we describe the problems more specifically and suggest possible solutions for the aspectual and modal constructions.

### 3.2.1 Aspectual Construction

In English, aspect is realized by means of a periphrastic construction involving one or more auxiliary verbs and the main verb (in bold face below).

(15) Mary **has gone** to New York

*Mary has*

```
<EVENT eid="e1" class="OCCURRENCE" tense="PRESENT"
  aspect="PERFECTIVE" polarity="POS">
```

*gone* </EVENT>

*to New York*

TimeML applies the EVENT tag only to its head, if the event is expressed by a verbal phrase. Therefore, it does not annotate auxiliary verbs and encodes the aspect information at the *aspect* attribute, within the EVENT tag of the main verb. Now consider the Korean aspectual construction:

(16) 메리-는 뉴욕에 가-(어) 있-다

Mary-nun New York-ey ka-(e) iss-ta

M-Top New York-to go-ending exist-Dec

‘(lit.) Mary went to New York and stays there’

‘Mary has gone to New York’

ISO-TimeML proposes to annotate the verb phrase together as in (17).

(17) 미아-가 미국-에 가-(어) 있-다  
 Mia-ka mikwuk-ey ka-(e) iss-ta  
 M-Nom USA-to go-(ending) exist-Dec  
 ‘Mia has gone to USA’

*Mia-ka mikwuk-ey*

```
<EVENT eid="e1" yaleRomanization="ka iss-ta" content="GO"
  class="STATE" pos="VERB" tense="NONE" aspect="PROGRESSIVE">
ka iss-ta </EVENT>
```

Nevertheless, this approach is not compliant with the TimeML surface-based annotation philosophy. So we need to consider the other ways of annotation for this case. There can be two. A first possibility is to annotate only the verb ‘ka-(e)’ but not ‘iss-’ (18), hence treating it as a kind of auxiliary verb. The aspect and tense information of the whole sentence is encoded at the *tense* and *aspect* attributes. This solution goes along the lines of the treatment for the equivalent constructions in English:

(18) *Mia-ka mikwuk-ey*

```
<EVENT eid="e1" class="OCCURRENCE" tense="PRESENT"
  aspect="PERFECTIVE" polarity="POS">
ka-(e) </EVENT>
iss-ta
```

The second possible solution consists in annotating both events as such, and then connecting them via a TLINK:

(19) *Mia-ka mikwuk-ey*

```
<EVENT eid="e1" class="OCCURRENCE" tense="NONE" aspect="NONE"
  polarity="POS">
ka-(e) </EVENT>
<EVENT eid="e2" class="STATE" tense="PRESENT" aspect="NONE"
  polarity="POS">
iss-ta </EVENT>

<TLINK eventInstanceID="e1" relatedToEventInstance="e2"
  relType="I_BEFORE"/>
```

This second option is surface-based, hence respecting TimeML basic philosophy, but it cannot express the perfective aspectual value because neither of the represented events has aspect. Many modal expressions bring about the same problem, as discussed in the next section.

### 3.2.2. Modality

In English, modality is expressed in a periphrastic way, in many cases by means of auxiliary verbs. TimeML encodes this information at the attribute `modality` that is assigned to the main verb:

(20) I must buy some wine

*I must*

```
<EVENT eid="e1" class="OCCURRENCE" tense="PRESENT"
  aspect="NONE" modality="must" polarity="POS">
```

*buy* </EVENT>

*some wine*

Now consider the Korean counterpart of modal constructions:

(21) 나-는 와인-을 사-야 하-ㄴ-다

na-nun wine-ul sa-ya ha-n-ta

I-Top wine-Acc buy-modal do-Pres-Dec

'I must buy some wine'

The combination of a morpheme and a verb stem derives into the modal expression '-ya ha-' in Korean. It is not one word, unlike English modal auxiliary verbs (e.g., *must*). In spite of that, the proposed treatment in ISO-TimeML considers the two elements as one chunk and annotates them together. This is specifically the solution it proposes for handling the verb stem 'o-' and the conjectural modal expression '-l kesita':

(22) 부산-에-는 지금 비-가 오-ㄴ 것-이다

Pusan-ey-nun cikum pi-ka o-l kes-ita

Pusan-in-Top now rain-Nom come-ending thing-Dec

'Now, it will be raining in Pusan'

*Pusan-ey-nun cikum pi-ka*

```
<EVENT eid="e1" content="COME" class="OCCURRENCE" pos="VERB"
  tense="NONE" modality="CONJECTURAL" verbalEnding="sFINAL">
```

*o-l kes-ita* </EVENT>

Nevertheless, such treatment is not compliant with the TimeML surface-based annotation philosophy. Let us go back to the modal construction of necessity in (21). Similar to aspectual constructions in Korean, there are also two possible annotations for modal expressions in Korean. One is to consider the verb 'ha-' as an auxiliary verb and not to annotate it:

(23) *na-nun wine-ul*

```
<EVENT eid="e1" class="OCCURRENCE" tense="PRESENT"
  aspect="NONE" polarity="POS" modality="-ya ha-">
```

*sa-ya* </EVENT>

*ha-n-ta*

This solution is consistent with the treatment for the English counterpart, but is not surface-based. The second possibility consists in annotating both verbs as EVENTS and introducing a TLINK expressing that they are identical (`relType="IDENTITY"`), given that there is only one event expressed in fact by of the sentence.

(24) *na-nun wine-ul*

```
<EVENT eid="e1" class="OCCURRENCE" tense="PRESENT"
  aspect="NONE" polarity="POS" modality="NECESSITY">
  sa-ya </EVENT>
<EVENT eid="e2" class="OCCURRENCE" tense="PRESENT"
  aspect="NONE" polarity="POS">
  ha-n-ta </EVENT>
```

```
<TLINK eventInstanceID="e1" relatedToEventInstance="e2"
  relType="IDENTITY"/>
```

This is, however, a more complicated and redundant solution, since it marks up two elements that refer to the same entity.

#### 4. Conclusion and Future Work

TimeML annotation scheme was developed taking English as the language of reference, which typologically belongs to the group of isolating languages. Given TimeML surface-based approach to annotating temporal information in text, porting it to agglutinative languages such as Korean poses problems regarding different types of constructions. Where English resources to expressing grammatical or semantic information in a periphrastic way, Korean tends to appeal to different types of morphological combinations.

In this paper, we analyzed some Korean constructions that do not have an easy treatment within TimeML and suggested possible solutions. In particular, we address two general situations. English conveys information by means of two independent event expressions (quotative and evidential constructions), while Korean employs a single event together with one or more morphemes. On the other hand, those structures realized with a verbal periphrasis in English (constructions with modal and aspectual auxiliaries) but with a verbal cluster in Korean, composed of two distinguished event-tagable expressions.

For all these cases, we considered two alternative solutions: a first one that is surface-based and, consequently, language-specific, and a second one that parallels the annotation structure for English and which therefore conveys a conceptual analysis of the Korean structure. We consider this second option more useful for potential tasks concerning the extraction of implied events. But it has potentially lower inter-annotator agreement, and thus can lead to less consistently annotated data.

Together with the ISO-TimeML proposal, the present research is one of the first steps towards porting TimeML to languages very different from English, such as agglutinative ones, focusing in particular on Korean. In this work, we did not choose between the alternative solutions that we put forward, since making a final decision requires deepening into the theoretical analysis of Korean grammar, as well as enlarging the data sets to explore. This is, in fact, research that we are carrying on at present, and which we expect will lead to conclusive results in a near future.

# An Exemplar-based Approach to Automatic Burst Detection in Spontaneous Speech

Yao Yao

University of California, Berkeley  
1203 Dwinelle Hall, Linguistics Department, UC Berkeley, CA94720  
yaoyao@berkeley.edu

## Abstract

This paper introduces a novel algorithm for detecting burst in voiceless stops in spontaneous speech. This algorithm uses an exemplar-based approach for detecting aspiration noise, and avoids the normalization problem since the exemplars are inherently speaker-specific and environment-specific. The algorithm is trained and tested on 19 speakers' data. The overall error is estimated to be under 5 ms. We also show the wide range of variation in the phonetic makeup of stops in spontaneous speech and how the algorithm is improved to deal with the difficult cases.

**Keywords:** automatic burst detection, VOT, spontaneous speech.

## 1. Background

### *1.1 Methodological issue in research on pronunciation variation*

In recent years, as many large-scale speech corpora (TIMIT, Switchboard, the Buckeye corpus, among others) are made available, quantitative analysis of these corpora has become an active new research area. In a seminal work, Keating et al. (1994) demonstrated two studies on the TIMIT corpus of read speech: a transcription study on segmental variation and an acoustic study using the audio signal. Since then, a growing body of literature has developed in the area of pronunciation variation in spontaneous speech (Byrd 1993; Keating 1997; Jurafsky et al. 1998, 2002; Gregory et al, 1999; Bell et al 2003, to appear; Raymond et al, 2006; Gahl, 2008; among others). However, the majority of these studies are limited to segmental and durational variation, such as shortening/lengthening, t/d deletion, flapping, and vowel alternation. Acoustic signal analysis is relatively rare (maybe with the only exception of vowel formants). This asymmetry in the literature is at least partly due to the fact that segmental/durational variation is easy to code as the information is already available in the transcription.

However, as the research on pronunciation variation develops in both depth and breadth, it becomes necessary to go beyond the transcription files and enter the acoustic signal. In order to do so, new methods need to be developed for extracting phonetically-important information from the speech data.

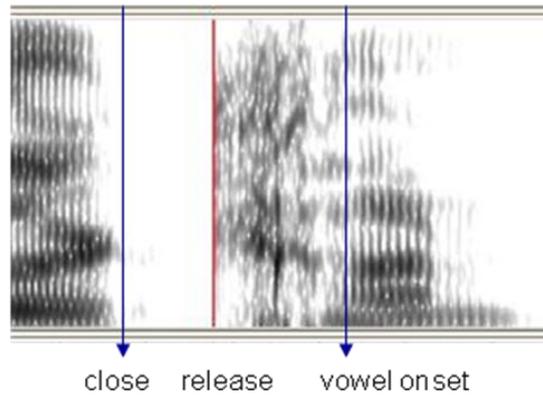

For many acoustic measures, there already exist automatic processing techniques. Nonetheless, these techniques are mostly developed for speech

engineering and may not be directly applicable to the type of the research discussed here. Among other things, the techniques used in speech engineering are often designed to aid speech recognition and therefore precision (either in time domain or in frequency domain) is not of the highest concern. In pronunciation variation studies, however, precision is highly important, both because the acoustic measures are the actual objects of investigation, and that the size of the effect that researchers are looking for is often very small. For instance, it is not uncommon that certain factors are found to correlate with less than 5% of the variation in the acoustic measure, which would require the random error in the acoustic measure to be well under 5%.

### *1.2 The current study*

In this paper, we report an attempt to address the above methodological issue, by presenting a case study on automatic burst detection in English voiceless stops. Automatic burst detection is widely used in speech engineering. The prevailing algorithm is one that detects the point of maximal energy change in high frequencies (Liu 1996; Niyogi and Ramesh, 1998; Das and Hansen, 2004). Liu (1996) reported an automatic burst detector as part of a larger landmark detecting system. The detector was trained on four speakers' read speech recordings (20 sentences per speaker) and was tested on two new speakers' recordings of 20 new sentences. In the training set, the detector had 5% deletion errors (i.e. missing real bursts) and 6% insertion errors (i.e. detecting spurious bursts) while in the test set, the rates are 10% and 2%, respectively. Liu didn't specify the temporal precision of the burst detector, but it was mentioned that of all landmarks (three different types altogether), 44% were detected within 5ms of the hand-labeled transcription, and 73% within 10ms. Though the system was not designed with high precision requirement, it still serves as a baseline model for the current study.

Our system makes use of a different approach. The general idea is that before burst (i.e. during closure phase), the spectrogram is similar to that of silence, while after burst (i.e. during aspiration phase), the spectrogram is similar to that of a fricative (see Figure 1). Therefore, the program finds the point of burst by constantly comparing the spectra of a moving time window to the spectral templates of silence and fricatives and looking for the point where silence-like-ness suddenly drops and fricative-like-ness suddenly rises. The system is trained and tested on 19 speakers' data from the Buckeye speech corpus (Pitt et al., 2007). The average temporal error is estimated to be within 5ms. The spectral template approach was first introduced in Johnson (2006), as an attempt to automatically analyze large speech corpora in a speaker-specific way. The main advantage of this approach is that it is inherently sensitive to differences among talkers and recording environments and therefore is more generalizable to new data.

**Figure 1.** Spectrogram of a typical voiceless stop (the blue arrows mark the beginning and the end of the stop, while the red line marks the point of release.)

## 2. Data

### 2.1. Corpus

The Buckeye Corpus contains interview recordings of 40 speakers, all local residents of Columbus, OH. Each speaker was interviewed for about an hour with one interviewer. Only the interviewee’s speech was digitally recorded. At the time of this study, 20 speakers’ transcription was available, among which, one speaker’s data were not used due to inconsistencies in the transcripts. The remaining 19 speakers are nearly balanced in gender and age (10 female, 9 male; 10 above 40 years, 9 under). Non-linguistic sounds, including silence, noise, laughter, and interviewer’s speech, are also time-marked in the transcription. Silence in a running speech flow is not transcribed as silence, but attributed to neighboring sounds.

### 2.2. Target set

Since word-medial stops are often flapped in American English, we limit our target set to word-initial [p], [t] and [k], of which each speaker has from 231 to 1243 tokens (see Table 1).

Speaker	F01	F02	F03	F04	F05	F06	F07	F08	F09	F10
N	674	572	777	900	1243	490	231	449	699	412

Speaker	M01	M02	M03	M04	M05	M06	M07	M08	M09
N	514	931	624	793	657	406	541	557	628

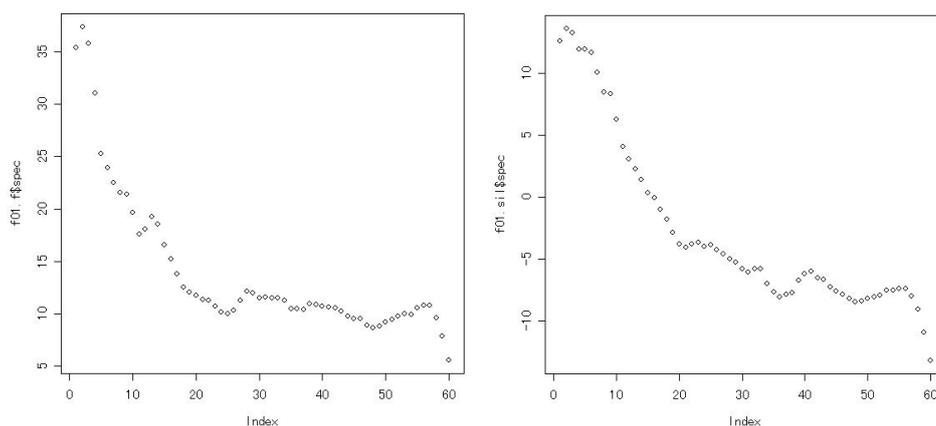

**Table 1.** Count of target tokens in all speakers (top: female speakers; bottom: male speakers). N= number of tokens

### 3. Algorithm design

In view of the pattern in Figure 1, we build spectral templates of silence and voiceless fricatives for each speaker, and use these templates as references for evaluating how silence-like and fricative-like a certain chunk of acoustic data is.

#### 3.1. Building spectral templates

Separate spectral templates are built for silence and voiceless fricatives of each speaker, using the following procedure. First, find all tokens of the phone in the speaker's speech data and discard the ones that are shorter than the medial duration (which would technically exclude half of the tokens). For each remaining token, calculate a 1X60 Mel frequency spectral vector using a 20 ms analysis window centered at the center of the phone and average across all tokens. The final template consists of an average Mel spectral vector, as well as the standard deviation of each dimension. Figure 2 below illustrates the spectral templates of [f] and silence of one speaker as examples.

**Figure 2.** The Mel spectral vector in the templates for [f] (left) and silence (right) of speaker F01. The X-axis represents 60 equidistant bins on the Mel scale from 0 to 8000 and the Y-axis is the value of the corresponding dimension.

#### 3.2. Calculating similarity scores

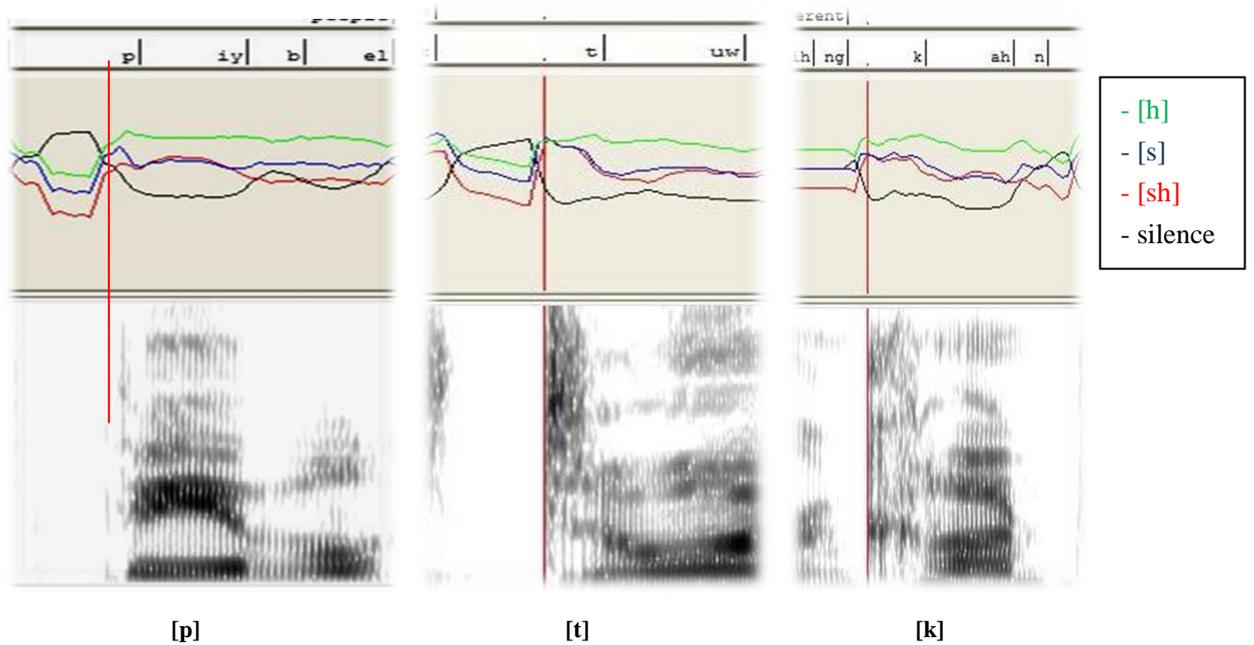

A similarity score measures how similar the acoustic data in the current window (size=20ms) is to a spectral template. It is calculated in two steps. A distance measure is first calculated between the Mel spectral vector of the current window and the average Mel spectral vector the template (see (1)), and then normalized to be the similarity score (see (2)).

$$(1) \quad d_{x,u} = \frac{\sum_{j=1}^{60} |x_j - u_j| \frac{1}{sd(u_j)}}{60}$$

(where  $d_{x,u}$  is the distance measure between the Mel spectral vector of window  $x$  and the template  $u$ ;  $x_j$  is the  $j$ th coordinate in the Mel spectral vector of  $x$ , and  $u_j$  is the  $j$ th coordinate of the Mel spectral vector of template  $u$ ;  $sd(u_j)$  is the standard deviation of the  $j$ th coordinate in the Mel spectral vector of template  $u$ .)

$$(2) \quad S_i = e^{-0.005d_i} \quad (\text{where } S_i \text{ is the similarity score of the current window to template } i.)$$

The window moves with a step size equal to 5ms. Figure 3 below illustrates the similarity scores for silence and some fricatives during three example tokens of speaker F01. It can be seen that in all three tokens, the fricative similarity scores all rise around the point of release whereas the silence score drops.

**Figure 3.** Similarity scores and spectrogram of three stop tokens of F01: [p] (left), [t] (middle) and [k] (right). A red bar marks the position of first release in every token. Four similarity scores are shown: [h] (green), [s] (blue), [sh] (red) and silence (black).

### 3.3. Finding the point of release

As mentioned above, the general idea of the algorithm is to find the point within the stop where the silence similarity score suddenly drops and the fricative similarity score suddenly rises. There are two issues that need to be resolved here: (a) which period of rise/drop should be used, and (b) which fricative sound(s) should be used in spectral comparison. In the preliminary analysis, we found that the point of burst occurs most consistently after the point of fastest change in the similarity scores (i.e. maximal/minimal slope), and that using only one fricative score, the [sh] similarity score, is enough to capture the fricative-like-ness. Thus our baseline

algorithm (see (3)) makes use of the silence similarity score (hereafter the <silence> score) and the [sh] similarity score (hereafter the <sh> score).

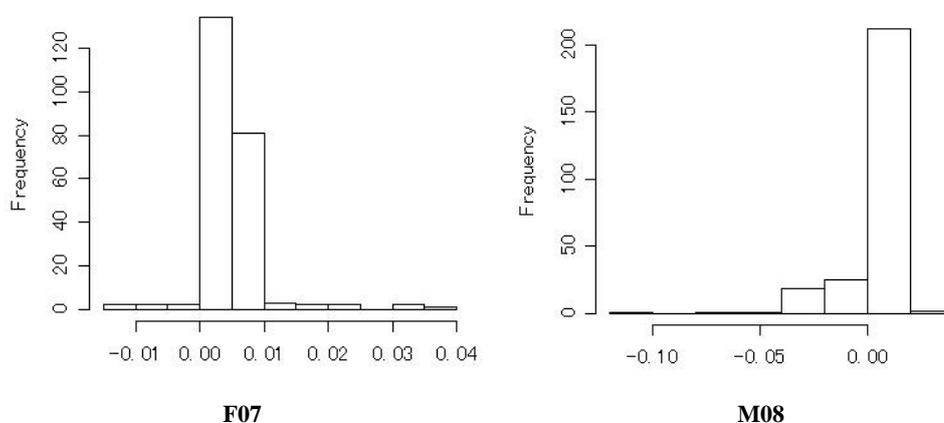

(3) *Baseline algorithm*

Find the end point of the period of fastest decrease in <silence> score and the end point of the period of fastest increase in <sh> score, and return the midpoint of the two as the point of release. If no decreasing period is found in <silence> score or no increasing period is found in <sh> score, exclude the token from the data set.

#### 4. Testing and tuning

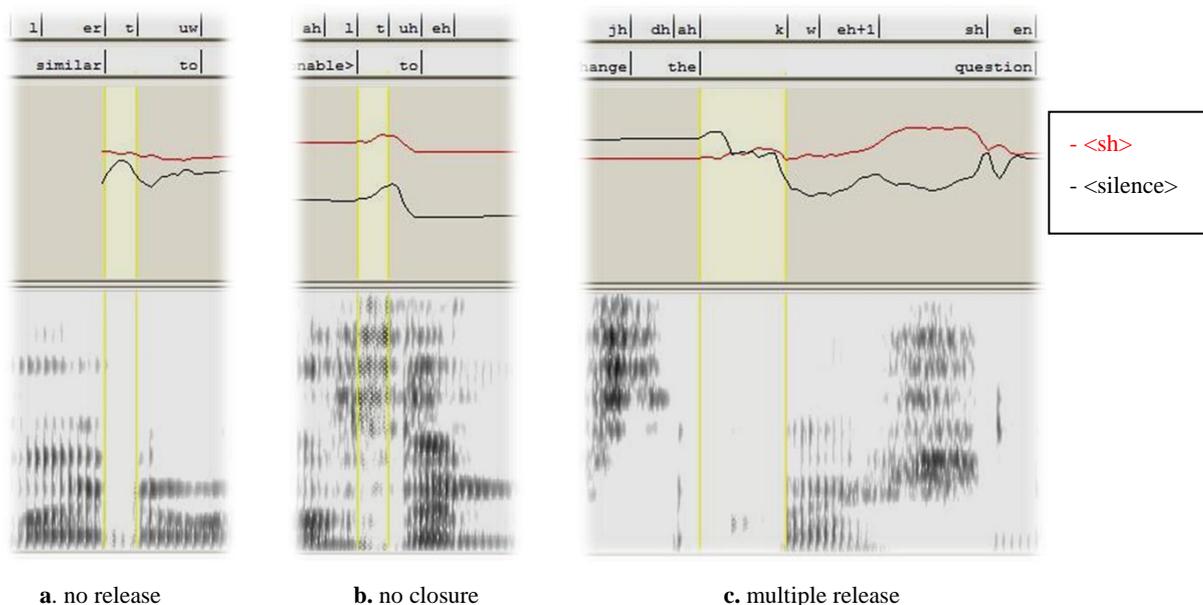

Part of speakers F07 and M08’s data are used as developmental data. These two speakers are selected because they differ from each other in all available dimensions. Speaker F07 is an older female speaker, with the lowest average speaking rate (4.022 syll/s) of all 19 subjects, while speaker M08 is a young male speaker, with the highest average speaking rate (6.434 syll/s) (see Appendix I for all speaker’s average speech rate). The developmental dataset consists of 231 tokens from F07 and 261 tokens from M08. Each token is hand-tagged for the point of release, judging from both the waveform and the spectrogram. If a stop token has no reliable trace for release, the beginning point of the phone is marked as the point of release, for the sake of calculating errors. If the stop has more than one release, the first release point is recorded.

Using the baseline algorithm, the root mean square (RMS) of error (calculated as the lag between estimated point and tagged point) for F07 is 7.22ms. Moreover, errors are mostly distributed around 5ms, with a mean of 5.35ms (see Figure 4). This suggests that the estimated point is consistently earlier by about 5ms than the real point of release. If 5ms is added to all estimated values, the RMS of error is further reduced to 4.85ms.

**Figure 4.** Distribution of error values (in s) in F07 (left) and M08 (right). X-axis shows the error intervals in s, and Y-axis is the number of cases in the error interval. Error is calculated as the lag between the estimated point and the tagged point

When the baseline algorithm is applied to M08's training data, the RMS of error is much bigger, exceeding 13ms. The majority of errors are within 20ms, but there are a number of outliers that are more than 50ms in absolute value (see Figure 4). Similar to F07's data, most errors are positive, suggesting that the estimated point is consistently earlier than the real burst point. However, when 5ms is added to the estimation, the RMS error goes up to 14ms, probably due to the negative outliers. A closer examination of the outlier cases reveals three common types: cases with no release, cases with no closure, and cases of multiple releases (see Figure 5).

**Figure 5.** Illustration of three problematic cases in M08: (a) no release, (b) no closure and (c) multiple release. The duration of the target stop token is highlighted. <sh> score is shown in red and <silence> score is shown in black.

In Figure 5a, the transcribed duration of [t] is basically all blank in spectrogram. In other words, the release happens as the following vowel starts, but not during the stop. Figure 5b shows a case where the transcribed duration of the stop is all aspiration, with no closure portion. Being an extremely fast and soft talker, M08 has many tokens like these in the training set (23 out of 261). Since the points of release in these cases are hand-tagged as the starting point of the phone (for the purpose of calculating error), they greatly inflate the average error. Figure 5c shows a word-initial [k] in speaker M08. This velar stop is weakly (and doubly) released, which corresponds to two faint lines on the spectrogram around the mid point of the duration of the phone, with no noise-like distribution of energy following the release, which makes it hard for the program to recognize.

#### 4.1 First rejection rule

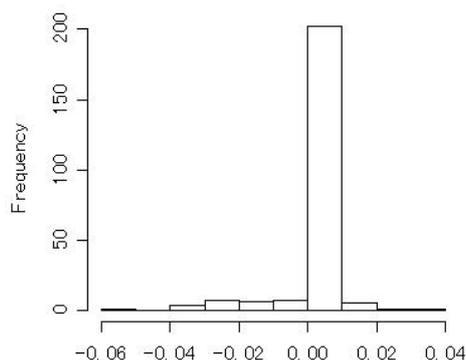

In view of the first two types of problematic cases (see Figure 5a and 5b), we implemented the first rejection rule (see (4)) to reject cases that have insignificant

changes in the similarity scores due to no obvious closure-burst transition.

#### (4) *First rejection rule*

A target word will be rejected if the most drastic changes found in scores are not drastic enough. The delta criterion is defined as a rising rate of 0.02 per step (i.e. per 5 ms) for <sh> score and a dropping rate of 0.04 per step for the <silence> score. If the <silence> score and <sh> score don't meet the delta criterion, the case will be rejected, i.e. no release point will be estimated.

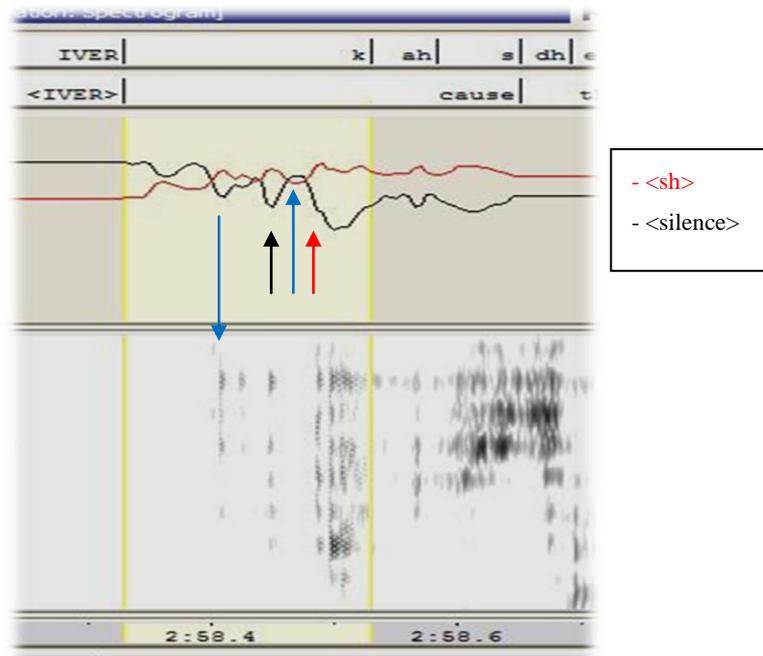

The two cutoff numbers, 0.02 and 0.04, are decided based on the observation from the training dataset. By applying the first rejection rule, 28 cases in M08's training data are rejected, 19 of which are hand-tagged for not having a reliable release point. The RMS error in M08's training data goes down to 9.27ms (see Figure 6). When 5ms is added to the estimated point, the error goes down by 0.01ms. For comparison, when applied to F07's data, the rule rejects 4 cases, and the RMS error goes down to 6.81ms. When 5ms is added to the estimated points, the RMS error further goes down to 4.22ms.

**Figure 6.** Error distribution in M08 after the first rejection rule is applied

#### 4.2 *Second rejection rule*

The first rejection rule is designed to tackle with cases with no obvious closure-burst transition, due to missing closure or release gestures. What remains a problem are the cases with multiple releases. The program is designed to find the most significant change in similarity scores, but not necessarily the first one. This becomes a problem in multiple-release cases, since the first release is not always the most significant one. Multiple-release happens most often in velar stops. In fact, the case with the greatest error value (error = -60ms) in M08 is a multiply-released initial [k] in the word *cause* (see Figure 7). Not only is the velar stop multiply-released but also the first three (or four) releases are widely apart. Instead of finding the first release, the <silence> score tracker finds the second major release while the <sh> score tracker finds the third major release, and thus the program returns the mid point of the two, which is 60ms later than the first release.

**Figure 7.** Multiply-released initial [k] in the word *cause* of speaker M08. First release is marked by the blue downward arrow; the candidate point found by the <silence> score is marked by the black upward arrow while the point found by <sh> score is marked by the red upward arrow; the final point of burst returned by the program is marked by the blue upward arrow in the middle

It would be ideal if the program find all points of release during the stop and return the first one. However, in practice, this is hard to do. Among other things, this would potentially interfere with the rejection of spurious releases. Therefore for the time being, we use a simple rule to reject cases of multiple releases, which partially addresses the problem. The general idea is to exclude cases where the two candidate points of release, returned by the <silence> score and the <sh> score respectively, are too far apart, which is indicative of an unusual multiple-release.

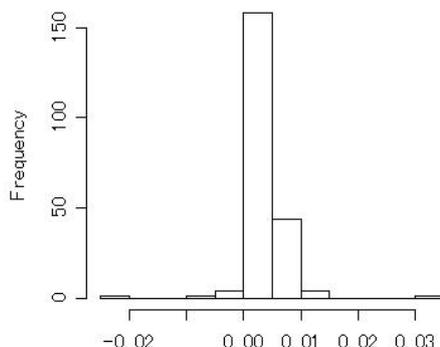

*(5) Second rejection rule*

If the two candidate points, one located in the <sh> score and the other one located in the <silence> score, are apart by more than 20ms, the case will be rejected, i.e. excluded from the data set.

By using the second rejection rule, the case shown in Figure 8 will be rejected because the two candidate points are apart by 40ms. It should be noted that this rule only rejects a particular type of multiple-release cases, i.e. the two candidate points (returned by the silence score and the fricative score) represent two separate releases and the two releases are more than 20ms apart. Even for this type, what the rejection rule does is simply exclude the case from the training set, without returning any release point.

Applying the second rejection rule to M08's data excludes 20 more cases and the RMS error is 5.64ms. After adding 5ms to the estimate values, the error is reduced

to 3.44ms (see Figure 8). Notice that the number of outliers (i.e. residual after the rejection rules) is reduced to only 2, one on the positive side and one on the negative side. After applying the rule to F07's data, 3 more cases are rejected, and the RMS error goes down to 6.02ms. When 5ms is added to the prediction, the error is further reduced to 3.22 ms.

**Figure 8.** Error distribution in M08 after the second rejection rule is applied

#### 4.3. Testing the algorithm on the rest of data

We have shown that the two rejection rules significantly improve the performance of the algorithm in both speakers' training data, especially in speaker M08's. Table 2 summarizes the number of cases excluded and the decrease in RMS error in both speakers after applying the two rejection rules sequentially.

	F07				M08			
	size	error	error <sub>+5</sub>	sd	size	error	error <sub>+5</sub>	sd
<b>Baseline algorithm</b>	231	7.22	4.85	4.85	261	13.11	14.00	13.17
<b>after 1<sup>st</sup> rejection</b>	227	6.81	4.19	4.19	233	9.27	9.26	8.94
<b>after 2<sup>nd</sup> rejection</b>	224	6.02	3.22	3.23	213	5.64	3.44	3.41

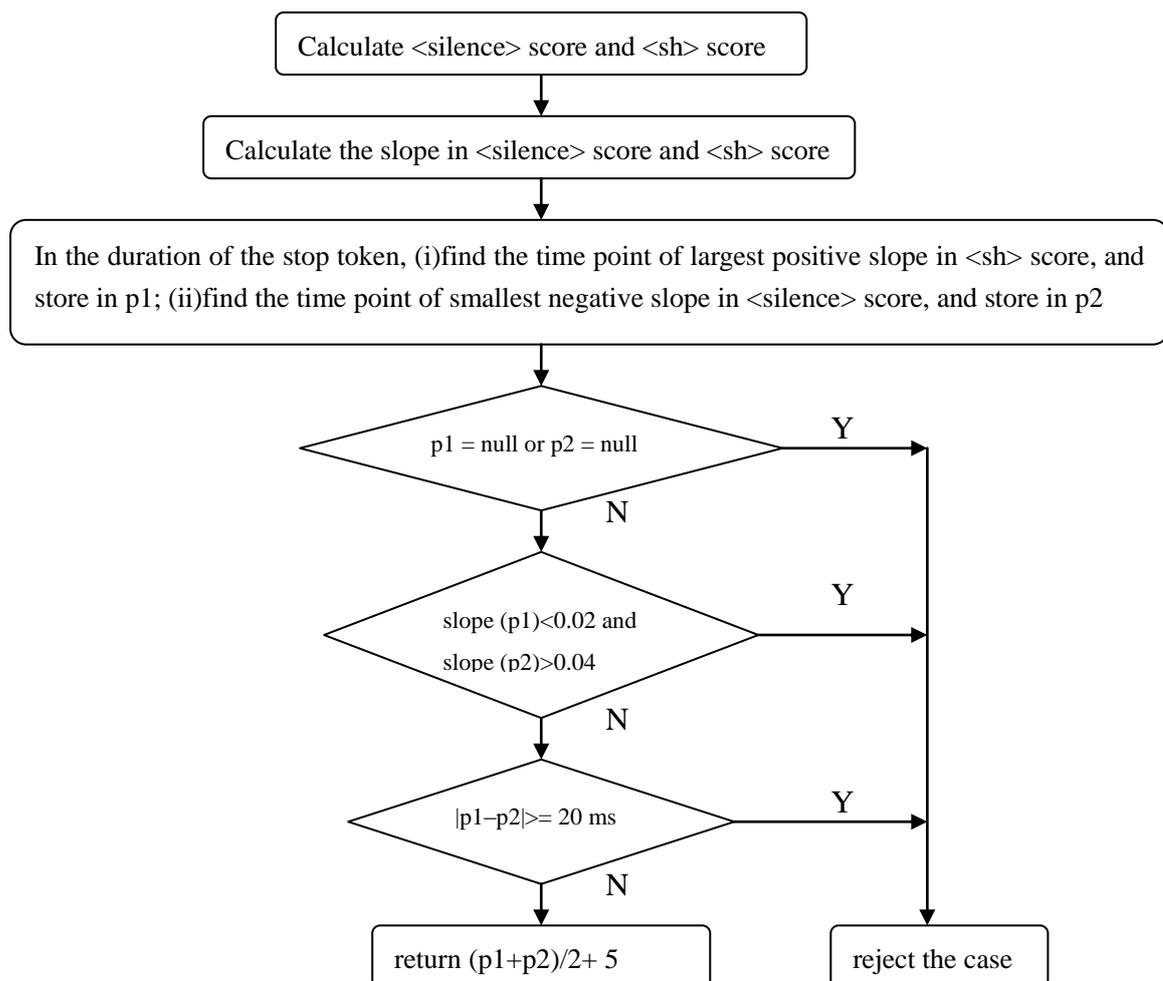

**Table 2.** Results with speaker F07's and speaker M08's developmental data. *Size* is the number of cases; *error* is the RMS error value; *error<sub>+5</sub>* is the RMS error after the estimates are shifted by 5ms to the right; *sd* is the standard deviation of error.

Overall, 7 of 231 cases are dropped from F07's data (rejection rate = 3.03%), and the RMS error is improved by 33.6%; in M08's data, 48 of 261 cases are dropped (rejection rate = 15.05%), and the RMS error is improved by 75.4%. For both speakers, the RMS error is further reduced when 5 ms is added to all estimated values, which suggests that the point found by the algorithm is consistently earlier than the real point of burst. Both speakers achieved a RMS error lower than 3.5ms after applying the two rejection rules. This is near-optimal, because given the step size of 5ms when calculating similarity scores, the optimal error in theory is  $5/2 = 2.5$ ms. However, the large difference in rejection rates, 3.03% vs. 15.05%, suggests that there is a great amount of individual differences, in terms of the detectability of stop releases. Apart from gender and age, the most important difference between F07 and

M08 is probably in speech style, as F07 is a relatively slow talker while M08 is extremely fast and soft (though the softness might be due to recording conditions).

We applied the baseline algorithm as well as the two rejection rules to all speakers' data, and found that the rejection rate ranges from 3.03% to 30.5%, with the average value of 13.13% and a standard deviation of 8.6%. (The details of rejection in all speakers are attached in Appendix II.) We also conducted a second test, using a random sample of 50 target tokens from all speakers, in which about half of the cases were from speakers with a high rejection rate (>20%). All 50 cases were hand-tagged for point of burst and the results were checked against the estimated values given by the program. Altogether 7 cases were rejected. In the remaining 43 cases, RMS error is within 5ms; in the 7 cases that were rejected, 4 were rejected by the first rule and 3 the second rule. Two rejected cases, one from each rule, were judged to be not strongly evidenced.

The complete algorithm, together with two rejection rules, is illustrated in the flow chart below.

**Figure 9.** Flow chart for finding the point of release

#### 4. Summary of results

Table 3 lists the estimated mean values and standard deviations of closure duration, VOT, and total duration across all speakers by place of articulation.

	labial ([p])	alveolar ([t])	velar ([k])
<b>N</b>	2461	4142	3566
<b>Mean(D<sub>c</sub>)</b>	69.5	48.9	54.9
<b>Sd (D<sub>c</sub>)</b>	36.4	23.9	22.9
<b>Mean(D<sub>r</sub>)</b>	48.0	51.2	57.9
<b>Sd (D<sub>r</sub>)</b>	25.1	27.5	26.0
<b>Mean(D<sub>t</sub>)</b>	117.6	100.2	112.9
<b>Sd (D<sub>t</sub>)</b>	46.5	41.2	37.7

**Table 3.** Summary of duration values (in ms). N = total number of tokens; D<sub>c</sub> = closure duration; D<sub>r</sub> = VOT; D<sub>t</sub> = total duration

Compared with the average durations found in Byrd (1993) for read speech in TIMIT (see Table 4), the Buckeye values are very similar, though the VOT values are a little bit longer.

	labial ([p])	alveolar ([t])	velar ([k])
<b>Mean(D<sub>c</sub>)</b>	69	53	60
<b>Sd (D<sub>c</sub>)</b>	24	29	26
<b>Mean(D<sub>r</sub>)</b>	44	49	52
<b>Sd (D<sub>r</sub>)</b>	22	24	24

**Table 4.** Duration values (in ms) from Byrd (1993). D<sub>c</sub> = closure duration; D<sub>r</sub> = VOT; D<sub>t</sub> = total duration

#### 5. General discussion

We present in this paper a pioneer case study in burst detection in voiceless stops in spontaneous speech. We use the exemplar-based spectral template approach, which was first proposed in Johnson (2006), and implement a burst detection program that finds the most likely point of burst within the duration of a voiceless stop in word-initial position.

A large part of the paper is devoted to the illustration of the wide range of variation in the realization of voiceless stops in spontaneous speech. Little is reported on this issue in the current literature, but we believe that it is central to the success of any automatic burst detection algorithm, especially those designed for spontaneous speech. We show in detail how different types of realization affects the performance of the algorithm, and how the algorithm can be improved to deal with the diversity. Two rejection rules are implemented to exclude cases where there is no obvious closure-burst transition and cases with more than one releases. Altogether these two rejection rules reduce the error by about 33.6% and 75.4% in

two speakers' training data. The final RMS error is around 3.22ms in the training data, and is within 5ms in the 50 random test cases (for comparison, 44% of the landmarks in Liu [1996] are found within 5ms of the hand-transcription). The estimated values of closure duration and VOT in this study are similar to previous results of corpus studies. In particular, the estimated VOT values show the canonical pattern of increasing as the place of articulation moves from the lips to the velum (i.e. [p] < [t] < [k]).

Further improvement of the algorithm can be made in the following aspects. First, in the current study, we only tested two speakers' data in detail but didn't explore the full range of speaker differences. In the next step, we plan to test the algorithm more thoroughly, using all 19 speakers' data (and presumably the other 21 speakers in the corpus, whose data have been made available recently). Second, the cases of multiple releases can be investigated in more detail. The second rejection rule in the current algorithm doesn't fully address this problem – it only excludes the most extraordinary cases of multiple-release, i.e. the cases where the silence score and the fricative score find two separate releases and the two releases are apart by more than 20ms. Future work will focus on the modification of this rule by providing a way to identify all existing releases and return the earliest one. Last but not least, the current algorithm is only trained and tested on word-initial voiceless stops. It should be possible to extend the current program to stops that are word-medial or word-final, as well as voiced stops, for finding point of release and calculating VOT values.

N = the total number of target cases

Rsil = the number of cases where no decreasing period is found in <silence> score

Rsh = the number of cases where no increasing period is found in <sh> score

R1 = the number of cases rejected by the first rejection rule

R2 = the number of cases rejected by the second rejection rule

Ngood = the number of remaining cases after all rejection

R% =  $1 - \text{Ngood} / \text{N}$ , the rejection rate

Rejection is applied in the above sequence.

# Implementation of Syntax and Semantics of Questions in Computational Minimalism

Yong-hun Lee

Dept. of English Language & Literature, Chungnam National University  
220 Gung-dong, Yuseong-gu, Daejeon, 305-764, S. Korea  
yleeuiuc@hanmail.net

## Abstract

Questions are one of the major sentence types in natural languages, and syntax and semantics of questions have been studied in linguistics for a long time. We use them to ask something. This paper provides computational algorithms by which we can implement syntax and semantics of questions in computational minimalism. For the implementation of questions, this paper modifies Stabler's Computational Minimalism and proposes an RCM system. Within the RCM system, syntactic behaviors of questions are implemented by syntactic operations in Chomsky's recent minimalist syntax. Semantic interpretations of questions are calculated when one syntactic operation ends, because syntactic operations and their semantic counterparts are connected by *homomorphism*. In addition, the semantic interpretations of questions are compositionally calculated based on Montagivan semantics.

**Keywords:** questions, computational minimalism, an RCM system, compositionality.

## 1. Introduction

Questions are one of the important sentence types, and we usually use them when we want to ask something.<sup>1</sup> Every language has questions, and we can derive different types of questions from a declarative sentence. Let's see an example.

- (1) a. John loves Mary
- b. Does John love Mary?
- c. Who loves Mary?
- d. Who(m) does John love?

From a declarative sentence (1a), we can derive two different kinds of questions. (1b) is a yes-no question, and (1c) and (1d) are wh-questions.

The goal of this paper is to provide computational algorithms by which we can implement syntax and semantics of questions in computational minimalism (CM). In order to computationally implement questions, this paper modifies Stabler’s system and proposes a Revised Computational Minimalism (RCM) system. Within this RCM system, the syntactic behaviors of questions are implemented by syntactic operations in Chomsky’s recent minimalist syntax (Chomsky, 2000, 2001, 2005). For the semantic part, this paper incorporates Montague grammar (Montague, 1974), and all the semantic interpretations of questions are compositionally calculated based on mechanisms in Montagivan semantics. For the implementational efficiency, this paper supposes that syntactic operations and their semantic counterparts are connected by *homomorphism*, and all the semantic interpretations of questions are automatically calculated whenever one syntactic operation terminates.

This paper is organized as follows: Section 2 provides brief overviews of previous approaches to questions, which contain the approaches in syntax and semantics. Section 3 introduces computational minimalism. Two types of computational approaches are introduced: Stabler’s CM and Lee’s RCM system. Section 4 develops computational algorithms for questions within the RCM system, and Section 5 summarizes this paper.

## 2. Previous Approaches to Questions

### 2.1. Syntactic Approaches

Syntactic approaches to questions can be divided into two categories depending on whether they employ *movement* as a major syntactic operation or not. One category is the movement approach which analyzes questions with movements. The other is the lexicalist approach which analyzes them without any movement operation.

In Chomskyan syntax, major focuses have been on how questions can be derived from their declarative counterparts. The table in (2) summarizes how the syntactic analyses on questions have historically developed in Chomskyan traditions.

#### (2) Syntactic Analyses with Movement

	Yes-No Question	Wh-Question
TG (Chomsky 1957/1977)	Subject-Aux Inversion	Wh-movement
GB (Chomsky 1981/1986)	I-to-C Movement	Wh-movement
MP (Chomsky 1995)	Move (Head Mvt.)	Move (Wh-Mvt.)

As you can observe in this table, *movement* is crucial in explaining syntactic behaviors of questions, whether it is a yes-no question or a wh-question.

There are other types of syntactic analyses where *movement* plays no role. They include the analyses in GPSG (Generalized Phrase Structure Grammar; Gazdar et al. 1985) and HPSG (Head-driven Phrase Structure Grammar; Pollard and Sag 1994, Sag and Wasow 1999). In those kinds of syntactic approaches, both yes-no and wh-questions are analyzed with feature instantiation and feature percolation.

## 2.2. *Semantic Approaches*

Semantic approaches to questions have mainly focused on what the semantic interpretations of various types of questions are. They can be divided roughly into three groups. The first is *Categorial Approaches*, where semantic types are used to catch the meaning of questions. The second is *Embedding Approaches*, where the meaning of questions is captured by embedding the questions into declarative sentences, along with some verbs such as *know*, *wonder*, etc. The last one is *Propositional Approaches*, where the meaning of questions is represented by propositions.

There are three major claims in *Propositional Approaches* to questions. Hamblin (1973) said that the meaning of a question is the set of possible answers. Karttunen (1977), however, claimed that the meaning of a question is the set of true answers. Groenendijk & Stokhof (1982, 1984) took a little different position and said that the meaning of a question is just propositions, not a set of propositions.

## 3. **Computational Minimalism**

### 3.1. *Stabler's System*<sup>3</sup>

Stabler's works (1997, 2001, forthcoming) have tried to implement the ideas in Chomsky's *Minimalist Program* (1995). He defined minimalist grammar as follows.

(3) Definition of Minimalist Grammar (Stabler, 2001:73)

A *minimalist grammar* is a 4-tuple  $(V, Cat, Lex, F)$ , where

$V = (P \quad I)$ , (non-syntactic feature)

$Cat = (base \quad select \quad licensors \quad licensees)$ , (syntactic features)

$Lex$  is a finite set of expressions built from  $V$  and  $Cat$  (the lexicon)

(where an "expression" is a tree), and

$F = \{merge, move\}$  (the generating functions)

Here,  $P$  refers to the phonetic feature and  $I$  to the semantic feature. Their examples are shown in (4). These examples are for English lexicon.

(4) Phonetic Feature  $P$  and Semantic Feature  $I$

$P = \{/marie/, /quechua/, /speaks/, /believes/, \dots \}$

$I = \{(marie), (quechua), (speaks), (believes), \dots \}$

As you can see, phonetic features are indicated by placing slashes around the standard orthographic representations of the word, and semantic features are indicated by placing parentheses around standard orthographic representations.

The syntactic feature  $Cat$  can be partitioned into four parts as in (5).

(5) Syntactic Feature  $Cat$

$Cat = (base \quad select \quad licensors \quad licensees)$ , where

$base = \{C, T, v, D, N, \dots \}$ ,

$select = \{=x, =X, X= \mid x \in base\}$ ,

$licensors = \{+nom, +acc, +wh, +WH, \dots \}$ ,

$licensees = \{-nom, -acc, -wh, \dots \}$ .

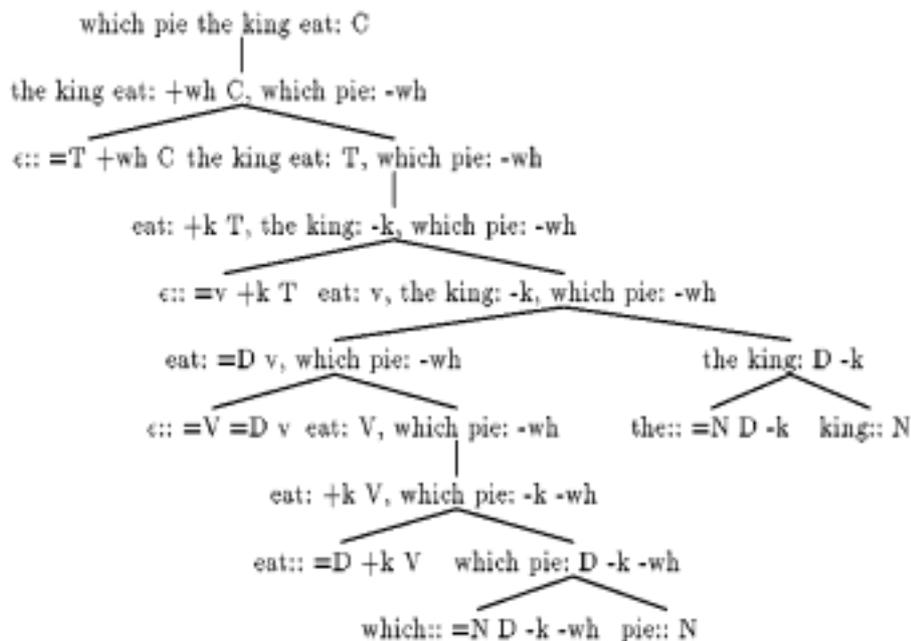

Here,  $base$  refers to a set of basic syntactic categories such as C, T, N, V, v, and so on. For each type of the syntactic category, we may have three types of selecting constituent(s) of the category, which is encoded in  $select$ . The feature  $=x$  or  $=X$  implies that the category  $x$  or  $X$  follows the current category, whereas  $X=$  means that the category  $X$  precedes the current category. Here, upper case letters refer to the feature that causes an overt movement, whereas lower case ones refer to the feature that causes a covert movement. The remaining feature sets are  $licensors$  and  $licensees$ . These feature sets are involved in phrasal movements. A head assigns a feature  $+f$  or  $+F$  to  $-f$  constituents.

The generating function  $F$  consists of two operations *merge* and *move*. *Merge* is an operation that combines two syntactic constituents, where one of two constituents serves as a head. *Move* is an operation that moves a constituent from one position to another position. This *move* operation is triggered to cancel out [-interpretable] feature +f or +F. In Stabler (2001), he revised some notational conventions. Accordingly, in Stabler (2001), *merge* is represented by binary branch, whereas *move* is indicated by unary branch.

In his system, an example sentence (6) is analyzed as in (7).<sup>2</sup>

(6) Which pie did the king eat?

(7) Analysis Tree for the Sentence, *Which pie did the king eat?*

An important trait of Stabler's system is that the analyses proceed in a bottom-up style. That is, the first operation in (7) is to combine (or to merge) *which* and *pie*. Because the *select* of *which* is =N and the *Cat* of *pie* is N, the *Cat* of *pie* satisfies the *select* of *which*. Therefore, the former cancels out the latter. The other features of *which* and *pie* are unified. Then, *which pie* combine with *eat*. The analyses proceed as such until all the words in the sentences are exhausted

### 3.2. Lee's System

Lee (2005a, 2005b) modified Stabler's CM, and introduced a Revised Computational Minimalism (RCM) system. The most important change in the RCM system is that ideas in Chomsky (2000, 2001), such as probe-goal relations, are implemented computationally. The characteristics of the RCM system are enumerated in (8).

- (8) Characteristics of the RCM System
  - a. attribute-value ordered pairs (**avop**)
  - b. Probe-Goal relations
  - c. feature matching processes
  - d. modified unification algorithms
  - e. Montagovian semantics in semantic interpretations

These characteristics can be explained as follows:

First, the RCM system uses attribute-value ordered pairs in (9). Three attributes are separated by colon (:), and these attributes are explained in (10).

- (9) Attribute-Value Ordered Pairs (**avop**)  
PHON : SYN : SEM

- (10) Three Attributes
  - a. PHON
    - (i) phonological/morphological form
    - (ii) concatenates words to form a stream of words
  - b. SYN
    - (i) category information
    - (ii) other syntactic features
  - c. SEM
    - (i) semantic interpretation
    - (ii) based on Montagovian semantics

Stabler used parentheses for semantic interpretations. In the RCM system, however, semantic parts are based on Montagovian semantics, and semantic interpretations are compositionally calculated.

Second, the RCM system adopts Chomsky's probe-goal relations for syntactic operations. The locality condition between probe-goal is shown in (11).

- (11) Locality Condition between Probe and Goal (Chomsky, 2000:122)
- a. Matching is feature identity.
  - b. D(P) is the sister of P.
  - c. Locality reduces to closest c-command.

Case markers are one of the typical examples where these probe-goal relationships play a role. In order to implement these relations, this paper proposes the following techniques.

- (12) Implementation of Probe-Goal Relations for Case in the RCM System
- a. The feature-matching process for [acc] is activated when  $\nu$  is merged.
  - b. The feature-matching process for [nom] is activated when T is merged.

Though V has the [acc], the feature-matching process is not activated until  $\nu$  is merged. When  $\nu$  is merged, the feature-matching process is activated and it checks if the [acc] feature of the probe matches with that of the goal. In order to distinguish between the [acc] feature in V and that of DP/NP, let's use subscript notations for them. That is, let's call the [acc] feature in V [acc<sub>0</sub>] and the others in DP/NP [acc<sub>1</sub>], [acc<sub>2</sub>], etc. When the feature-matching process is activated, [acc<sub>0</sub>] and the others make a pair, viz., [acc<sub>0</sub>]-[acc<sub>1</sub>], [acc<sub>0</sub>]-[acc<sub>2</sub>], [acc<sub>0</sub>]-[acc<sub>3</sub>], etc. If the [acc<sub>0</sub>] feature of V matches with [acc<sub>i</sub>] of NP/DP, the matched [acc<sub>0</sub>]-[acc<sub>i</sub>] pair itself disappears (where  $i = 1, 2, 3, \dots$ ). The feature-matching process for [nom] is similar. Along with these algorithms, we can implement probe-goal relations in Chomsky (2000).

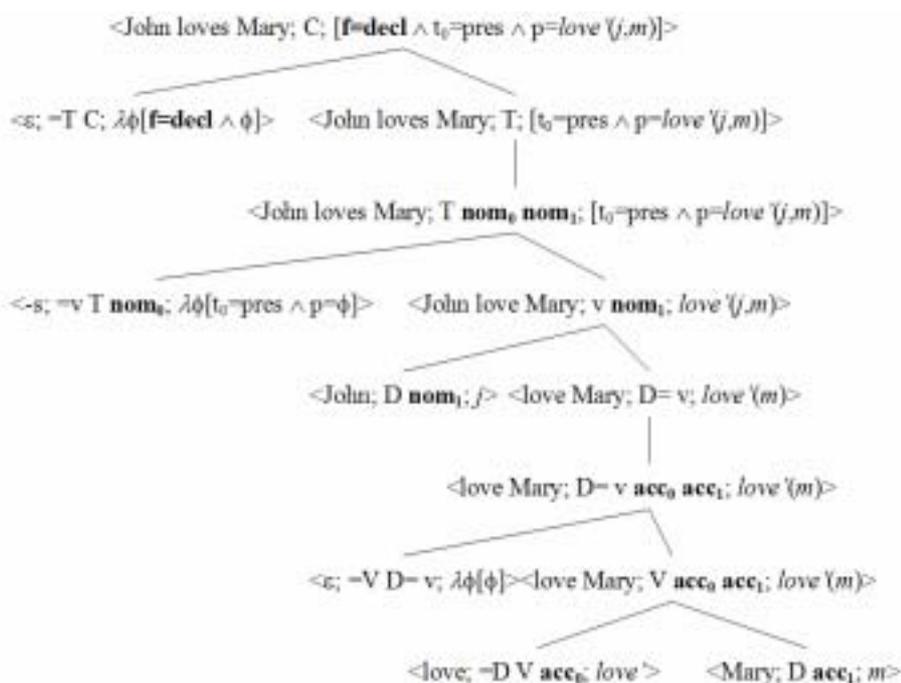

Third, the RCM system in this paper makes use of feature-matching processes. How these processes are activated, especially those for Case feature, is explained in the above paragraph. Like [acc] or [nom], we will make use of these feature-checking processes also for wh-movements along with an uninterpretable feature [wh].

Fourth, the RCM system makes use of modified unification algorithms for other features. In the original unification algorithms such as those in HPSG, when there are incompatible features, we determine that the input sentence is ungrammatical. On the contrary, in the RCM system, when we meet incompatible features, the system does not crash immediately. Instead, it will postpone the crash until the relevant feature is activated.

Finally, the RCM system takes Montague grammar in its semantic part, and all the semantic interpretations are compositionally calculated based on the mechanisms in Montague semantics. As mentioned above, the RCM system takes a bottom-up parsing strategy. Therefore, it is easy to implement Montague-style semantics. In Stabler's CM system, semantic features are indicated by placing parentheses around a standard orthographic representation. This kind of representation makes it quite simple to understand what the semantic interpretation of the given sentence is. The RCM system takes Montague grammar in its semantic part and solves the shortcomings in Stabler's system. Now, let's take an example sentence and see how sentences are analyzed in the RCM system. In comparison with interrogatives/questions, I start from a declarative sentence in (1a). A declarative sentence in (1a) is analyzed as in (13) in the RCM system.

(1) a. John loves Mary

(13) Analysis Tree for the Sentence, *John loves Mary*

The analysis proceeds as follows: First, *love* is merged with *Mary*. Because the category D of *Mary* satisfies the select feature =D in *love*, D of *Mary* is matched with =D in *love*. The other features are unified. Then, *love Mary* is combined with a light verb *v*. Since the category V of *love Mary* satisfies the select feature =V of the light verb *v*, V of *love Mary* is matched with =V in the light verb. The other features are unified. As *v* is

merged, we may activate the feature-matching process, and we check the identity of the pair  $[\text{acc}_0]$ - $[\text{acc}_1]$ . Since these two features are identical, this pair disappears. That is, Accusative Case in *Mary* is licensed. Now, *John* is merged with *love Mary*. Because the category D of *John* satisfies the *select* feature  $D=$  in *love Mary*, D of *John* is matched with  $D=$  in *love Mary*. The other features are unified. Now, T *-s* is merged, and  $v$  of *John love Mary* is matched with  $v=$  of T. The other features are unified. Since T is merged, we may activate the feature-matching process, and we check the identity of the pair  $[\text{nom}_0]$ - $[\text{nom}_1]$ . Since these two features are identical, this pair disappears. Finally, C is merged with *John loves Mary*, and T of *John loves Mary* is matched with  $=T$  in C. In the tree of (13),  $t_0$  refers to the tense of the sentence, and  $f$  to the force of sentence, i.e. type of sentences.

#### 4. Implementations of Questions in Computational Minimalism

##### 4.1. Deriving Semantic Interpretations of Questions

Before we implement syntax and semantics of questions, let's see how we can represent the semantic interpretation of questions. In order to derive questions from a declarative sentence, Karttunen(1977) made use of the following rule in (14).

(14) Proto-Question Rule (Karttunen, 1977:13)

If  $\Phi \in P_t$ , then  $?\Phi \in P_Q$ .

If  $\Phi$  translates to  $\Phi'$ , then  $?\Phi$  translates to  $p[\vee p \wedge p = \wedge \Phi']$

Here,  $\Phi$  is a declarative sentence, and  $?\Phi$  refers to a question.

In his system, a yes-no question in (15a) can be translated as in (15b) (Karttunen, 1977:16).

(15) a. Does Mary cook?

b.  $p[\vee p \wedge [p = \wedge \text{cook}'(m) \vee p = \wedge \neg \text{cook}'(m)]]$

c.  $[\text{cook}'(m) \vee \neg \text{cook}'(m)]$

As you can see in (15b), the semantic interpretation of yes-no questions is too complex. It is also too difficult to implement *intensionality* in computational implementations. Therefore, this paper simplifies the semantic interpretation of (15b) and uses that of

(15c), where all the complex notations are eliminated including *intensionality*. This paper will use the semantic interpretation in (15c) for implementational efficiency.

Now, let's move on to the semantic interpretations of wh-questions. Karttunen(1997) analyzed a wh-question in (16) through the steps in (17).

(16) Who dates Mary?

(17) Semantic Interpretation (Karttunen, 1977:20)

- a. ?he<sub>i</sub> dates Mary       $p[\forall p \wedge p = \wedge date'(x_i, m)]$
- b. who                       $P \ xP\{x\}$
- c. Who dates Mary?       $p \ x[\forall p \wedge p = \wedge date'(x_i, m)]$

He translated *who* into  $P \ xP\{x\}$ . Because this semantic interpretation contains *intensionality*, it is also necessary to simplify the notations in order to implement it computationally. Let's do it from the semantic interpretation of *some* in Montague grammar, which is shown in (18).

(18) Semantic Interpretation of *some* and *someone* (Dowty et al., 1981:108)

- a. *some*:       $Q[ \ P \ x[Q(x) \wedge P(x)]]$
- b. *someone*:  $P \ x[person'(x) \wedge P(x)]$
- c. *anyone*:     $P \ x[person'(x) \wedge P(x)]$

If *some* can be translated into the semantic interpretation in (18a), *someone* can be translated into the semantic interpretation in (18b). Likewise, *anyone* can be translated into the semantic interpretation in (18c). Note that *someone* and *anyone* have the same semantic interpretations. The only difference lies in their syntactic distributions. That is, *someone* is used in affirmative sentences, whereas *anyone* is used in negatives and interrogatives. Then, the semantic interpretation of wh-words such as *who* can be derived as in (19).

(19) Semantic Interpretation of *anyone* and *who*

- a. *anyone*:     $P \ x[person'(x) \wedge P(x)]$
- b. *who*:         $P \ x[person'(x) \wedge P(x)]$

Here, note that  $x$  of *anyone* is changed into  $x$  in *who*. Along with this semantic interpretation, we can implement wh-questions in the RCM system.

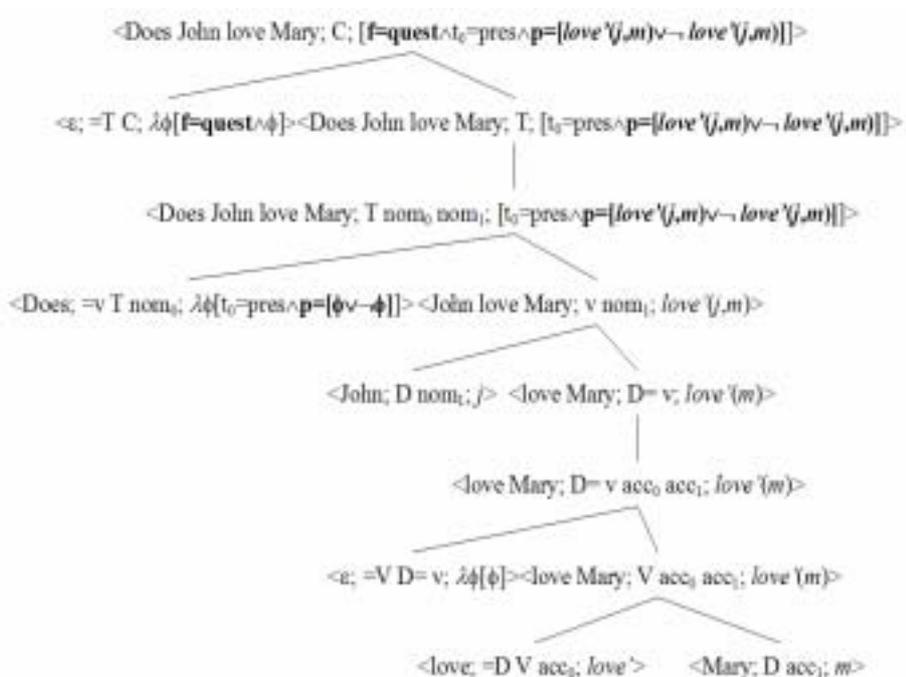

In sum, the semantic interpretations of yes-no questions and wh-questions are implemented in the RCM system as follows: The semantic interpretations of yes-no questions are represented by two propositions, one of which is true and the other is false. The semantic interpretations of wh-questions are represented by a set of entities that satisfied the propositions.

#### 4.2. Yes-No Questions

Now, let's start to implement syntax and semantics of questions. From a declarative sentence (1a), we can derive a yes-no question in (1b). This sentence can be analyzed as in (20).

- (1) a. John loves Mary  
 b. Does John love Mary?

(20) Analysis Tree for the Sentence, *Does John love Mary*

The analyses up to *John love Mary* are the same as those of (13). Then, T *does* is merged, and *v* of *John love Mary* is matched with *v*= of T. The other features are unified. Since T is merged, we may activate the feature-matching process, and we check the identity of the pair [nom<sub>0</sub>]-[nom<sub>1</sub>]. Because these two features are identical, this pair

disappears. Note that the semantic interpretation changes from  $love'(j,m)$  to  $[t_0=pres \wedge p=[love'(j,m) \vee \neg love'(j,m)]]$ , because  $love'(j,m)$  combines with  $\lambda\phi[t_0=pres \wedge p=[\phi \vee \neg \phi]]$  where the former is an argument and the other is a functor. Finally, C is merged with *Does John loves Mary*, and T of *Does John loves Mary* is matched with =T in C. Also note that the semantic interpretation changes from  $[t_0=pres \wedge p=[love'(j,m) \vee \neg love'(j,m)]]$  to  $[f=quest \wedge t_0=pres \wedge p=[love'(j,m) \vee \neg love'(j,m)]]$  because  $[t_0=pres \wedge p=[love'(j,m) \vee \neg love'(j,m)]]$  combines with  $\lambda\phi[f=quest \wedge \phi]$ , where the former is an argument and the other is a functor.

### 4.3. Wh-Questions

Now, let's move to wh-questions. From a declarative sentence (1a), we can derive wh-questions in (1c) and (1d). (1c) can be analyzed as in (21).

- (1) a. John loves Mary
- c. Who loves Mary?
- d. Who(m) does John love?

(21) Analysis Tree for the Sentence, *Who loves Mary*

The analyses up to *John love Mary* are the same as those of (13). Then, *Who* is merged

with *love Mary*. Because the category D of *Who* satisfies the select feature D= in *love Mary*, D of *Who* is matched with D= in *love Mary*. The other features are unified. Note that the semantic interpretation of *who* is  $\lambda P \lambda x_1 [person'(x_1) \wedge P(x_1)]$ . It becomes a functor, and the semantic interpretation of *love Mary* becomes an argument. Therefore, the semantic interpretation of *Who love Mary* becomes  $\lambda x_1 [person'(x_1) \wedge love'(x_1, m)]$ . Also note that *Who* contains a wh-feature  $[wh_1]$ . Now, T -s is merged, and *v* of *Who love Mary* is matched with  $v=$  of T. The other features are unified. Since T is merged, we may activate the feature-matching process, and we check the identity of the pair  $[nom_0]$ - $[nom_1]$ . Because these two features are identical, this pair disappears. Finally, C is merged with *Who loves Mary*, and T of *Who loves Mary* is matched with  $=T$  in C. Here  $[wh_1]$  feature of T is checked with  $[wh_0]$  of C, and *f* has a value *quest* (question).

Now, let's move on to the second wh-question. From a declarative sentence (1a), we can derive a wh-question in (1d), and (1d) can be analyzed as in (22).

(22) Analysis Tree for the Sentence, *Whom does John love*

The analysis proceeds as follows: First, *love* is merged with *whom*. Because the category D of *whom* satisfies the select feature =D in *love*, D of *whom* is matched with =D in *love*. The other features are unified. Note that the semantic interpretation of *whom* is  $\lambda P \lambda x_2 \lambda x_1 [person'(x_2) \wedge P(x_2)]$ . It becomes a functor, and the semantic interpretation of *love* becomes an argument. Therefore the semantic interpretation of *love whom* becomes

$\lambda x_2 \lambda x_1 [person'(x_1) \wedge love'(x_1, x_2)]$ . Also note that *whom* contains a wh-feature  $[wh_2]$ . Then, *love whom* is combined with a light verb  $v$ . Since the category V of *love whom* satisfies the select feature  $=V$  of the light verb  $v$ , V of *love whom* is matched with  $=V$  in the light verb. The other features are unified. Because  $v$  is merged, we may activate the feature-matching process, and we check the identity of the pair  $[acc_0]$ - $[acc_1]$ . Since these two features are identical, this pair disappears. That is, Accusative Case in *whom* is licensed. Now, *John* is merged with *love whom*. Because the category D of *John* satisfies the select feature  $D=$  in *love whom*, D of *John* is matched with  $D=$  in *love whom*. The other features are unified. Now, T *does* is merged, and  $v$  of *John love whom* is matched with  $v=$  of T. The other features are unified. Since T is merged, we may activate the feature-matching process, and we check the identity of the pair  $[nom_0]$ - $[nom_1]$ . Because these two features are identical, this pair disappears. Finally, C is merged with *does John love whom*, and T of *does John love whom* is matched with  $=T$  in C. Here, *whom* moves into the sentence-initial position by the operation on the PHON value, making a sentence *Whom does John love*. Here  $[wh_2]$  feature of T is checked with  $[wh_0]$  of C, and  $f$  has a value *quest*.

## 5. Conclusion

This paper provides computational algorithms by which we can implement syntax and semantics of questions in computational minimalism. In order to implement questions, this paper modifies Stabler's system and proposes an RCM system. Within this RCM system, the semantic interpretations of yes-no questions are represented by two propositions, one of which is true and the other is false. The semantic interpretations of wh-questions are represented by a set of entities that satisfied the propositions. Furthermore, the semantic interpretations are compositionally calculated based on the mechanisms in Montague semantics.

## Notes

<sup>1</sup> When we say *questions*, rather than *interrogatives*, it usually implies that we especially focus on semantic interpretations in addition to syntactic behaviors.

<sup>2</sup> Here, double colon ( $::$ ) stands for lexical items, and single colon ( $:$ ) stands for derived items.

# Subjunctive-Negation Interaction in Persian

Ali Darzi

University of Tehran  
Department of linguistics  
Faculty of Letters and Humanities  
Tehran University  
Tehran, Iran  
alidarzi@ut.ac.ir

## Abstract

The goal of this paper is to offer a morpho-syntactic account of the co-occurrence restrictions between the subjunctive marker in Persian on the one hand and the negative marker and aspect marker on the other. To do this, a polarity phrase is proposed with a head bearing either a negative or a [-imperfective] feature. Also, the aspect marker, heading the aspect phrase, is assumed to have a [+imperfective] feature. The complementary distribution of the subjunctive marker and the aspect marker is regulated by the feature composition of the verb which may bear a [+/-imperfective] feature. A Pol with a Neg feature lacks any specification for the [imperfective] feature, permitting the co-occurrence of the negative marker and the aspect marker.<sup>1</sup>

## 1. Introduction

Though mood has been discussed in traditional grammar books on Persian, there is no discussion on how it interacts with negation in this language. Persian has a relatively rich verbal morphology with the majority of verbal concepts expressed via complex predicates. A verb, light or heavy, may bear up to two inflectional prefixes and the maximum of three inflectional suffixes. The inflectional prefixes come from a set including the negative marker, the subjunctive marker, and the aspect marker. The suffixes come from a set including markers of tense, perfectivity, and subject agreement in that order. This is illustrated in (1) in which the negative marker precedes the aspect marker, and with the tense, the perfective marker and the subject agreement suffixes following the present stem of the verb in that order. Subjunctive clauses, marked with

the verbal prefix *-be* are usually selected by the matrix verb (2), an adverbial element, a modal (3), etc, or appear in imperative clauses (4).<sup>2</sup>

- (1) U nahar ne-mi-xor-d-e.  
 S/he luch not-Asp-eat-PST-PSP.3sg  
 ‘S/he has not been eating lunch.’
- (2) Pro mi-xa-m [<sub>CP</sub> PRO<sub>i</sub> be-r-æm unja].  
 Asp-want-1.sg Sub-go-1sg there  
 ‘I want to go there.’
- (3) Pro bayæd be-r-æm unja.  
 must Sub-go-1sg there  
 ‘I must go there.’
- (4) Ketab-a-ro be-zar ru miz.  
 Book-pl-Ac Sub-put on desk  
 ‘Put the books on the desk.’

The main concern of this paper is the strict co-occurrence restriction between the subjunctive mood marker on the one hand and the aspect marker and the negative marker on the other. I basically focus on simple verbs as the proposal in this article can easily be extended to compound verbs or complex predicates. The restrictions are shown in (5) and (6). While the subjunctive marker is in complementary distribution with both the negative marker and the aspect marker as shown in (5), there is no such restriction between the negative marker and the aspect marker as illustrated in (6).<sup>3</sup> Note that there is a strict ordering relationship between the negative marker and the aspect marker with the former always preceding the latter if the latter is present.

- (5) Pro mi-xa-m [<sub>CP</sub> PRO<sub>i</sub> be-(\*næ/\*mi)-r-æm unja].  
 Asp-want-1sg Sub(not/Asp)-go-1sg there  
 ‘I want (\*not) to go there.’
- (6) Mæn ne-mi-r-æm unja.  
 I not-Asp- go-1sg there  
 ‘I do not go there / I am not going there / I will not go there.’

In imperative sentences too, the verb is either marked with the subjunctive marker or with the negative marker. This is illustrated in (7) and (8), in which the relative ordering of the verbal prefixes in the complex predicate corresponding to ‘sign’ in English is irrelevant as they may not cooccur to begin with.<sup>4</sup>

- (7) Ketab-o (\*næ)-be-zar unja.  
 Book-Ac (not) Sub-put there  
 ‘(Don’t) put the book there.’

- (8) namæ-ro emzak be-(\*næ)-kon.  
 letter-Ac signature Sub(not)-do  
 ‘ (Don’t) sign the letter. ’

Section 2 discusses the affixal nature of the verbal prefixes. I show that the negative marker, the aspect marker and the subjunctive marker are better analyzed as verbal prefixes constituting a phonological word with the verb stem, rather than being independent heads to which the verb stem moves successive cyclically. In section 3 I discuss the structural position of these prefixes within the clause. Section 4 presents an account of the co-occurrence restrictions between the subjunctive marker and the other verbal prefixes. Section 5 concludes the paper.

## 2. The Affixal Nature of Verbal Prefixes

As noted earlier, there might be up to two verbal inflectional prefixes in Persian coming from a set including the negative marker, the subjunctive marker, and the aspect marker.

Subjunctive clauses in Persian, that are closest counterparts of English infinitival clauses, have a distribution similar to Greek subjunctive clauses marked with *na-* as discussed in Giannakidou (2007) in being selected by verbs of different semantic categories like volition (*xastæn* ‘want’), permission (*ejaze-dadæn* ‘allow’, *mæmnu’-kærdæn* ‘prohibition doing’), direction (*dæstur-dadæn* ‘order giving’, *tosiye-kærdæn* ‘advise doing’, *pišnæhad-kærdæn* ‘suggestion doing’) modality (*bayæd* ‘must’), verbs of fear (*tærsidæn* ‘be afraid’), and commission/implication (*mæjbur-budæn* ‘forced being’, *mæjbur-kærdæn* ‘force doing’) etc,. Of course, they may also be selected by a modal, an adverbial particle, etc, as was noted earlier

Though subjunctive clauses in this language usually seem to express a nonveridical proposition as in (2)-(3) above where they express a state of unknown (or as yet undefined) truth, Persian subjunctives are apparently not restricted to introduce a nonveridical proposition. The fact that the sentence in (9) entails that the referent of the main clause subject has been able to get to the goal of location of the embedded predicate suggests that Persian subjunctives do not necessarily express nonveridical propositions. Rather, they seem to state an unrealized tense with respect to the time of the main clause or the utterance time. This is similar to Baker’s (2004) treatment of *nà* in Lokaa which seems to be a general irrealis category, treated as mood marker in his analysis.<sup>5</sup>

- (9) Hæsæn tunest be-r-e unja.  
 Hassan could Sub-go-3sg there  
 ‘Hassan managed to go there.’

There are phonological reasons in support of analyzing the negative maker, the subjunctive marker, and the aspect marker as verbal affixes. To begin with the subjunctive marker, this prefix may participate in vowel harmony with the verb stem in colloquial Persian if the latter bears a high front or mid back vowel as shown in (10) below. This suggests that the subjunctive marker forms a phonological word with the verb stem.

- (10) a. æge be-šin-i → æge bi-šin-i  
 if Sub-sit-2sg  
 ‘if you sit down.’  
 b. æge be-xor-i → æge bo-xor-i  
 if Sub-eat-2sg  
 ‘if you eat.’

Moreover, the subjunctive prefix attracts the stress which usually falls on the last syllable of the verbal stem if the verb lacks any kind of inflectional prefixes. This is exemplified in (11)-(12), in which the stressed syllables are italicized. In (11), which lacks any verbal prefixes, the stress falls on the last syllable of the verb stem. However, in (12), where the verb stem is prefixed with the subjunctive marker, the stress falls on the prefix.

- (11) Mæn hedyæ-ro pæziroft-æm.  
 I gift-Ac accept.PST-1sg  
 ‘I accepted the gift.’  
 (12) Mæn bayæd hædyæ-ro be-pæzir-æm.  
 I must gift-Ac Sub-accept-1sg  
 ‘I must accept the gift.’

Once again, the stress attraction phenomenon would be accounted for straightforwardly if the subjunctive marker forms a single prosodic unit with the verb stem.

Another inflectional verbal prefix is *mi-*, which has traditionally been analyzed as the indicative mood marker. However, Windfuhr (1979:85) cites Lentz (1958) as stating that *mi-* marks an event not restricted in terms of its beginning or end. This makes it the marker of imperfect aspect, according to Windfuhr (1979:85). In a more recent analysis of *mi-* in Persian, Taleghani (2006:153) analyzes it as the head of the aspect phrase that marks imperfective aspect and encodes habituality or continuity of an action. This is

similar to the imperfective marker in Greek sentences that are generally ambiguous between the habitual and the progressive, as is often the case according to Comrie (1967). The interpretation of the sentences in (13)-(14) supports the analysis of this prefix as the aspect marker. Note that this prefix may mark the verb irrespective of its tense feature. This is in contrast to the subjunctive marker that strictly appears on the present stems of verbs in Persian. Interestingly, the aspect marker attracts the stress as well. This is illustrated in (13)-(14) with the stressed syllables italicized. In the absence of the aspect marker, the sentence in (13) would simply state a proposition that refers to a single action that was performed in the past corresponding to “I wrote a letter” in English.

(13) Mæn name *mi*-nevešt-æm.  
 I letter Asp-write.PST-1sg  
 ‘I (usually) wrote letters / I was writing letters.’

(14) Mæn name *mi*-nevis-æm.  
 I letter Asp-write -1sg  
 ‘I write letters / I am writing letters.’

The other remaining verbal prefix is the negative marker *næ-* ‘not’ which precedes the aspect marker if the latter is present on the verb. The stress shift phenomenon also holds true for the negative marker. In other words, the leftmost verbal inflectional prefix, being it the negative marker, the aspect marker or the subjunctive marker, attracts verbal stress as exemplified in (15)-(16). Therefore, I conclude that the verb stem already bears any permissible combination of mood, aspect, and negative features upon entering the derivation. (c.f, Baker 2004 and Blaszczyk 2007 for a similar treatment of infl in Lokaa, and the negative marker *nie-* in Polish respectively).

(15) Mæn name *ne*-mi-nevešt-æm.  
 I letter not-Asp-write.PST-1sg  
 ‘I did not (usually) write letters / I was not writing letters.’

(16) Mæn name *ne*-mi-nevis-æm.  
 I letter not-Asp-write-1sg  
 ‘I don’t write letters / I am not writing letters.’

As noted earlier, the stress attraction will be accounted for if the verbal prefixes form a single prosodic unit with the verb stem. Following the spirit of the Distributed Morphology (Halle & Marantz 1993), I take these inflectional prefixes as features on the verb stem that are phonologically realized after the application of postsyntactic Word Formation Rules and the insertion of lexical items at the morphological structure.

In other words, I do not take any of these prefixes as functional heads to which the verb stem moves successive cyclically.

### 3. The Structural Position of NegP in Persian

I assume that there is a parametric variation across languages with regard to the position of NegP in that in some languages NegP selects a TP as its complement, whereas in others NegP selects a VP (vP in more recent proposals for clause structure) (cf. Ouhalla 1990, Zanuttini 1991,1994, 1997, Acquaviva 1995, Cinque 1999 for this parametric view). Acquaviva (1995) maintains that negation does not have a fixed scope with respect to modal auxiliaries and does not have to occupy a fixed place or that it can only be interpreted in one particular position. It simply has to be above VP to include in its scope all the arguments of the sentence.

With regard to negation in Persian, Taleghani (2006:150) argues that NegP in sentence negation dominates TP in this language. She appeals to Laka's (1994) tense c-command condition in (17).

- (17) Tense C-command Condition: Tense must c-command at s-structure all propositional operators of the clause.

(Laka 1994:3)

She goes on to argue that the grammaticality of the Persian sentence in (18), as opposed to its English translation, indicates that the subject negative polarity item (NPI) *hičkæš* 'nobody' in Persian is in the c-command domain of the head Neg, as opposed to its English counterpart. This would be explained, according to her, if NegP is above TP, c-commanding the subject. She, then, follows Laka (1994) for a similar proposal for Basque and suggests that the tensed verb or the auxiliary raises to Neg to c-command the Neg in compliance with the Tense C-command condition.

- (18) *Hičkæš Sara-ro ne-mi-šenaxt.*  
nobody Sara-Ac not-Asp-knew.3sg  
\* 'Anybody didn't know Sara.' (Nobody knew Sara)

(Taleghani 2006:150:19b)

Leaving aside Kwak & Darzi's (2006) arguments in support of analyzing *hičkæš* 'nobody' as a Negative Concord Item (NCI) as opposed to an NPI, these items in Persian are not necessarily c-commanded by the licensing negative marker at spell out. What Taleghani (2006) treats as an NPI in Persian may scramble into a higher clause with the negative verb remaining in the embedded clause. This is shown in (19)-(20).

- (19) *Hičkæs* pro fekr mi-kon-æm Sara-ro *næ-šenas-e*.  
 nobody thought ASP-do-1sg Sara-Ac not-know-3sg  
 ‘Nobody, I think knows Sara.’
- (20) *Hičkæs-o* pro hæds mi-zæn-æm Ali *næ-šenas-e*.  
 nobody-Ac guess ASP-hit-1sg Ali not-know-3sg  
 ‘I guess that Ali does not know anybody.’

The sentences in (19)-(20) may be explained if the subject NPI/NCI is licensed in its merge position in the spec of vP, where it is c-commanded both by the Neg and by the T before it is scrambled into the matrix clause. In other words, the tense c-command condition is satisfied before the subject NPI/NCI undergoes any movement operations. Therefore, I assume that negation in Persian is embodied in a projection that is dominated by the TP and that dominates vP with an empty specifier position for the scope of negation (Haegeman 1995). This analysis is in line with Karimi’s (2005) proposal that subjects in Persian stay within the domain of vP unless they are topicalized or focused. As such, in-situ subject NPI/NCIs in negative sentences which do not bear any discursal features are licensed in the vP domain asymmetrically c-commanded by the head hosting the Neg feature.

Turning now to the so-called subjunctive marker in Persian, this prefix is in complementary distribution with both the negative marker and the aspect marker as shown in (5) above repeated here in (21).

- (21) Pro mi-xa-m [<sub>CP</sub> PRO<sub>i</sub> be-(\*næ/\*mi)-r-æ unja].  
 Asp-want-1sg Sub(not/Asp)-go-1sg there  
 ‘I want (\*not) to go there.’

However, the negative marker and the aspect marker may co-occur with the former always preceding the latter as exemplified in (15)-(16) above repeated here in (22)-(23).

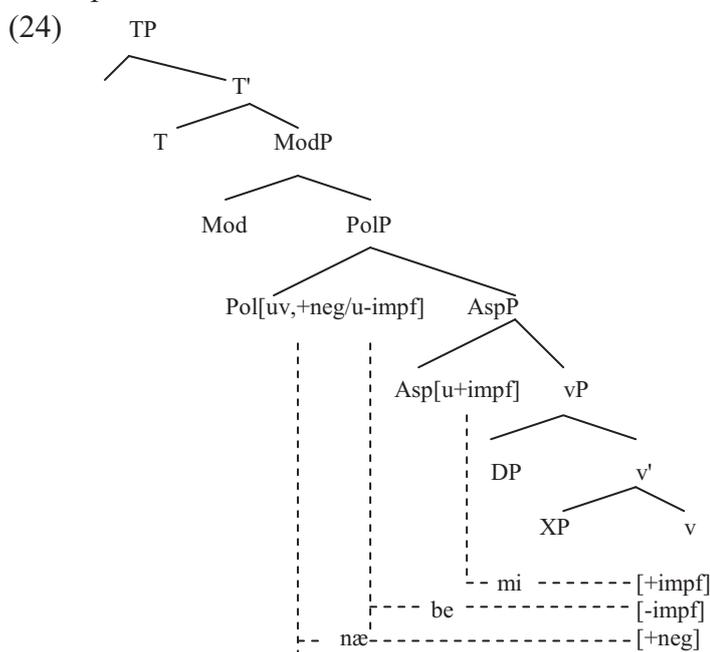

- (22) Mæn name **ne**-mi-nevešt-æm.  
 I letter not-Asp-write.PST-1sg  
 ‘I did not (usually) write letters / I was not writing letters.’
- (23) Mæn name **ne**-mi-nevis-æm.  
 I letter not-Asp-write -1sg  
 ‘I don’t write letters / I am not writing letters.’

Having this discussion in mind, I propose, in the next section, a hierarchical structure of functional projections responsible for negation, subjunctivity and aspect in Persian. Though I propose a feature-based analysis of the functional projections in question, I would adopt Baker’s (1985) Mirror Principle according to which there is a close parallelism between morphology and syntax. More specifically, I propose a PolP

that hosts negation and subjunctivity and that dominates the AspP, which in turn dominates the vP.

#### 4. Analysis

Following Taleghani (2006:196), I posit the modal *bayæd* ‘must’ as the head of a Modal Phrase (ModP). Also, following Baker’s (2004) proposal for Lokaa, I propose a PolP for Persian non indicative clauses with a head specified either for the subjunctive or the negative feature (see Haegeman 1995 for an overview; see also Zanuttini 1997). The PolP is assumed to be selected by a modal, a selecting verb or an adverbial, etc.. As such, I propose the structure in (24) for sentence negation in Persian. Under this proposal, negation would not only include in its scope all the arguments of the verb but is also c-commanded by the head T in compliance with the tense c-command condition. Note that whether the functional heads TP, PolP and AspP are head initial or head final does not have any bearing on my analysis. I have simply taken them to be head-initial just for exposition.

The head Pol is proposed to have an uninterpretable [v] feature (uv) requiring the head verb v to enter into a checking relation with the Pol. This head is the locus of

either the subjunctive or the post-modal negative feature, capturing the complementary distribution of the two. The head of the AspP has an uninterpretable [+imperfective] feature requiring a verb with the relevant feature. The complementary distribution of the subjunctive marker and the aspect suffix is regulated by the feature composition of the head *v*. If the head *v* has the [+imperfective] feature, it can only come into a checking relation with the head of the aspect phrase realizing *mi-* on the verb. The head Pol may have different sets of features just like the head T which may have different sets of features for number, person and tense. If the Pol is specified for an uninterpretable [-imperfective] feature, it checks the relevant feature on the verb giving rise to subjunctive morphology. This explains the complementarity of the aspect marker with the subjunctive marker. If the head Pol bears the [+neg] feature and lacks any specification for the [imperfective] feature, we may have a negative subjunctive clause, or a negative imperfective clause just in case the aspect phrase is present in the latter case, or a negative perfective clause.

## 5. Conclusion

In this paper I presented a morpho-syntactic account of Persian verbal morphology focusing on verbal prefixes. Co-occurrence restrictions were shown to hold among prefixes in that the subjunctive marker was incompatible with both the aspect marker and the negative marker. I proposed a structure for Persian clauses with a PolP dominating the AspP, which in turn dominates the vP. The head of the aspect phrase and the head of PolP were assumed to bear certain morpho-syntactic features that interacted with corresponding syntactic features on the head *v*. The head Pol is either the locus of the [neg] feature, or the locus of subjunctivity. More specifically, the Pol may come with either an uninterpretable [-imperfective] feature or a [+neg] feature. If it bears the [-imperfective] feature, it will be incompatible with the aspect marker which bears a [+imperfective] feature by nature. The head Pol may also bear the negative feature in which case it is compatible with the aspect marker. The [+neg] feature on the head Pol checks the relevant feature against the corresponding feature on the verb and is indifferent to the presence of the head Asp, accounting for the permissible co-occurrence of negation marker and the aspect marker. Of course the aspect phrase or the PolP or both may be absent.

---

## Endnotes:

---

<sup>1</sup> This paper was partially supported by a grant from the Vice Chancellor for Research at the University of Tehran.

<sup>2</sup> Persian is a pro-drop SOV language, however clausal complements in this language follow their selecting heads. The verb stems come in two forms, past and present (Lazard 1957:157). The past morpheme is not independently marked on past stems. This does not have much bearing on the analysis I will propose in this article within the distributed morphology framework.

It is to be noted that *-bi*, and *-bo* are two other allomorphs of the subjunctive marker as *ne-* and *ni-* are two other allomorphs of the negative marker *næ-*. In the literary register of Persian, *mæ-* is often employed as another allomorph of the negative marker.

I am using the following abbreviations:

Asp; aspect marker (also taken as the indicative marker in the Persian traditional grammars.)

Sub: subjunctive                      sg:singular

PSP: past participle                  Neg: Negative

Ac: accusative                         PST: past

<sup>3</sup> The only exception to this generalization in Persian is the suppletive subjunctive form of the verb corresponding to 'be' in English which may co-occur with both the negative marker and the subjunctive marker as in (i) below. Interestingly, this form, which is proscribed by grammarians, is not necessarily selected by a modal, a selecting verb etc, and is interpreted jus like an indicative form.

(i) In    be    ma    mærbut    ne-mi-ba-š-æd.

      This to us related    not-Asp-be.Sub-3s

      This is none of our business.

<sup>4</sup> The subjunctive marker may optionally be absent on the light verb of some complex predicates in Persian through which the bulk of Persian verbal concepts are expressed. This is shown in (i) below.

(i) Mæn mi-xa-m [CP PRO<sub>i</sub> namæ-ro emza (be)-kon-æm

      I      Asp-want-1.sg      letter-Ac      Signature (Sub)-do-1sg

      'I want to sign the letter.'

---

<sup>5</sup> It is to be noted that in non-literary register of Modern Persian, the subjunctive mood marker does not get prefixed to verbs in the past tense. Compare the sentence in (9) in the text to that in (i) below.

- (i) \*Hæsæn tunest be-ræft unja.  
Hassan could Sub-went.3sg there  
'\*Hassan was able to went there.'

# Number Agreement in a Sign Language

Anne-Marie Parisot — Denis Bouchard

Université du Québec à Montréal

[bouchard.denis@uqam.ca](mailto:bouchard.denis@uqam.ca)

## Abstract

Several authors have described agreement in American Sign Language in terms of abstract features (Padden 1983; Bahan 1996), of locative case (Janis 1995) or relatively to a two-person (Meier 1990). However, others have questioned the relevance of the notion of agreement for ASL, on the basis that there is an infinite number of variations for the third person (Liddell 2000). We show that there are no paradigmatic features of agreement in sign languages, notably in Langue des Signes québécoise. Why is that so? To answer this question, we must understand how the differences in modality affect the functioning of agreement in the linguistic system of oral languages and gestural languages. We concentrate on the case of Number agreement in LSQ.

**Keywords:** number agreement, quantification, Sign language, LSQ, space.

## 1. Introduction

There are numerous phenomena of agreement in oral languages, e.g., between a pronoun and its antecedent, or a noun phrase and a predicate. There are no instances of agreement in Langue des Signes Québécoises (LSQ, the sign language used by deaf people in the province of Quebec). We show that this absence of agreement is not fortuitous, but that it is due to a fundamental difference between some properties of the substance of the form in an oral language and a sign language. Agreement takes place in oral languages either because the signifier is short-lived and we must produce a new one to reactualize its denotation, or in order to facilitate parsing by introducing redundancy in the information which is provided. In a sign language, the elements which correspond to the ephemeral oral elements have a certain permanency in space, and this is why there is no agreement. Moreover, gestural information is typically more precise, less ambiguous, and grammatical parsing can operate without problems in the cases which

correspond to those which necessitate redundant agreement in oral languages. Therefore, agreement has no function to fulfill in sign languages and we predict that agreement should be absent from all sign languages. We show that cases which have been analysed as agreement are actually something else. In this paper, we illustrate this with the example of Number agreement, which in sign language is actually either quantification or aspect. In order to clarify the place of grammatical Number in the system, we describe the expression of plurality in LSQ and compare it with how it is expressed in an oral language with a fairly rich morphology in this regard, i.e., French. Next we clarify what agreement is and its function in grammar. We then analyze the LSQ constructions which are equivalent to those where there is Number agreement in oral languages and we show that there is never agreement in those cases in LSQ. We conclude with some thoughts on language universals.

## 2. The expression of quantity

Quantity in languages can be about the actants of the event expressed by a sentence (like singularity or plurality of the individuals to which a nominal expression refers). The quantity of individuals is expressed either by quantifiers with quite varied meanings (all, many, some, every, half, etc.), or by grammatical inflections of Number, which are relatively restricted semantically (singular, plural, sometimes dual, rarely more). Quantifiers can appear in nominal expressions (1) or as adverbials in the sentence (2).

It should be numbered with Arabic numerals (1,2,3, etc.) in parentheses and indented:

- (1) *Tous ces journaux originaux sont internationaux.*  
[All these original newspapers are international.]
- (2) *Les journaux originaux sont tous internationaux.*  
[(The) original newspapers are all international.]

The Number inflections can appear on various elements. As can be seen in (1), in French, there can be Number inflections on a noun (*journaux*, vs singular *journal*), on a determiner (*ces*, vs singular *ce*), on a quantifier (*tous*, vs singular *tout*), on an attributive adjective (*originaux*, vs singular *original*), on a verb (*sont*, vs singular *est*), on a predicative adjective (*internationaux*, vs singular *international*). The determiner bears the semantically meaningful Number in French; the Number inflections on the other elements are due to agreement and no meaning of quantity is attributed to them (as

shown in Bouchard 2002).

In addition to quantity about the individuals denoted by nominal expressions, languages may also express quantity about the events and sub-events expressed by a sentence (aspect, aktionsart). In this paper, we look mainly at the expression of the quantity of individuals referred to by a nominal.

### 2.1. Number inflections in LSQ

In order to understand how quantity is expressed in a nominal expression in sign languages, it is important to know how nouns are introduced in discourse in these languages. The substance of the signifier of a noun is spatial: a noun is introduced when its sign is produced in space. The noun may simply be produced without any particular localization in space (3), or, more typically, it is also assigned a locus in the signing space. This locus assignment can be done by directly signing the noun on the locus in space (4), or by a *pointer* (5) (a manual sign, but also possibly a glance (6) or an inclination of the torso (7) “pointing” to the locus) (Parisot and Rinfret, to appear). The loci assigned this way remain in the discourse until they are changed (Lillo-Martin 1986).

- (3) NOT-EASY FOR DEAF.<sup>1</sup>  
[It’s not easy for a/some/the(plur/sing) deaf-person(s).]
- (4) PHONE(loc) TO-RING.  
[The phone is ringing.]
- (5) ME TO-GUESS PHONE *pointer*.  
[I guess that it’s the phone (which is there that is ringing) ]
- (6) WHEN TO-WANT TO-CALL FRIEND(glance) DEAF ...]  
[When I want to call a deaf friend... ]
- (7) FIFTY PERCENT MINUS REBATE FOR DEAF(shoulder)  
[It’s a special fifty percent rebate for the deaf. ]

This assignment is a way to associate a noun with a locus. The locus can then be used to associate the noun with a predicate to assign it a grammatical function (subject if it is the first locus associated with the verb, object if it is the second one). Grammatical Number is expressed by the shape of the pointer at the initial assignment

---

<sup>1</sup> The examples (3) to (7) are taken from a public interview in LSQ of a native deaf signer, broadcasted during a program called *La parole en mains*.

of a locus to the noun. If the pointer is a point on the locus, this corresponds to singular; if the pointer traces a circular movement which designates a zone in the locus (8), this corresponds to plural (Padden 1990).<sup>2</sup>

- (8) STUDENT pointer (zone) BOOK GIVE-1  
[The students give me a book.]

## 2.2. *Quantifiers in LSQ*

LSQ has signs corresponding to quantifiers like EVERY, SOME, ALL. For instance, universal quantification can be expressed or by using a linear movement across a series of loci:

- (9) DOOR pointer (linear movement) MAN CLOSE  
[The man closes all the doors.]

Quantification can also take place by incorporating a quantifier of cardinality which assimilates phonologically to a noun expressing time (2-HOUR), money (5-PENNY), or number (4-THOUSAND).

Because they operate in space, sign languages have a greater potential of iconicity. For instance, it is possible to express a plural quantity by assigning several loci to a noun as in (10), or by indicating several points inside the zone of a locus (11) (see Pizzuto and Corazza 1996, among others).

- (10) SHOE pointer pointer pointer MARIE GIVE -1  
[Marie gives me shoes.]

The number of loci does not correspond to an exact amount but is an indication of a certain quantity. This kind of reduplication appears in many sign languages. For instance, Johnston and Schembri (2007) mention that reduplication of the noun to express plural is optional in Australian Sign Language. In LSQ, this kind of modification is rare. It is typically found in cases of semantic plurals like FOREST (many trees) or LEXICON (many words), in a few cases where grammaticalization is productive like CHILDREN, or in contexts of iconic specification concerning the layout

---

<sup>2</sup> Note that some nouns are semantically incompatible with the assignment of grammatical Number. For instance, LUMIÈRE ('light') expresses a non-countable concept and a special classifier must be used if we want to attribute a countable quantity to it by a point or a zone locus.

of units like CHAIRS (row of chairs) or BOOKS (pile of books).

Iconicity also makes it possible to use a zone-locus to indicate the size of a referent. If the referent is small (AMOEBA) or unique (CAT), it is assigned a point-locus. If it is big (REGION) or numerous (CHILDREN), it is assigned a zone-locus. When the referent is a collectivity, its zone corresponds to the type of quantity involved: a set of atomic units receives a series of point-loci, whereas a set expressed as a singularity receives a delimited zone. Collective zones can be divided in sub-zones to express a partition of the quantity (some of these units, half of the set, etc.). This partition can be highly iconic, as in (11), where the first point-pointer situates MONTREAL whereas the circular movement of the zone-pointer situates the collective REGION in which the nearby suburbs LONGUEUIL, LAVAL and ST-HUBERT are actualized, followed by another point-pointer which situates the geographically more distant SOREL.

- (11) FOR MONTRÉAL POINTER(point) REGION POINTER(zone)  
[LONGUEUIL LAVAL ST-HUBERT] SOREL POINTER(point)  
[[The services are] for here, in Montreal, [for the other cities of the region]  
Longueuil, Laval, St-Hubert, and [further away] Sorel]

It is also possible to express quantity by assigning to the noun a locus with different kinds of arrangements as, for example, on a linear dimension (12).

- (12) CHILD (linear movement) 1-GIFT  
[I give a present to the children.]

### 3. Agreement

Since quantifiers and Number inflections often involve the locus assigned to the noun, and since the locus is also used to establish a link between the noun and the predicate with which it has a grammatical relation (subject, object), these modifications of the shape of the locus are often analyzed as verbal inflections of agreement in Number (and person). But as we will now see, that is not the case. These are either simple assignments of grammatical functions, or aspectual markings bearing on the number of sub-events instead of the number of individuals.

### 3.1. Definition and function of agreement

In order to determine whether there is agreement or not, we must agree on a definition of what agreement is. We propose a classical definition: there is agreement when a word depends on another word or phrase for some of its features. Typically, the features involved are associated with morphological markings such as gender, Number or person, but they need not, as in *Mary, a joyful woman/\*man, stepped forward*. The morphological features can be associated with a referential or semantic content, such as *them* in (13a) which refers to more than one individual, distinct from the speaker or hearer, or the morphological features can be purely formal, like all the plural markings in (13b) except the one on *ces*.

- (13) a. Mary doesn't see them.  
b. *Ces journaux originaux sont internationaux.*

It is not surprising that theories to account for agreement phenomena oscillate between these two poles—semantic-discursive vs formal. For instance, Lehmann (1988) and Barlow (1992) propose a discursive approach in which agreement operates on features which have an informative value about the reference of the elements.<sup>3</sup> This approach can account for cross-sentential agreement, which cannot depend on syntactic operations, these being restricted to intra-sentential dependencies.

- (14) Mary and John came by yesterday. She left you some flowers.

Others, like Lapointe (1980, 1988), have defined grammatical agreement in a purely semantic perspective.<sup>4</sup> He includes in agreement the morphological features of nouns which vary according to grammatical functions, i.e., case markings.

In contrast, some adopt a strictly formal perspective, where agreement is a correlation of morphological features, including some features which are uninterpretable both semantically and phonologically, as in the minimalist program since Chomsky

---

<sup>3</sup> “Agreement according to this theory consists not of a matching of features at a syntactic level, but rather a matching of properties contained in discourse referents equivalent to the source and target” (Barlow, 1992, p. 155). “[...] agreement is referential in nature. It helps identify or reidentify referents. It does this by giving information on grammatical properties of its referent and, thus, of the NP representing it if one is around. The function of agreement in the marking of syntactic relations derives from this primary function” (Lehmann, 1988, p. 55).

<sup>4</sup> “The term *agreement* will be applied to those morphosyntactic cooccurrences in which there is an overt controller and overt controllee and in which the form of the controllee depends on universally specified semantic categories of the controller” (Lapointe, 1988, p. 70).

(1995).

The theory of agreement of Bouchard (1984, 1987, 1995) is based on the notion of coherence. It covers all these variants of agreement—referential, semantic and formal— because coherence can operate on various types of elements : a reference, an interpretation, or a structure. Moreover, this approach allows us to understand the function of agreement, which is to ensure the coherence of the interpretation of the elements in order to facilitate parsing. This coherence can operate on the discursive/referential level as in pronominal reaccessing: for instance, a plural marking on a pronoun helps to determine its antecedent by reducing the potential antecedents to those which are more than one. When coherence operates on the formal level, as in *ces journaux originaux*, it serves to make the phrasal cohesion more salient in order to facilitate syntactic parsing.

We can now ask why there is agreement in a language like French (and other oral languages). In oral languages, abstract feature agreement is necessary when we want to actualize a referent anew because the perceptual substance of these languages restricts utterances to temporal sequences of elements which have no permanency. Any oral signifier is ephemeral: once pronounced, it cannot be reused (Bouchard 2002). For example, once we have said *La comtesse est sortie à cinq heures* ('The countess went out at five'), we cannot reuse this instance of the phrase *la comtesse*: we must say once again *la comtesse*, or introduce another specialized signifier, like a pronoun, to reactualize the information. There must be a new signifier, yet at the same time there must be an indication of permanency, of a recall of a previously established actualization. Since this cannot be done by a signifier which has a certain permanency like the locus in sign languages, the means used in oral languages to establish a certain permanency must be indirect: it is done through a paradigm of abstract features, and it is this paradigm which has permanency— in this case, the paradigmatic slot [+FEM; +SING; 3PERS] of *la comtesse*. So only pronouns with these feature values (such as *elle* or *la*) are appropriate to reactualize the information of *la comtesse*, because their morphological features are coherent with those of *la comtesse*. As mentioned by Lehmann (1988: 61), the referent is not identified by specifying all its attributes each time it is reactualized in discourse. It is identified by specifying only some of its features, for the sake of economy: it is less costly to use only a subset of its features. However, this economy comes with a certain lack of precision. For instance, the set of feature values [+FEM; +SING; 3PERS] may correspond to several antecedents in the context. However, discursive strategies usually restrict the possibilities to one element which is more salient at a given moment of discourse.

In contrast, in sign languages, the perceptual substance operates in space and the elements of the utterances are not as strongly restricted to temporal sequences, nor are they as momentary as in oral languages. The assignment of a locus to a noun is unique and non-ambiguous. According to Liddell (2000), a locus represents an entity directly and iconically in the sign space. Moreover, a locus assignment remains in the discourse unless it is changed (Lillo-Martin 1986). Therefore, loci have a certain permanency, in the sense that we can reuse the same locus—a tangible element, a signifier—whereas this is not possible for a signifier in an oral language. This special property allows a locus signifier not only to actualize a referent, but also to be reused, either with an anaphoric function to recall a discourse element, or to establish a grammatical relation between an argument and a verb (by producing the sign of the verb toward this locus, for example), all of this regardless of the number of signs produced between the assignment of the locus and its reuse (Parisot 2003). Because a locus assignment is relatively durable, a sign language need not have recourse to the permanency of a paradigm of features nor to restrictive discourse strategies in order to reactualize a referent. All the theories of agreement appeal to notions of agreement features (a partial set of features of the controller which are also on the target), and to morphosyntactic marking. But the need to mark an element with a set of formal features in an agreement relation seems to come from factors of articulation and economy arising from the exclusively temporal modality of oral languages rather than from a universal component. The oral modality has the property that its signifiers are momentary. On the other hand, in sign languages, there is no need for this kind of marking with morphosyntactic features coming from a paradigm, because their modality allows the signifier-loci to remain active during an exchange.

### *3.2. Agreement with a predicate in LSQ*

We propose that there is no agreement in sign languages because the need for morphosyntactic paradigms is a consequence of the modality of oral languages, which makes their signifiers ephemeral: belonging to a paradigm allows a certain permanency to reactualize actants. This proposal contrasts with several analyses which view certain phenomena in sign languages as instances of agreement. For instance, there are two classes of verbs in sign languages which directly relate with loci: directional verbs create a path towards a locus, or between two loci, and locative verbs are signed on a

locus.<sup>5</sup> According to Padden (1983, 1990), these are inflected verbs because they spatially agree in person and Number with their syntactic arguments. Padden assumes that the initial and final loci of the path of a directional verb are a subject marking and an object marking, respectively, which are added to the root of these verbs. The choice of signing a locative verb on a different locus depending on its subject or object, is also considered by Padden to be an agreement marker. Similarly, Bahan (1996) claims that anchored verbs also agree, by means of nonmanual markings, with features of person and Number of their arguments. In these analyses, the loci are defined as formal features of the nouns, the structural elements of the verb which are changed (place of articulation and orientation) are assumed to be agreement morphemes, and the association of the verb and the locus is seen as a relation of verbal agreement.

However, Liddell (2000) questions the relevance of the notion of agreement for ASL, on the basis that there is an infinite number of variations for the third person in ASL. He does not consider the reuse of loci as agreement morphemes. He even rejects the idea that the association of the verb to loci is a grammatical process. He claims that signs are located in space with respect to mental representations and not grammatical representations: the loci represent a conceptualization of the entities, as if they were present.

We partly agree with Liddell. These phenomena are not instances of agreement; however, they do partake in grammatical processes. They are not cases of agreement because there is no appeal to an abstract paradigm, *in absentia*: the verb is directly superimposed on a locus, *in praesentia*. It is therefore a syntagmatic signifier which expresses a grammatical function, just like a particular juxtaposition of a noun phrase with the verb can signify a particular grammatical function, as in *Paul loves Mary*. Producing a verb on a locus is a signifier belonging to the spatial substance, which is why we don't find it in oral languages; apart from that, there is nothing particular about it (Bouchard 1996, 2002). Establishing grammatical relations by means of loci is not an instance of agreement, but of syntagmatic relation. If it was an instance of agreement in features, in particular of Number, we would expect to find distinctions in the pointers which relate the verbs and the loci: the loci of the singular arguments should be reused by point-pointers, whereas those of plural arguments should be reused by zone-pointers. In fact, the pointers of verbs do not distinguish singular (15) from plural (16) in ASL (nor in LSQ). We never find a verb with plural agreement by a zone-pointer, even when

---

<sup>5</sup> The same strategies as those described for the assignment of a noun to a locus are used to identify the locus of an argument of a verb: directly signing the verb on the locus assigned to the argument, or by a *pointer* to that locus (a manual sign, a glance or an inclination of the torso). There is a third class, that of verbs anchored on the body: these cannot be displaced in space to create a link with the actants, so pointers must be used in this case.

the argument was initially identified as plural by associating it with a zone-locus.

(15)  $_1$ INDEX  $_1$ ASK $_j$   $_2$ INDEX GO

[I ask her if she is leaving.]

(16)  $_{ipl}$ INDEX  $i$ HATE $_j$   $_{jpl}$ INDEX

[They hate them.]

However, several specialists of ASL consider that the verb can agree in Number with its object, due to examples with exhaustive plural (17) or multiple plural (18), and sometimes it appears to agree with its subject in case of dual agreement (19) and (20).<sup>6</sup>

(17) PAST CHRISTMAS C-0  $o$ GIFT $_j$ ,exhaus  $_{jpl}$ INDEX WORK+Ag TURKEY

[Last Christmas the company gave a turkey to each worker.]

(18) PRESIDENT STAND-UP  $O$ INFORM $_{i,mult}$

[The president stood up and informed them.]

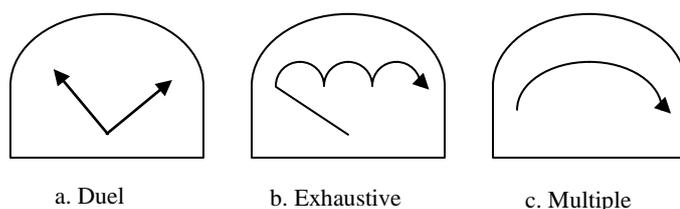

(19) SISTER BROTHER  $1$ ASK $_{i,du}$

[I asked my sister and my brother.]

(20) BOTH CHILDREN  $I,du$ ASK $1$  SIMULTANEOUSLY

[The two children asked me [that] at the same time.]

Figure 1, taken from Sandler and Lillo-Martin (2006), shows the movement of the verb for agreement with a dual object (a), each unit of the object (b), or with all the units of the object (c).

**Figure 1.** Schema of three types of additions of quantity, reproduced from Sandler et Lillo-Martin (2006: 39)

The analysis of these cases is doubtful, however. The change in the verb never

<sup>6</sup> Examples (15) to (20) are taken from Padden (1983).

seems to be an instance of formal agreement, with only some redundancy to facilitate the parsing: there is always some meaning of quantification which is added. For instance, example (18) actually expresses universal quantification on individuals (INFORM-EVERYONE). In general, the parts of paths schematized above seem to attribute a quantification bearing on the sub-events, hence aspect. Engberg-Pedersen (1993) considers that this type of movement of the verb in space has a distributive function in Danish Sign Language: “In Danish Sign Language, verbs are never modified for Number just because their arguments are nonsingular. Signs in predicative use, with an added linear, circular, semicircular, or random movement, with or without reduplication, have a distributive meaning beside denoting Number.” Klima and Bellugi (1979: 280) had already noted that “[t]he grammatical categories of Number and distributional aspect are so interrelated in ASL that we have treated them together as expressions of numerosity.” The change in the path of the verb has been abundantly described as a means to express variations in different aspects of an action, such as distributivity, continuity, or accomplishment (Cuxac, 1997 ; Dubuisson *et al.*, 1996 ; Engberg-Pedersen, 1993 ; Supalla and Newport, 1978 ; among others). Therefore, there is no formal agreement with the verb in Number (or any other feature): either it is an instance of a syntagmatic relation which establishes a grammatical function, or there is aspectual quantification.

### *3.3. Agreement inside a DP in a sign language*

As we saw in (1) and (2), in French, there can be Number inflections in a nominal expression on various elements (a noun, a determiner, a quantifier, or an attributive adjective). We also saw that in LSQ, the pointer expresses a singular or a plural depending on whether we designate a point-locus or a zone-locus. However, there is no inflection of Number on the noun: if there is an indication of quantity for the noun, it is not a simple inflection but the incorporation of a quantifier of cardinality (5-PENNY). The noun may be repeated on several loci, but this reduplication is an assignment of multiple loci: it relates to the link between the noun and loci and is not a Number inflection on the noun itself. As for the adjective, it never agrees in Number in LSQ. Therefore, the only indication of grammatical Number in LSQ shows up when the locus is assigned (point or zone): this is not agreement, not a redundant indication to help parsing, but rather the expression of semantic Number.

### 3.4. Anaphoric agreement in a sign language

In sign language, a locus can be reused in an anaphoric function to recall an element of the discourse. A locus reused in this way assumes a function similar to the one of a pronoun in oral languages. However, contrary to pronouns which often exhibit Number agreement with their antecedents, the reuse of loci never shows Number agreement. A locus is always reused by a point-pointer, without a circular movement delimiting a zone, even when the original assignment of a noun to that locus was as a plural, a zone. This lack of reuse of a locus by a zone-pointer holds both when there is anaphoric recall and when a grammatical relation is established with a verb.

### 3.5. Some thoughts on the absence of agreement in sign languages

Grammatical agreement is widespread among oral languages. It has a function of distinctivity. To operate this distinctivity, we associate an element with a slot in a paradigm. This slot is defined by a set of values for abstract features. For instance, a pronoun in English may have values for gender, Number and person which reduce the search space of identification to the elements evoked in the context which bear the same set of features: thus, the features allow us to distinguish this subset of elements. These three features are partially motivated at the semantic/conceptual level and are grammaticalized as abstract features. Agreement is a constraint on the distribution of the features of an element relative to those of another element. This constraint does not require that the material forms be identical, but that they express identical values of abstract features in a paradigmatic slot. In the terms of Saussure (1916: 171), this relation established by means of abstract features is an associative relation which unites terms *in absentia* in a virtual mnemonic series.

The absence of agreement in Number (or any other paradigmatic feature) in sign languages is due to the use of loci which is made possible by the spatial substance of their modality. A locus is a point in space which is physically present all through the exchange between signers: so it has a certain temporal permanency which makes it possible for us to reuse it to recall a discourse element. Since it is *in praesentia*, a locus operates a unique and unambiguous distinction among the elements. A language with this precise means of distinctivity does not have to resort to means *in absentia*, such as the use of abstract paradigmatic features. So in a sign language, reference is not ambiguous, even minimally, because locus assignment is precise, unique, whereas paradigmatic diversity is not extensive enough nor flexible enough to ensure unambiguity in an oral

language. Similarly, whereas the spatial relations between the elements of a sentence are unique and precise in sign languages, this is not the case in oral languages, where ambiguities are frequent, which is why oral languages often resort to redundancy by agreement in order to facilitate parsing. Grammatical agreement therefore seems to come from a property of the modality of oral languages, i.e., the ephemeral nature of their material content. The absence of agreement phenomena follows in languages with another modality that has material content that is not as ephemeral, like sign languages.

## Abstract

This paper investigates the question of whether or not scope rigidity is a feature of the grammar of Japanese. Using a Truth Value Judgment Task experiment, we tested the judgments of 256 native speakers of Japanese on sentences containing both a subject and object quantifier. We conclude that scope rigidity does indeed have a role to play in the grammar of Japanese, but that other factors, such as the choice of quantifier can interact with scope rigidity, allowing for more readings than just the one provided by the surface scope.

**Keywords:** Japanese, scope, quantification, Truth Value Judgment Task.

## 1. Introduction

### 1.1. *Scope Rigidity in Japanese*

Scope ambiguity can be readily illustrated using an example from English:

- (1) Someone criticized every person.  
(✓some>every, ✓every>some)

Sentences of this type, containing an existential and a universal quantifier are classically ambiguous, with one reading, the surface scope reading, in which there is a single

---

\* We thank the audience at CIL 18 for their lively discussion at the presentation of this paper, which has enhanced the quality of our work. All remaining errors are our own. This work was supported by SSHRC Standard Research Grant 410-2007-2169 to Han.

person criticizing everyone else, and the inverse reading in which the universal takes the wider scope, and for each person there is a unique critic.

As widely noted in the literature (Kuroda, 1970; Kuno, 1973; Hoji 1985), scope is rigid in Japanese and the scope ambiguity attested in (1) does not occur in the corresponding Japanese sentence:

- (2) a. Dareka-ga hitobito daremo-o hihanshi-ta  
someone-NOM people every-ACC criticize-PST  
'Someone criticized every person.'  
(✓some>every, \*every>some)
- b. [Hitobito daremo-o]<sub>i</sub> dareka-ga t<sub>i</sub> hihanshi-ta.  
people every-ACC someone-NOM criticize-PST  
'Someone criticized every person.'  
(✓some>every, ✓every>some)

In (2a), it is shown that only the surface scope reading is possible for the sentence. The inverse reading, where the quantified object takes scope over the quantified subject is not available. To obtain that reading, scrambling must take place, shown in (2b), where the object has overtly moved to a position at the left periphery of the sentence.

The relative scope of quantified elements is calculated based upon asymmetric c-command. That is, a quantifier takes scope over everything within its c-command domain. In English, the ambiguity is accounted for by LF quantifier raising (QR), which allows the object to move into a position c-commanding the subject. However, Japanese does not take advantage of this mechanism, and only those scope readings reflected by the surface c-command relation of quantifiers is obtained; scope is calculated before, rather than at, LF.

Because of scope rigidity in Japanese, the relative scope of quantified items can be employed as a test of syntactic structure: the available scope reading for a given sentence immediately makes clear the relative c-command relation between quantified elements.

## 1.2. Challenges to the Rigid Analysis

Recently, there have been challenges made to the claim that scope rigidity is indeed a property of the grammar of Japanese. Futagi (2004) notes the following

ambiguous example, whose ambiguity is previously cited by Shoji (1986) and Harada and Noguchi (1992):

- (3) Taro-wa Hanako-dake-to asob-eru.  
Taro-TOP Hanako-only-with play-able  
'It is possible that Taro plays only with Hanako.' (can>only)  
'Hanako is the only person Taro can play with.' (only>can)

This sentence has two possible readings, the first of which being the case where the modal *eru* takes the wider scope over the particle *dake*, making a claim that it is possible that Taro plays only with Hanako, but not ruling out other playmates. Conversely, *dake* can take the wider scope, yielding a reading where Hanako is the only possible playmate for Taro.

While one could attempt to make the argument that the scope of quantified elements might behave differently than the scope of something like a modal, this example still raises a challenge for the claim that Japanese is a scope rigid language. The expectation under scope rigidity is that only one of these readings should obtain, not both. Thus, two questions can be posed for further investigation: (i) how robust is the scope rigidity phenomenon for quantified elements in Japanese? That is, in a case such as (2), with a quantified subject and a quantified object, how pronounced is the effect of scope rigidity? (ii) does scope rigidity depend upon the choice of quantifiers in Japanese? It is these questions that we put to the test using an experimental approach.

The paper is organized as follows: in section 2, we provide a general description of the Truth Value Judgment Task (TVJT) as a means of extracting subtle semantic judgments from native speakers, followed by a more detailed explanation of our implementation of TVJT in section 3. Our experimental results are summarized in section 4, with a discussion of the implications of those findings in section 5. Finally, section 6 provides a brief conclusion and summary of further questions.

## **2. Truth Value Judgment Task**

### *2.1. The Method*

To test scope judgments from a large population, we make use of a Truth Value Judgment Task (TVJT), as described in Crain and Thornton (1998). This method,

designed originally for use with children, allows for judgments to be collected in a rich context with little functional load on the participants. This method calls for two experimenters: one telling a story using a series of small toys and props, and another playing the role of a puppet, Mickey Mouse in our case, who watches the story, and then provides a one-sentence summary of the action which took place. The task for participants is to judge whether or not Mickey's statement was true or false in the given context.

In a situation where the stimulus sentence is potentially ambiguous, it can be presented with a story that is compatible with only one of the two readings. For example, sentence (2a) could be presented with a scenario in which there is a group of eight people, shown to be comprised of four critic-criticized pairs (the inverse scope reading). If a participant were to say that sentence (2a) was false in such a scenario, we would conclude that the inverse scope reading is not available to that participant. If the participant answers that the sentence is true, then we would conclude that the inverse scope reading is available. Conversely, the same sentence (2a) could be presented with a scenario in which there is one single person criticizing a large group. Here, a response of "false" would indicate that the surface scope reading is not available. Only if the sentence were true in both scenarios could we conclude that it was ambiguous.

## *2.2 Implementation*

To apply this methodology for adults, we have made some modifications. Firstly, while the original protocol made use of live action presentations for each participant, we video-taped the interactions between the experimenters, focusing on the telling of the story and keeping the experimenter holding the Mickey puppet out of frame. This is not only more appropriate for adult participants, who might view a live performance of the scenarios as childish, but by using recorded scenarios, we ensure that all participants see and hear exactly the same stimulus.

Moreover, we further reduced the role of the experimenter with the puppet by presenting the statement to be evaluated as a printed subtitle on screen, rather than having it spoken aloud. This was done to minimize the effect of intonation upon the judgment of the stimuli. We assume that participants will invoke the Gricean maxim of quality, and expect that Mickey's statement is intended to be a true one. Upon seeing the printed stimulus, participants will assign to the sentence an intonational pattern which is most compatible with judging the sentence to be true in the given scenario.

Finally, while the original protocol is meant to be implemented with one

participant at a time, we carried out our experiments in groups of four to six, with one experimenter monitoring the group and controlling the video clips and screen presentations while another delivered the instructions. This does result in the loss of the opportunity to directly follow up on each participant’s answer as they work through the stimuli, but it was judged to be a worthwhile choice in that it allowed for many more participants to be surveyed. Justifications for each response were gathered in writing, and all participants were verbally debriefed as a group at the end of the experiment.

### 3. Experiment Design

#### 3.1. Stimuli

To test the questions posed at the end of section 1, we constructed sentences pairing four different quantifiers (*daremo* ‘every’, *minna* ‘every’, *subete* ‘all’, *futa-* ‘two’) with the existential quantifier *dareka* (‘some’). The four quantifiers were placed in object position, in order to determine whether they could scope over *dareka* in the subject position, similar to the sentence shown in (2a). As a control, stimuli were also prepared in which *dareka* was in the object position, with the other four quantifiers each appearing in subject positions. Crossing the four different quantifiers with two different syntactic positions yields eight different experimental conditions, outlined in Table 1.

To test the judgments, participants were shown a scenario in which three boys are playing in a park with three girls. They play a variety of hide-and-seek in which all the boys hide around the park, and all the girls must seek. By the end of the scenario, each girl has found a boy, and all stand paired, emphasizing that each girl found a different boy, as shown in Figure 1. The full paradigm of test sentences is shown below in examples (4) through (7). For the stimuli in (7), corresponding to Conditions 7 and 8 where the numeral *futa-* was used, the scenario was slightly modified. In this case, only two of the girls catch one boy each; the scenario ends with one girl not having found a boy, and one boy still in hiding, as shown in Figure 2.

Condition	Subject	Object	Target Scope
1	<i>daremo</i>	<i>dareka</i>	<i>daremo</i> > <i>dareka</i>
2	<i>dareka</i>	<i>daremo</i>	<i>daremo</i> > <i>dareka</i>
3	<i>minna</i>	<i>dareka</i>	<i>minna</i> > <i>dareka</i>

4	dareka	minna	minna > dareka
5	subete	dareka	subete > dareka
6	dareka	subete	subete > dareka
7	futa-	dareka	futa- > dareka
8	dareka	futa-	futa- > dareka

Table 1: Summary of experiment conditions

Figure 1: End state of hide-and-seek scenario (Conditions 1-6)

Figure 2: End state of hide-and-seek scenario (Conditions 7 and 8)

- (4) a. On'nanoko daremo-ga dareka otokonoko-o tsukamae-ta.  
 girl every-NOM some boy-ACC catch-PST  
 'Every girl caught some boy.' (Expecting true)
- b. Dareka on'nanoko-ga otokonoko daremo-o tsukamae-ta.

- some girl-NOM boy every-ACC catch-PST  
 ‘Some girl caught every boy.’ (Expecting false)
- (5) a. On'nanoko minna-ga dareka otokonoko-o tsukamae-ta.  
 girl every-NOM some boy-ACC catch-PST  
 ‘Every girl caught some boy.’ (Expecting true)
- b. Dareka on'nanoko-ga otokonoko minna-o tsukamae-ta.  
 some girl-NOM boy every-ACC catch-PST  
 ‘Some girl caught every boy.’ (Expecting false)
- (6) a. Subete-no on'nanoko-ga dareka otokonoko-o tsukamae-ta.  
 all-GEN girl-NOM some boy-ACC catch-PST  
 ‘All the girls caught some boy.’ (Expecting true)
- b. Dareka on'nanoko-ga subete-no otokonoko-o tsukamae-ta.  
 some girl-NOM all-GEN boy-ACC catch-PST  
 ‘Some girl caught all the boys.’ (Expecting false)
- (7) a. Futa-ri-no on'nanoko-ga dareka otokonoko-o tsukamae-ta.  
 two-CL-GEN girl-NOM some boy-ACC catch-PST  
 ‘Two girls caught some boy.’ (Expecting true)
- b. Dareka on'nanoko-ga futa-ri-no otokonoko-o tsukamae-ta.  
 some girl-NOM two-CL-GEN boy-ACC catch-PST  
 ‘Some girl caught two boys.’ (Expecting false)

Looking at (4a), where the universal appears in the subject position, and the existential in the object position, under the scenario described, scope rigidity would lead us to expect that the sentence should be true for all participants; for each girl there exists a specific boy she caught. However, for (4b), where the quantifiers are reversed and the universal is in the object position under the existential subject, scope rigidity predicts that all participants should evaluate this sentence as false. The surface scope reading describes a situation in which one girl caught all the boys, not one in which each boy is caught by a different girl. Similar predictions are made for the stimuli in (5) through (7). Even where (7) uses the modified scenario, the wide scope reading of *futa-* is expected to be true, reflected by the surface scope of (7a).

The structure of the quantified DP's varies between the quantifiers, with *daremo* and *minna* appearing between the head noun and the case marker, while *subete* and *futari* are positioned at the periphery of the DP preceding the noun and the case marker. Both orderings of elements are attested in a corpus study of the language (Kim, 1995), but the specific choices above were judged by a native speaker of Japanese to be the

most natural applications of these various quantifiers. While it does introduce a measure of variation, this choice was made to eliminate the possibility that a peripheral issue such as an unnatural word order might influence the participants' responses. We return to this issue in the discussion section of the paper.

### 3.2. Participants

In all, 256 participants took part in this experiment. All were native speakers of Japanese, living in the city of Vancouver, Canada. To qualify for the experiment, participants could have spent no more than one year living in an English-speaking country. Most were living in Vancouver to pursue ESL studies, and ranged in age from 18 to 39 years old, though the vast majority fell within the 20-30 range. All experiments took place in a classroom at the Vancouver campus of Simon Fraser University.

The sentences described above in (4) through (7) were embedded within a larger TVJT study involving quantifiers and negation. In all, participants saw sentences of numerous different configurations, generally with one quantifier, in either subject or object position, with or without negation. For the eight conditions in the scope rigidity study, stimuli of each condition were seen by 32 different participants out of the 256 total.

## 4. Results

The results of our experiment are shown in Figure 3. From these results, we derive four major findings.

Firstly, we see that in subject position, all four of our test quantifiers can take scope over an object existential, reflected in the near universal acceptance of sentences in which the target scope was reflected by the surface structure of the sentence. *Daremo* and *subete* were accepted as having a wide scope reading from subject position for all participants, while the acceptance was slightly lower (but still over 90%) for wide scope readings of both *minna* and *futa-* in the same position.

The second major finding was that in all cases, the acceptance rates for the wide scope readings of our quantifiers were significantly lower when those quantifiers appeared in the object position ( $F(1, 254) = 181.04; p < .0001$ ).

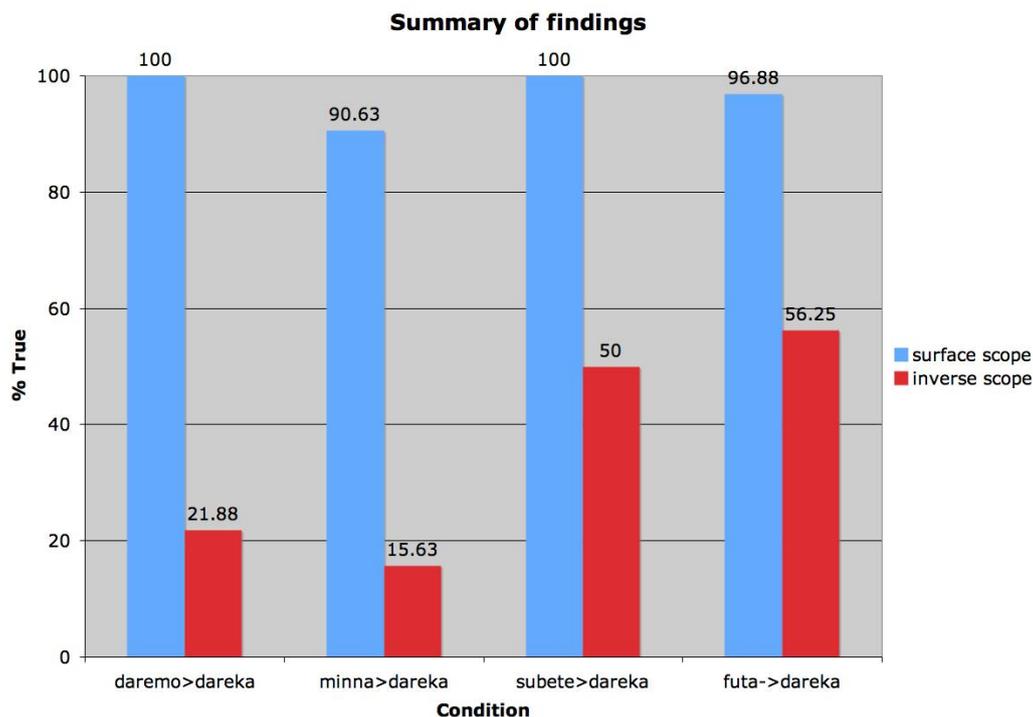

Figure 3: % True responses for each condition

Next, we observe from the distinctions between Conditions 2 & 4 and Conditions 6 & 8 that the wide scope readings of *subete* and *futa-* from object position were significantly more accessible to our participants than the wide scope readings of *daremo* and *minna* from the same position ( $F(1, 126) = 18.547; p < .0001$ ).

Finally, an examination of the results for Conditions 6 & 8 indicates that there is no significant difference in the acceptance rates for wide scope readings of *subete* and *futa-* from object position ( $F(1, 62) = 2.44; p > .05$ ).

## 5. Discussion

### 5.1. Does Japanese have scope rigidity?

The first two findings of section 4 speak to the first question posed at the outset of the paper, is scope rigidity a reality in the grammar of Japanese? The first finding, that there is a near-universal acceptance of the wide-scope readings of the quantifiers in a subject position, demonstrates that surface scope readings are readily available for native speakers of the language. Speakers do not appear to interpret sentences with their

inverse readings as opposed to the surface one.

The second finding re-enforces the conclusion that scope rigidity is indeed a reality in Japanese. The significantly lower acceptance of inverse scope readings points toward scope rigidity being a real factor in the interpretation of Japanese sentences. Especially in the case of *minna* and *daremo*, inverse scope readings are simply not available to a majority of Japanese speakers. Even including the cases of *subete* and *futa-* does not change the fact that as a whole: the inverse scope readings were significantly less available for the participants in our experiment. Based on these findings, we conclude that yes, scope rigidity does indeed exist within the grammar of Japanese; scopal interactions are calculated before LF, based upon the surface structure of the sentence before any covert movements after spellout.

## 5.2. Variability in the results

However, the results from Conditions 6 & 8 cannot be simply dismissed. To account for the variance with these two cases, we begin by examining the case of *futa-*. Unlike the other three quantifiers in this study, *futa-* is a numeral rather than a universal quantifier. As noted in Reinhart (1997), numerals have the ability to take their scope using a mechanism outside of quantifier raising. Using a choice function strategy, numerals can take scope over a c-commanding quantifier in cases where QR is not structurally possible. We postulate that the increased acceptance for wide scope readings of the numeral from object position is due to this choice function strategy being adopted by some of the participants.

Next, we consider the fourth finding, which is that there was no significant difference between the results for *futa-* and for *subete*. From this finding, we conclude that these two quantifiers receive the same treatment by speakers of Japanese. We therefore further postulate that the choice function strategy is available for *subete* as well as for *futa-*. This is not surprising, as it is not the fact that *futa-* is a numeral which allows the choice function strategy to be employed. Rather, it is the fact that numerals can be considered to be indefinites, and it is indefinites which can make use of the choice function. By extension, we then conclude that *subete* is also acting as an indefinite in a case like (6b).

One factor which remains to be accounted for is the different internal structure of the quantified phrases. As shown through word order and case marking, the object quantifiers in (6b) and (7b) are still within the c-command domain of the subject. As such, there should be no impact on the relative scope between the subject and object

quantifiers. However, in his corpus study of Japanese quantified DP's, Kim (1995) notes that the order of noun-quantifier-case marker, as in (4) and (5), is most often used for definite, discourse-old information. This suggests that the *subete* and *futa-* phrases of (6) and (7), having the order quantifier-case marker-noun, may be a signal of indefiniteness, which could encourage the use of the choice function strategy.

## 6. Conclusion

In short, the answer to both questions posed at the end of section 1 is yes. Japanese does indeed exhibit scope rigidity, and the apparent reach of scope rigidity does depend on the choice of scopal elements. The caveat suggested here is that the findings which appear to contradict the claim that Japanese is a scope rigid language are not a result of a failure of scope rigidity *per se*, but rather a circumvention of it. It is not that scope rigidity applies only in some cases, but rather that other properties of the lexical items at play may provide different mechanisms for the calculation of scope.

This idea that scope rigidity is not strictly an absolute, but interacts with other factors, is not new to this paper. Work on negation and quantifier scope in Japanese and Korean (a syntactically similar head-final language which has been argued to be scope rigid) has shown that there is disagreement in the literature on whether sentential negation scopes over an object quantifier or vice versa.<sup>1</sup> In those cases, it was concluded that a choice over verb raising was responsible for the various results, rather than a failure of scope rigidity (Han et. al. 2007, Han et. al. 2008).

A wider discussion of the different syntactic and semantic properties of scopal elements, such as modals and negation, and their interactions with scope rigidity is clearly called for, but outside the scope of the present paper. A part of this work would be to determine more systematically whether there are factors (such as word order) which seemed to make it possible to employ the choice function as a means of generating a wide-scope reading not supported by scope rigidity, and why this only happens about half of the time. Also left unanswered at this time is the question of scrambling. The present study only deals with quantified DP's in their canonical positions; variations in the word order and their effect on scope interpretation are held over for future work.

---

# Verbs projecting as Nouns

Han-Byul Chung

Seoul National University/CUNY  
86 A Cedar Lane, Highland Park, NJ  
Han1230@hotmail.com

## Abstract

Korean process nominals are different from English process nominals in that they do not allow all adverbial modifications. Some have argued, upon this phenomenon, that unlike English process nominals Korean process nominals do not possess a verbal sub-structure. However, not all adverbial modifications are ungrammatical in Korean process nominals. When adverbs are attached low enough, below the VP, such as ‘tasi’ are allowed to modify Korean process nominals. Therefore, in this paper, I argue that Korean process nominals do in fact possess verbal sub-structure. The asymmetry between English and Korean process nominals is caused by the amount of verbal projection available under the nominals.

**Keywords:** process nominals, adverbial modification, verbal sub-structure, verbal nouns

## 1. Introduction

Fu, Roeper and Borer 2001 proposed that English process nominals, nominals bearing arguments, possess verbal sub-structure. The proposal is mainly based on the presence of verbal properties surfacing in the process nominals. Process nominals like ‘destruction’, appearing in (1a), can be modified by an adverb, as in (1b), which is generally regarded as a property of a verb.

- (1) a. John’s destruction of the city  
b. John’s destruction of the city completely

There are argument-bearing nominals in Korean as well, namely Verbal Nouns. Sentences in (2a-d) are examples of Korean verbal nouns surfacing as process nominal.<sup>1</sup>

---

<sup>1</sup> All Korean data were Romanized using Yale Romanization. The grammaticality of Korean data was tested upon 39 subjects. Sentences that were rated grammatical by 65 to 100 percent of the testers are marked grammatical. Sentences that were rated grammatical by 35 to 65 percent of the testers are marked questionable. Sentences that

Generally, they are analyzed as some variation of English Process Nominals (Jung 1995, Miyamoto 1999).

- (2) a. [*pepkwan-uy*    *pephaysek-uy*                      *silswu*]-*nun*

       “The trains arrival that everybody has anticipated, brought about an unexpected result.”

[Korean]

However, as already observed by Yoon and Park (2004), they show different behavior concerning adverbial modification. As seen in (3a), English process nominals can be modified by ‘completely’. But Korea verbal nouns become ungrammatical when it is modified by *wancenhi*, a Korean version of completely (3b).

Based on this data, Yoon and Park (2004) claims Korean verbal nouns do not possess a verbal sub-structure. Following Yoon and Park, the ungrammaticality of (3b) would be natural, as there is no verbal structure. Consequently, they claim that Verbal Nouns are not derived from verbs. They are base generated as Nouns.

---

were marked grammatical by 0 to 35 percent of the testers are marked ungrammatical.

- (3) a. John's destruction of the city **completely**  
 b. \**John-uy tosi-uy wancenhi phakoy*  
 John-Gen city-Gen completely destroy-N  
 "John's destruction of the city completely"

## 2. The Asymmetry within Korean Process Nominals

But not all Korean process nominals can be analyzed as base generated nouns. Verbal nouns, though they may be dominant, are not the only argument-bearing nominals in Korean. There are process nominals that are derived from Korean native verbs, such as 'tolao-m' in (4).<sup>23</sup>

- (4) a. [*cecwu-lul phepwusko ttenakan John-uy tolao-m*]-*un*  
 [curse-Acc pour leave John-Gen return-N]-Top  
*motwu-lul eiepskey mantulessta.*  
 everybody-Acc dumbfounded make

 b. *cecwu-lul phepwusko ttenakan John-i tolao-ta*  
 curse-Acc pour leave John-Nom return  
 "John who had left after cursing all returned."

What is interesting is that these morphologically complex, derived nominals behave like Korean verbal nouns. As shown in (5a), process nominals derived from

<sup>2</sup> All Korean verbal nouns are of Chinese origin by definition.

<sup>3</sup> Unergative construction is used because transitive and unergative native verbs cannot surface as process nominals, as in (a-b). The cause of this phenomenon will be discussed later in the paper.

- a. \**[ku-uy pap-uy mek-um]-un*  
 [he-Gen rice-Gen eat-N]-Top  
*yeykyentoyn swuswuniessta.*  
 expected sequence  
 "Him eating the rice was an expected result."

 [marathoner-Gen run-N]-Top  
*nwukwuto makul swu epsta.*  
 nobody stop can not  
 "Nobody can stop the marathoner from running."

verbs do not allow the modification by ‘*wancenhi*’.<sup>4</sup> This is unexpected by Yoon and Park’s analysis. The account for this phenomenon, they would have to postulate another factor independently blocking the modification in Korean process nominals derived from verbs.

 […train-Gen completely arrival]-Top…  
 “The trains complete arrival…”

### 3. Proposal

In this paper, I propose an analysis that can capture the behavior of Korean Process Nominals as a whole. I claim that Korean Process Nominals, including Verbal Nouns, do, in fact, possess a verbal sub-structure. The adverbial modification in (5) is ungrammatical only because adverbs such as ‘completely’ and ‘*wancenhi*’ attaches to a higher functional projection than what is available to the Korean process nominals. I claim that Korean process nominals possess verbal structure only up to VP.

#### 3.1. Korean process nominals possess VP structure

Korean process nominals are nominal heads taking VP as its complement. (6) and (7) is the structure I propose for Korean process nominals. The embedded verb of the

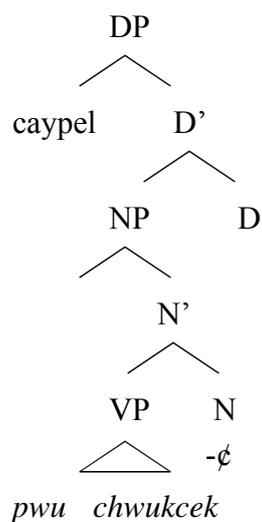

---

<sup>4</sup> The process nominals derived from Korean native verbs concerned here are only those nominals that mark their arguments with genitive markers. When one of the arguments is marked with verbal case markers they are generally regarded as gerunds. Gerunds allow modification by *wancenhi* as shown below.

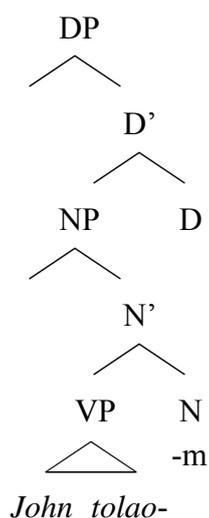

- i) [*John-i wancenhi tolao-m*] -*un*  
 John-Nom completely return -Top
- ii) [*pepkwan-uy pephaysek-ul wancenhi silswu-ha-m*]-*un*…  
 judge-Gen interpretation of law-Acc completely mistake] -Top

Verbal nouns and process nominals derived from native verbs alike, project only up to large VP. Then, a nominal head takes large VP as its complement embedding the verbal structure in the nominal projection. The only difference between Verbal Nouns and Process Nominals derived from native verbs is that the nominal head attaching to the Verbal Nouns is phonologically empty, where as, nominal head attaching to the Process Nominals derived from native verbs contains a phonological feature /-m/.

(6) Verbal Nouns

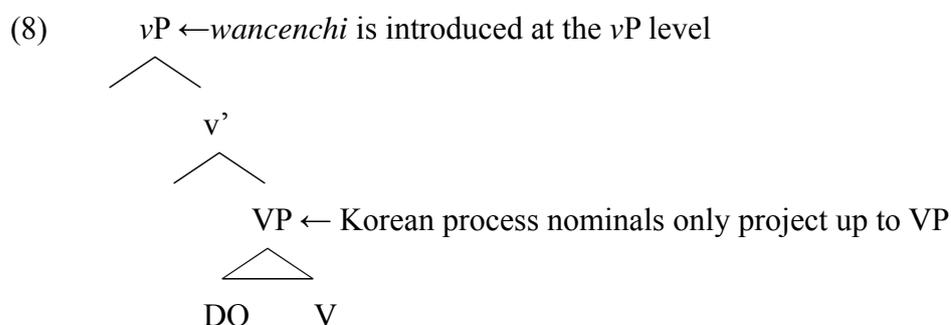

(7) Process Nominals derived from native verbs

3.2. Ungrammaticality of vP level adverbial modification

Cinque (1999) showed that the positions to which each adverb attaches are set, and adverbs can be categorized in a hierarchical order. Adverbs may attach to large VP,

little  $\nu$ P, TP or any other functional projection. According to Cinque 1999, completely is an adverb attaching at the  $\nu$ P level. I assume, following Cinque 1999, that *wancenhi* is an adverb attaching at the  $\nu$ P level.

Modification by *wancenhi* is ungrammatical because the functional head necessary for  $\nu$ P adverb modification, namely  $\nu$ P, is absent in Korean process nominals, as depicted in (8). It is not due to the absence of the entire verbal structure.

#### 4. Prediction

The proposal has some predictions. As there is a verbal sub-structure, adverbs merging low enough should be able to modify Korean process nominals. And as process nominal embed only large VP structure, verbal properties attributed to structures higher in the verbal projection would not be present. The prediction is born out.

##### 4.1. Restitutive ‘tasi’

Restitutive ‘tasi’ modifies the status event of the event structure. Assuming that restitutive ‘tasi’ attaches to a structure below the VP, in line with Stechow 1996 and Ko 2005, they should be allowed to modify Korean process Nominals. And as predicted, Process Nominals derived from native verbs modified by ‘tasi’ are perfectly grammatical as in (9).<sup>5</sup> Not only are they grammatical, they can all be interpreted with restitutive reading.<sup>6</sup>

---

<sup>5</sup> The sentences

(9b) and

(9c) were found through Google search.

<sup>6</sup> The sentences in (9) are not interpreted with restitutive meaning obligatorily. However, mere fact that it could be interpreted with restitutive meaning indicates that *tasi* is inside the VP domain. If *tasi* is merged outside of VP, repetitive interpretation is forced, blocking the possibility of restitutive interpretation.

- (9) a. [*cecwu-lul phepwusko ttenakan John-uy tasi*  
 [curse-Acc pour leave John-Gen again  
*tolao-m]-un ...*  
 return-N]-Top  
 “That John, who had fled after cursing all, came back again...”
- b. [*yeyswu-nim-uy tasi sasi-m]-un*  
 [Jesus-Hon-Gen again live-N]-Top  
 “The rebirth of Jesus”
- c. [*kkoch-uy tasi phi-m]-un*  
 [flower-Gen again blossom-N]-Top  
 “The flower blossoming again”
- d. [*pi-uy tasi nayli-m]-un*  
 [rain-Gen again fall-N]-Top  
 “The rain falling again”

However, as you can see in (10), Verbal Nouns show different behavior. Verbal Nouns do not allow the modification by ‘tasi’.

- (10) a. \**[pepkwan-uy pephaysek-uy tasi silswu]-nun*  
 [judge-Gen interpretation of law-Gen again mistake]-Top  
*phikoin-eykey chimyengcekiesta*  
 defendant-Dat critical  
 “Judge’s mistake in the interpretation of law again was critical to the defendant.”
- b. \**[caypel-uy pwu-uy tasi chwukcek]-un*  
 [conglomerate-Gen wealth-Gen again accumulation]-Top  
*amwuto makul swu epsta*  
 nobody stop can not  
 “Accumulation of wealth by the conglomerates again cannot be stopped by anybody.”
- c. \**[othopai-uy tasi cilcwu]-nun nwukwuto*  
 [motorcycle-Gen again run]-Top nobody  
*makul swu epsta*  
 stop can not  
 “Nobody could stop the motorcycle from speeding again.”

- d. \*[*motwuka kotayhaten kicha-uy tasi tochak*]-*un*  
 [Everybody anticipating train-Gen again arrival]-Top  
*yeysangwanun talun kyelkwul nahassta*  
 expectation-Nom different result-Acc bring about  
 “The trains arrival again that everybody has anticipated,  
 brought about an unexpected result.”

Instead they are modified by *cay*, a Korean counterpart of English ‘re-’, as in (11). In line with Marantz 2007, I assume that Korean *cay* functions syntactically identical to restitutive *tasi*. Therefore my assumption is the modification by ‘*tasi*’ in Verbal Nouns is ungrammatical not because of the absence of verbal structure, but because the modification is morphologically blocked by ‘*cay*’ attachment.<sup>7</sup>

- (11) a. [*pepkwan-uy pephaysek-uy cay-silswu*]-*nun*  
 [judge-Gen interpretation of law-Gen again-mistake]-Top  
*phikoin-eykey chimyengcekiesta*  
 defendant-Dat critical  
 “Judge’s mistake in the interpretation of law again was critical  
 to the defendant.”
- b. [*caypel-uy pwu-uy cay-chwukcek*]-*un*  
 [conglomerate-Gen wealth-Gen re-accumulation]-Top  
*amwuto makul swu epsta*  
 nobody stop can not  
 “Accumulation of wealth by the conglomerates again cannot  
 be stopped by anybody.”
- c. ?[*othopai-uy cay-cilcwu*]-*nun* *nwukwuto*  
 [motorcycle-Gen again-run]-Top nobody  
*makul swu epsta*  
 stop can not  
 “Nobody could stop the motorcycle from speeding again.”
- d. [*motwuka kotayhaten kicha-uy cay-tochak*]-*un*  
 [Everybody anticipating train-Gen again-arrival]-Top  
*yeysangwanun talun kyelkwul nahassta*  
 expectation-Nom different result-Acc bring about

---

<sup>7</sup> If *cay* functions syntactically identical to restitutive *tasi*, the possibility of *cay* modification in itself supports the existence of VP structure, as it would be an adverb merging below the VP.

“The trains arrival again that everybody has anticipated,  
brought about an unexpected result.”

#### 4.2. Secondary Predicates

Another class of adverb attaching below the VP is secondary predicates. I assume, along with Japanese object-oriented depictive predicates and secondary resultative predicates, that Korean Object-oriented Depictive Predicates (hereafter: ODP) and Secondary Resultative Predicates (hereafter; SRP) are also generated inside the large VP (cf. Koizumi 1994, Takezawa 1993).<sup>8</sup> Subject oriented depictive predicates are generated external to the large VP. As a result ODP and SRP should be allowed to modify Korean process nominals.

##### (12) Korean Process Nominals modified by ODPs

- a. ?[*wuntongsenswu-uy*    ***huthulecin chaylo***    *tochak*]-*ul*  
 athlete-Gen                      distracted                      arrival]-Acc  
*salamtul-un*    *yongnaphal*    *swu*    *epsessta*  
 people-Top            tolerate            can    not

“People could not tolerate the fact that the athlete has arrived distracted.”

- b. [*chelswu-uy*    ***maynpallo***    *tolao-m*]-*un*    *yeysangpakkuy*  
 chelswu-Gen    bare-foot            return-N-Top    unexpected  
*kyelkwayessta*  
 outcome

“Chelswu returning bare-footed was an unexpected situation.”

##### (13) Korean Process Nominals modified by SRPs

- a. [*ai-uy*    ***elunulo***    *sengcang*]-*un*    *wuli-lul*  
 child-Gen    to man            grow-N-Top    we-Acc  
*ppwutushakey*    *hayssta*  
 proud                      made

“That the child became a man, made us proud.”

- b. [*namwu-uy*    ***phwulukey***    *cala-m*]-*un*    *cayen-uy*    *ichiita*  
 tree-Gen            green                      grow-N-Top    nature-Gen    axiom

---

<sup>8</sup> Secondary depictive predicates describe the state of the referent when the action denoted by the primary predicate occurs. Secondary resultative predicate describes the result state of the referent. When the referent is the object of the primary predicate it is termed object oriented. When the referent is the subject, it is termed subject oriented. For more discussion on Korean secondary predicates refer to Chung 2007

“A tree growing green is the axiom of nature.”

Sentences in (12) and (13) show that the modification is possible. But the results for ODP were not as straight forward as expected. However there is a clear distinction from sentences that are modified by adverbs merging external to the VP. As you can see in (14) sentences modified by *wancenhi* or by subject-Oriented Depictive Predicate *maynpallo* are rated ungrammatical.<sup>9</sup>

(14) Korean Process Nominals modified by high level adverbs

a. \*[…*kicha-uy wancenhi tochak*]-*un* ...

[...train-Gen completely arrival]-Top...

“The trains complete arrival...”

b. \*[…*malathon senswu-uy maynpallo cilcwu*]-*nun*

marathoner-Gen bare-foot run-Top

*wuli-lul kamtongsikhyessta*

we-Acc impressed

“The fact that the marathoner ran bare-footed impressed us.”

#### 4.3. Case

If Korean process nominals possess verbal structure only up to VP, functional structures responsible for case assignments such as *vP* or *TP* must be absent. Therefore no verbal case markers should be present in Korean process nominals. This is true by definition, as a structure possessing any sort of verbal case marker will not be defined a process nominal. Therefore by definition, all process nominal receive nominal case.

#### 4.4. External Argument

Another prediction is that, as none of the functional projection above the VP is present, only internal argument will be assigned. In turn, external argument of the embedded verb would not surface.

A sentence with transitive verb of native origin cannot surface as a Process nominal, as in (15b). This phenomenon seems to comply with the absence of external argument position in process nominals. The absence of external argument position in Korean process nominals could be the factor disallowing transitive process nominals.

---

<sup>9</sup> *Maynpallo* can surface as either Subject or Object Oriented Depictive Predicate, depending on the position of the nominal it modifies.

However, the transitive Verbal Nouns are grammatical, as in (16b).

- (15) a. *John -i*            *pap-ul*        *mek-ta*  
           John -Nom        rice-Acc        eat-Comp  
           “John eats rice”
- b. \* *John -uy*        *pap-uy*        *mek-um*  
           John -Gen        rice-Gen        eat-N  
           “Eating of rice by John”
- (16) a. *caypel-i*                    *pwu-lul*            *cay-chwukcek-ha-da*  
           conglomerate-Gen        wealth-Gen        re-accumulate  
           “Conglomerates accumulate wealth again...”
- b. *caypel-uy*                    *pwu-uy*            *cay-chwukcek-un*  
           conglomerate-Gen        wealth-Gen        re-accumulation-Top  
           “Accumulation of wealth by the conglomerates again...”

The asymmetry in the behavior between Korean process nominals of native origin and Verbal Nouns is persistent in unergative verbs. As you can see in (17), process nominals derived from native unergative verbs are the only ones that are ungrammatical.

- (17) a. *chelswu-uy*        *cilcwu*  
           chelswu-Gen        run-N  
           “chelswu’s run”
- b. \**chelswu-uy*        *talli-m*  
           chelswu-Gen        run-N  
           “Chelswu running”

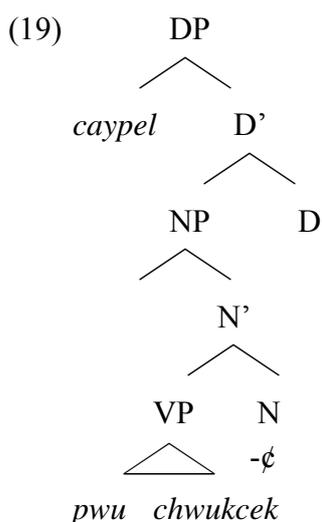

Unlike transitives and unergatives that show asymmetry, process nominals derived from unergative verbs are all grammatical, as shown in (18).

- (18) a. [*John-uy*        *tolao*]-*m*  
           John-Gen        return-N  
           “John’s return”
- b. [*kicha-uy*        *tochak*]  
           train-Gen        arrive-N

“Train’s arrival”

- c. [*chelswu-uy samang*]  
 chelswu-Gen die-N  
 “chelswu’s death”

At first glance, unlike the prediction, the dividing line seems to exist between the verbal nouns and native process nominals and not between verbs with external arguments and those without it. If all process nominals possess verbal sub-structure, and ungrammaticality of (5) is due to the absence of *vP* structure in Korean process nominals, the external argument position should be not present in process nominals, and one could predict that all transitive and unergative verbs would not surface as process nominals.

(6), repeated here as (19), is the structure I propose for Verbal Nouns surfacing as process nominals. *caypel* is base generated at the specifier of the DP with a general relatedness (cf. Kratzer 1996). The claim can be backed up by the fact that *caybel* is not always interpreted as the agent of the embedded VP. Therefore, I claim that *caybel* is not an external argument of the embedded VP.

My claim is that the apparent external argument of the Verbal Nouns is, in fact, not an argument of the embedded verb. They are introduced by a nominal functional projection higher in the structure. Therefore, the anomaly is not in the grammaticality of transitive and unergative Verbal Nouns, but in the ungrammaticality of transitive and

unergative process nominals of native origin.

As I have stated above, the ungrammaticality of process nominals derived from transitive and unergative verbs of Korean native origin is unexpected in my analysis. However, not all process nominals of native origin are impossible. Process nominals derived from native unergative verbs are grammatical, as shown in (18).

To accommodate this data, I claim that VP node of Korean native verb can not act as a syntactic unit.<sup>10</sup> Korean verbs must project up to *v*P to work as a syntactic unit. Process nominals can be derived from unergative verb only because the *v*P node of the unergative verb is defective or absent. The same analysis is adopted for Korean Verbal Nouns. Verbal Nouns are loanwords from Chinese. As loanwords, they lack proper functional projections. Therefore, Process nominals can be derived from Verbal Nouns without restriction.

## 5. Consequences

### 5.1. Korean *-um* nominalization

If my proposal is on the right track, Korean ‘*-um*’ nominalization can be explained as a whole. Previously, *-m* in (20a) and (20b, c) were analyzed as different syntactic units with different functions. *-m* in (20a) targets lexical units and lacks verbal properties, whereas *-m* in (20b, c) targets verbal projections and possesses verbal properties.

Opposing to previous analysis, I claim that *-m* in (20) all provides same function; nominalization of the verbal projection. The difference in the appearance of the verbal properties is only due to the difference in the amount of verbal projection available under the *-m* head. When ‘*-um*’ targets large VP, only internal argument is present. When it targets *v*P, external argument and accusative case marker is also present. When it targets TP, nominative case marker and tense marker also surface as well.

- (20) a. [*John-uy*            *tolao*]-*m*  
          John-Gen            return-N  
          ‘John’s return

---

<sup>10</sup> Difference could be in the nominalizing suffix. If suffix ‘*-um*’ only targets higher verbal projections, unlike  $\emptyset$ -morpheme nominalizing suffix attaching to Verbal Nouns, the ungrammaticality of transitive and unergative Process Nominals derived from native verbs could be explained. However, it would wrongly predict that as unaccusative Process Nominals derived from native verbs are grammatical, they would possess higher verbal structures allowing modifications by higher adverbs.

- b. [*John -uy pap-ul mek*]-*um*  
 John -Gen rice-Acc eat-N  
 “John eating rice”
- c. [*John -i pap-ul mek-ess*]-*um*  
 John -Nom rice-Acc eat-past-N  
 “John eating rice”

## 5.2. Verbal Nouns

The analysis will apply to Verbal Nouns as well. When VP is embedded, only the internal argument is present. When *vP* is embedded, external argument and accusative case marker is also present. When TP is embedded, nominative case marker and tense marker surface as well. In (21a), Verbal Noun seems to appear as a bare Verbal Noun. I assume that a phonologically empty nominalizer attaches to the Verbal Noun and creates the process nominal. (21b,c) shows that *ha* emerges when a nominal embeds a structure containing *vP*.

- (21) a. [*Chelswu-uy tosi-uy phakoy*] -  $\emptyset$   
 Chelswu-Gen city-Gen destroy-N  
 “Chelswu’s destruction of the city”
- b. [*Chelswu-uy tosi-lul phakoy -ha*]- *m*  
 Chelswu-Gen city-Acc destroy-*v*-N  
 “Chelswu destroying the city”
- c. [*Chelswu-ka tosi-lul phakoy -ha-yess*]-*um*  
 Chelswu-Nom city-Acc destroy-*v*-past-N  
 “Chelswu having destroyed the city”

What is interesting is the unacceptability of *ha* insertion in process nominals without *vP* projections. Not only does the sentence become ungrammatical when *ha* is absent in the presence of higher verbal structures, as in (22b,c), the sentence become ungrammatical if *ha* emerges in sentences containing only VP structure, as in (22a). This is unexpected in analysis that postulate *ha* as a verbalizer; a lexical category changing affix turning nouns to verbs. I have shown above that process nominal with genitive marker in all of its arguments contains a VP. If *phakoy* is base generated as noun and *ha* is a lexical category changing affix turning nouns to verbs, *ha* must be needed and (22a) should be grammatical.

- (22) a. \**Chelswu-uy*      *tosi-uy*      *phakoy-ha-m*  
 Chelswu-Gen      city-Gen      destroy-N  
 “Chelswu’s destruction of the city”
- b. \**Chelswu-uy*      *tosi-lul*      *phakoy*  
 Chelswu-Gen      city-Acc      destroy-N  
 “Chelswu destroying the city”
- c. \**Chelswu-ka*      *tosi-lul*      *phakoy-yess-um*  
 Chelswu-Nom      city-Acc      destroy-past-N  
 “Chelswu having destroyed the city”

From this I claim that *ha* is not a derivational affix functioning as lexical category changer, but a verbal functional affix supplementing a defective verb to form a complete verbal projection. In (21b, c), *ha* is inserted to substitute the missing *vP* projection in Verbal Nouns.

- (23) a. *Chelswu-ka*      *tosi-lul*      *phakoy-ha-ta*  
 Chelswu-Nom      city-Acc      destroy-*v*-Comp  
 “Chelswu’s destruction of the city”
- b. \**Chelswu-uy*      *tosi-lul*      *phakoy-ta*  
 Chelswu-Gen      city-Acc      destroy-Comp  
 “Chelswu destroying the city”
- c. \**Chelswu-ka*      *tosi-lul*      *phakoy-yess-ta*  
 Chelswu-Nom      city-Acc      destroy-past-Comp  
 “Chelswu having destroyed the city”

(23a) is an example of Verbal Noun projecting up to the sentential projection to form a complete sentence. (23b, c) is ungrammatical because *phakoy* by itself cannot form a complete verb. The defective verb needs *ha* to complete its verbal projection.

## 6. Conclusion

In this paper, I have claimed that unlike previous analysis Korean process nominals embed verbal structure, though defective. To support my claim, I have shown that there are some adverbs such as *tasi*, which are able to modify Korean process nominals and that adverbs that can not modify Korean process nominals are *vP* level adverbs. I have also shown that Verbal case markers and External arguments of the verb

are absent in Korean process nominals.

If my proposal is on the right track, *-um* nominalizations previously thought as lexical nominalizations could be analyzed as phrasal nominalizations targeting lower projections. It would also shed new light on the long standing debate over the status of *ha*. If process nominals are verb derived nouns possessing incomplete verbal projection, *ha* is not be a verbalizer turning nouns into verbs, but is a verbalizer turning defective verbs to complete ones.

## Abstract

This paper investigates the possible patterns of A'-chains in relative clauses in Ulster Irish, when the relative clauses contain two embedded sentences, that is, three COMP positions and one trace/resumptive pronoun. As Ulster Irish has three types of COMPs and the tail end of an A'-chain involved in a relative clause is either a trace or a resumptive pronoun, the number of the logically possible combinations of the COMPs and the tail end of the chain in the relevant examples is 54. We found that 18 patterns were possible, some of which had the sequence (aL, that). We propose that these patterns suggest that *aL* and *that* are in an agreement relation, forcing *that* to function as *aN*.

**Keywords:** A'-chains, agreement, COMP alternation, relative clauses, Ulster Irish.

## 1. Introduction

Modern Irish (Irish, hereafter) has three types of complementizers: the [-Q] marker, the direct relative marker, and the indirect relative marker. The [-Q] marker *go/gur* behaves in the same fashion as English [-Q] COMP *that*. The direct and indirect relative markers appear in relative clauses and wh-interrogatives, among others.

---

\* An earlier version of this paper was presented at the 18th International Congress of Linguists held at Korea University on July 26, 2008. We would like to thank the audience at the meeting, as well as Farrell Ackerman, Dong-Hwan An, Dae-Ho Chung, Jessica Dunton, Yeun-Jin Jung, Chie Nakamura, Fumikazu Niinuma, Keun-Won Sohn, and Shigeki Taguchi, for their helpful comments. All errors are our own. Research by the first author was supported in part by Japan Society for the Promotion of Science Grant #18520303 to Gifu University.

McCloskey (1979) proposes to use *aL* for the former, and *aN* for the latter for phonological reasons. The properties of the COMPs are illustrated by the examples in (1-3). (1) is a declarative sentence, and the embedded clause is headed by *gur* “that.” When the sentence involves relative clause formation, as in (2), the embedded COMP must change to *aL*, and another COMP *aL* must be inserted right after the head noun.

- (1) *Creideann Seán gur cheannaigh Máire an carr*  
 believe John that bought Mary the car  
 “John believes that Mary bought the car”

- (2) (*aL*, *aL*, *t*)  
*Sin an carr a chreideann tú a cheannaigh Seán t*  
 that the car *aL* believe you *aL* bought John  
 “That’s the car that you believe that John bought”

There is another way to form a relative clause, as shown in (3), where *rp* stands for resumptive pronoun.

- (3) (*aN*, *that*, *rp*)  
*Sin an carr a gcreideann tú gur cheannaigh Seán é*  
 that the car *aN* believe you that bought John it  
 “That’s the car that you believe that John bought”

In (3), the topmost COMP of the relative clause is an indirect relative marker *a*, the COMP of the embedded clause is a [-Q] COMP, and the embedded clause contains a resumptive pronoun *é* “it” instead of a gap.

The purpose of this paper is to investigate the possible patterns of A'-chains in relative clauses in the Ulster variety of Irish (Ulster Irish, hereafter), when the relative clauses contain two embedded sentences, that is, three COMP positions and one trace/resumptive pronoun. In this survey, we used relative clauses in Ulster Irish, one of three main dialects (Ulster, Connacht, and Munster) in Irish, because Ulster Irish retains a clearer distinction among the three COMPs than the other two varieties. As Ulster Irish has three types of COMPs and the tail end of an A'-chain involved in a relative clause is either a trace or a resumptive pronoun, when it has three COMP positions (COMP1, COMP2, COMP3, trace (*t*)/resumptive pronoun (*rp*)), the number of the logically possible combinations of the COMPs and the tail end of the chain is 54 ( $3 \times 3 \times 3 \times 2 = 54$ ). In the present survey, we discovered three facts shown in (4).

- (4) a. No relative clause with the COMP *go* “that” as the first member of the chain (*go*, COMP2, COMP3, *t/rp*) is grammatical, so that 18 patterns with this chain ( $1 \times 3 \times 3 \times 2 = 18$ ) are ungrammatical.

- b. Out of the remaining 36 potentially possible A'-chains, the chains in which the relationship between the COMP3 and the final member of the chain is either one of (*aL*, *rp*), (*aN*, *t*), and (*go*, *t*) are all illegitimate ( $2 \times 3 \times 3 \times 1 = 18$ ), so that there remain 18 potentially possible A'-chains.
- c. The remaining 18 A'-chains are all possible in Ulster Irish.

In this paper, we present the possible patterns of A'-chains in relative clauses in Ulster Irish, and discuss what these facts might suggest for the theory of (Ulster Irish) syntax.

The organization of this paper is as follows. Section 2 provides the properties of the complementizers in Irish and the types of A'-chains thus far observed as a background to the subsequent sections. Section 3 presents the data with possible patterns of A'-chains in relative clauses in Ulster Irish. Section 4 discusses implications of the findings. Section 5 points out a remaining issue. Finally, Section 6 concludes the paper.

## 2. Background

James McCloskey has investigated the mechanisms of COMP alternation in Irish since 1976 (McCloskey (1976)). Irish has three types of complementizers: the [-Q] marker, the direct relative marker, and the indirect relative marker. The [-Q] marker is realized as either *go* (non-past) or *gur* (past), and this behaves in the same fashion as English [-Q] COMP *that*. The direct and indirect relative markers appear in relative clauses and *wh*-interrogatives, among others. The basic form of the two markers is *a*, but the direct relative marker induces Lenition and the indirect relative marker Eclipsis/Nasalization on a following element. Therefore, McCloskey (1979) proposes to use *aL* for the former, and *aN* for the latter. The direct relative marker is realized as *a* (non-past and past), and the indirect relative marker as either *a* (non-past) or *ar* (past).<sup>1</sup> In this paper, following McCloskey (1979), we use the symbols *aL* and *aN* for the direct relative marker and the indirect relative marker, respectively. The properties of the three COMPs are summarized in (5).

- (5) Properties of the COMPs in Irish

---

<sup>1</sup> Note that the indirect relative marker in the past form, whose default form is *ar*, is realized as *a* in front of a handful of irregular verbs such as *bí* "to be," *déan* "to do," and *feic* "to see."

	types of COMPs	non-past form	past form	symbol
a.	the [-Q] marker	<i>go</i>	<i>gur</i>	<i>that</i>
b.	the direct relative marker	<i>a</i>	<i>a</i>	<i>aL</i>
c.	the indirect relative marker	<i>a</i>	<i>ar</i>	<i>aN</i>

Let us illustrate the properties of the COMPs by using actual examples. (1), reproduced as (6), is a declarative sentence, and the embedded clause is headed by the [-Q] COMP *gur* “that.”

- (6) *Creideann Seán gur cheannaigh Máire an carr*  
 believe John that bought Mary the car  
 “John believes that Mary bought the car”

(6) is a declarative sentence, and the embedded clause is headed by the [-Q] COMP *gur* “that.” When the sentence involves relative clause formation, as in (2), reproduced as (7), the embedded COMP must change to the direct relative marker *aL*, and at the same time, another COMP *aL* must be inserted right after the head noun.

- (7) (aL, aL, *t*)  
*Sin an carr a chreideann tú a cheannaigh Seán t*  
 that the car aL believe you aL bought John  
 “That’s the car that you believe that John bought”

(7) would be ungrammatical if either one of the two COMPs were *go/gur* “that,” as shown in (8).

- (8) a. \*(aL, that, *t*)  
 \**Sin an carr a chreideann tú gur cheannaigh Seán t*  
 that the car aL believe you that bought John  
 “That’s the car that you believe that John bought”  
 b. \*(that, aL, *t*)  
 \**Sin an carr go gcreideann tú a cheannaigh Seán t*  
 that the car that believe you aL bought John  
 c. \*(that, that, *t*)  
 \**Sin an carr go gcreideann tú gur cheannaigh Seán t*  
 that the car that believe you that bought John

There is another way to form a relative clause in Irish, as shown in (3), reproduced as (9).

- (9) (aN, that, rp)  
*Sin an carr a gcreideann tú gur cheannaigh Seán é*  
 that the car aN believe you that bought John it  
 “That’s the car that you believe that John bought”

In (9), the topmost COMP of the relative clause is an indirect relative marker *a*, the COMP of the embedded clause is a [-Q] COMP, and the embedded clause contains a resumptive pronoun *é* “it” instead of a gap. The examples in (10) and (11) suggest that *aN* must bind a resumptive pronoun, and as long as the former binds the latter, no locality restriction is imposed on them.

(10) \*(aN, that, *t*)

*\*Sin an carr a gcreideann tú gur cheannaigh Seán t*  
 that the car aN believe you that bought John  
 “That’s the car that you believe that John bought”

(11) a. (aN, that, that, *rp*)

*Sin an carr a gcreideann tú gur dhúirt siad gur cheannaigh Seán é*  
 that the car aN believe you that said they that bought John it  
 “That’s the car which you believe that they said that John bought it”

b. (aN, *rp*)

*Sin teanga a mbeadh meas agam ar dhuine ar bith atá ábalta í a*  
 that a language aN would be respect at me on person any aL+is able it to  
*labhairt*  
 speak  
 “??That’s a language that I would respect anyone who could speak it”

((11b) is cited from McCloskey (1979) with slight editing.)

In (10), there is no resumptive pronoun which *aN* could bind, and the example is ungrammatical. In (11a) and (11b), *aN* binds the resumptive pronoun *é* across two CP boundaries, and *í* across a complex NP, respectively, and the examples are all grammatical.

McCloskey (2002) further investigates the patterns of COMP alternation in Irish, and presents three new patterns shown from (12) to (14).

(12) (aN, aN, *rp*)

*Sin an carr a gcreideann tú ar cheannaigh Seán é*  
 that the car aN believe you aN bought John it  
 “That’s the car that you believe that John bought”

(13) (aL, aN, *rp*)

*Sin an carr a chreideann tú ar cheannaigh Seán é*  
 that the car aL believe you aN bought John it  
 “That’s the car that you believe that John bought”

(14) (aN, aL, *t*)

*Sin an carr a raibh súil agam a cheannófá t*

that the car aN was hope at-me aL buy (COND) (S2)

“That’s the car that I hoped that you would buy”

Therefore, Irish allows five patterns of COMP alternation, when there are two COMP positions in the sentence. This is summarized in (15).

- (15) a. (aL, aL, *t*)  
b. (aN, that, *rp*)  
c. (aN, aN, *rp*)  
d. (aL, aN, *rp*)  
e. (aN, aL, *t*)

McCloskey (2002) provides an elegant analysis of the five patterns in (15) by proposing (16).

- (16) a. C whose specifier is filled by Move is realized as *aL*.  
b. C whose specifier is filled by Merge is realized as *aN*.  
c. C whose specifier is not filled is realized as *go/gur*.

McCloskey assumes that the SPEC of *aL* contains a null operator/null pronoun (henceforth, null operator) as a result of movement, that in the SPEC of *aN*, there is a base-generated operator, and that in the SPEC of *go/gur*, there is no operator.

Note, however, that Maki and Ó Baoill (2005) found the sixth pattern of COMP alternation in Ulster Irish, when there are two COMP positions in a relative clause. The pattern is (aL, *go, rp*), as shown in (17) and (18). These examples are modified versions of the original examples shown in Maki and Ó Baoill (2005).

- (17) (aL, that, *rp*)

*Sin an carr a mheasann Seán gur cheart dúinn é a cheannach*

that the car aL think John that right for-us it to buy

“That’s the car that John thinks that we ought to buy it”

- (18) (aL, that, *rp*)

*Sin an carr a mheasann tú gurbh fhiú dúinn é a cheannach*

that the car aL think you that worth for-us it to buy

“That’s the car that you think that it would be worth our while to buy it”

Note that in Ulster Irish, direct object in an infinitival clause is placed before the verb (verbal noun), so that in (17) and (18), the resumptive pronoun *é* “it” is put before the verbal noun (*a*) *cheannach* “(to) buy.” Note also that *gurbh* in (18) is the form of *gur* used before vowels and *fh* + vowel in the Conditional Mood.

Therefore, Ulster Irish allows six patterns of COMP alternation, when there are two COMP positions in the sentence, as shown in (19).

- (19) a. (aL, aL, *t*)

- b. (aN, that, *rp*)
- c. (aN, aN, *rp*)
- d. (aL, aN, *rp*)
- e. (aN, aL, *t*)
- f. (aL, that, *rp*)

### 3. Possible Patterns of A'-Chains

With the background established, let us examine the possible patterns of A'-chains in Ulster Irish. There were 18 possible patterns of A'-chains, when the relative clauses contain two embedded sentences, that is, three COMP positions and one trace/resumptive pronoun. The relevant data are provided from (20) to (37). Note that for some reasons still unknown, some chain patterns require particular predicates, so that not all the possible chain patterns contain exactly the same predicates in the relative clauses.<sup>2</sup> The examples from (20) to (28) start with *aL*, and the examples from (29) to (37) with *aN*.

(20) (aL, aL, aL, *t*)

*Sin an carr a chreideann Seán a dúirt Máire a cheannaigh Pól t*  
 that the car aL believe John aL said Mary aL bought Paul  
 “That’s the car that John believes that Mary said that Paul bought”

(21) (aL, aL, aN, *rp*)

*Sin an carr a chreideann Seán a dúirt Máire ar cheannaigh Pól é*  
 that the car aL believe John aL said Mary aN bought Paul it  
 “That’s the car that John believes that Mary said that Paul bought it”

(22) (aL, aL, that, *rp*)

*Sin an carr a mheasann tú a mheasann Seán gur cheart dúinn é a*  
 that the car aL think you aL think John that right for-us it to  
 cheannach  
 buy  
 “That’s the car that you think that John thinks that we ought to buy it”

(23) (aL, aN, aL, *t*)

*Sin an carr a bhí súil agam a mbeadh súil acusan a*  
 that the car aL was hope at-me aN be (COND) hope at-them(emphatic) aL

---

<sup>2</sup> See Maki and Ó Baoill (2007) for relevant discussion.

cheannófá *t*

buy (COND) (S2)

“That’s the car that I hoped that they would hope that you would buy”

(24) (aL, aN, aN, *rp*)

*Sin an fear a chreid sé a raibh a fhios aige a raibh sé tinn*

that the man aL believed he aN was his knowledge at-him aN was he sick

“That’s the man that he believed that he knew that he was sick”

(25) (aL, aN, that, *rp*)

that the graveyard aN thought he aL COP remembered with-him aN were they  
*curtha inti*

buried in-it

“That’s the graveyard that he thought that he remembered that they were buried in it”

(31) (aN, aL, that, rp)

*Sin an carr a gcreideann Seán a shamhlaigh Máire gur cheannaigh Pól é*  
that the car aN believe John aL imagined Mary that bought Paul it  
“That’s the car that John believes that Mary imagined that Paul bought it”

(32) (aN, aN, aL, t)

*Sin an carr a raibh súil agam a mbeadh súil acusan a*  
that the car aN was hope at-me aN be (COND) hope at-them(emphatic) aL  
*cheannófa t*  
buy (COND) (S2)

“That’s the car that I hoped that they would hope that you would buy”

(33) (aN, aN, aN, rp)

*Sin an fear ar chreid sé a raibh a fhios aige a raibh sé tinn*  
that the man aN believed he aN was his knowledge at-him aN was he sick  
“That’s the man that he believed that he knew that he was sick”

(34) (aN, aN, that, rp)

*Sin an carr ar mheas sé ar dhúradh leis go raibh feidhm leis*  
that the car aN thought he aN was-told with-him that was need with-it  
“That’s the car that he thought that he was told that it was needed”

(35) (aN, that, aL, t)

*Sin an carr a gcreideann Seán gur mhaígh Máire a cheannaigh Pól t*  
that the car aN believe John that claimed Mary aL bought Paul  
“That’s the car that John believes that Mary claimed that Paul bought”

(36) (aN, that, aN, rp)

*Sin an rud ar smaoinigh sé gur dhúradh leis a bhfaigheadh sé*  
that the thing aN remembered he that was-told with-him aN found he  
*ann é*  
there it

“That’s the thing that he remembered that he was told that he would find it there”

(37) (aN, that, that, rp)

*Sin an rud ar smaoinigh sé gur dhúradh leis go bhfaigheadh sé*  
that the thing aN remembered he that was-told with-him that found he  
*ann é*

there it

“That’s the thing that he remembered that he was told that he would find it there”

Out of the 18 possible A’-chains with three COMPs and one trace/resumptive pronoun, there are 5 chains, among others, that have not been reported in the literature. These chains contain the sequence in (38), as shown in (39).

(38) (aL, that)

(39) a. (aL, aL, that, rp) (=22)

b. (aL, that, aL, t) (=26)

c. (aL, that, aN, rp) (=27)

d. (aL, that, that, rp) (=28)

e. (aN, aL, that, rp) (=31)

Also, out of the 6 possible A’-chains with two COMPs and one trace/resumptive pronoun, there is a chain with the sequence in (38), as shown in (40).

(40) (aL, that, rp)

These newly found facts will contribute to uncovering the precise mechanism of A’-chain formation and the nature of the three COMPs in Ulster Irish. In the following, we will consider what they suggest for the theory of (Ulster Irish) syntax.

Under McCloskey’s (2002) system, all the chain patterns in (39) and (40) should be illicit, as *aL* appears without an obvious movement operation, that is, the element locally bound by the relevant *aL* is not a trace. Therefore, the fact that the chains in (39) and (40) are all licit is an interesting problem for the theory of chain formation in general.

Let us start with a case with two COMP positions in a relative clause. We have seen above that the chain pattern in (40) is allowed in Ulster Irish. The representative example was (17), reproduced as (41).

(41) (aL, that, rp)

*Sin an carr a mheasann Seán gur cheart dúinn é a cheannach*

that the car aL think John that right for-us it to buy

“That’s the car that John thinks that we ought to buy it”

Let us consider what McCloskey’s (2002) system in (16) will predict for (41). As there is an *aL* in (41), movement of some sort should have been involved. However, there is no trace in (41). Therefore, (16a) would incorrectly rule out (41).

There are three possible approaches to this problem. First, one may assume that *go* “that” could function as *aN*. If this option were allowed, however, (42), with *go* “that,” would be incorrectly predicted to be grammatical, contrary to fact.

(42) (aN/\*that, *rp*)

*Sin an carr ar/\*gur cheannaigh Seán é*  
that the car aN/that bought John it  
“That’s the car that John bought”

Second, one may assume that *aL* could function as *aN*. If this option were allowed, however, (43), with *aL*, would be incorrectly predicted to be grammatical, contrary to fact.

(43) (aN/\*aL, *rp*)

*Sin an carr ar/\*a cheannaigh Seán é*  
that the car aN/aL bought John it  
“That’s the car that John bought”

The third hypothesis is that (*aL*, *that*) would function as either (*aL*, *aN*) or (*aN*, *that*), only when *aL* and *that* are in a local agreement relation. Given this, (41) would be just like (13) ((*aL*, *aN*, *rp*)), reproduced as (44), under the first option, or (9) ((*aN*, *that*, *rp*)), reproduced as (45), under the second option.

(44) (*aL*, *aN*, *rp*)

*Sin an carr a chreideann tú ar cheannaigh Seán é*  
that the car aL believe you aN bought John it  
“That’s the car that you believe that John bought”

(45) (*aN*, *that*, *rp*)

*Sin an carr a gcreideann tú gur cheannaigh Seán é*  
that the car aN believe you that bought John it  
“That’s the car that you believe that John bought”

Note that if we follow McCloskey’s (2002) system, in (44), *aL* is in agreement with the operator base-generated in the SPEC of *aN*, and thus, the former attracts the latter, while in (45), an operator is simply base-generated in the SPEC of *aN*, and there is no agreement relation between *aN* and any element in the lower clause. If this is correct, the second option will not be correct, because by hypothesis, *aL* and *that* are in an agreement relation, and the former changes the latter to *aN* in its function.

Therefore, we propose that in (41), *aL* and *that* are in an agreement relation, and because of this, *that* functions as *aN*. To be more precise, we propose that given McCloskey’s claim that COMP whose specifier is not filled is realized as *that*, *that* may optionally have a feature that would reside in the operator base-generated in the SPEC of *aN*, and only when it agrees with *aL* in a local relation, does this feature force *that* to function as *aN*.

The claim that *that* functions as *aN* when it is in an agreement relation with *aL* makes a prediction. That is, whenever a chain containing (*aL*, *aN*) is allowed, a chain containing (*aL*, *that*) is also allowed. This prediction is borne out by the very examples with the chains in (39), reproduced as (46), and their counterparts with the sequence (*aL*, *aN*) in (47).

- (46) a. (*aL*, *aL*, *that*, *rp*) (= (22))  
 b. (*aL*, *that*, *aL*, *t*) (= (26))  
 c. (*aL*, *that*, *aN*, *rp*) (= (27))  
 d. (*aL*, *that*, *that*, *rp*) (= (28))  
 e. (*aN*, *aL*, *that*, *rp*) (= (31))
- (47) a. (*aL*, *aL*, *aN*, *rp*) (= (21))  
 b. (*aL*, *aN*, *aL*, *t*) (= (23))  
 c. (*aL*, *aN*, *aN*, *rp*) (= (24))  
 d. (*aL*, *aN*, *that*, *rp*) (= (25))  
 e. (*aN*, *aL*, *aN*, *rp*) (= (30))

The examples are repeated below in pairs.

### Pair 1

- (21) (*aL*, *aL*, *aN*, *rp*)

*Sin an carr a chreideann Seán a dúirt Máire ar cheannaigh Pól é*  
 that the car aL believe John aL said Mary aN bought Paul it  
 “That’s the car that John believes that Mary said that Paul bought it”

- (22) (*aL*, *aL*, *that*, *rp*)

*Sin an carr a mheasann tú a mheasann Seán gur cheart dúinn é a*  
 that the car aL think you aL think John that right for-us it to  
*cheannach*  
 buy  
 “That’s the car that you think that John thinks that we ought to buy it”

### Pair 2

- (23) (*aL*, *aN*, *aL*, *t*)

*Sin an carr a bhí súil agam a mbeadh súil acusan a*  
 that the car aL was hope at-me aN be (COND) hope at-them(emphatic) aL  
*cheannófá t*  
 buy (COND) (S2)  
 “That’s the car that I hoped that they would hope that you would buy”

- (26) (*aL*, *that*, *aL*, *t*)

*Sin an carr a bhí súil agam go mbeadh súil acusan a*

that the car aL was hope at-me that be (COND) hope at-them(emphatic) aL  
*cheannófá t*

buy (COND) (S2)

“That’s the car that I hoped that they would hope that you would buy”

### Pair 3

(24) (aL, aN, aN, rp)

*Sin an fear a chreid sé a raibh a fhios aige a raibh sé tinn*

that the man aL believed he aN was his knowledge at-him aN was he sick

“That’s the man that he believed that he knew that he was sick”

(27) (aL, that, aN, rp)

*Sin an rud a chreid sé gur dhúradh leis a bhfaigheadh sé ann é*

that the thing aL believed he that was-told with-him aN found he there it

“That’s the thing that he believed that he was told that he would find it there”

### Pair 4

(25) (aL, aN, that, rp)

*Sin an rud a smaoinigh sé ar dhúradh leis go bhfaigheadh sé*

that the thing aL remembered he aN was-told with-him that found he

*ann é*

there it

“That’s the thing that he remembered that he was told that he would find it

there”

(28) (aL, that, that, rp)

*Sin an carr a chreideann Seán gur chreid Máire gur cheannaigh Pól é .*

that the car aL believe John that believed Mary that bought Paul it

“That’s the car that John believes that Mary believed that Paul bought it”

### Pair 5

(30) (aN, aL, aN, rp)

*Sin an roilig ar mheas sé a ba chuimhneach leis a raibh siad*

that the graveyard aN thought he aL COP remembered with-him aN were they

*curtha inti*

buried in-it

“That’s the graveyard that he thought that he remembered that they were buried

in it”

(31) (aN, aL, that, rp)

*Sin an carr a gcreideann Seán a shamhlaigh Máire gur cheannaigh Pól é*

that the car aN believe John aL imagined Mary that bought Paul it

“That’s the car that John believes that Mary imagined that Paul bought it”

The two examples in each of the 5 pairs are both grammatical. They only differ in either the second COMP or the third COMP. The upper example in each pair contains the sequence (aL, aN), and the lower example in each pair the sequence (aL, that). Therefore, in the lower example in each pair, *that* functions just like *aN*.

#### 4 Implications

In the above discussion, we proposed that given McCloskey’s claim that COMP whose specifier is not filled is realized as *that*, *that* may optionally have a feature that would reside in the operator base-generated in the SPEC of *aN*, and only when it agrees with *aL* in a local relation, does this feature force *that* to function as *aN*. If this proposal is correct, it has two interesting implications for the theory of (Ulster Irish) syntax.

First, the claim that *aL* may agree with *that* in the lower clause suggests that the locality of Move and Agree is actually different, supporting Bošković’s (2007) view. Under the phase-based model in Chomsky (2000, 2001), CP and *vP* are phases, and the relation between *aL* in an upper clause and *go* in a lower clause would be in violation of the Phase-Impenetrability Condition in (48).

(48) *Phase-Impenetrability Condition* (PIC)

In phase  $\alpha$  with head H, the domain of H is not accessible to operations outside  $\alpha$ , only H and its edge are accessible to such operations.

(Chomsky (2000: 108))

Given (48), the relation between C1 and C2 in (49) is blocked, when C1 agrees with C2.

(49) [<sub>CP1</sub> C1 [... [<sub>vP</sub> *v* [... [<sub>CP2</sub> C2

In the present case, (49) is represented as (50).

(50) [<sub>CP1</sub> *aL* [... [<sub>vP</sub> *v* [... [<sub>CP2</sub> *go*

In (50), when *aL* tries to agree with *go* after the *vP* phase has been completed, this agreement operation would violate the PIC, since the complement of *v*, which contains *go*, is not accessible to any operation outside of *vP*, given (48). One might argue that *go* may first agree with *v*, which in turn may agree with *aL*, without violating the PIC in each application of Agree. However, there arises a problem of “look-ahead.”<sup>3</sup> That is, the question arises why *go*, after agreeing with *v*, can predict that *aL* would appear in the upper clause with which it would ultimately like to agree. In order to avoid the

---

<sup>3</sup> Fumikazu Niinuma (personal communication) brought this issue to our attention.

problem of “look-ahead,” it should be assumed that *go* will agree with *aL*, right after the latter is introduced to the phrase structure. Therefore, under the phase-based theory, the proposed claim poses a serious problem, that is, a problem of a PIC violation in (50).

However, this apparent problem constitutes evidence for Bošković (2007), who argues, contra Chomsky (2000, 2001), that the locality of Move and Agree is radically different in the sense that Agree is free from mechanisms constraining Move, such as the PIC in (48). Therefore, the fact that *aL* may agree with *that* in the lower clause supports Bošković’s (2007) idea that Agree is not constrained by the PIC, unlike Move.

Second, given the fact that the pattern (*aL*, *that*, *rp*) is legitimate, the direct relative marker *aL* may appear without an operator in its SPEC, because *that* does not have an operator in its SPEC, but it has a feature that will agree with *aL*. Therefore, (16a) will be restated as in (51).

(51) C is realized as *aL* if it locally agrees with an operator feature.

If (51) is correct, it poses a question to McCloskey’s (2002) claim regarding (16) that *aL* and *aN*, but not *that*, have an EPP feature that requires an operator to be in their SPECs. This is because in the pattern (*aL*, *that*, *rp*), the topmost *aL* does not have an operator in its SPEC.

## 5. A Remaining Issue

The existence of the pattern (*aL*, *that*, *rp*) raises an interesting issue about whether *aN* must have an operator in its SPEC. Given (16c), in the chain (*aL*, *that*, *rp*), *that* in the intermediate COMP cannot have an operator in its SPEC, and given the fact that the chain (*aL*, *aN*, *rp*) is licit, we need to say that *that* may have a feature that would reside in the operator base-generated in the SPEC of *aN*. However, if we say so, it is not clear whether *aN* must have a base-generated operator in its SPEC, and this operator must move to the SPEC of *aL*, since, as stated in (51), C is realized as *aL* if it locally agrees with an operator feature. Therefore, it may be the case that *aN* itself has a relevant feature which would reside in the operator base-generated in its SPEC, and does not actually have an operator in its SPEC, so that the relevant feature in *aN* simply agrees with *aL* without any movement operation.

One may argue that in the resumptive construction, the resumptive pronoun must be bound by an operator. However, this is not always the case. Japanese allows a null resumptive pronoun in the relative clause construction, which is evidenced by the fact

that the head noun may be separated from the null pronoun by an island. This is shown in (52).

- (52) [<sub>NP</sub> [<sub>IP</sub> [<sub>NP</sub> [<sub>IP</sub> *e<sub>i</sub> kiteiru*] *huku*]-*ga* *yogoreteiru*] *sinsi<sub>i</sub>*]  
wearing suit-nom dirty gentleman  
“the gentleman [the suit (he) is wearing] is dirty”

In (52) an element in a complex NP is relativized, and the example is grammatical. This suggests that there is no complex NP Constraint effect for relativization. Based on this, Kuno (1973) argues that relativization in Japanese does not involve movement, but rather involves a base-generated empty pronoun. If Murasugi’s (1991) claim is correct that Japanese relative clauses are bare IPs and do not contain an operator, it is not always the case that in the resumptive construction, the resumptive pronoun must be bound by an operator. Therefore, we cannot say that *aN* must have a base-generated operator in its SPEC in Ulster Irish. Whether it does or does not is an open issue, which we leave for future research.

## 6. Conclusion

In this paper, we presented the hitherto unreported patterns of COMP alternation in Ulster Irish with the sequence (*aL*, *that*), and proposed that these patterns suggest that *aL* and *that* are in an agreement relation, forcing *that* to function as *aN*. Then, based on this, we argued that this would imply that *C* is realized as *aL* if it locally agrees with an operator feature.

# A usage-based account of verbal reduplication in Taiwan Southern Min

Hui-Ju Chuang & James H-Y. Tai

## Abstract

Verbal reduplicative construction (VRC) in Taiwan Southern Min (TSM) is highly productive and is manifested in its own fashion in prosodic/phonology, syntax, semantics and pragmatics. Under the framework of construction grammar, we propose that TSM VRC forms a family of constructions, comprising various subtypes of VRCs, which are linked up by inheritance relations. Further, we claim that the  $XX\ le^0$  VRC is the most prototypical construction, and others inherit the schema from it. Finally, building on a usage-based account, we show some evidences that  $XX\ le^0$  VRC occurs the most frequently and, thus, the most entrenched among other TSM VRCs.

**Keywords:** verbal reduplicative construction, Taiwan Southern Min, construction grammar, a usage-based account

## 1. Introduction

Reduplication is a commonly seen linguistic phenomenon across different language families, such as Sino-Tibetan, Indo-European, Australasian families and many others. As a morphological process, reduplication operates cross-linguistically on nouns, verbs, adjectives, adverbs, and classifiers. The worldwide distribution of reduplication also shows diversity of meanings. Meanings expressed by the reduplicated forms, as suggested in previous studies (Haiman 1980, Moravcsik 1987, Tai 1993, Huang 1996, Regier 1998, and Zhang 1999), are enveloped in the meanings of “repetition” (e.g., Mongolian *bayn bayb* ‘often, constantly’ (Regier 1998)), “plurality” (e.g., Tagalog *araw<sup>c</sup> araw* ‘every day’ (Blake 1917)) (cite from Moravcsik 1987: 318), distributivity (Mandarin *renren* ‘everybody’ Tai (1993)), “intensity” (e.g., Thai *dīdīi* ‘to be extremely good’ (Haas1946)) (cite from Moravcsik 1987: 321), “attenuation” (e.g., Swahili *maji-maji* ‘somewhat wet’ (Ashton 1952)) (cite from Moravcsik 1987: 323), and so forth. Although the reduplications are varied in forms and meanings, they are, however, triggered by different iconicity motivations. (Haiman 1980).

The purpose of this paper is to identify different types of verbal reduplication

found in Southern Min (a Chinese dialect/language) as spoken in Taiwan. It will be shown that verbal reduplications in Taiwan Southern Min (TSM) correspond to different but related iconic motivations, and can be construed as related constructions. Furthermore, based on the frequency count of the five types of verbal reduplications in TSM, it is to be demonstrated that these verbal reduplication constructions also link up as a family.

## 2. Verbal reduplication in Taiwan southern Min

It is proposed by Tang (1992) that reduplication can be divided into two types. One type of the reduplication is called “morphological reduplication”, in which the reduplication is unproductive, irregular and unpredictable. The reduplication for this type is obligatory since the reduplicated part together with its non-repeated part can be taken as a lexical word. In TSM, some adjectives and verbs as well, fall under this category (e.g., *ang<sup>5</sup> ki<sup>3</sup> ki<sup>3</sup>* ‘very red’, *kik<sup>4</sup> thui<sup>5</sup> thui<sup>5</sup>* ‘pretend dull’). The other type of reduplication, on the contrary, is productive, regular and predictable. This type of reduplication is subject to syntactic regulation, also called “syntactic reduplication”, which will be dealt with in this paper. In TSM, verbs can be simply grouped in a general way by the number of syllables, monosyllabic and disyllabic. For monosyllabic verbal reduplications, five types of postverbal elements are taken after the reduplicated verbs, as shown below.

- |     |  |                                       |  |                        |
|-----|--|---------------------------------------|--|------------------------|
| (1) | <i>cau<sup>2</sup>cau<sup>2</sup></i>      | <b>le<sup>0</sup></b>                 | (final particle <i>le<sup>0</sup></i> )  |                        |
|     | run-run                                    | PTC                                   |  |                        |
|     | ‘to run for a little while’                |                                       |  |                        |
| (2) | <i>ciah<sup>8</sup>ciah<sup>8</sup></i>    | <b>tiau<sup>7</sup></b>               | (phase complement)                       |                        |
|     | eat-eat                                    | away                                  |  |                        |
|     | ‘to eat up (something)’                    |                                       |  |                        |
| (3) | <i>iong<sup>7</sup>iong<sup>7</sup></i>    | <b>hai<sup>7</sup>khi<sup>3</sup></b> | (resultative complement)                 |                        |
|     | use-use                                    | break-away                            |  |                        |
|     | ‘to be broken because of over use’         |                                       |  |                        |
| (4) | <i>se<sup>2</sup>se<sup>2</sup></i>        | <b>hoo<sup>7</sup></b>                | <b>ching<sup>1</sup>-khi<sup>3</sup></b> | (causative complement) |
|     | wash-wash                                  | CM                                    | clean                                    |                        |
|     | ‘cause (something) to be clean by washing’ |                                       |  |                        |

- (5) cu<sup>2</sup>cu<sup>2</sup>            cit<sup>8</sup>-tua<sup>7</sup>-tui<sup>1</sup>            (quantifier complement)  
 cook-cook    one-big-heap  
 ‘cook (something) overmuch’

As shown in (1)-(5) examples, monosyllabic verbs in TSM, can be followed by five types of postverbal elements: final particle *le*<sup>0</sup>, phase complement, resultative complement, causative complement and quantifier complement. There are four types of disyllabic verbal reduplications. They involve compound verbs, verb-object phrases, verb-complement phrases, and coordinate compound verbs, as illustrated in the following examples.

- |  |   |
|--|---|
| (6) a. siu <sup>1</sup> li <sup>2</sup>    | a'. siu <sup>1</sup> li <sup>2</sup> li <sup>2</sup> le <sup>0</sup>      |
| fix  | fix-fix    PTC  |
| ‘to fix’                                   | ‘to fix (something) a little’   |
| (7) a. lau <sup>5</sup> kuann <sup>7</sup> | a'. kuann <sup>7</sup> lau <sup>5</sup> lau <sup>5</sup> le <sup>0</sup>  |
| run-sweat                                  | sweat    run-run    PTC   |
| ‘to sweat’                                 | ‘make yourself sweat for a little while’                                  |
| (8) a. li <sup>3</sup> phua <sup>3</sup>   | a'. li <sup>3</sup> li <sup>3</sup> phua <sup>3</sup>                     |
| tear-break                                 | tear-tear    break  |
| ‘tear up’                                  | ‘to tear up thoroughly’   |
| (9) a. chut <sup>4</sup> jip <sup>8</sup>  | a'. chut <sup>4</sup> chut <sup>4</sup> jip <sup>8</sup> jip <sup>8</sup> |
| exit-enter                                 | exit-exit enter-enter   |
|  | ‘in and out’  |

These four types of verbal reduplication exhibit different reduplication patterns, such as *XYX* in (6a'), *YXX* in (7a'), *XXY* in (8a') and *XXYY* in (9a'). Although these four types of disyllabic verbal reduplications are regular, productive and predictable, they are, however, less productive than monosyllabic verbal reduplications. Hence, this paper will mainly focus on monosyllabic verbal reduplications, and more in-depth discussion will be presented in the following sections.

### 3. Verbal reduplication in TSM as construction

Verbal reduplication in TSM should not be treated simply as the formation of a lexical word under morphological processes. As pointed out by Cheng (1988), it also involves the semantic properties of aspect and phase. It can be taken as a construction

from the perspective of construction grammar (Goldberg 1995, 2006) since it has phonological, syntactic, semantic, and pragmatic characteristics which are absent in non-reduplicative counterpart. Below, we briefly discuss these characteristics of the verbal reduplicative construction (VRC) in TMS.

### 3.1 Phonological properties

Cheng (1988) maintains that in TSM, those reduplicative verbs that need to take postverbal elements (see section 2) are separated from their postverbal elements by pauses. Furthermore, the second syllable of the reduplicative verbs remains juncture tone while the first syllable shifts to context tone in terms of the Taiwanese tone sandhi rules.

### 3.2 Syntactic properties

The syntactic behaviors of VRCs in TSM are quite different from their non-reduplicative counterparts. The differences have to do with verbs, arguments and scope of negation. First, the direct object must be placed before the verb but not after the verb as illustrated below.

- (10) a. li<sup>2</sup>    ciah<sup>8</sup>    png<sup>7</sup>    liau<sup>2</sup>    chiah<sup>4</sup>    khi<sup>3</sup>  
           you    eat        rice        finished then    go  
           ‘You must finish the meal and then you can go (somewhere).’
- b. li<sup>2</sup>    png<sup>7</sup>    ciah<sup>8</sup>ciah<sup>8</sup>le<sup>0</sup>    ciah<sup>4</sup>    khi<sup>3</sup>  
           you    rice        eat-eat    PTC        then    go  
           ‘Finish eating your meal and then you can go (somewhere).’
- \*c. li<sup>2</sup>    ciah<sup>8</sup>ciah<sup>8</sup>    le<sup>0</sup>    png<sup>7</sup>    ciah<sup>4</sup>    khi<sup>3</sup>  
           you    eat-eat        PTC        rice        then    go
- \*d. li<sup>2</sup>    ciah<sup>8</sup>ciah<sup>8</sup>    png<sup>7</sup>    le<sup>0</sup>    ciah<sup>4</sup>    khi<sup>3</sup>  
           you    eat-eat        rice        PTC        then    go

In (10a), the direct object *png*<sup>7</sup> ‘rice’ follows the transitive verb *chiah*<sup>8</sup> ‘eat’. But (10b) shows that when the transitive verb reduplicates itself to be *chiah*<sup>8</sup>*chiah*<sup>8</sup> ‘eat-eat’, the direct object precedes the reduplicated verb. Moreover, the ungrammaticality of (10c) and (10d) shows that the direct object can only precede the reduplicative verb. Next, in terms of referentiality, the direct arguments of VRCs, can be either nonreferential, or definite referential, but not indefinite referential as shown below.

- (11) a. ka<sup>7</sup> png<sup>7</sup> ciah<sup>8</sup>ciah<sup>8</sup> le<sup>0</sup>  
 OM rice eat-eat PTC  
 ‘Finish eating your meal.’ (nonreferential)
- b. li<sup>2</sup> cit<sup>4</sup> uann<sup>2</sup> png<sup>7</sup> chiah<sup>8</sup>chiah<sup>8</sup> le<sup>0</sup>  
 2sg this CL rice eat-eat PTC  
 ‘Finish eating this bowl of rice.’ (definite referential)
- \*c. li<sup>2</sup> cit<sup>8</sup> uann<sup>2</sup> png<sup>7</sup> chiah<sup>8</sup>chiah<sup>8</sup> le<sup>0</sup>  
 2sg one CL rice eat-eat PTC  
 ‘Finish eating one bowl of rice.’ (indefinite referential)
- d. li<sup>2</sup> cit<sup>4</sup> nng<sup>7</sup> uann<sup>2</sup> png<sup>7</sup> chiah<sup>8</sup>chiah<sup>8</sup> le<sup>0</sup>  
 2sg this two CL rice eat-eat PTC  
 ‘Finish these two bowls of rice.’ (definite referential)

Last, the reduplicated verbs cannot be negated in TSM. This is evidenced by the ungrammaticality of (12b).

- (12) a. i<sup>1</sup> bo<sup>5</sup> kong<sup>3</sup>phua<sup>3</sup> pue<sup>1</sup>a<sup>2</sup>  
 3sg NEG strike-break cup  
 ‘He did not break the cup.’
- \*b. i<sup>1</sup> pue<sup>1</sup>a<sup>2</sup> bo<sup>5</sup> kong<sup>3</sup>kong<sup>3</sup>phua<sup>3</sup>  
 3sg cup NEG strike-strike-break

### 3.3 Semantic properties

Cheng (1988) categorizes two types of verbs to account for the semantic properties of the reduplicative verbs in TSM. The first type consists of semantic feature [+ volitional] and [+ durable], i.e., *ciah*<sup>8</sup> ‘eat’ and *kong*<sup>7</sup> ‘say’; the second type, of semantic features [𠵼| volitional] and [𠵼| durable], i.e., *si*<sup>2</sup> ‘die’ and *phua*<sup>3</sup> ‘broke’. However, verbs such as *ho*<sup>2</sup> ‘good’, *uai*<sup>1</sup> ‘crooked’, *oo*<sup>1</sup> ‘black’ and so forth, with the features [𠵼| volitional] and [+ durable] are unaccounted for by Cheng’s classification.

- (13) chiu<sup>2</sup> bong<sup>1</sup> liau<sup>2</sup> oo<sup>1</sup>oo<sup>1</sup> khi<sup>3</sup>  
 hand touch finish black-black away  
 ‘Hands are all dirty by touching (something).’

For a more comprehensive and systematic account, we adopt Van Valin’s (2005) classification of verb types to show the range of semantic properties exhibited in reduplicated verbs in TSM. Van Valin’s verb classes are state, activity, achievement,

semelfactive, accomplishment, active accomplishment verbs. As shown in Table 1 below, all five types of verbs can be reduplicated in TSM, yielding different but related meanings.

Table 1 Verb classes for TSM VRCs

Verb type	Reduplication	Meaning
Activity	<i>be<sup>2</sup> be<sup>2</sup> le<sup>0</sup></i>	'buy (something) for a little while'
Active accomplishment	<i>mia<sup>5</sup> chiam<sup>1</sup>chiam<sup>1</sup> le<sup>0</sup></i>	'Sign your name.'
State	<i>bai<sup>2</sup> bai<sup>2</sup> khi<sup>3</sup></i>	'cause to be ugly'
Achievement	<i>si<sup>2</sup> si<sup>2</sup> khi<sup>3</sup></i>	'cause to become dead'
Semelfactive	<i>sau<sup>3</sup>sau<sup>3</sup> le<sup>0</sup></i>	'cough for a little while'

### 3.4 Pragmatic properties

Verb reduplications in TSM are often used to soften the imperative speech act. (14a) is a blunt and direct command, but (14b) is a mild request or suggestion.

- (14) a. li<sup>2</sup>    chiu<sup>2</sup>    se<sup>2</sup>    liau<sup>2</sup>    chiah<sup>4</sup>    ciah<sup>8</sup>  
           you    hand    wash    finished    then    eat  
           'Before you eat (something), you must wash your hands.'
- b. li<sup>2</sup>    chiu<sup>2</sup>    se<sup>2</sup>se<sup>2</sup>    le<sup>0</sup>    ciah<sup>4</sup>    ciah<sup>8</sup>  
           you    hand    wash    PTC    then    eat  
           'Wash your hands before you eat (something).'

## 4 A usage-based account

A usage-based approach to linguistic analysis and explanation has been proposed by a number of cognitive linguists (Langacker 1987, 1988, Bybee 1995, Goldberg 1995, 2006, Croft 2001). The essential spirit of a usage-based account is that grammatical knowledge is not merely a structural representation in the mind of a speaker as assumed in the paradigm of structuralist-generative grammar, it also contains the knowledge of the use of utterances in communication. Thus, in a usage-based account, frequency of occurrence of particular grammatical constructions with their associated meanings also plays a central role. The account is largely experience-driven rather than given a priori in the mind of human beings. Frequency would, therefore, be a prime factor in examining the degree of entrenchment. Hence,

we propose a usage-based approach to account for how TSM VRCs are used. More specifically, we propose that they form a “construction family”. It is maintained by Goldberg and Jackendoff (2004) that the “family” of constructions is defined as that they co-exist important properties but can be differentiated from certain specifics, containing their degree of productivity (e.g., the English resultatives). In the following paragraphs, we will show that TSM VRCs form a “construction family” with a hierarchy of subconstructions.

As mentioned in section 2, TSM monosyllabic verbs can take five types of postverbal element when undergoing reduplicate process. As discussed in section 3, this type of VRCs is a highly productive construction, and exhibits its unique properties in phonology, syntax, semantics and pragmatics. Therefore, from the perspective of Construction Grammar, we consider TSM monosyllabic verbal reduplication as a schematic construction, and the schema can be generalized as [XX *postverbal element*]. In the schema [XX *postverbal element*], the *XX* represents the reduplicative verbs which is fixed, while the variant item *postverbal element* represents an open slot that any equivalent grammatical item can fit in this slot, (e.g., final particle *le<sup>0</sup>* ‘PTC’, *phase complements*, *resultative complements*, *hoo<sup>7</sup> complements or clauses*, and *quantifier complements*). The [XX *postverbal element*] schema can be divided into two subconstructions: [XX *le<sup>0</sup>*] and [XX *C*]. For the [XX *C*] VRC, it is further categorized into four different subtypes of complements that follow the reduplicative verb *XX*: [XX *PC*], [XX *CC*], [XX *RC*] and [XX *QC*].

Goldberg (1995:67) indicates that “constructions form a network and are linked up by inheritance relations, which motivate many of the properties of particular constructions”. She proposes four inheritance links: polysemy links, metaphorical extension links, subpart links, and instance links. The motivation of inheritance links is described by Goldberg (1995: 72) as that “construction A motivates construction B iff B inherits from A”. Accordingly, we would propose that in the [XX *postverbal element*] VRC, there exists an inheritance relation among the subconstructions: *XXle<sup>0</sup>* and *XXC*.

Croft and Cruse (2004) also propose that every time a word or a construction is employed, a node or pattern of nodes is activated in the mind, and frequency of activation affects the establishment of that information, which brings its ultimate storage as an idiomatic unit in grammar. The storage is referred to as “entrenched”. In terms of entrenchment, if a word form is frequently enough in use, it will be stored independently (Langacker 1987). Based on the usage-based model, we count the tokens that co-occur with the reduplicative verbs. The data source is from the Taiwanese Spoken Corpus directed by Jane Tsay and James Myers at National Chung Cheng University. From this corpus, two different live broadcasts, totally around 35

hours, are selected. The result of frequency count is shown in table 2.

Table 2 Token that co-occur with [XX *postverbal element*] VRC

Type of construction	Token
XX <i>le</i> <sup>0</sup>	86
XX <i>phase complement</i>	6
XX <i>resultative complement</i>	10
XX <i>causative complement</i>	8
XX <i>quantifier complement</i>	1
